		Friends	[{"M": {"FriendId": {"S": "player002"}, "FriendName": {"S": "Alice"}}, {"M": {"FriendId": {"S": "player003"}, "FriendName": {"S": "Bob"}}}]

Step 2: Address access patterns 2 (getPlayerAllProfile), 3 (getPlayerAllItems), and 4 (getPlayerSpecificItem)

We address access patterns 2 (getPlayerAllProfile), 3 (getPlayerAllItems), and 4 (getPlayerSpecificItem) using this step. What these three access patterns have in common is a range query, which uses the [Query](#) operation. Depending on the scope of the query, [Key Condition](#) and [Filter Expressions](#) are used, which are commonly used in practical development.

In the Query operation, we provide a single value for Partition Key and get all items with that Partition Key value. Access pattern 2 (getPlayerAllProfile) is implemented in this way. Optionally, we can add a sort key condition expression — a string that determines the items to be read from the table. Access pattern 3 (getPlayerAllItems) is implemented by adding the key condition of sort key begins_with ITEMS#. Further, in order to simplify the development of the application side, we can use filter expressions to implement access pattern 4 (getPlayerSpecificItem).

Here's a pseudocode example using filter expression that filters items of the Weapon category:

```
filterExpression: "ItemType = :itemType"
expressionAttributeValues: {":itemType": "Weapon"}
```

Primary key		Attributes				
Partition key: PK	Sort key: SK	Type	ItemName	ItemType	ItemCount	ItemAttributes
player001	ITEMS#001	Type	Health Potion	Consumable	5	{"M":{"HP": {"N":"50"}}}
		Item	Armor of the Knight	Armor	1	{"M":{"DEF": {"N":"100"}}}
	ITEMS#002	Type	Sword of the Dragon	Weapon	1	{"M":{"ATK": {"N":"100"}, "DEF": {"N":"50"}}}
		Item	Armor of the Knight	Armor	1	{"M":{"DEF": {"N":"100"}}}

Note

A filter expression is applied after a Query finishes, but before the results are returned to the client. Therefore, a Query consumes the same amount of read capacity regardless of whether a filter expression is present.

If the access pattern is to query a large dataset and filter out a large amount of data to keep only a small subset of data, the appropriate approach is to design DynamoDB Partition Key and Sort Key more effectively. For example, in the above example for obtaining a certain ItemType, if there are many items for each player and querying for a certain ItemType is a typical access pattern, it would be more efficient to bring ItemType into the SK as a composite key. The data model would look like this: ITEMS#ItemType#ItemId.

Step 3: Address access patterns 5 (updateCharacterAttributes) and 6 (updateItemCount)

We address access patterns 5 (updateCharacterAttributes) and 6 (updateItemCount) using this step. When the player needs to modify the character, such as reducing the currency, or modifying the quantity of a certain weapon in their items, use [UpdateItem](#) to implement these access patterns. To update a player's currency but ensure it never goes below a minimum amount, we can add a [the section called “Condition expressions”](#) to reduce the balance only if it's greater than or equal to the minimum amount. Here is a pseudocode example:

```
UpdateExpression: "SET currency = currency - :amount"
ConditionExpression: "currency >= :minAmount"
```

Primary key		Attributes										
Partition key: PK	Sort key: SK	Type	CreatedAt	UpdatedAt	Nickname	Email	Gender	Avatar	Currency	PlayerLevel	PlayerHealth	PlayerExperience
player001	#METADATA #player001	Metadata	1618500000	1620000000	John	john@example.com	male	s3://gaming-beki65wn3bgc-lb-avatar/player001.png	500 Updated to 500-Amount	10	80	1000

When developing with DynamoDB and using [Atomic Counters](#) to decrement inventory, we can ensure idempotency by using optimistic locking. Here is a pseudocode example for Atomic Counters:

```
UpdateExpression: "SET ItemCount = ItemCount - :incr"
expression-attribute-values: '{":incr":{"N":"1"}}'
```

Primary key		Attributes						
Partition key: PK	Sort key: SK	Type	ItemName	ItemType	ItemCount	ItemAttributes		
player001	ITEMS#001	Item	Health Potion	Consumable	5 Updated to 4	{"M":{"HP": {"N":"50"}}}		

In addition, in a scenario where the player purchases an item with currency, the entire process needs to deduct currency and add an item at the same time. We can use DynamoDB Transactions to group multiple actions together and submit them as a single all-or-nothing TransactWriteItems or TransactGetItems operation. TransactWriteItems is a synchronous and idempotent write operation that groups up to 100 write actions in a single all-or-nothing operation. The actions are completed atomically so that either all of them succeed or none of them succeeds. Transactions help eliminate the risk of duplication or vanishing currency. For more information on transactions, see [DynamoDB transactions example](#).

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getPlayerFriends	Base table	GetItem	PK=PlayerID	SK="FRIENDS#playerID"	

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getPlayerAllProfile	Base table	Query	PK=PlayerID		
getPlayerAllItems	Base table	Query	PK=PlayerID	SK begins_with "ITEMS#"	
getPlayerSpecificItem	Base table	Query	PK=PlayerID	SK begins_with "ITEMS#"	filterExpression: "ItemType" = :itemType expressionAttributeValues: { ":itemType": "Weapon" }
updateCharacterAttributes	Base table	UpdateItem	PK=PlayerID	SK="#METADATA#playerID"	UpdateExpression: "SET currency = currency - :amount" Condition Expression: "currency >= :minAmount"

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
updateItem mCount	Base table	UpdateItem	PK=PlayerID	SK = "ITEMS#ItemID"	update-expression: "SET ItemCount = ItemCount - :incr" expression-attribute-values : '{":incr": {"N":"1"}}'

Gaming profile final schema

Here is the final schema design. To download this schema design as a JSON file, see [DynamoDB Examples](#) on GitHub.

Base table:

Primary key		Attributes										
Partition key: PK	Sort key: SK	Type	CreatedAt	UpdatedAt	Nickname	Email	Gender	Avatar	Currency	PlayerLevel	PlayerHealth	PlayerExperience

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called “Download”](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called “Importing an existing model”](#).
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called “Editing an existing model”](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Complaint management system schema design in DynamoDB

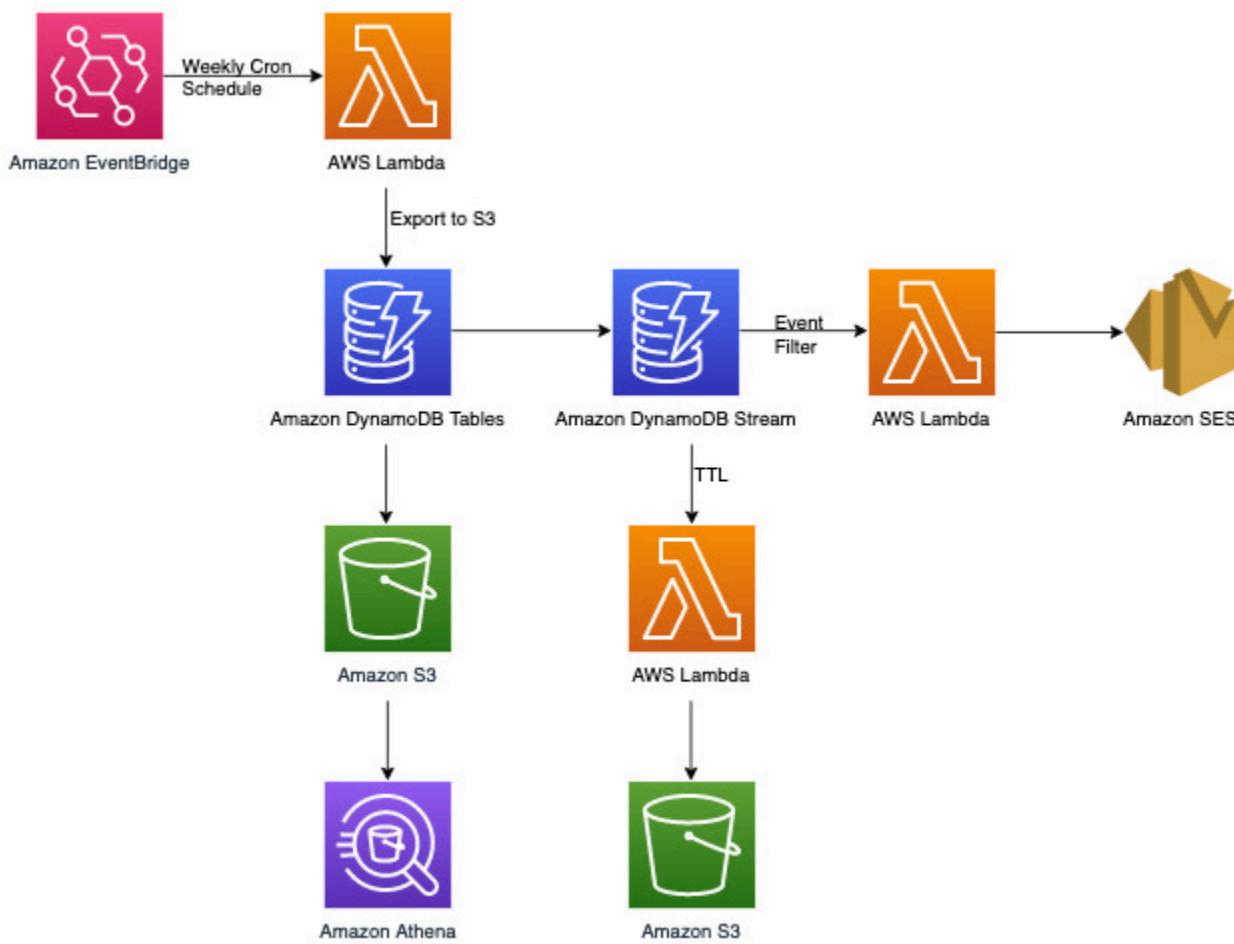

Complaint management system business use case

DynamoDB is a database well-suited for a complaint management system (or contact center) use case as most access patterns associated with them would be key-value based transactional lookups. The typical access patterns in this scenario would be to:

- Create and update complaints
- Escalate a complaint
- Create and read comments on a complaint
- Get all complaints by a customer
- Get all comments by an agent and get all escalations

Some comments may have attachments describing the complaint or solution. While these are all key-value access patterns, there can be additional requirements such as sending out notifications when a new comment is added to a complaint or running analytical queries to find complaint distribution by severity (or agent performance) per week. An additional requirement related to lifecycle management or compliance would be to archive complaint data after three years of logging the complaint.

Complaint management system architecture diagram

Apart from the key-value transactional access patterns that we will be handling in the DynamoDB data modeling section later, we have three non-transactional requirements. The architecture diagram above can be broken down into the following three workflows:

1. Send a notification when a new comment is added to a complaint
2. Run analytical queries on weekly data
3. Archive data older than three years

Let's take a more in-depth look at each one.

Send a notification when a new comment is added to a complaint

We can use the below workflow to achieve this requirement:

[DynamoDB Streams](#) is a change data capture mechanism to record all write activity on your DynamoDB tables. You can configure Lambda functions to trigger on some or all of these changes. An [event filter](#) can be configured on Lambda triggers to filter out events that are not relevant to the use-case. In this instance, we can use a filter to trigger Lambda only when a new comment is added and send out notification to relevant email ID(s) which can be fetched from [AWS Secrets Manager](#) or any other credential store.

Run analytical queries on weekly data

DynamoDB is suitable for workloads that are primarily focused on online transactional processing (OLTP). For the other 10-20% access patterns with analytical requirements, data can be exported to S3 with the managed [Export to Amazon S3](#) feature with no impact to the live traffic on DynamoDB table. Take a look at this workflow below:

[Amazon EventBridge](#) can be used to trigger AWS Lambda on schedule - it allows you to configure a cron expression for Lambda invocation to take place periodically. Lambda can invoke the ExportToS3 API call and store DynamoDB data in S3. This S3 data can then be accessed by a SQL engine such as [Amazon Athena](#) to run analytical queries on DynamoDB data without affecting the live transactional workload on the table. A sample Athena query to find number of complaints per severity level would look like this:

```
SELECT Item.severity.S as "Severity", COUNT(Item) as "Count"
FROM "complaint_management"."data"
WHERE NOT Item.severity.S = ''
GROUP BY Item.severity.S ;
```

This results in the following Athena query result:

Results (3)

Search rows

#	Severity	Count
1	P3	1
2	P2	2
3	P1	1

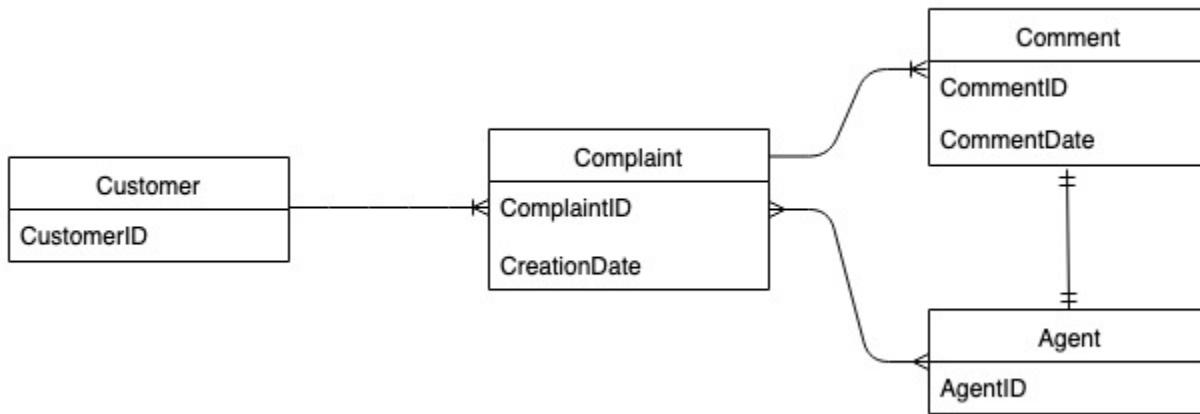

Archive data older than three years

You can leverage the DynamoDB [Time to Live \(TTL\)](#) feature to delete obsolete data from your DynamoDB table at no additional cost (except in the case of global tables replicas for the 2019.11.21 (Current) version, where TTL deletes replicated to other Regions consume write capacity). This data appears and can be consumed from DynamoDB Streams to be archived off into Amazon S3. The workflow for this requirement is as follows:

Complaint management system entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the complaint management system schema design.

Complaint management system access patterns

These are the access patterns we'll be considering for the complaint management schema design.

1. `createComplaint`
2. `updateComplaint`
3. `updateSeveritybyComplaintID`
4. `getComplaintByComplaintID`
5. `addCommentByComplaintID`
6. `getAllCommentsByComplaintID`
7. `getLatestCommentByComplaintID`
8. `getAComplaintbyCustomerIDAndComplaintID`
9. `getAllComplaintsByCustomerID`
10. `escalateComplaintByComplaintID`
11. `getAllEscalatedComplaints`
12. `getEscalatedComplaintsByAgentID` (order from newest to oldest)
13. `getCommentsByAgentID` (between two dates)

Complaint management system schema design evolution

Since this is a complaint management system, most access patterns revolve around a complaint as the primary entity. The `ComplaintID` being highly cardinal will ensure even distribution of data

in the underlying partitions and is also the most common search criteria for our identified access patterns. Therefore, ComplaintID is a good partition key candidate in this data set.

Step 1: Address access patterns 1 (`createComplaint`), 2 (`updateComplaint`), 3 (`updateSeveritybyComplaintID`), and 4 (`getComplaintByComplaintID`)

We can use a generic sort key valued called "metadata" (or "AA") to store complaint-specific information such as CustomerID, State, Severity, and CreationDate. We use singleton operations with PK=ComplaintID and SK="metadata" to do the following:

1. [PutItem](#) to create a new complaint
2. [UpdateItem](#) to update the severity or other fields in the complaint metadata
3. [GetItem](#) to fetch metadata for the complaint

Primary key		Attributes				
Partition key: PK	Sort key: SK	customer_id	current_state	creation_time	severity	complaint_description
Complaint1321	metadata	custXYZ	assigned	2023-05-10T15:58:00	P2	<Complaint Description>

Step 2: Address access pattern 5 (`addCommentByComplaintID`)

This access pattern requires a one-to-many relationship model between a complaint and comments on the complaint. We will use the [vertical partitioning](#) technique here to use a sort key and create an item collection with different types of data. If we look at access patterns 6 (`getAllCommentsByComplaintID`) and 7 (`getLatestCommentByComplaintID`), we know that comments will need to be sorted by time. We can also have multiple comments coming in at the same time so we can use the [composite sort key](#) technique to append time and CommentID in the sort key attribute.

Other options to deal with such possible comment collisions would be to increase the granularity for the timestamp or add an incremental number as a suffix instead of using Comment_ID. In this case, we'll prefix the sort key value for items corresponding to comments with "comm#" to enable range-based operations.

We also need to ensure that the currentState in the complaint metadata reflects the state when a new comment is added. Adding a comment might indicate that the complaint has been assigned to an agent or it has been resolved and so on. In order to bundle the addition of comment and

update of current state in the complaint metadata, in an all-or-nothing manner, we will use the TransactWriteItems API. The resulting table state now looks like this:

Primary key		Attributes				
Partition key: PK	Sort key: SK	comm_id	comm_date	complaint_state	comm_text	agentID
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm3	2023-05-10T16:00:00	investigating	<Comment text>	AgentB
		customer_id	current_state	creation_time	severity	complaint_description
	metadata	custXYZ	investigating	2023-05-10T15:58:00	P2	<Complaint Description>

Let's add some more data in the table and also add ComplaintID as a separate field from our PK for future-proofing the model in case we need additional indexes on ComplaintID. Also note that some comments may have attachments which we will store in Amazon Simple Storage Service and only maintain their references or URLs in DynamoDB. It's a best practice to keep the transactional database as lean as possible to optimize cost and performance. The data now looks like this:

Primary key		Attributes				
Partition key: PK	Sort key: SK	comm_id	comm_date	complaint_state	comm_text	agentID
Complaint123	comm#2023-04-30T12:00:24#comm1	comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA
		comm_id	comm_date	complaint_state	comm_text	attachments
	comm#2023-04-30T12:35:54#comm2	comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]
		customer_id	complaint_id	current_state	creation_time	severity
	metadata	custABC	Complaint123	resolved	2023-04-30T12:00:00	P2
						<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB
		customer_id	complaint_id	current_state	creation_time	severity
	metadata	custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2
						<descr_text>

Step 3: Address access patterns 6 (getAllCommentsByComplaintID) and 7 (getLatestCommentByComplaintID)

In order to get all comments for a complaint, we can use the query operation with the begins_with condition on the sort key. Instead of consuming additional read capacity to read

the metadata entry and then having the overhead of filtering the relevant results, having a sort key condition like this help us only read what we need. For example, a [query](#) operation with PK=Complaint123 and SK begins_with comm# would return the following while skipping the metadata entry:

Primary key		Attributes					
Partition key: PK	Sort key: SK						
Complaint123	comm#2023-04-30T12:00:24 #comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
	comm#2023-04-30T12:35:54 #comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
Complaint1321	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
	metadata	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	

Since we need the latest comment for a complaint in pattern 7

(getLatestCommentByComplaintID), let's use two additional query parameters:

1. ScanIndexForward should be set to False to get results sorted in a descending order
2. Limit should be set to 1 to get the latest (only one) comment

Similar to access pattern 6 (getAllCommentsByComplaintID), we skip the metadata entry using begins_with comm# as the sort key condition. Now, you can perform access pattern 7 on this design using the query operation with PK=Complaint123 and SK=begins_with comm#, ScanIndexForward=False, and Limit 1. The following targeted item will be returned as a result:

Partition key: PK	Sort key: SK	Attributes					
	comm#2023-04-30T12:00:24 #comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
Complaint123	comm#2023-04-30T12:35:54 #comm2	comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
		comm_id	comm_date	complaint_state	comm_text	attachments	agentID
	metadata	comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
		customer_id	complaint_id	current_state	creation_time	severity	complaint_description
Complaint1321	comm#2023-05-10T16:00:00 #comm3	custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
		comm_id	comm_date	complaint_state	comm_text	agentID	
	metadata	comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
		customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>

Let's add more dummy data to the table.

Primary key		Attributes					
Partition key: PK	Sort key: SK						
Complaint123	comm#2023-04-30T12:00:24#comm1	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm1	2023-04-30T12:00:24	investigating	<comm text>	AgentA	
	comm#2023-04-30T12:35:54#comm2	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm2	2023-04-30T12:35:54	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]	AgentA
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custABC	Complaint123	resolved	2023-04-30T12:00:00	P2	<description text>
Complaint1321	comm#2023-05-10T16:00:00#comm3	comm_id	comm_date	complaint_state	comm_text	agentID	
		comm3	2023-05-10T16:00:00	investigating	<comm text>	AgentB	
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>
Complaint1444	comm#2022-12-31T19:32:00#comm4	comm_id	comm_date	complaint_state	comm_text		
		comm4	2022-12-31T19:32:00	waiting	<comm text>		
	comm#2022-12-31T19:40:00#comm5	comm_id	comm_date	complaint_state	comm_text	attachments	agentID
		comm5	2022-12-31T19:40:00	assigned	<comm text>	["s3://URL_for_attachment1"]	AgentC
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXY32	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>
Complaint0987	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description
		custXYZ	Complaint0987	assigned	2023-06-10T12:30:08	P3	<description text>

Step 4: Address access patterns 8 (getAComplaintbyCustomerIDAndComplaintID) and 9 (getAllComplaintsByCustomerID)

Access patterns 8 (getAComplaintbyCustomerIDAndComplaintID) and 9 (getAllComplaintsByCustomerID) introduces new a search criteria: CustomerID. Fetching it from the existing table requires an expensive [Scan](#) to read all data and then filter relevant items for the CustomerID in question. We can make this search more efficient by creating

a [global secondary index \(GSI\)](#) with CustomerID as the partition key. Keeping in mind the one-to-many relationship between customer and complaints as well as access pattern 9 (getAllComplaintsByCustomerID), ComplaintID would be the right candidate for the sort key.

The data in the GSI would look like this:

Primary key		Attributes					
Partition key: customer_id	Sort key: complaint_id	PK	SK	current_state	creation_time	severity	complaint_description
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXYZ32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
custXYZ	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

An example query on this GSI for access pattern 8

(getAComplaintbyCustomerIDAndComplaintID) would be: `customer_id=custXYZ, sort key=Complaint1321`. The result would be:

Primary key		Attributes					
Partition key: customer_id	Sort key: complaint_id	PK	SK	current_state	creation_time	severity	complaint_description
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXYZ32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
custXYZ	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

To get all complaints for a customer for access pattern 9 (`getAllComplaintsByCustomerID`), the query on the GSI would be: `customer_id=custXYZ` as the partition key condition. The result would be:

Primary key		Attributes					
Partition key: <code>customer_id</code>	Sort key: <code>complaint_id</code>	PK	SK	current_state	creation_time	severity	complaint_description
custABC	Complaint123	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint123	metadata	resolved	2023-04-30T12:00:00	P2	<description text>
custXYZ32	Complaint1444	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1444	metadata	assigned	2022-12-31T19:39:57	P1	<description text>
custXYZ	Complaint0987	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint0987	metadata	assigned	2023-06-10T12:30:08	P3	<description text>
	Complaint1321	PK	SK	current_state	creation_time	severity	complaint_description
		Complaint1321	metadata	investigating	2023-05-10T15:58:00	P2	<descr_text>

Step 5: Address access pattern 10 (`escalateComplaintByComplaintID`)

This access introduces the escalation aspect. To escalate a complaint, we can use `UpdateItem` to add attributes such as `escalated_to` and `escalation_time` to the existing complaint metadata item. DynamoDB provides flexible schema design which means a set of non-key attributes can be uniform or discrete across different items. See below for an example:

`UpdateItem` with `PK=Complaint1444`, `SK=metadata`

Complaint1444	comm#2022-12-31T19:32:00#comm4	comm_id	comm_date	complaint_state	comm_text				
	comm4	2022-12-31T19:32:00	waiting	<comm text>					
	comm#2022-12-31T19:40:00#comm5	comm_id	comm_date	complaint_state	comm_text	attachments	agentID		
	comm5	2022-12-31T19:40:00	assigned	<comm text>	["s3://URL_for_attachment1"]	AgentC			
	metadata	customer_id	complaint_id	current_state	creation_time	severity	complaint_description	escalated_to	escalation_time
	custXYZ32	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>	AgentB	2023-01-03T04:00:07	

Step 6: Address access patterns 11 (`getAllEscalatedComplaints`) and 12 (`getEscalatedComplaintsByAgentID`)

Only a handful of complaints are expected to be escalated out of the whole data set. Therefore, creating an index on the escalation-related attributes would lead to efficient lookups as well as

cost-effective GSI storage. We can do this by leveraging the [sparse index](#) technique. The GSI with partition key as `escalated_to` and sort key as `escalation_time` would look like this:

Primary key		Attributes								
Partition key: <code>escalated_to</code>	Sort key: <code>escalation_time</code>	PK	SK	customer_id	complaint_id	current_state	creation_time	severity	complaint_description	
AgentB	2023-01-03T04:00:07	PK	SK	customer_id	complaint_id	current_state	creation_time	severity	complaint_description	
		Complaint1444	metadata	custXYZ2	Complaint1444	assigned	2022-12-31T19:39:57	P1	<description text>	
AgentB	2023-05-15T14:00:00	PK	SK	customer_id	complaint_id	current_state	creation_time	severity	complaint_description	
		Complaint1321	metadata	custXYZ	Complaint1321	investigating	2023-05-10T15:58:00	P2	<descr_text>	

To get all escalated complaints for access pattern 11 (`getAllEscalatedComplaints`), we simply scan this GSI. Note that this scan will be performant and cost-efficient due to the size of the GSI. To get escalated complaints for a specific agent (access pattern 12 (`getEscalatedComplaintsByAgentID`)), the partition key would be `escalated_to=agentID` and we set `ScanIndexForward` to `False` for ordering from newest to oldest.

Step 7: Address access pattern 13 (`getCommentsByAgentID`)

For the last access pattern, we need to perform a lookup by a new dimension: `AgentID`. We also need time-based ordering to read comments between two dates so we create a GSI with `agent_id` as the partition key and `comm_date` as the sort key. The data in this GSI will look like the following:

Primary key		Attributes						
Partition key: <code>agentID</code>	Sort key: <code>comm_date</code>	PK	SK	comm_id	complaint_state	comm_text		
AgentA	2023-04-30T12:00:24	PK	SK	comm#2023-04-30T12:00:24#comm1	comm1	investigating	<comm text>	
		PK	SK	comm_id	complaint_state	comm_text	attachments	
AgentB	2023-05-10T16:00:00	PK	SK	comm#2023-05-10T16:00:00#comm3	comm3	investigating	<comm text>	
		PK	SK	comm_id	complaint_state	comm_text	attachments	
AgentC	2022-12-31T19:40:00	PK	SK	comm#2022-12-31T19:40:00#comm5	comm5	assigned	<comm text>	["s3://URL_for_attachment1"]

An example query on this GSI would be `partition key agentID=AgentA and sort key=comm_date between (2023-04-30T12:30:00, 2023-05-01T09:00:00)`, the result of which is:

Primary key		Attributes					
Partition key: agentID	Sort key: comm_date	PK	SK	comm_id	complaint_state	comm_text	
AgentA	2023-04-30T12:00:24	Complaint1	comm#2023-04-30T12:00:24#comm1	comm1	investigating	<comm text>	
		Complaint1	comm#2023-04-30T12:35:54#comm2	comm2	resolved	<comm text>	["s3://URL_for_attachment1","s3://URL_for_attachment2"]
AgentB	2023-05-10T16:00:00	PK	SK	comm_id	complaint_state	comm_text	
		Complaint1	comm#2023-05-10T16:00:00#comm3	comm3	investigating	<comm text>	
AgentC	2022-12-31T19:40:00	PK	SK	comm_id	complaint_state	comm_text	attachments
		Complaint1	comm#2022-12-31T19:40:00#comm5	comm5	assigned	<comm text>	["s3://URL_for_attachment1"]

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/filters
createComplaint	Base table	PutItem	PK=complaint_id	SK=metadata	
updateComplaint	Base table	UpdateItem	PK=complaint_id	SK=metadata

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called "Download"](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called "Importing an existing model"](#).
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called "Editing an existing model"](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Recurring payments schema design in DynamoDB

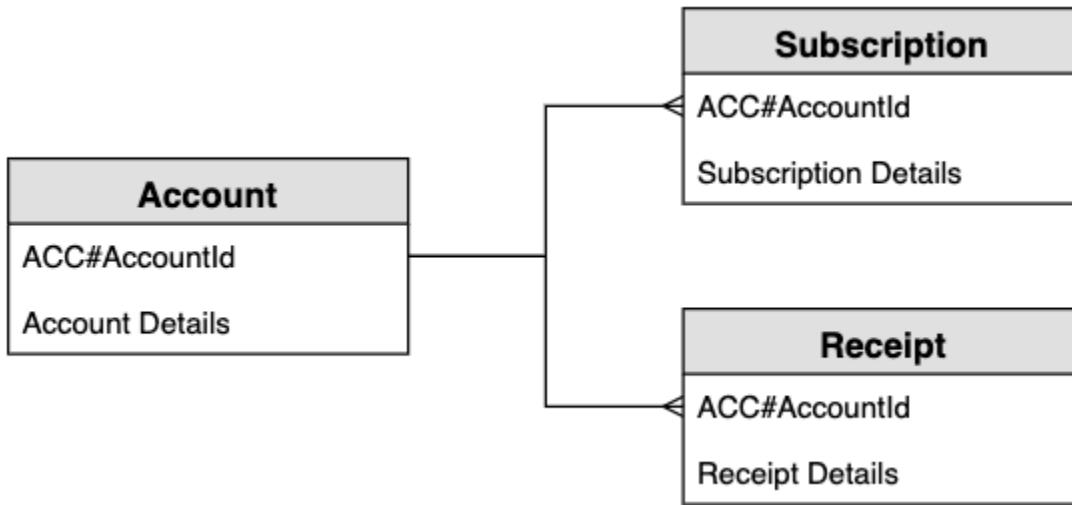

Recurring payments business use case

This use case talks about using DynamoDB to implement a recurring payments system. The data model has the following entities: *accounts*, *subscriptions*, and *receipts*. The specifics for our use case include the following:

- Each *account* can have multiple *subscriptions*
- The *subscription* has a `NextPaymentDate` when the next payment needs to be processed and a `NextReminderDate` when an email reminder is sent to the customer
- There is an item for the *subscription* that is stored and updated when the payment been processed (the average item size is around 1KB and the throughput depends on the number of *accounts* and *subscriptions*)
- The *payment processor* will also create a *receipt* as part of the process which is stored in the table and are set to expire after a period of time by using a [TTL](#) attribute

Recurring payments entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the recurring payments system schema design.

Recurring payments system access patterns

These are the access patterns we'll be considering for the recurring payments system schema design.

1. `createSubscription`
2. `createReceipt`
3. `updateSubscription`
4. `getDueRemindersByDate`
5. `getDuePaymentsByDate`
6. `getSubscriptionsByAccount`
7. `getReceiptsByAccount`

Recurring payments schema design

The generic names `PK` and `SK` are used for key attributes to allow storing different types of entities in the same table such as the account, subscription, and receipt entities. The user first creates a subscription, which is where the user agrees to pay an amount on the same day each month in return for a product. They get the choice on which day of the month to process the payment. There is also a reminder that will be sent prior to the payment being processed. The application works by having two batch jobs that run each day: one batch job sends reminders due that day and the other batch job processes any payments due that day.

Step 1: Address access pattern 1 (`createSubscription`)

Access pattern 1 (`createSubscription`) is used to initially create the subscription, and the details including SKU, NextPaymentDate, NextReminderDate and PaymentDetails are set. This step shows the state of the table for just one account with one subscription. There can be multiple subscriptions in the item collection so this is a one-to-many relationship.

Primary key		Attributes										
Partition key: PK	Sort key: SK	Email	PaymentDay	PaymentAmount	LastPaymentDate	NextPaymentDate	LastReminderDate	NextReminderDate	SKU	PaymentDetails	CreatedDate	
ACC#123	SUB#123#SKU#999 s@s.com	28	12.99	1970-01-01T00:00:00.000Z	2023-05-28	1970-01-01T00:00:00.000Z	2023-05-21	999	{"default-card": {"\$": "1234123412341234"}, "default-address": {"\$": "12 Bridge Street, Birmingham, B12 7ST"}}	2023-05-18T09:41:25.856Z		

Step 2: Address access patterns 2 (`createReceipt`) and 3 (`updateSubscription`)

Access pattern 2 (`createReceipt`) is used to create the receipt item. After the payment is processed each month, the payment processor will write a receipt back to the base table. There, could be multiple receipts in the item collection so this is a one-to-many relationship. The payment processor will also update the subscription item (access Pattern 3 (`updateSubscription`)) to update for the `NextReminderDate` or the `NextPaymentDate` for the next month.

Primary key		Attributes										
Partition key: PK	Sort key: SK	Email	SKU	ProcessedDate	ProcessedAmount	TTL						
ACC#123	REC#12023-05-28T14:15:39.24#SKU#999 s@s.com	999	2023-05-28T14:15:39.247Z	12.99	1700318200							
	SUB#123#SKU#999 s@s.com	28	12.99	2023-05-18T14:15:39.247Z	2023-06-28	2023-05-21T14:15:39.247Z	2023-06-21	999	{"default-card": {"\$": "1234123412341234"}, "default-address": {"\$": "12 Bridge Street, Birmingham, B12 7ST"}}	2023-05-18T09:41:25.856Z		

Step 3: Address access pattern 4 (`getDueRemindersByDate`)

The application processes reminders for the payment in batches for the current day. Therefore the application needs to access the subscriptions on a different dimension: date rather than account. This is a good use case for a [global secondary index \(GSI\)](#). In this step we add the index GSI-1, which uses the `NextReminderDate` as the GSI partition key. We do not need to replicate all the items. This GSI is a [sparse index](#) and the receipts items are not replicated. We also do not need to project all the attributes—we only need to include a subset of the attributes. The image below shows the schema of GSI-1 and it gives the information needed for the application to send the reminder email.

Primary key		Attributes				
Partition key: NextReminderDate	Sort key: LastReminderDate	SK	PK	SKU	Email	NextPaymentDate
2023-06-21	2023-05-21T14:15:39.247Z	SUB#123#SKU#999	ACC#123	999	s@s.com	2023-06-28

Step 4: Address access pattern 5 (`getDuePaymentsByDate`)

The application processes the payments in batches for the current day in the same way it does with reminders. We add GSI-2 in this step, and it uses the `NextPaymentDate` as the GSI partition key. We do not need to replicate all the items. This GSI is a sparse index as the receipts items are not replicated. The image below shows the schema of GSI-2.

Primary key		Attributes						
Partition key: <code>NextPaymentDate</code>	Sort key: <code>LastPaymentDate</code>	PK	SK	Email	PaymentDay	PaymentAmount	SKU	PaymentDetails
2023-06-28	2023-05-18T14:15:39.247Z	ACC#123	SUB#123#SKU#999	s@s.com	28	12.99	999	{"default-card":{"S":"1234123412341234"}, "default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}

Step 5: Address access patterns 6 (`getSubscriptionsByAccount`) and 7 (`getReceiptsByAccount`)

The application can retrieve all the subscriptions for an account by using a [query](#) on the base table that targets the account identifier (the PK) and uses the range operator to get all the items where the SK begins with “SUB#”. The application can also use the same query structure to retrieve all the receipts by using a range operator to get all the items where the SK begins with “REC#”. This allows us to satisfy access patterns 6 (`getSubscriptionsByAccount`) and 7 (`getReceiptsByAccount`). The application uses these access patterns so the user can see their current subscriptions and their past receipts for the last six months. There is no change to the table schema in this step and we can see below how we target just the subscription item(s) in access pattern 6 (`getSubscriptionsByAccount`).

Primary key		Attributes								
Partition key: PK	Sort key: SK	Email	SKU	ProcessedDate	ProcessedAmount	TTL				
	REC#12023-05-28T14:15:39.24#SKU#999	s@s.com	999	2023-05-28T14:15:39.247Z	12.99	1700318200				
ACC#123	SUB#123#SKU#999	Email	PaymentDay	PaymentAmount	LastPaymentDate	NextPaymentDate	LastReminderDate	NextReminderDate	SKU	PaymentDetails
		s@s.com	28	12.99	2023-05-18T14:15:39.247Z	2023-06-28	2023-05-21T14:15:39.247Z	2023-06-21	999	{"default-card":{"S":"1234123412341234"}, "default-address":{"S":"12 Bridge Street, Birmingham, B12 7ST"}}
										2023-05-18T09:41:25.856Z

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/GSI/ LSI	Operation	Partition key value	Sort key value
createSubscription	Base table	PutItem	ACC#account_id	SUB#<SUBID>#SKU<SKU>

Access pattern	Base table/GSI/ LSI	Operation	Partition key value	Sort key value

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called “Download”](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called “Importing an existing model”](#).
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called “Editing an existing model”](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Monitoring device status updates in DynamoDB

This use case talks about using DynamoDB to monitor device status updates (or changes in device state) in DynamoDB.

Use case

In IoT use-cases (a smart factory for instance) many devices need to be monitored by operators and they periodically send their status or logs to a monitoring system. When there is a problem with a device, the status for the device changes from *normal* to *warning*. There are different log levels or statuses depending on the severity and type of abnormal behavior in the device. The system then

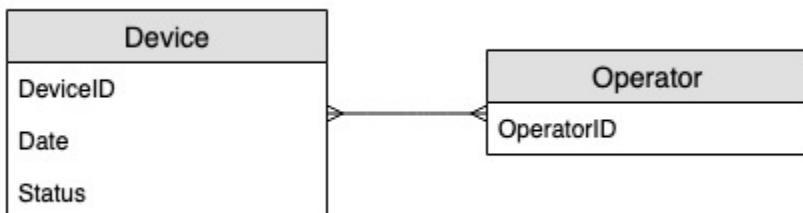

assigns an operator to check on the device and they may escalate the problem to their supervisor if needed.

Some typical access patterns for this system include:

- Create log entry for a device
- Get all logs for a specific device state showing the most recent logs first
- Get all logs for a given operator between two dates
- Get all escalated logs for a given supervisor
- Get all escalated logs with a specific device state for a given supervisor
- Get all escalated logs with a specific device state for a given supervisor for a specific date

Entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for monitoring device status updates.

Access patterns

These are the access patterns we'll be considering for monitoring device status updates.

1. `createLogEntryForSpecificDevice`
2. `getLogsForSpecificDevice`
3. `getWarningLogsForSpecificDevice`
4. `getLogsForOperatorBetweenTwoDates`
5. `getEscalatedLogsForSupervisor`
6. `getEscalatedLogsWithSpecificStatusForSupervisor`
7. `getEscalatedLogsWithSpecificStatusForSupervisorForDate`

Schema design evolution

Step 1: Address access patterns 1 (`createLogEntryForSpecificDevice`) and 2 (`getLogsForSpecificDevice`)

The unit of scaling for a device tracking system would be individual devices. In this system, a `deviceID` uniquely identifies a device. This makes `deviceID` a good candidate for the partition key. Each device sends information to the tracking system periodically (say, every five minutes or so). This ordering makes date a logical sorting criterion and therefore, the sort key. The sample data in this case would look something like this:

Primary key		Attributes
Partition key: DeviceID	Sort key: Date	
d#12345	2020-04-24T14:40:00	State WARNING1
	2020-04-24T14:45:00	State WARNING1
	2020-04-24T14:50:00	State WARNING1
	2020-04-24T14:55:00	State NORMAL
d#54321	2020-04-11T05:50:00	State WARNING3
	2020-04-11T05:55:00	State WARNING3
	2020-04-11T06:00:00	State NORMAL
	2020-04-11T09:25:00	State WARNING2
d#11223	2020-04-11T09:30:00	State NORMAL
	2020-04-27T16:10:00	State WARNING4
	2020-04-27T16:15:00	State WARNING4

To fetch log entries for a specific device, we can perform a [query](#) operation with partition key DeviceID="d#12345".

Step 2: Address access pattern 3 (getWarningLogsForSpecificDevice)

Since State is a non-key attribute, addressing access pattern 3 with the current schema would require a [filter expression](#). In DynamoDB, filter expressions are applied after data is read using key condition expressions. For example, if we were to fetch warning logs for d#12345, the query operation with partition key DeviceID="d#12345" will read four items from the above table and then filter out the one item with the *warning* status. This approach is not efficient at scale. A filter expression can be a good way to exclude items that are queried if the ratio of excluded items is low or the query is performed infrequently. However, for cases where many items are retrieved from a table and the majority of the items are filtered out, we can continue evolving our table design so it runs more efficiently.

Let's change how to handle this access pattern by using [composite sort keys](#). You can import sample data from [DeviceStateLog_3.json](#) where the sort key is changed to State#Date. This sort key is the composition of the attributes State, #, and Date. In this example, # is used as a delimiter. The data now looks something like this:

Primary key	
Partition key: DeviceID	Sort key: State#Date
d#12345	NORMAL#2020-04-24T14:55:00
	WARNING1#2020-04-24T14:40:00
	WARNING1#2020-04-24T14:45:00
	WARNING1#2020-04-24T14:50:00

To fetch only warning logs for a device, the query becomes more targeted with this schema. The key condition for the query uses partition key DeviceID="d#12345" and sort key State#Date

`begins_with "WARNING"`. This query will only read the relevant three items with the *warning* state.

Step 3: Address access pattern 4 (`getLogsForOperatorBetweenTwoDates`)

You can import [DeviceStateLog_4.json](#) where the `Operator` attribute was added to the `DeviceStateLog` table with example data.

Primary key		Attributes		
Partition key: DeviceID	Sort key: State#Date	Operator	Date	State
d#12345	NORMAL#2020-04-24T14:55:00	Liz	2020-04-24T14:55:00	NORMAL
		Liz	2020-04-24T14:40:00	WARNING1
	WARNING1#2020-04-24T14:45:00	Liz	2020-04-24T14:45:00	WARNING1
		Liz	2020-04-24T14:50:00	WARNING1
	NORMAL#2020-04-11T06:00:00	Liz	2020-04-11T06:00:00	NORMAL
		Sue	2020-04-11T09:30:00	NORMAL
	WARNING2#2020-04-11T09:25:00	Sue	2020-04-11T09:25:00	WARNING2
		Sue	2020-04-11T05:50:00	WARNING3
d#54321	WARNING3#2020-04-11T05:55:00	Liz	2020-04-11T05:55:00	WARNING3
		Sue	2020-04-27T16:10:00	WARNING4
	WARNING4#2020-04-27T16:15:00	Sue	2020-04-27T16:15:00	WARNING4
		Sue	2020-04-27T16:15:00	WARNING4
d#11223	Since Operator is not currently a partition key, there is no way to perform a direct key-value lookup on this table based on Operator ID. We'll need to create a new item collection with a			

global secondary index on OperatorID. The access pattern requires a lookup based on dates so Date is the sort key attribute for the [global secondary index \(GSI\)](#). This is what the GSI now looks like:

Primary key		Attributes		
Partition key: Operator	Sort key: Date			
Liz	2020-04-11T05:55:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:55:00	WARNING3
	2020-04-11T06:00:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T06:00:00	NORMAL
	2020-04-24T14:40:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:40:00	WARNING1
	2020-04-24T14:45:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:45:00	WARNING1
	2020-04-24T14:50:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:50:00	WARNING1
	2020-04-24T14:55:00	DeviceID	State#Date	State
		d#12345	NORMAL#2020-04-24T14:55:00	NORMAL
Sue	2020-04-11T05:50:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:50:00	WARNING3
	2020-04-11T09:25:00	DeviceID	State#Date	State
		d#54321	WARNING2#2020-04-11T09:25:00	WARNING2
	2020-04-11T09:30:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T09:30:00	NORMAL
	2020-04-27T16:10:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:10:00	WARNING4
	2020-04-27T16:15:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:15:00	WARNING4

For access pattern 4 (getLogsForOperatorBetweenTwoDates), you can query this GSI with partition key OperatorID=Liz and sort key Date between 2020-04-11T05:58:00 and 2020-04-24T14:50:00.

Primary key		Attributes		
Partition key: Operator	Sort key: Date	DeviceID	State#Date	State
Liz	2020-04-11T05:55:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:55:00	WARNING3
	2020-04-11T06:00:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T06:00:00	NORMAL
	2020-04-24T14:40:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:40:00	WARNING1
	2020-04-24T14:45:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:45:00	WARNING1
	2020-04-24T14:50:00	DeviceID	State#Date	State
		d#12345	WARNING1#2020-04-24T14:50:00	WARNING1
Sue	2020-04-24T14:55:00	DeviceID	State#Date	State
		d#12345	NORMAL#2020-04-24T14:55:00	NORMAL
	2020-04-11T05:50:00	DeviceID	State#Date	State
		d#54321	WARNING3#2020-04-11T05:50:00	WARNING3
	2020-04-11T09:25:00	DeviceID	State#Date	State
		d#54321	WARNING2#2020-04-11T09:25:00	WARNING2
	2020-04-11T09:30:00	DeviceID	State#Date	State
		d#54321	NORMAL#2020-04-11T09:30:00	NORMAL
	2020-04-27T16:10:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:10:00	WARNING4
	2020-04-27T16:15:00	DeviceID	State#Date	State
		d#11223	WARNING4#2020-04-27T16:15:00	WARNING4

Step 4: Address access patterns 5 (`getEscalatedLogsForSupervisor`) 6 (`getEscalatedLogsWithSpecificStatusForSupervisor`), and 7 (`getEscalatedLogsWithSpecificStatusForSupervisorForDate`)

We'll be using a [sparse index](#) to address these access patterns.

Global secondary indexes are sparse by default, so only items in the base table that contain primary key attributes of the index will actually appear in the index. This is another way of excluding items that are not relevant for the access pattern being modeled.

You can import [DeviceStateLog_6.json](#) where the `EscalatedTo` attribute was added to the `DeviceStateLog` table with example data. As mentioned earlier, not all of the logs gets escalated to a supervisor.

Primary key		Attributes		
Partition key: DeviceID	Sort key: State#Date	Operator	Date	State
d#12345	NORMAL#2020-04-24T14:55:00	Liz	2020-04-24T14:55:00	NORMAL
	WARNING1#2020-04-24T14:40:00	Liz	2020-04-24T14:40:00	WARNING1
	WARNING1#2020-04-24T14:45:00	Liz	2020-04-24T14:45:00	WARNING1
	WARNING1#2020-04-24T14:50:00	Liz	2020-04-24T14:50:00	WARNING1
	NORMAL#2020-04-11T06:00:00	Liz	2020-04-11T06:00:00	NORMAL
	NORMAL#2020-04-11T09:30:00	Sue	2020-04-11T09:30:00	NORMAL
	WARNING2#2020-04-11T09:25:00	Sue	2020-04-11T09:25:00	WARNING2
	WARNING3#2020-04-11T05:50:00	Sue	2020-04-11T05:50:00	WARNING3
d#54321	WARNING3#2020-04-11T05:55:00	Liz	2020-04-11T05:55:00	WARNING3
	WARNING4#2020-04-27T16:10:00	Sue	2020-04-27T16:10:00	WARNING4
	WARNING4#2020-04-27T16:15:00	Sue	2020-04-27T16:15:00	WARNING4
				Sara
d#11223	EscalatedTo			

You can now create a new GSI where EscalatedTo is the partition key and State#Date is the sort key. Notice that only items that have both EscalatedTo and State#Date attributes appear in the index.

Primary key		Attributes			
Partition key: EscalatedTo	Sort key: State#Date	DeviceID	Operator	Date	State
Sara	WARNING4#2020-04-27T16:15:00	d#11223	Sue	2020-04-27T16:15:00	WARNING4

The rest of the access patterns are summarized as follows:

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
createLogEntryForSpecificDevice	Base table	PutItem	DeviceID=deviceld	State#Date=e=state#date	
getLogsForSpecificDevice	Base table	Query	DeviceID=deviceld	State#Date begins_with "state1#"	ScanIndexForward = False
getWarningLogsForSpecificDevice	Base table	Query	DeviceID=deviceld	State#Date begins_with "WARNING"	
getLogsForOperatorBetweenTwoDates	GSI-1	Query	Operator=operatorName	Date between date1 and date2	
getEscalatedLogsForSupervisor	GSI-2	Query	EscalatedTo=supervisorName		

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getEscalatedLogsWithSpecificStatusForSupervisor	GSI-2	Query	Escalated To=supervisorName	State#Date begins_with "state1#"	
getEscalatedLogsWithSpecificStatusForSupervisorForDate	GSI-2	Query	Escalated To=supervisorName	State#Date begins_with "state1#date1"	

Final schema

Here are the final schema designs. To download this schema design as a JSON file, see [DynamoDB Examples](#) on GitHub.

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called “Download”](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called “Importing an existing model”](#).
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called “Editing an existing model”](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Using DynamoDB as a data store for an online shop

This use case talks about using DynamoDB as a data store for an online shop (or e-store).

Use case

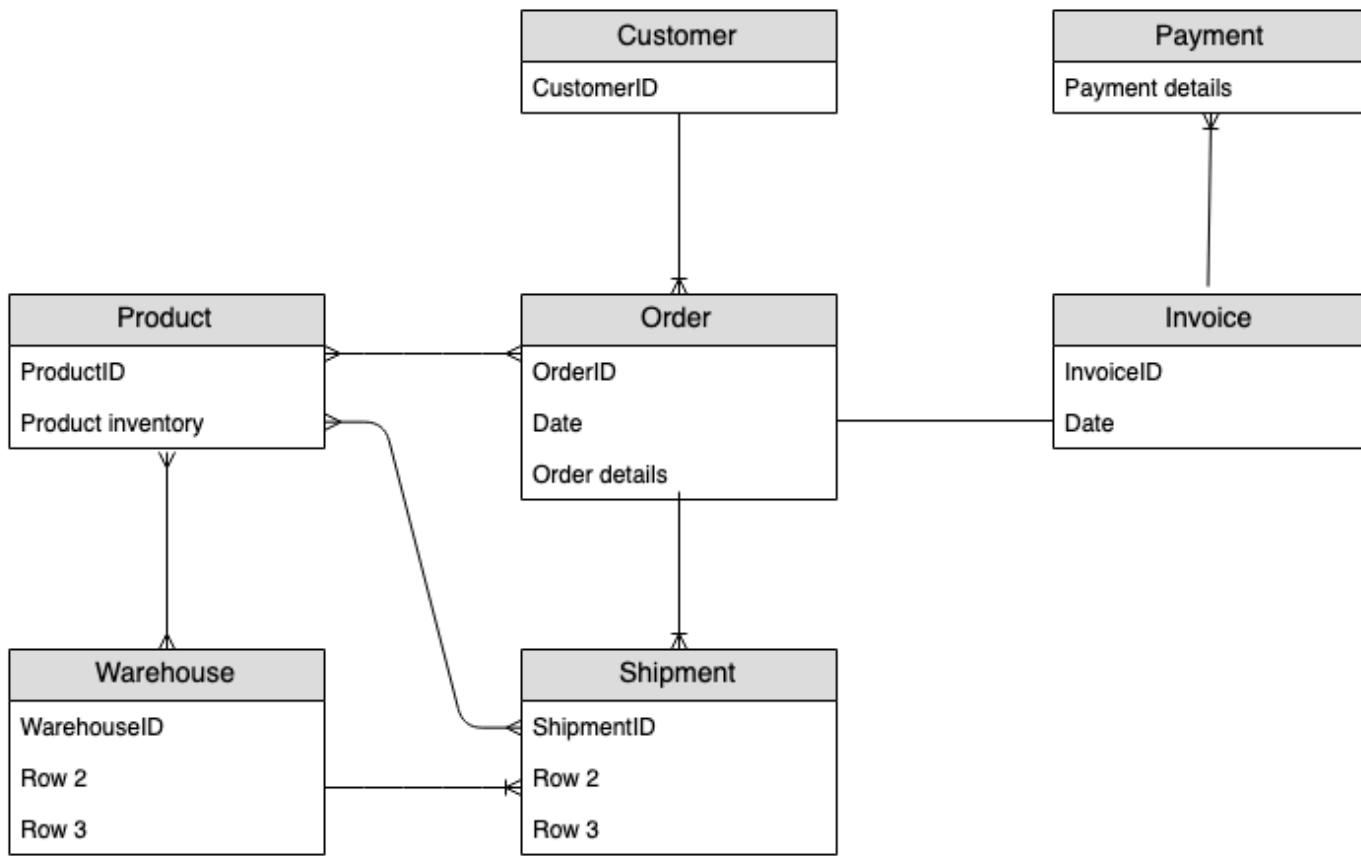

An online store lets users browse through different products and eventually purchase them. Based on the generated invoice, a customer can pay using a discount code or gift card and then pay the remaining amount with a credit card. Purchased products will be picked from one of several warehouses and will be shipped to the provided address. Typical access patterns for an online store include:

- Get customer for a given customerId

- Get product for a given productId
- Get warehouse for a given warehouseId
- Get a product inventory for all warehouses by a productId
- Get order for a given orderId
- Get all products for a given orderId
- Get invoice for a given orderId
- Get all shipments for a given orderId
- Get all orders for a given productId for a given date range
- Get invoice for a given invoiceId
- Get all payments for a given invoiceId
- Get shipment details for a given shipmentId
- Get all shipments for a given warehouseId
- Get inventory of all products for a given warehouseId
- Get all invoices for a given customerId for a given date range
- Get all products ordered by a given customerId for a given date range

Entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using to model DynamoDB as a data store for an online shop.

Access patterns

These are the access patterns we'll be considering when using DynamoDB as a data store for an online shop.

1. `getCustomerByCustomerId`
2. `getProductByProductId`
3. `getWarehouseByWarehouseId`
4. `getProductInventoryByProductId`
5. `getOrderDetailsByOrderId`
6. `getProductByOrderId`
7. `getInvoiceByOrderId`
8. `getShipmentByOrderId`
9. `getOrderByProductIdForDateRange`
10. `getInvoiceByInvoiceId`

```
11getPaymentByInvoiceId  
12getShipmentDetailsByShipmentId  
13getShipmentByWarehouseId  
14getProductInventoryByWarehouseId  
15getInvoiceByCustomerIdForDateRange  
16getProductsByCustomerIdForDateRange
```

Schema design evolution

Using [NoSQL Workbench for DynamoDB](#), import [AnOnlineShop_1.json](#) to create a new data model called AnOnlineShop and a new table called OnlineShop. Note that we use the generic names PK and SK for the partition key and sort key. This is a practice used in order to store different types of entities in the same table.

Step 1: Address access pattern 1 (getCustomerById)

Import [AnOnlineShop_2.json](#) to handle access pattern 1 (getCustomerById). Some entities do not have relationships to other entities, so we will use the same value of PK and SK for them. In the example data, note that the keys use a prefix c# in order to distinguish the customerId from other entities that will be added later. This practice is repeated for other entities as well.

To address this access pattern, a [GetItem](#) operation can be used with PK=customerId and SK=customerId.

Step 2: Address access pattern 2 (getProductById)

Import [AnOnlineShop_3.json](#) to address access pattern 2 (getProductById) for the product entity. The product entities are prefixed by p# and the same sort key attribute has been used to store customerID as well as productId. Generic naming and [vertical partitioning](#) allows us to create such item collections for an effective single table design.

To address this access pattern, a GetItem operation can be used with PK=productId and SK=productId.

Step 3: Address access pattern 3 (getWarehouseById)

Import [AnOnlineShop_4.json](#) to address access pattern 3 (getWarehouseById) for the warehouse entity. We currently have the customer, product, and warehouse entities added

to the same table. They are distinguished using prefixes and the `EntityType` attribute. A type attribute (or prefix naming) improves the model's readability. The readability would be affected if we simply stored alphanumeric IDs for different entities in the same attribute. It would be difficult to tell one entity from the other in the absence of these identifiers.

To address this access pattern, a `GetItem` operation can be used with `PK=warehouseId` and `SK=warehouseId`.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
c#12345	c#12345	EntityType	Email	Name
		customer	samaneh@example.com	Samaneh Utter
p#12345	p#12345	EntityType	Detail	Price
		product	{"Name": {"S": "Options Open"}, "Description": {"S": "The latest album"}}	100
w#12345	w#12345	EntityType	Address	
		warehouse	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "MainStreet"}, "Number": {"S": "20"}, "ZipCode": {"S": "41111"}}	

Step 4: Address access pattern 4 (`getProductInventoryByProductId`)

Import [AnOnlineShop_5.json](#) to address access pattern 4 (`getProductInventoryByProductId`). `warehouseItem` entity is used to keep track of the number of products in each warehouse. This item would normally be updated when a product is added or removed from a warehouse. As seen in the ERD, there is a many-to-many relationship between `product` and `warehouse`. Here, the one-to-many relationship from `product` to `warehouse` is modeled as `warehouseItem`. Later on, the one-to-many relationship from `warehouse` to `product` will be modeled as well.

Access pattern 4 can be addressed with a query on `PK=ProductId` and `SK begins_with "w#"`.

For more information about `begins_with()` and other expressions that can be applied to sort keys, see [Key Condition Expressions](#).

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
c#12345	c#12345	EntityType	Email	Name
		customer	samaneh@example.com	Samaneh Utter
p#12345	p#12345	EntityType	Detail	Price
		product	{"Name": {"S": "Options Open"}, "Description": {"S": "The latest album"}}	100
p#12345	w#12345	EntityType	Quantity	
		warehousesItem	50	
w#12345	w#12345	EntityType	Address	
		warehouse	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "MainStreet"}, "Number": {"S": "20"}, "ZipCode": {"S": "41111"}}	

Step 5: Address access patterns 5 (`getOrderDetailsByOrderId`) and 6 (`getProductByOrderId`)

Add some more customer, product, and warehouse items to the table by importing [AnOnlineShop_6.json](#). Then, import [AnOnlineShop_7.json](#) to build an item collection for order that can address access patterns 5 (`getOrderDetailsByOrderId`) and 6 (`getProductByOrderId`). You can see the one-to-many relationship between order and product modeled as orderItem entities.

To address access pattern 5 (`getOrderDetailsByOrderId`), query the table with `PK=orderId`. This will provide all information about the order including `customerId` and ordered products.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
o#12345	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

To address access pattern 6 (getProductByOrderId), we need to read products in an order only. Query the table with PK=orderId and SK begins_with “p#” to accomplish this.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
o#12345	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

Step 6: Address access pattern 7 (getInvoiceByOrderId)

Import [AnOnlineShop_8.json](#) to add an invoice entity to the order item collection to handle access pattern 7 (getInvoiceByOrderId). To address this access pattern, you can use a query operation with PK=orderId and SK begins_with “i#”.

Base table:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
o#12345	c#12345	EntityType	Date	
		order	2020-06-21T19:10:00	
	i#55443	EntityType	Amount	Date
		invoice	400	2020-06-21T19:18:00
	p#12345	EntityType	Price	Quantity
		orderItem	100	2
	p#99887	EntityType	Price	Quantity
		orderItem	40	5

Step 7: Address access pattern 8 (getShipmentByOrderId)

Import [AnOnlineShop_9.json](#) to add shipment entities to the `order` item collection to address access pattern 8 (getShipmentByOrderId). We are extending the same vertically partitioned model by adding more types of entities in the single table design. Notice how the `order` item collection contains the different relationships that an `order` entity has with the `shipment`, `orderItem`, and `invoice` entities.

To get shipments by `orderId`, you can perform a query operation with `PK=orderId` and `SK begins_with "sh#"`.

Base table:

Primary key		Attributes			
Partition key: PK	Sort key: SK				
o#12345	c#12345	EntityType	Date		
		order	2020-06-21T19:10:00		
o#12345	i#55443	EntityType	Amount	Date	
		invoice	400	2020-06-21T19:18:00	
o#12345	p#12345	EntityType	Price	Quantity	
		orderItem	100	2	
o#12345	p#99887	EntityType	Price	Quantity	
		orderItem	40	5	
o#12345	sh#88899	EntityType	Address	Type	Date
		shipment	{"Country":{"S":"Sweden"}, "County":{"S":"Vastra Gotaland"}, "City":{"S":"Goteborg"}, "Street":{"S":"Slanbarsvagen"}, "Number":{"S":"34"}, "ZipCode":{"S":"41787"}}	Express	2020-06-22T08:20:00
	sh#98765	EntityType	Address	Type	Date
		shipment	{"Country":{"S":"Sweden"}, "County":{"S":"Vastra Gotaland"}, "City":{"S":"Goteborg"}, "Street":{"S":"Slanbarsvagen"}, "Number":{"S":"34"}, "ZipCode":{"S":"41787"}}	Express	2020-06-22T10:20:00

Step 8: Address access pattern 9 (getOrderByIdForDateRange)

We created an *order* item collection in the previous step. This access pattern has new lookup dimensions (ProductID and Date) which requires you to scan the whole table and filter out relevant records to fetch targeted items. In order to address this access pattern, we'll need to create a [global secondary index \(GSI\)](#). Import [AnOnlineShop_10.json](#) to create a new item collection using the GSI that makes it possible to retrieve *orderItem* data from several *order* item collections. The data now has GSI1-PK and GSI1-SK which will be GSI1's partition key and sort key, respectively.

DynamoDB automatically populates items which contain a GSI's key attributes from the table to the GSI. There is no need to manually do any additional inserts into the GSI.

To address access pattern 9, perform a query on GSI1 with GSI1-PK=productId and GSI1-SK between (date1, date2).

Base table:

Primary key		Attributes				
Partition key: PK	Sort key: SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity
o#12345	p#12345	EntityType	GSI1-PK	GSI1-SK	Price	Quantity
		orderItem	p#12345	2020-06-21T19:18:00	100	2
	p#99887	EntityType	GSI1-PK	GSI1-SK	Price	Quantity
		orderItem	p#99887	2020-06-21T19:20:00	40	5

GSI1:

Primary key		Attributes				
Partition key: GSI1-PK	Sort key: GSI1-SK	PK	SK	EntityType	Quantity	Price
p#12345	2020-06-21T19:18:00	PK	SK	EntityType	Quantity	Price
		o#12345	p#12345	orderItem	2	100
p#99887	2020-06-21T19:20:00	PK	SK	EntityType	Quantity	Price
		o#12345	p#99887	orderItem	5	40

Step 9: Address access patterns 10 (`getInvoiceByInvoiceId`) and 11 (`getPaymentByInvoiceId`)

Import [AnOnlineShop_11.json](#) to address access patterns 10 (`getInvoiceByInvoiceId`) and 11 (`getPaymentByInvoiceId`), both of which are related to `invoice`. Even though these are two different access patterns, they are realized using the same key condition. Payments are defined as an attribute with the map data type on the `invoice` entity.

Note

GSI1-PK and GSI1-SK is overloaded to store information about different entities so that multiple access patterns can be served from the same GSI. For more information about GSI overloading, see [Overloading Global Secondary Indexes](#).

To address access pattern 10 and 11, query GSI1 with GSI1-PK=invoiceId and GSI1-SK=invoiceId.

GSI1:

Primary key		Attributes							
Partition key: GSI1-PK	Sort key: GSI1-SK	PK	SK	EntityType	GSI2-PK	GSI2-SK	Detail	Amount	Date
i#55443	i#55443	o#12345	i#55443	invoice	c#12345	i#2020-06-21T19:18:00	{"Payments": [{"L": [{"M": {"Type": "S": "GiftCard"}, "Amount": "N": "100"}, {"Data": {"S": "GiftCard data here..."}}, {"M": {"Type": "S": "MasterCard"}, "Amount": "N": "300"}, {"Data": {"S": "Payment data here..."}]}]}	400	2020-06-21T19:18:00

Step 10: Address access patterns 12 (getShipmentDetailsByShipmentId) and 13 (getShipmentByWarehouseId)

Import [AnOnlineShop_12.json](#) to address access patterns 12 (getShipmentDetailsByShipmentId) and 13 (getShipmentByWarehouseId).

Notice that shipmentItem entities are added to the *order* item collection on the base table in order to be able to retrieve all details about an order in a single query operation.

Base table:

Primary key		Attributes							
Partition key: PK	Sort key: SK	EntityType	GSI1-PK	GSI1-SK	GSI2-PK	GSI2-SK	Address	Type	Date
o#12345	sh#88899	EntityType	GSI1-PK	GSI1-SK	GSI2-PK	GSI2-SK	Address	Type	Date
		shipment	sh#88899	sh#88899	w#12376	sh#88899	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}	Express	2020-06-22T08:20:00
	sh#98765	EntityType	GSI1-PK	GSI1-SK	GSI2-PK	GSI2-SK	Address	Type	Date
		shipment	sh#98765	sh#98765	w#12345	sh#98765	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}	Express	2020-06-22T10:20:00
	shp#12345	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#98765	p#99887	3				
	shp#54321	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#88899	p#99887	2				
	shp#55555	EntityType	GSI1-PK	GSI1-SK	Quantity				
		shipmentItem	sh#98765	p#12345	2				

The GSI1 partition and sort keys have already been used to model a one-to-many relationship between `shipment` and `shipmentItem`. To address access pattern 12 (`getShipmentDetailsByShipmentId`), query GSI1 with `GSI1-PK=shipmentId` and `GSI1-SK=shipmentId`.

GSI1:

Primary key		Attributes							
Partition key: GSI1-PK	Sort key: GSI1-SK	PK	SK	EntityType	Quantity				
sh#88899	p#99887	PK	SK	EntityType	Quantity				
		o#12345	shp#54321	shipmentItem	2				
sh#98765	sh#98765	PK	SK	EntityType	GSI2-PK	GSI2-SK	Address	Type	Date
		o#12345	sh#88899	shipment	w#12376	sh#88899	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}	Express	2020-06-22T08:20:00
sh#98765	p#12345	PK	SK	EntityType	Quantity				
		o#12345	shp#55555	shipmentItem	2				
sh#98765	sh#98765	PK	SK	EntityType	Quantity				
		o#12345	shp#12345	shipmentItem	3				
sh#98765	sh#98765	PK	SK	EntityType	GSI2-PK	GSI2-SK	Address	Type	Date
		o#12345	sh#98765	shipment	w#12345	sh#98765	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}	Express	2020-06-22T10:20:00

We'll need to create another GSI (GSI2) to model the new one-to-many relationship between warehouse and shipment for access pattern 13 (getShipmentByWarehouseId). To address this access pattern, query GSI2 with GSI2-PK=warehouseId and GSI2-SK begins_with "sh#".

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK	PK	SK	EntityType	GSI1-PK	GSI1-SK	Address	Type	Date
w#12376	sh#88899	o#12345	sh#88899	shipment	sh#88899	sh#88899	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}}	Express	2020-06-22T08:20:00
w#12345	sh#98765	o#12345	sh#98765	shipment	sh#98765	sh#98765	{"Country": {"S": "Sweden"}, "County": {"S": "Vastra Gotaland"}, "City": {"S": "Goteborg"}, "Street": {"S": "Slanbarsvagen"}, "Number": {"S": "34"}, "ZipCode": {"S": "41787"}}}	Express	2020-06-22T10:20:00

Step 11: Address access patterns 14 (`getProductInventoryByWarehouseId`) 15 (`getInvoiceByCustomerIdForDateRange`), and 16 (`getProductsByCustomerIdForDateRange`)

Import [AnOnlineShop_13.json](#) to add data related to the next set of access patterns. To address access pattern 14 (`getProductInventoryByWarehouseId`), query GSI2 with GSI2-PK=warehouseId and GSI2-SK begins_with “p#”.

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK	PK	SK	EntityType	Quantity				
w#12345	p#12345	PK	SK	EntityType	Quantity				
		p#12345	w#12345	warehouselt em	50				
	p#99887	PK	SK	EntityType	Quantity				
		p#99887	w#12345	warehouselt em	4				
c#12345	i#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Detail	Amount	Date
		o#12345	i#55443	invoice	i#55443	i#55443	{"Payments": [{"L": [{"M": {"Type": {"S": "GiftCard"}, "Amoun": {"N": "100"}, "Data": {"S": "GiftCard data here..."}}, {"M": {"Type": {"S": "MasterCard"}, "Amout": {"N": "300"}, "Data": {"S": "Payment data here..."}}}]}], "M": {"Type": {"S": "MasterCard"}, "Amout": {"N": "300"}, "Data": {"S": "Payment data here..."}}}}}	400	2020-06-21T19:18:00
	p#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#12345	orderItem	p#12345	2020-06-21T19:18:00	100	2	
	p#2020-06-21T19:20:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#99887	orderItem	p#99887	2020-06-21T19:20:00	40	5	

To address access pattern 15 (getInvoiceByCustomerIdForDateRange), query GSI2 with GSI2-PK=customerId and GSI2-SK between (i#date1, i#date2).

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK	PK	SK	EntityType	Quantity				
w#12345	p#12345	PK	SK	EntityType	Quantity				
		p#12345	w#12345	warehousetem	50				
	p#99887	PK	SK	EntityType	Quantity				
		p#99887	w#12345	warehousetem	4				
c#12345	i#2020-06-21T19:18:00	PK	SK	EntityType	GSI1-PK	GSI1-SK	Detail	Amount	Date
		o#12345	i#55443	invoice	i#55443	i#55443	{"Payments": [{"L": [{"M": {"Type": {"S": "GiftCard"}, "Amoun": {"N": "100"}, "Data": {"S": "GiftCard data here..."}}, {"M": {"Type": {"S": "MasterCard"}, "Amoun": {"N": "300"}, "Data": {"S": "Payment data here..."}}}]}], "M": {"Type": {"S": "MasterCard"}, "Amoun": {"N": "300"}, "Data": {"S": "Payment data here..."}}}}}	400	2020-06-21T19:18:00
		PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#12345	orderItem	p#12345	2020-06-21T19:18:00	100	2	
		PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#99887	orderItem	p#99887	2020-06-21T19:20:00	40	5	

To address access pattern 16 (getProductsByCustomerIdForDateRange), query GSI2 with GSI2-PK=customerId and GSI2-SK between (p#date1, p#date2).

GSI2:

Primary key		Attributes							
Partition key: GSI2-PK	Sort key: GSI2-SK	PK	SK	EntityType	Quantity				
w#12345	p#12345	PK	SK	EntityType	Quantity				
		p#12345	w#12345	warehousetem	50

		o#12345	p#12345	orderItem	p#12345	2020-06-21T19:18:00	100	2	
		PK	SK	EntityType	GSI1-PK	GSI1-SK	Price	Quantity	
		o#12345	p#99887	orderItem	p#99887	2020-06-21T19:20:00	40	5	

Note

In [NoSQL Workbench](#), *facets* represent an application's different data access patterns for DynamoDB. Facets give you a way to view a subset of the data in a table, without having to see records that don't meet the constraints of the facet. Facets are considered a visual data modeling tool, and don't exist as a usable construct in DynamoDB as they are purely an aid for modeling access patterns.

Import [AnOnlineShop_facets.json](#) to see the facets for this use case.

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/GSI/ LSI	Operation	Partition key value	Sort key value
getCustomerByCustomerId	Base table	GetItem	PK=customerId	SK=customerId
getProductByProductId	Base table	GetItem	PK=productId	SK=productId
getWarehouseByWarehouseId	Base table	GetItem	PK=warehouseId	SK=warehouseId
getProductInventoryByProductId	Base table	Query	PK=productId	SK begins_with "w#"
getOrderDetailsByOrderId	Base table	Query	PK=orderId	
getProductByOrderId	Base table	Query	PK=orderId	SK begins_with "p#"
getInvoiceByOrderId	Base table	Query	PK=orderId	SK begins_with "i#"
getShipmentByOrderId	Base table	Query	PK=orderId	SK begins_with "sh#"
getOrderByProductIdForDateRange	GSI1	Query	PK=productId	SK between date1 and date2
getInvoiceByInvoiceId	GSI1	Query	PK=invoiceld	SK=invoiceld

Access pattern	Base table/GSI/ LSI	Operation	Partition key value	Sort key value
getPaymentByInvoiceId	GSI1	Query	PK=invoiceId	SK=invoiceId
getShipmentDetailsByShipmentId	GSI1	Query	PK=shipmentId	SK=shipmentId
getShipmentByWarehouseId	GSI2	Query	PK=warehouseId	SK begins_with "sh#"
getProductInventoryByWarehouseId	GSI2	Query	PK=warehouseId	SK begins_with "p#"
getInvoiceByCustomerIdForDateRange	GSI2	Query	PK=customerId	SK between i#date1 and i#date2
getProductsByCustomerIdForDateRange	GSI2	Query	PK=customerId	SK between p#date1 and p#date2

Online shop final schema

Here are the final schema designs. To download this schema design as a JSON file, see [DynamoDB Design Patterns](#) on GitHub.

Base table

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called “Download”](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called “Importing an existing model”](#).
4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called “Editing an existing model”](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Migrating to DynamoDB from a relational database

Migrating a relational database into DynamoDB requires careful planning to ensure a successful outcome. This guide will help you understand how this process works, what tools you have available, and then how to evaluate potential migration strategies and select one that'll fit your requirements.

Topics

- [Reasons to migrate to DynamoDB](#)
- [Considerations when migrating a relational database to DynamoDB](#)
- [Understanding how a migration to DynamoDB works](#)
- [Tools to help migrate to DynamoDB](#)
- [Choosing the appropriate strategy to migrate to DynamoDB](#)
- [Performing an offline migration to DynamoDB](#)
- [Performing a hybrid migration to DynamoDB](#)
- [Performing an online migration to DynamoDB by migrating each table 1:1](#)
- [Perform an online migration to DynamoDB using a custom staging table](#)

Reasons to migrate to DynamoDB

Migrating to Amazon DynamoDB presents a range of compelling benefits for businesses and organizations. Here are some key advantages that make DynamoDB an attractive choice for database migration:

- **Scalability:** DynamoDB is designed to handle massive workloads and scale seamlessly to accommodate growing data volumes and traffic. With DynamoDB, you can easily scale your database up or down based on demand, ensuring that your applications can handle sudden spikes in traffic without compromising performance.
- **Performance:** DynamoDB offers low-latency data access, enabling applications to retrieve and process data with exceptional speed. Its distributed architecture ensures that read and write operations are distributed across multiple nodes, delivering consistent, single-digit millisecond response times even at high request rates.
- **Fully managed:** DynamoDB is a fully managed service provided by AWS. This means that AWS handles the operational aspects of database management, including provisioning, configuration,

patching, backups, and scaling. This allows you to focus more on developing your applications and less on database administration tasks.

- **Serverless architecture:** DynamoDB supports a serverless model, known as [DynamoDB on-demand](#), where you pay only for the actual read and write requests your application makes with no upfront capacity provisioning required. This pay-per-request model offers cost efficiency and minimal operational overhead, as you only pay for the resources you consume without the need to provision and monitor capacity.
- **NoSQL flexibility:** Unlike traditional relational databases, DynamoDB follows a NoSQL data model, providing flexibility in schema design. With DynamoDB, you can store structured, semi-structured, and unstructured data, making it well-suited for handling diverse and evolving data types. This flexibility enables faster development cycles and easier adaptation to changing business requirements.
- **High availability and durability:** DynamoDB replicates data across multiple availability zones within a Region, ensuring high availability and data durability. It automatically handles replication, failover, and recovery, minimizing the risk of data loss or service disruptions. DynamoDB provides an availability SLA of up to 99.999%.
- **Security and compliance:** DynamoDB integrates with AWS Identity and Access Management for fine-grained access control. It provides encryption at rest and in-transit, ensuring the security of your data. DynamoDB also adheres to various compliance standards, including HIPAA, PCI DSS, and GDPR, enabling you to meet regulatory requirements.
- **Integration with AWS Ecosystem:** As part of the AWS ecosystem, DynamoDB seamlessly integrates with other AWS services, such as AWS Lambda, AWS CloudFormation, and AWS AppSync. This integration enables you to build serverless architectures, leverage infrastructure as code, and create real-time data-driven applications.

Considerations when migrating a relational database to DynamoDB

Relational database systems and NoSQL databases have different strengths and weaknesses. These differences make database design different between the two systems.

	Relational database	NoSQL database
Querying the database	In relational databases, data can be queried flexibly,	In a NoSQL database such as DynamoDB, data can be

	Relational database	NoSQL database
	<p>but queries are relatively expensive and don't scale well in high-traffic situations (see First steps for modeling relational data in DynamoDB). A relational database application may implement business logic in stored procedures, SQL subqueries, bulk update queries, and aggregation queries.</p>	<p>queried efficiently in a limited number of ways, outside of which queries can be expensive and slow. Writes to DynamoDB are singletons. Application business logic that formerly ran in stored procedures must be refactored to run outside of DynamoDB in custom code running on a host such as Amazon Amazon EC2 or AWS Lambda.</p>
Designing the database	<p>You design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.</p>	<p>You design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.</p>

Designing for NoSQL database requires a different mindset than designing for a relational database management system (RDBMS). For an RDBMS, you can create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. You can organize each type of data into its own table.

With NoSQL design, you shouldn't start designing your schema for DynamoDB until you know the questions it will need to answer. Understanding the business problems and the application read and write patterns is essential. You should also aim to maintain as few tables as possible in a DynamoDB application. Having fewer tables keeps things more scalable, requires less permissions management, and reduces overhead for your DynamoDB application. It can also help keep backup costs lower overall.

The task of modeling relational data for DynamoDB and building a new version of the front-end application is a [separate topic](#). This guide assumes you have a new version of your application built to use DynamoDB, but you still need to determine how best to migrate and synchronize historical data during the cutover.

Sizing Considerations

The maximum size of each item (row) that you store in a DynamoDB table is 400KB. For more information, see [Quotas and limits](#). The item size is determined by the total size of all attribute names and attribute values in an item. For more information, see [the section called “Item sizes and formats”](#).

If your application needs to store more data in an item than the DynamoDB size limit permits, break the item into an item collection, compress the item data, or store the item as an object in Amazon Simple Storage Service (Amazon S3) while storing the Amazon S3 object identifier in your DynamoDB item. See [the section called “Large items”](#). The cost to update an item is based on the full size of the item. For workloads that require frequent updates to existing items, having small items of one or two KB will cost less to update than larger items. See [the section called “Working with Item Collections”](#) for more information on item collections.

When choosing the partition and sort key attributes, other table settings, item size and structure, and whether to create secondary indexes, be sure to review the [DynamoDB Modeling documentation](#) as well as the guide for [the section called “Cost optimization”](#). Be sure to test your migration plan so your DynamoDB solution is cost efficient and fits within DynamoDB's features and limitations.

Understanding how a migration to DynamoDB works

Before reviewing the migration tools available to us, consider how writes are processed by DynamoDB.

Note

DynamoDB automatically shards and distributes your data to multiple shared servers and storage locations so there isn't a direct way to bulk-import a large dataset directly onto a production server.

The default and most common write operation is a single [PutItem](#) API operation. You can perform a PutItem operation in a loop to process data sets. DynamoDB supports virtually unlimited concurrent connections, so assuming you can configure and run a massively multi-threaded loading routine such as MapReduce or Spark, the velocity of writes is only limited by the capacity of the target table (which is also generally unlimited).

When loading data into DynamoDB, it's important to understand your loader's write velocity. If the items (rows) you are loading are 1KB in size or less, this velocity is simply the number of items per second. The target table can then be provisioned with sufficient WCU (write capacity units) to handle this rate. If your loader exceeds the provisioned capacity in any given second, the extra requests may be throttled or rejected altogether. You can check for throttles in the CloudWatch charts found in the DynamoDB console monitoring tab.

The second operation that can be performed is with a related API called [BatchWriteItem](#). BatchWriteItem allows you to combine up to 25 write requests into one API call. These are received by the service and processed as separate PutItem requests to the table. When choosing BatchWriteItem, you will not get the advantage of automatic retries that is included with the AWS SDK when making singleton calls with PutItem. So if there are any errors (such as throttling exceptions), you'll have to look for the list of any failed writes on the response call to BatchWriteItem. For more information on handling throttling warnings in case these are detected in the CloudWatch throttling charts, see [the section called "Throttling"](#).

The third type of data import is possible with the [DynamoDB Import from S3 feature](#). This feature allows you to stage a large dataset in Amazon S3 and ask DynamoDB to automatically import the data into a new table. The import is not instant and will take time proportional to the size of the dataset. However, it provides convenience since it requires no ETL platform or custom DynamoDB code to be written. The import feature has limitations that make it suitable for migrations when downtime is acceptable. The data from S3 is loaded into a new table that is created by the import, and is not available to load data into any existing table. There is no transformation of data performed, so it requires an upstream process to prepare and store the data in the final format to an S3 bucket.

Tools to help migrate to DynamoDB

There are several common migration and ETL tools you can use to migrate data into DynamoDB.

Many customers choose to write their own migration scripts and jobs in order to build custom data transformations for the migration process. If you plan to operate a high volume DynamoDB

table with heavy write traffic or regular large bulk load jobs, you may wish to build migration tools yourself in order to gain confidence in the behavior of DynamoDB under heavy write traffic. Scenarios such as throttle handling and efficient table provisioning can be experienced early in the project when performing a practice migration.

Amazon provides a host of data tools that can be leveraged, including [AWS Database Migration Service \(DMS\)](#), [AWS Glue](#), [Amazon EMR](#), and [Amazon Managed Streaming for Apache Kafka](#). All of these tools can be used to perform a downtime migration, and certain tools that can leverage relational database Change Data Capture (CDC) features can support online migrations as well. When choosing the best tool, it will help to consider the skill set and experience your organization has with each tool along with the features, performance and cost of each one.

Choosing the appropriate strategy to migrate to DynamoDB

A large relational database application may span a hundred or more tables and support several different application functions. When approaching a large migration, consider breaking your application into smaller components or micro-services, and migrating a small set of tables at a time. You can then migrate additional components to DynamoDB in waves.

When selecting a migration strategy, certain parameters may steer you towards one solution or another. We can present these options in a decision tree to simplify the options available to us given our requirements and resources available. The concepts are briefly mentioned here (but will be covered in more depth later in the guide):

- **Offline migration**: if your application can tolerate some downtime during the migration, it will greatly simplify the migration process.
- **Hybrid migration**: this approach would allow for partial uptime during a migration, such as allowing reads but not writes, or allowing reads and inserts but not updates and deletes.
- **Online migration**: applications that require zero downtime during migration are less easy to migrate, and may require significant planning and custom development. One key decision will be to estimate and weigh the costs of building a custom migration process versus the cost to the business of having a downtime window during cutover.

If	And	Then
You are okay to		Use AWS DMS and perform an offline

If	And	Then
take the application down for some time during a maintenance window to perform the data migration . This is an offline migration		migration using a full load task. Pre-shape the source data with a SQL VIEW if desired.
You are okay to run the application in read-only mode during migration . This is a hybrid migration		Disable writes within the application or source database. Use AWS DMS and perform an offline migration using a full load task.

If	And	Then
You are okay to run the application with reads and new record inserts, but no updates or deletes, during the migration. This is a hybrid migration	You have application development skills and can update the existing relational app to perform dual writes including to DynamoDB, for all new records	Use AWS DMS and perform an offline migration using a full load task. Concurrently, deploy a version of the existing app that allows reads and performs dual writes.
You require a migration with minimal downtime. This is an online migration	You are migrating source tables 1-for-1 into DynamoDB without major schema changes	Use AWS DMS to perform an online data migration. Run a bulk load task followed by CDC sync task
	You are combining source tables into fewer DynamoDB tables following single table philosophy	<p>You have backend database development skills and spare capacity on the SQL host</p> <p>Create the NoSQL-ready table within the SQL database. Populate and synchronize it using JOINS, UNIONs, VIEWS, triggers, stored procedures</p>

If	And	Then
	You do not have backend database development skills and spare capacity on the SQL host	Consider the hybrid or offline migration approaches
	You are okay to skip migrating historical transaction data, or can archive it in Amazon S3 in lieu of migrating it. You just need to migrate a few small static tables	Write a script or use any ETL tool to migrate the tables. Pre-shape the source data with a SQL VIEW if desired.

Performing an offline migration to DynamoDB

Offline migrations are suitable for when you can allow a downtime window to perform the migration. Relational databases commonly take at least some downtime each month for maintenance and patching, or may take longer downtimes for hardware upgrades or major release upgrades.

Amazon S3 can be used as a staging area during a migration. Data stored in CSV (comma separated values) or DynamoDB JSON format can be automatically imported into a new DynamoDB table using the [DynamoDB import from S3 feature](#).

Plan

Perform an offline migration using Amazon S3

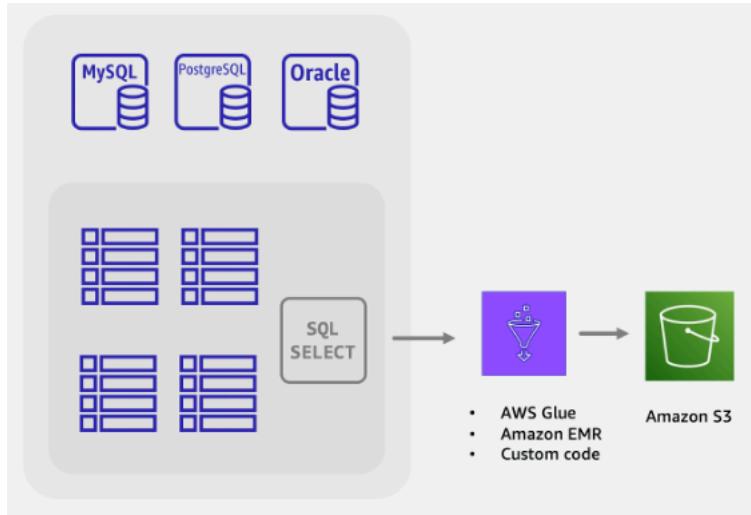

Tools

- An ETL job to extract and transform SQL data and store it in an S3 bucket such as:
 - AWS Glue

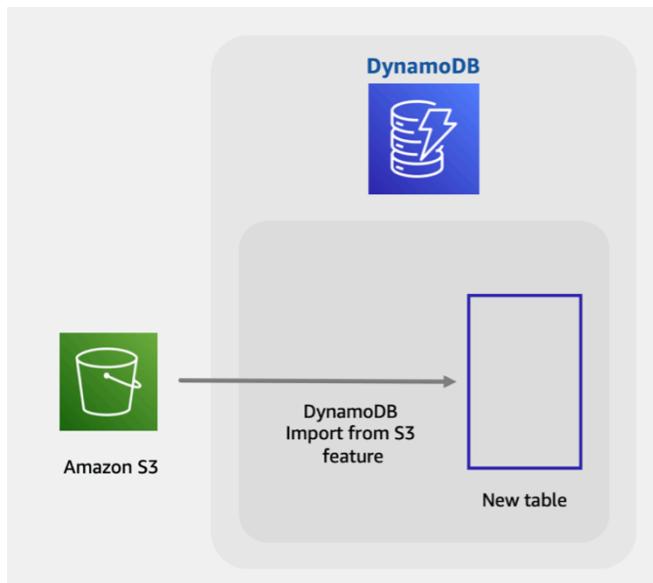

- Amazon EMR
- Your own custom code
- The DynamoDB import from S3 feature

Offline migration steps:

1. Build an ETL job that can query the SQL database, transform table data into DynamoDB JSON or CSV format, and save it to an S3 bucket.

2. The DynamoDB Import from S3 feature is invoked to create a new table and automatically load data from your S3 bucket.

The fully offline migration is simple and straightforward, but it may not be popular with application owners and users. Users would benefit if the application could provide reduced levels of service during the migration, instead of no service at all.

You could add functionality to disable writes during the offline migration, while allowing reads to continue as normal. Application users could still safely browse and query for existing data while the relational data is being migrated. If this is what you're looking for, continue reading to learn about [hybrid migrations](#).

Performing a hybrid migration to DynamoDB

While all database applications perform read and write operations, the types of write operations being performed should be considered when planning a hybrid or online migration. Database writes can be classified into three buckets: inserts, updates, and deletes. Some applications do not perform any updates to existing records. Other applications may not require deletes to be processed immediately, and could defer deletes to a bulk clean up process at the end of the month, for example. These types of applications can be simpler to migrate while allowing partial uptime.

Plan

Perform a hybrid online/offline migration with application dual writes

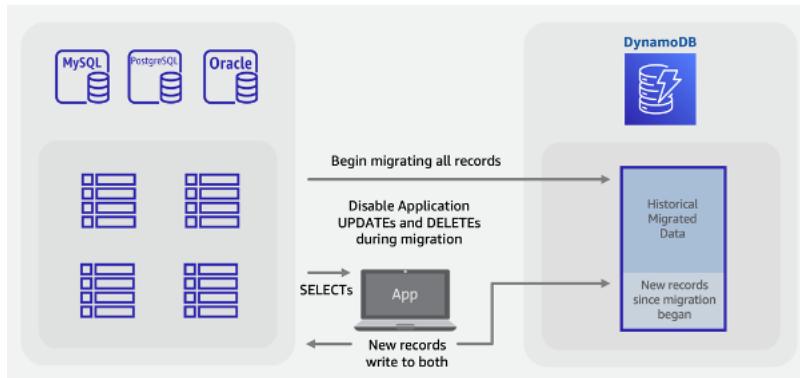

Tools

- An ETL job to extract and transform SQL data and store it in an S3 bucket such as:
 - AWS Glue
 - Amazon EMR
 - Your own custom code

Hybrid migration steps:

1. Create the target DynamoDB table. This table will receive both historical bulk data and new, live data
2. Create a version of the legacy application that has deletes and updates disabled while performing all inserts as dual writes to both the SQL database and DynamoDB
3. Begin the ETL job to migrate existing data and deploy the new application version at the same time

- When the ETL job completes, DynamoDB will have all existing and new records and be ready for application cutover

Note

The ETL job writes directly from SQL to DynamoDB. We are unable to use the S3 import feature as in the offline migration example, since the target table does not become public and available for other writes until the entire import completes.

Performing an online migration to DynamoDB by migrating each table 1:1

Many relational databases have a feature called Change Data Capture (CDC), where the database allows users to request a list of the changes to a table that happened before or after a specific point in time. CDC uses internal logs to enable this feature and it does not require the table to have any timestamp column in order to work.

When migrating a schema of SQL tables to a NoSQL database, you might want to combine and reshape your data into fewer tables. Doing so will allow you to collect data in a single place and avoid having to manually join related data in multi-step read operations. However, single table data shaping is not always required and sometimes you'll migrate tables 1-for-1 into DynamoDB. These 1-to-1 table migrations are less complicated as you can leverage the source database CDC feature, using common ETL tools that support this type of migration. The data for each row may still be transformed into new formats, but the scope of each table remains the same.

Consider migrating SQL tables 1-to-1 into DynamoDB, with the caveat that there are no server-side joins.

Plan

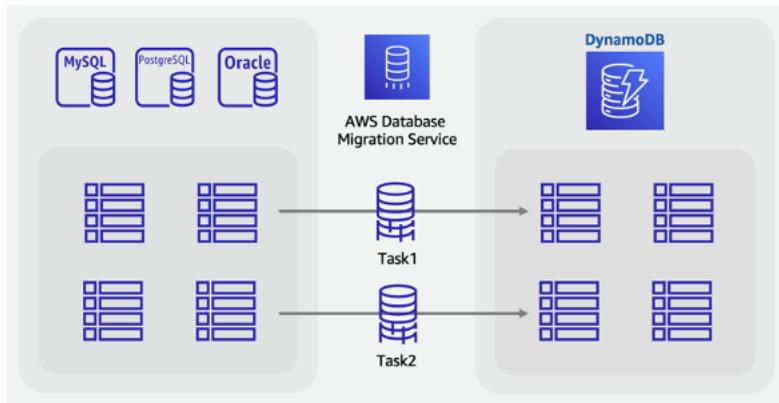

Perform an online migration of each table into DynamoDB using AWS DMS

Tools

- [AWS Database Migration Service \(DMS\)](#), an ETL tool that can both bulk load historical data and also leverage CDC to synchronize source and target tables

Online migration steps:

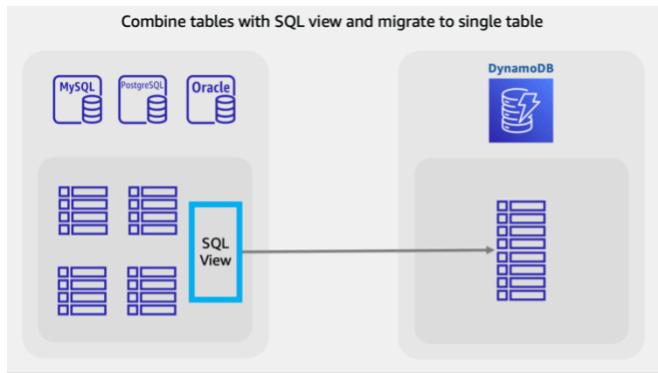

1. Identify the tables in your source schema that will be migrated
2. Create the same number of tables in DynamoDB with a similar key structure
3. Create a replication server in AWS DMS and configure the source and target endpoints
4. Define any per-row transformations required (such as concatenated columns or conversion of dates to ISO-8601 string format)
5. Create a migration task for each table for **Full Load and Change Data Capture**
6. Monitor these tasks until the ongoing replication phase has begun
7. At this point you may perform any validation audits and then switch users to the application that reads and writes to DynamoDB

Perform an online migration to DynamoDB using a custom staging table

You may wish to combine tables to leverage unique NoSQL access patterns (for example, transforming four legacy tables into one single DynamoDB table). A single key-value document

request, or a query for a pre-grouped item collection will usually return with better latency than a SQL database that performs a multi-table join. However, this makes the migration task becomes more difficult. A SQL VIEW could do the work within the source database to prepare a single dataset representing all four tables in one set.

This view might JOIN tables into a denormalized form, or could instead keep the entities normalized and stack tables using a SQL UNION. Key decisions around re-shaping relational data are covered in [this video](#). For offline migrations, using a view to combine tables is a great way to shape data for a DynamoDB single table schema.

However, for online migrations with live, changing data, you are unable to leverage CDC features as they are only supported for single table queries, not from within a VIEW. If your tables include a last-updated timestamp column, and these are incorporated into the VIEW, you can then build a custom ETL job that uses these to achieve a bulk load with synchronization.

A novel approach to this challenge would be to use standard SQL features such as views, stored procedures, and triggers to create a new SQL table that is in the final desired DynamoDB NoSQL format.

If your database server can allocate an additional amount of storage space, it is possible to create this single staging table before migration begins. This would be accomplished by writing a stored procedure that will read from existing tables, transform data as needed, and write to the new staging table. A set of triggers could be added to replicate changes in tables into the staging table in real time. If triggers are not allowed per company policy, changes to stored procedures can accomplish the same result. You would add a few lines of code to any procedure that writes data, to additionally write the same changes into the staging table.

Having this staging table in place that is fully synchronized with the legacy application tables will give you a great starting point for a live migration. Tools using database CDC to accomplish live migrations, such as AWS DMS, can now be used against this table. An advantage of this approach is that it uses well-known SQL skills and features available in the relational database engine.

Plan

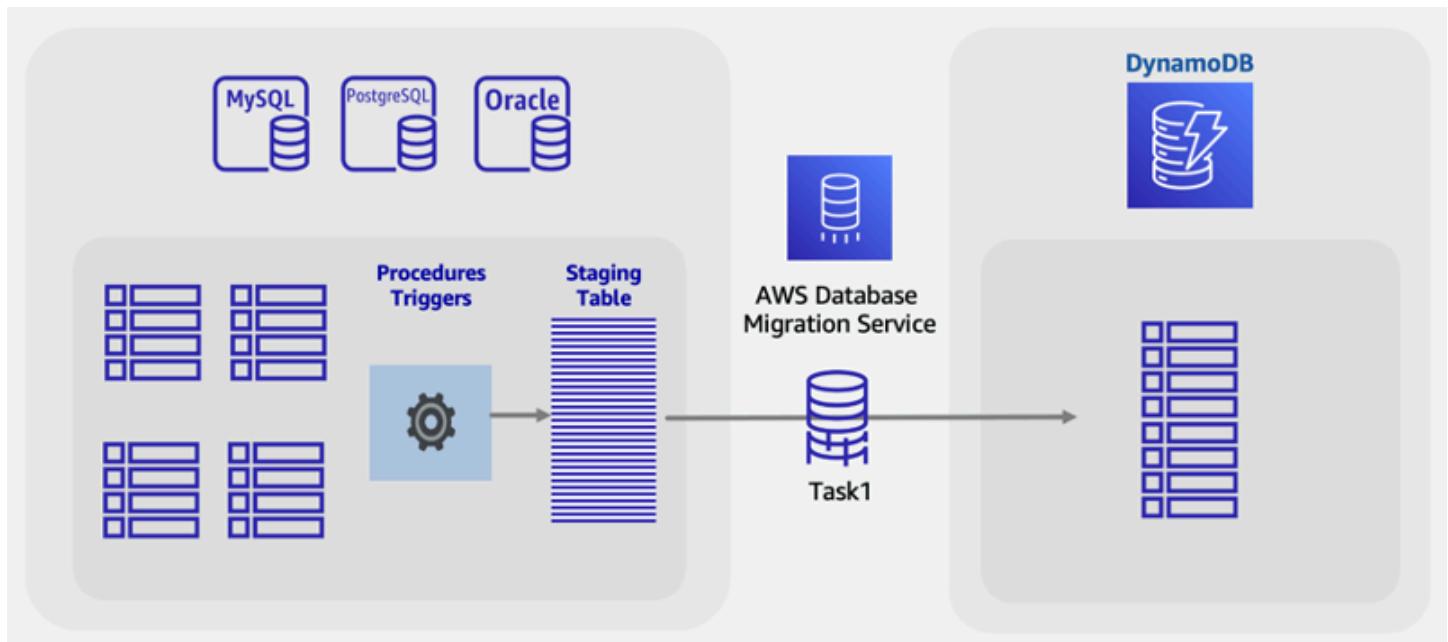

Perform an online migration with an SQL staging table using AWS DMS

Tools

- Custom SQL stored procedures or triggers
- [AWS Database Migration Service \(DMS\)](#), an ETL tool that can migrate a live staging table into DynamoDB

Online migration steps:

1. Within the source relational database engine, ensure there is some extra disk space and processing capacity.
2. Create a new staging table in the SQL database, with timestamps or CDC features enabled
3. Write and run a stored procedure to copy existing relational table data into the staging table
4. Deploy triggers or modify existing procedures to dual write into the new staging table while performing normal writes to existing tables
5. Run AWS DMS to migrate and synchronize this source table to a target DynamoDB table

This guide presented several considerations and approaches for migrating relational database data into DynamoDB, with a focus on minimizing downtime and using common database tools and techniques. For more information, see the following:

- [AWS DMS User Guide](#)
- [AWS Glue User Guide](#)
- [Best Practices for Migrating from RDBMS to DynamoDB](#)

NoSQL Workbench for DynamoDB

NoSQL Workbench for Amazon DynamoDB is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench is a visual development tool that provides data modeling, data visualization, and query development features to help you design, create, query, and manage DynamoDB tables. NoSQL Workbench now includes DynamoDB local as an optional part of the installation process, which makes it easier to model your data in DynamoDB local. To learn more about DynamoDB local and its requirements, see [Setting up DynamoDB local \(downloadable version\)](#).

Data modeling

With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see [Building data models with NoSQL Workbench](#).

Data visualization

The data model visualizer provides a canvas where you can map queries and visualize the access patterns (facets) of the application without having to write code. Every facet corresponds to a different access pattern in DynamoDB. You can autogenerate sample data for use in your data model. For more information, see [Visualizing data access patterns](#).

Operation building

NoSQL Workbench provides a rich graphical user interface for you to develop and test queries. You can use the *operation builder* to view, explore, and query live datasets. The structured operation builder supports projection expression, condition expression, and generates sample code in multiple languages. You can directly clone tables from one Amazon DynamoDB account to another one in different Regions. You can also directly clone tables between DynamoDB local and an Amazon DynamoDB account for faster copying of your table's key schema (and optionally GSI schema and items) between your development environments. For more information, see [Exploring datasets and building operations with NoSQL Workbench](#).

Topics

Download NoSQL Workbench for DynamoDB

Follow these instructions to download NoSQL Workbench and DynamoDB local* for Amazon DynamoDB.

Prerequisites

There are two prerequisite pieces of software required for Ubuntu installs: libfuse2 and curl.

libfuse2

As of Ubuntu 22.04, libfuse2 is no longer installed by default. To solve this, run `sudo add-apt-repository universe && sudo apt install libfuse2` to install for the [newest Ubuntu version](#).

curl

Update Ubuntu, run `sudo apt update && sudo apt upgrade`

Next, install curl, execute: `sudo apt install curl`

To download NoSQL Workbench and DynamoDB local

1. Download the appropriate version of NoSQL Workbench for your operating system.

Operating system	Download link
macOS (Intel)**	Download for macOS (Intel)
macOS (Apple silicon)	Download for macOS (Apple silicon)
Windows	Download for Windows

Operating system	Download link
Linux***	Download for Linux

* NoSQL Workbench includes DynamoDB local as an optional part of the installation process.

** If a warning message appears when you try to open NoSQL Workbench stating that the app isn't registered with Apple by an identified developer, do the following:

1. Locate the app and then open it.
2. Control+click the app icon, then choose Open from the shortcut menu.

This saves the app as an exception to your security settings. Open the app by double-clicking it just as you can open any registered app.

*** NoSQL Workbench supports Ubuntu 12.04, Fedora 21, and Debian 8, or any newer versions of these Linux distributions.

2. Start the application that you downloaded, and then follow the steps in [Install NoSQL Workbench](#).

 **Note**

Java Runtime Environment (JRE) version 11.x or newer is required for running DynamoDB local.

Install NoSQL Workbench for DynamoDB

Follow these steps to install NoSQL Workbench and DynamoDB local on a supported platform.

Windows

To install NoSQL Workbench on Windows

1. Run the NoSQL Workbench installer application and choose the setup language. Then choose **OK** to begin the setup. For more information about downloading NoSQL Workbench, see [Download NoSQL Workbench for DynamoDB](#).

2. Choose **Next** to continue the setup, and then choose **Next** on the following screen.
3. By default, the **Install DynamoDB Local** check box is selected to include DynamoDB local as part of the installation. Keeping this option selected ensures that DynamoDB local will be installed, and the destination path will be the same as the installation path of NoSQL Workbench. Clearing the check box for this option will skip the installation of DynamoDB local, and the installation path will be for NoSQL Workbench only.

Choose the destination where you want the software installed, and choose **Next**.

 **Note**

If you opted to not include DynamoDB local as part of the setup, clear the **Install DynamoDB Local** check box, choose **Next**, and skip to step 6. You can download DynamoDB local separately as a standalone installation at a later time. For more information, see [Setting up DynamoDB local \(downloadable version\)](#).

Configure your installation path during this step.

4. Choose the port number for DynamoDB local to use. The default port is 8000. After you enter the port number, choose **Next**.
5. Choose **Next** to begin setup.
6. When the setup has completed, choose **Finish** to close the setup screen.
7. Open the application in your installation path, such as `/programs/DynamoDBWorkbench/`.

macOS

To install NoSQL Workbench on macOS

1. Run the NoSQL Workbench installer application and choose the setup language. Then choose **OK** to begin the setup. For more information about downloading NoSQL Workbench, see [Download NoSQL Workbench for DynamoDB](#).
2. Choose **Next** to continue the setup, and then choose **Next** on the following screen.
3. By default, the **Install DynamoDB local** check box is selected to include DynamoDB local as part of the installation. Keeping this option selected ensures that DynamoDB local will be installed, and the destination path will be the same as the installation path of NoSQL

Workbench. Clearing this option will skip the installation of DynamoDB local, and the installation path will be for NoSQL Workbench only.

Choose the destination where you want the software installed, and choose **Next**.

 **Note**

If you opted to not include DynamoDB local as part of the setup, clear the **Install DynamoDB local** check box, choose **Next**, and skip to step 6. You can download DynamoDB local separately as a standalone installation at a later time. For more information, see [Setting up DynamoDB local \(downloadable version\)](#).

Configure your installation path during this step.

4. Choose the port number for DynamoDB local to use. The default port is 8000. After you enter the port number, choose **Next**.
5. Choose **Next** to begin setup.
6. When the setup has completed, choose **Finish** to close the setup screen.
7. Open the application in your installation path, such as */Applications/DynamoDBWorkbench/*.

 **Note**

NoSQL Workbench for macOS performs auto-updates. To get notification about updates, enable notification access to NoSQL Workbench in System Preferences > Notifications.

Linux

To install NoSQL Workbench on Linux

1. Run the NoSQL Workbench installer application and choose the setup language. Then choose **OK** to begin the setup. For more information about downloading NoSQL Workbench, see [Download NoSQL Workbench for DynamoDB](#).
2. Choose **Forward** to continue the setup, and choose **Forward** on the following screen.

3. By default, the **Install DynamoDB local** check box is selected to include DynamoDB local as part of the installation. Keeping this option selected ensures that DynamoDB local will be installed, and the destination path will be the same as the installation path of NoSQL Workbench. Clearing this option will skip the installation of DynamoDB local, and the installation path will be for NoSQL Workbench only.

Choose the destination where you want the software installed, and choose **Forward**.

 **Note**

If you opted to not include DynamoDB local as part of the setup, clear the **Install DynamoDB local** check box, choose **Forward**, and skip to step 6. You can download DynamoDB local separately as a standalone installation at a later time. For more information, see [Setting up DynamoDB local \(downloadable version\)](#).

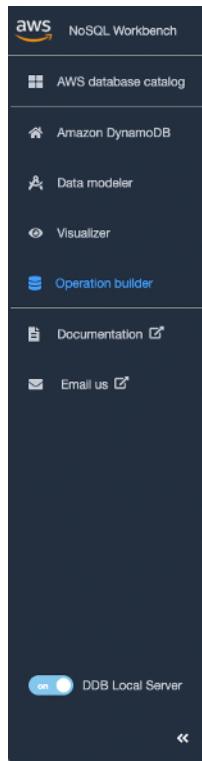

Configure your installation path during this step.

4. Choose the port number for DynamoDB local to use. The default port is 8000. After you enter the port number entered, choose **Forward**.
5. Choose **Forward** to begin setup.
6. When the setup has completed, choose **Finish** to close the setup screen.
7. Open the application in your installation path, such as `/usr/local/programs/DynamoDBWorkbench/`.

 **Note**

If you opted to install DynamoDB local as part of the installation of NoSQL Workbench, DynamoDB local will be preconfigured with default options. To edit the default options, modify the `DDBLocalStart` script located in the `/resources/DDBLocal_Scripts/` directory. You can find this in the path that you provided during installation. To learn more about DynamoDB local options, see [DynamoDB local usage notes](#).

If you opted to install DynamoDB local as part of the NoSQL Workbench installation, you will have access to a toggle to enable and disable DynamoDB local as shown in the following image.

Building data models with NoSQL Workbench

You can use the data modeler tool in NoSQL Workbench for Amazon DynamoDB to build new data models, or to design models based on existing data models that satisfy your applications' data access patterns. The data modeler includes a few sample data models to help you get started.

Topics

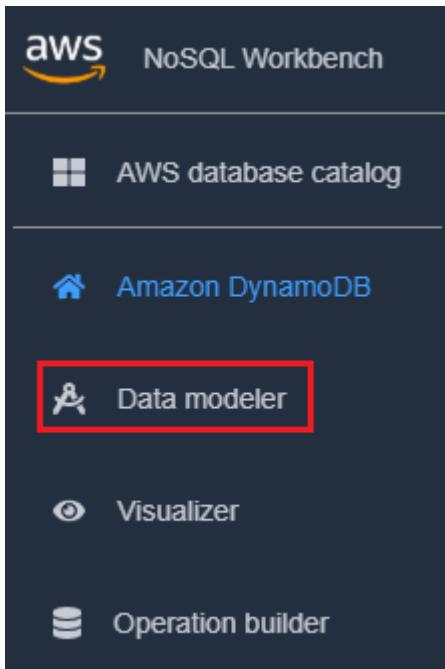

- [Creating a new data model](#)
- [Importing an existing data model](#)
- [Exporting a data model](#)
- [Editing an existing data model](#)

Creating a new data model

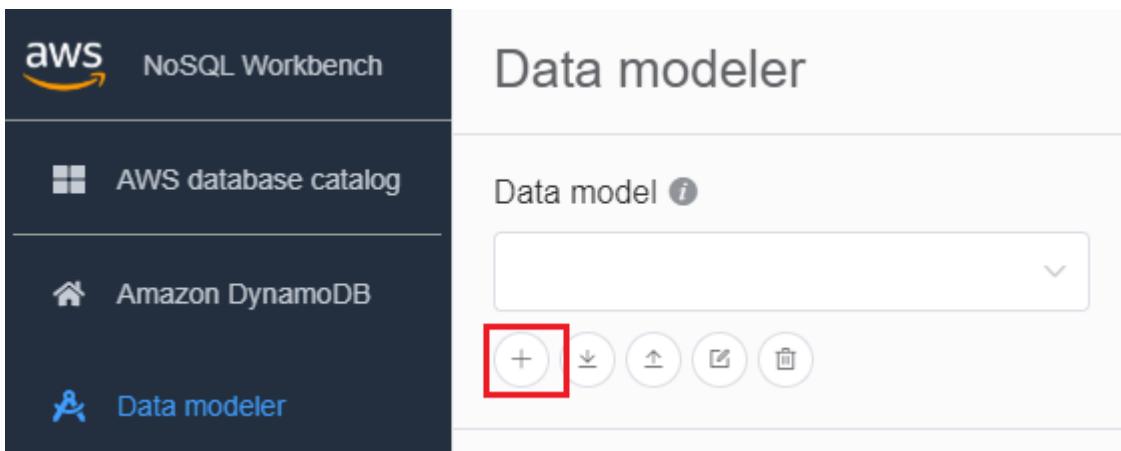

Follow these steps to create a new data model in Amazon DynamoDB using NoSQL Workbench.

To create a new data model

1. Open NoSQL Workbench, and in the navigation pane on the left side, choose the **Data modeler** icon.

2. Choose **Create data model**.

Create data model has two choices: Make model from scratch and Start from a template.

Create data model for Amazon DynamoDB

Make model from scratch

Selecting this option means you will have to create all tables, GSIs, attributes and elements yourself.

[Select](#)

Start from a template

Start with tables, GSIs and attributes to help guide you without losing any freedom to change everything.

AWS Discussion Forum Data Model

[Select](#)

This data model represents Amazon DynamoDB schema for AWS discussion forums, an example of an application for discussion forums or message boards....

Bookmarks Data Model

[Select](#)

This model is about storing URL bookmarks for customers. Even if the use case is relatively simple, there are still many interesting...

Employee Data Model

[More templates](#)

OR

[Cancel](#)

Make model from scratch

To make a model from scratch, enter a name, author, and description for the data model. Choose **Create** when finished.

Create data model for Amazon DynamoDB

* Name

Author

Description

[Back](#) [Cancel](#) [Create](#)

Start from a template

Starting from a template lets you choose a sample model to start from. Choose **More templates** to see more template options. Choose **Select** for the template that you want to use.

Enter a data model name, author, and description for the template you selected. You can choose between **Schema only** and **Schema with sample data**.

- **Schema only** creates an empty data model with the primary key (partition and sort key) and other attributes.
- **Schema with sample data** will create a data model complete with sample data for the primary key (partition and sort key) and other attributes.

When this information is complete, choose **Create** to create the model.

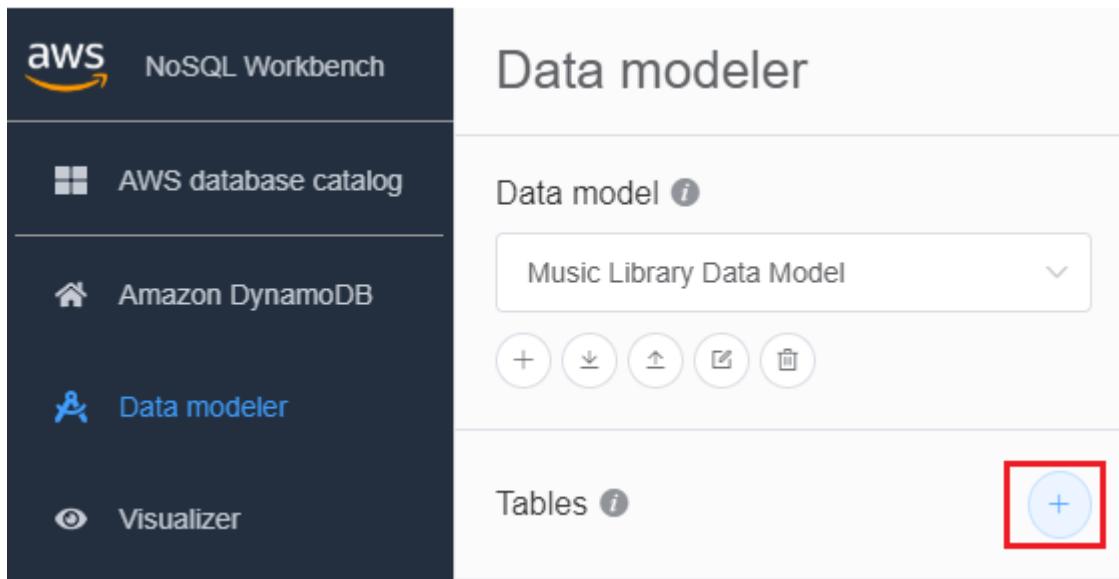

Create data model for Amazon DynamoDB

Data Model	New model	From template
Template	Ski Resort Data Model	▼
* Save as	Enter data model name	
Author	Enter author name	
Description	Describe this data model	
Sample Data	Schema only	Schema with sample data

Schema with sample data will create a data model complete with sample data for the primary keys (partition key and/or sort key) and other attributes.

[Back](#) [Cancel](#) [Create](#)

3. With the model created, choose **Add table**.

For more information about tables, see [Working with tables in DynamoDB](#).

4. Specify the following:

- **Table name** – Enter a unique name for the table.
- **Partition key** – Enter a partition key name, and specify its type. Optionally, you can also select a more granular data type format for sample data generation.
- If you want to add a sort key:
 1. Select **Add sort key**.
 2. Specify the sort key name and its type. Optionally, you can select a more granular data type format for sample data generation.

Note

To learn more about primary key design, designing and using partition keys effectively, and using sort keys, see the following:

- [Primary key](#)
- [Best practices for designing and using partition keys effectively](#)
- [Best practices for using sort keys to organize data](#)

5. To add other attributes, do the following for each attribute:

1. Choose **Add an attribute**.

2. Specify the attribute name and its type. Optionally, you can select a more granular data type format for sample data generation.
6. Add a facet:

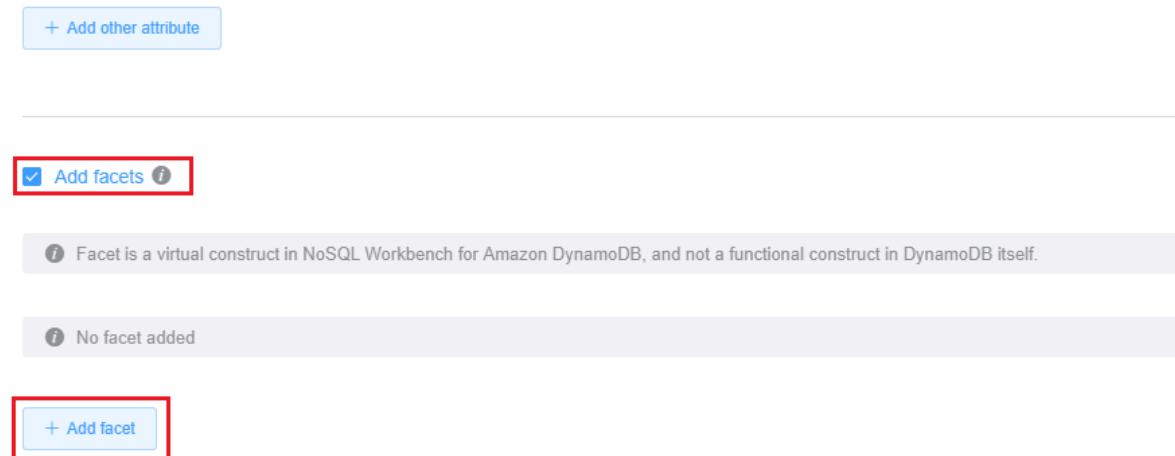

You can optionally add a facet. A facet is a virtual construct in NoSQL Workbench. It is not a functional construct in DynamoDB itself.

 **Note**

Facets in NoSQL Workbench help you visualize an application's different data access patterns for Amazon DynamoDB with only a subset of the data in a table. To learn more about facets, see [Viewing data access patterns](#).

To add a facet,

- Select **Add facets**.
- Choose **Add facet**.

- Specify the following:
 - The **Facet name**.
 - A **Partition key alias** to help distinguish this facet view.
 - A **Sort key alias**.
 - Choose the **Other attributes** that are part of this facet.

Choose Add facet.

[Add facets](#) i

i Facet is a virtual construct in NoSQL Workbench for Amazon DynamoDB, and not a functional construct in DynamoDB itself.

i No facet added

Add facet

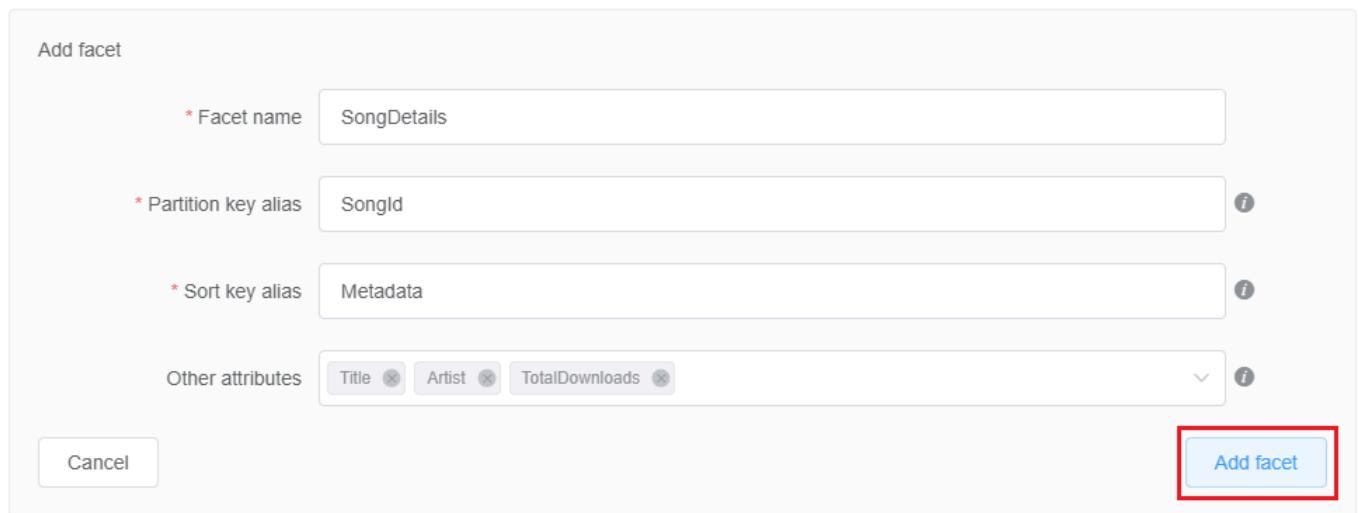

* Facet name

* Partition key alias i

* Sort key alias i

Other attributes v i

[Cancel](#) [Add facet](#)

Repeat this step if you want to add more facets.

7. If you want to add a global secondary index, choose **Add global secondary index**.

Specify the **Global secondary index name**, **Partition key** attribute, and **Projection type**.

Global secondary indexes

The screenshot shows the 'Global secondary indexes' configuration screen. It includes fields for 'Name' (index name), 'Partition key' (set to 'FirstName'), 'Add sort key' (checked), 'Sort key' (set to 'LastName'), and 'Projection type' (set to 'ALL'). A red box highlights the '+ Add global secondary index' button at the bottom left.

For more information about working with global secondary indexes in DynamoDB, see [Global secondary indexes](#).

8. By default, your table will use provisioned capacity mode with auto scaling enabled on both read and write capacity. If you want to change these settings, clear **Inherit capacity settings from base table** under **Capacity settings**.

Select your desired capacity mode, read and write capacity, and auto scaling IAM role (if applicable).

For more information about DynamoDB capacity settings, see [Read/write capacity mode](#).

9. Save the edits to your table settings..

A modal dialog box with 'Cancel' and 'Save edits' buttons.

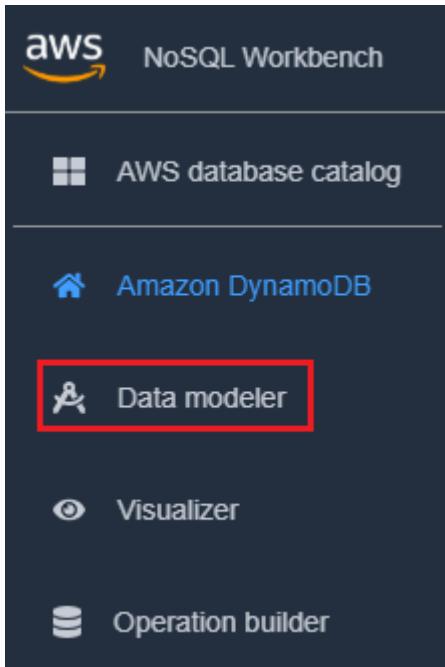

For more information about the `CreateTable` API operation, see [CreateTable](#) in the [Amazon DynamoDB API Reference](#).

Importing an existing data model

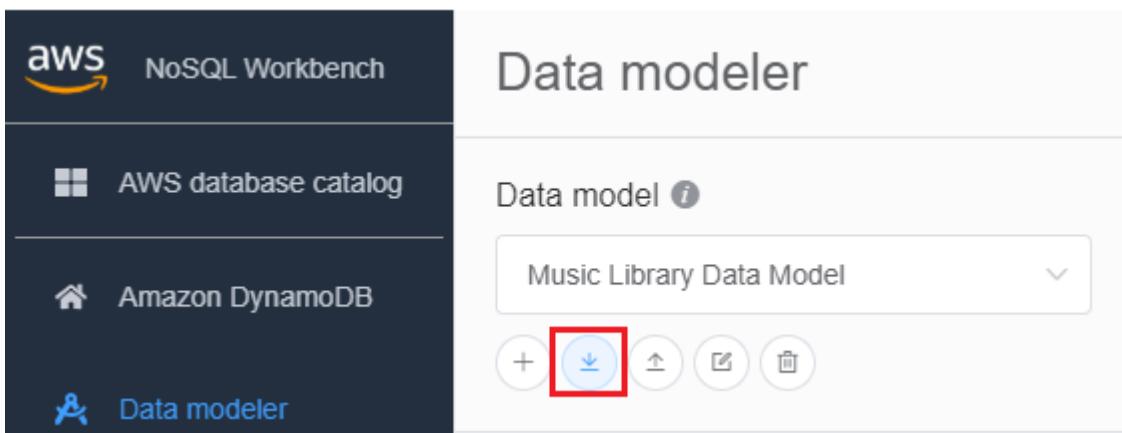

You can use NoSQL Workbench for Amazon DynamoDB to build a data model by importing and modifying an existing model. You can import data models in either NoSQL Workbench model format or in [AWS CloudFormation JSON template format](#).

To import a data model

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Data modeler** icon.

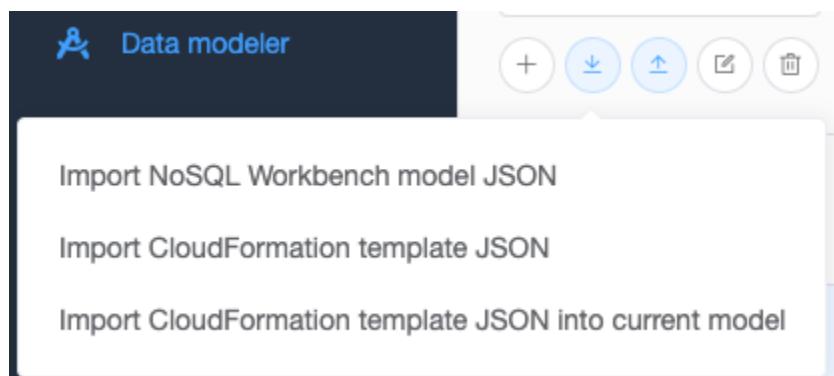

2. Hover your pointer over **Import data model**.

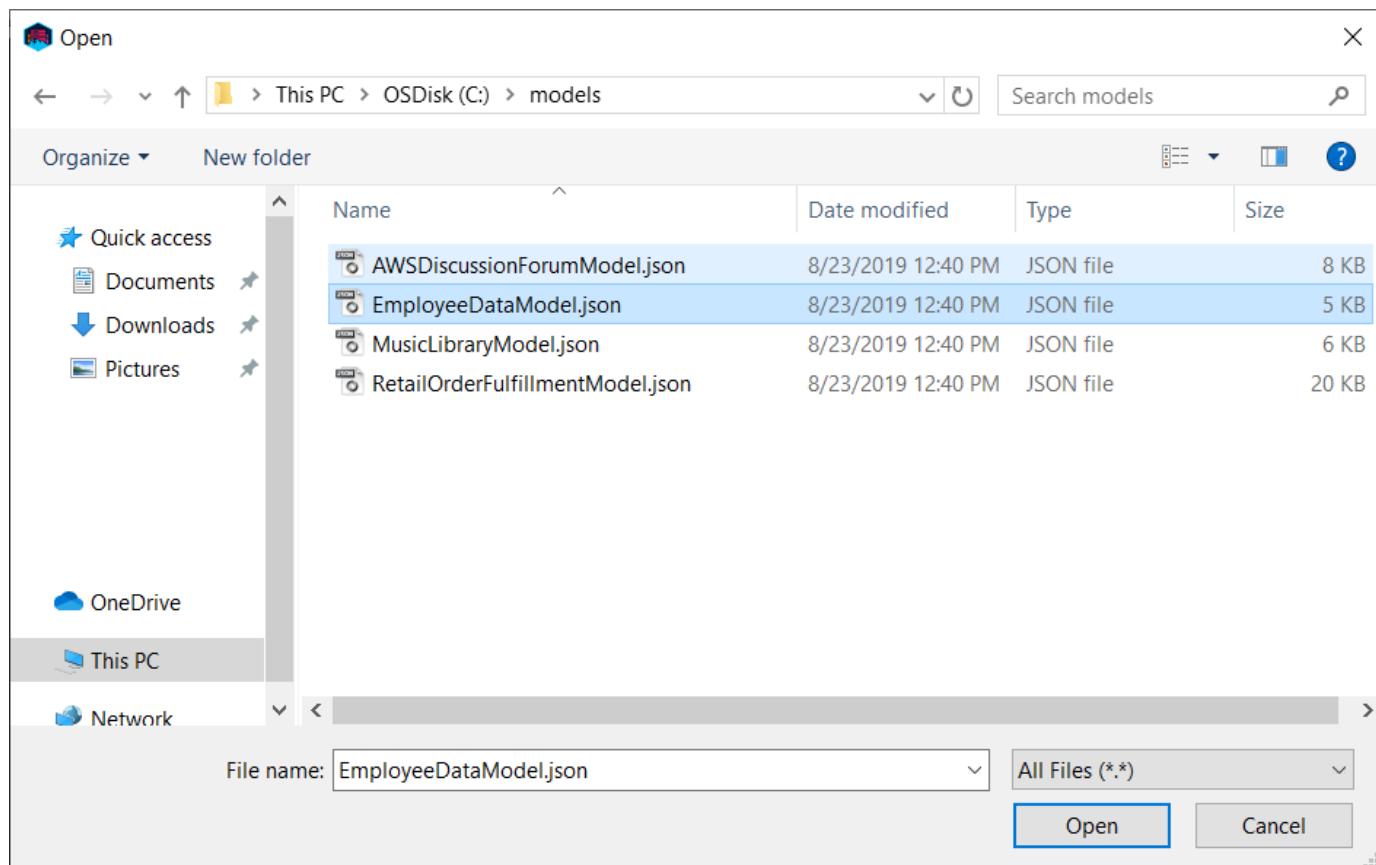

In the dropdown list, choose whether the model you want to import is in NoSQL Workbench model format or CloudFormation JSON template format. If you have an existing data model

open in NoSQL Workbench, you'll have the option to import a CloudFormation template into the current model.

3. Choose a model to import.

4. If the model you're importing is in CloudFormation template format, you'll see a list of tables to be imported and have an opportunity to specify a data model name, author, and description.

Create data model for Amazon DynamoDB

Only CloudFormation resources related to DynamoDB: tables and any related application auto scaling, **i** will be imported. Some fields within these resources are not supported by NoSQL Workbench and will also not be imported, including LocalSecondaryIndexes, RoleARN, and PolicyName.

Successfully imported tables (1)

Create

Exporting a data model

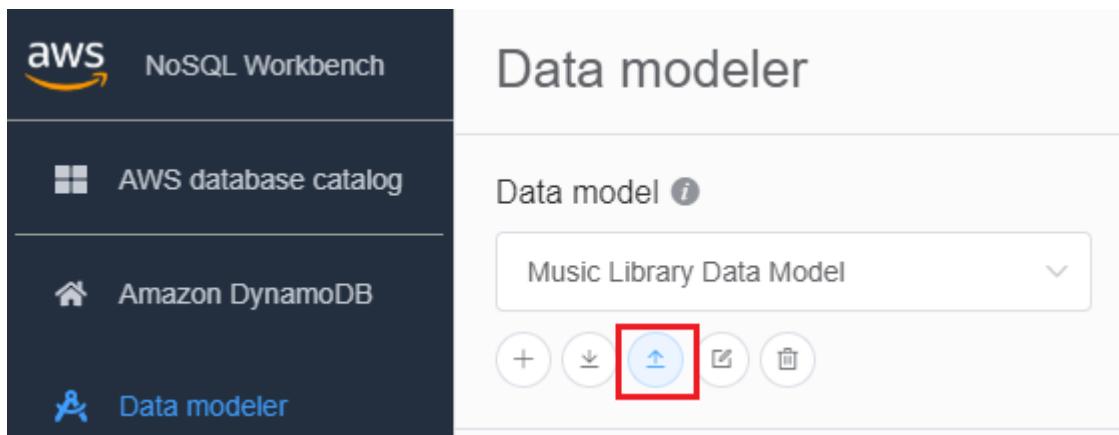

After you create a data model using NoSQL Workbench for Amazon DynamoDB, you can save and export the model in either NoSQL Workbench model format or [AWS CloudFormation JSON template format](#).

To export a data model

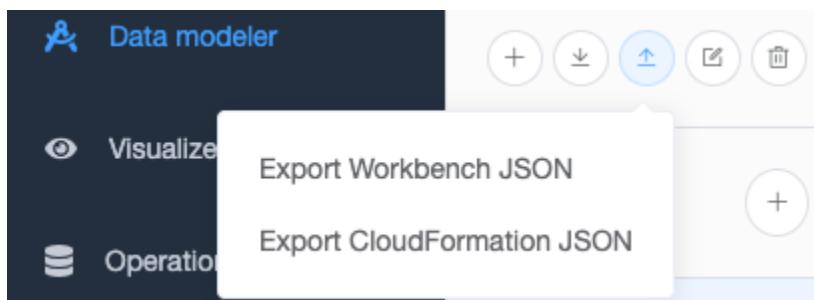

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Data modeler** icon.

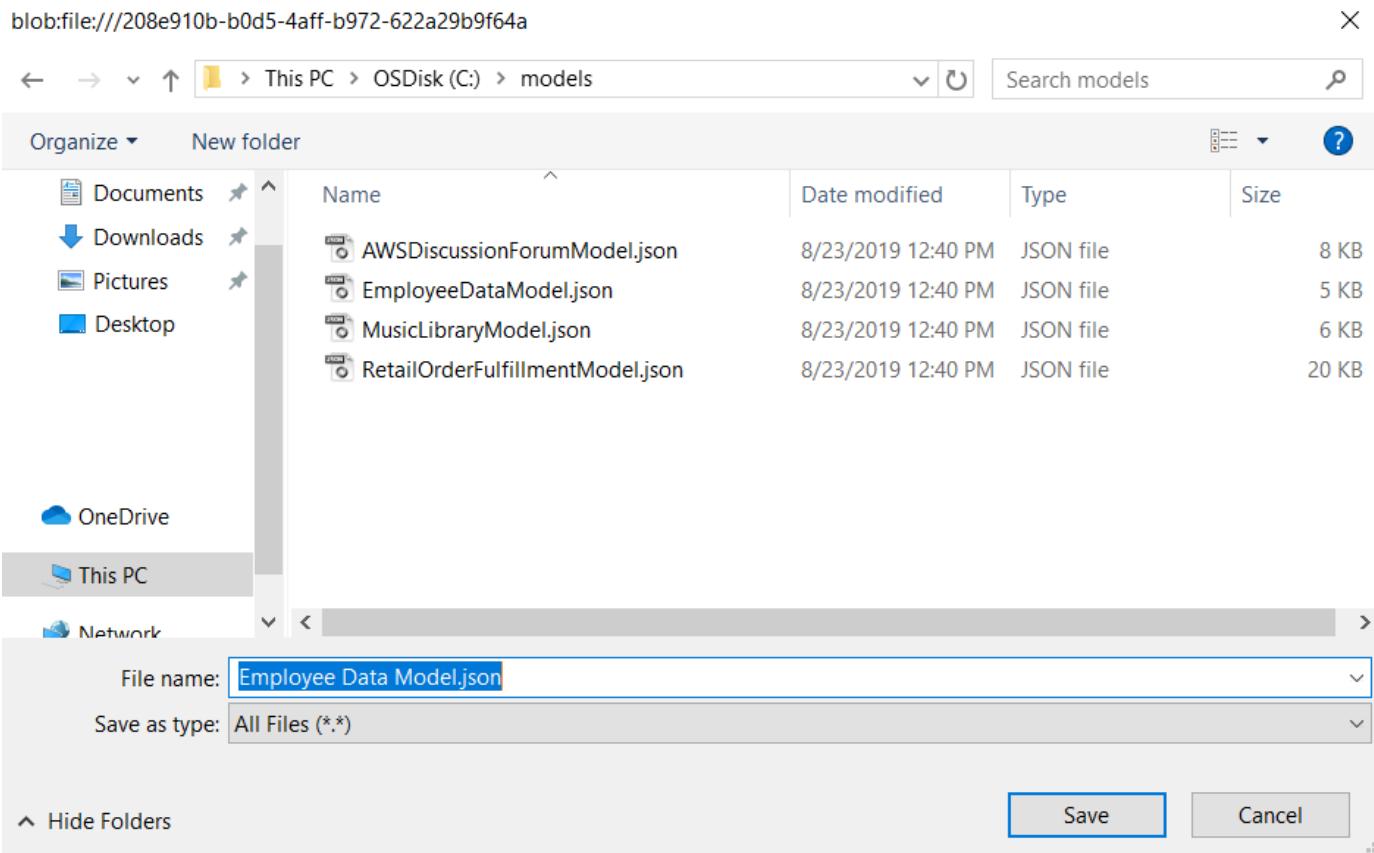

2. Hover your pointer over **Export data model**.

In the dropdown list, choose whether to export your data model in NoSQL Workbench model format or CloudFormation JSON template format.

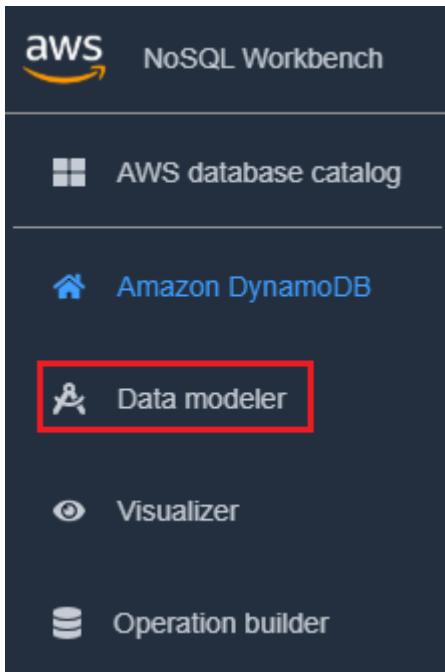

3. Choose a location to save your model.

Editing an existing data model

To edit an existing model

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Data modeler** button.

2. Select the data model and choose the table that you want to edit. Choose **Edit model**

The screenshot shows the Data modeler interface for the 'Songs' table. The 'Edit model' button is highlighted with a red box.

Attribute name	Attribute type	Key type	Sample data format
Songs			

3. Make the needed edits, and then choose **Save edits**.

To manually edit an existing model and add a facet

1. Export your model. For more information, see [Exporting a data model](#).
2. Open the exported file in an editor.
3. Locate the DataModel Object for the table that you want to create a facet for.

Add a TableFacets array representing all the facets for the table.

For each facet, add an object to the TableFacets array. Each array element has the following properties:

- FacetName – A name for your facet. This value must be unique across the model.

- **PartitionKeyAlias** – A friendly name for the table's partition key. This alias is displayed when you view the facet in NoSQL Workbench.
- **SortKeyAlias** – A friendly name for the table's sort key. This alias is displayed when you view the facet in NoSQL Workbench. This property is not needed if the table has no sort key defined.
- **NonKeyAttributes** – An array of attribute names that are needed for the access pattern. These names must map to the attribute names that are defined for the table.

```
{

        ]
    }
]
```

4. You can now import the modified model into NoSQL Workbench. For more information, see [Importing an existing data model](#).

Visualizing data access patterns

You can use the visualizer tool in NoSQL Workbench for Amazon DynamoDB to map queries and visualize different access patterns (known as *facets*) of an application. Every facet corresponds to a different access pattern in DynamoDB. You can also manually add data to your data model or import data from MySQL.

Topics

- [Adding sample data to a data model](#)
- [Importing sample data from a CSV file](#)
- [Viewing data access patterns](#)
- [Viewing all tables in a data model using aggregate view](#)
- [Committing a data model to DynamoDB](#)

Adding sample data to a data model

By adding sample data to your model, you can display data when visualizing the model and its various data access patterns, or *facets*.

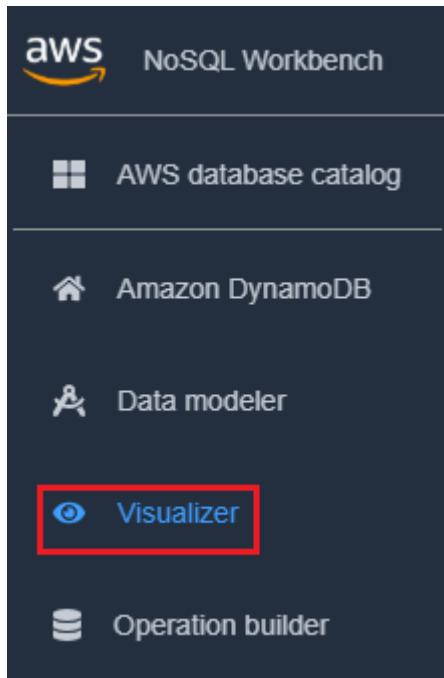

There are two ways to add sample data. One is using our sample data auto generation tool. The other is adding data one at a time.

Follow these steps to add sample data to a data model using NoSQL Workbench for Amazon DynamoDB.

To auto generate sample data

Auto generating sample data helps you generate between 1 to 5000 rows of data for immediate use. You can specify a granular sample data type to create realistic data based on your design and testing needs. To utilize the capability to generate realistic data, you need to specify the sample data type format for your attributes in the Data modeler. See [Creating a new data model](#) for specifying sample data type formats.

1. In the navigation pane on the left side, choose the **visualizer** icon.

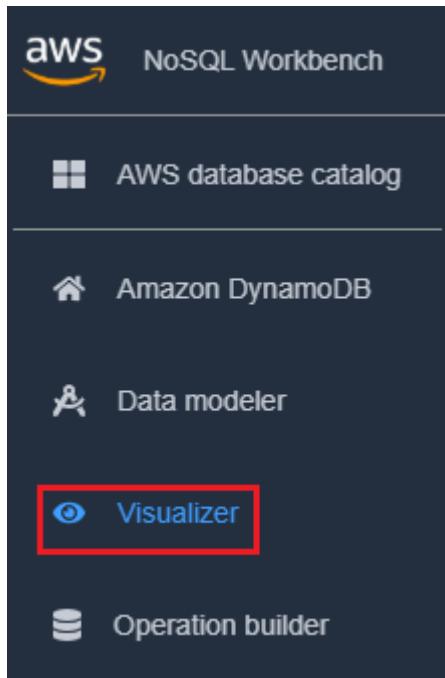

2. In the visualizer, select the data model and choose the table.
3. Choose the **Action** drop down, and select **Add sample data**.

A screenshot of the 'Songs' table in the Visualizer. The table has a primary key of 'Id'. A context menu is open at the top right of the table, listing: 'Actions', 'Configure sample data', 'Add sample data' (which is highlighted in blue), 'Edit data', and 'Import CSV file'.

4. Enter the number or items of sample data that you would like to generate, then select **Confirm**.

To add sample data one at a time

1. In the navigation pane on the left side, choose the **visualizer** icon.

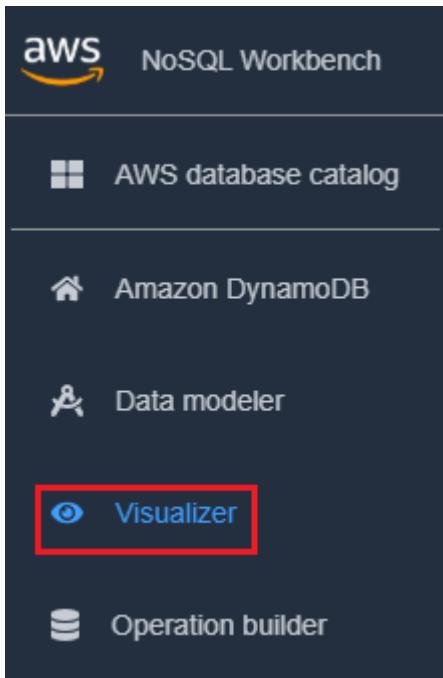

2. In the visualizer, select the data model and choose the table.
3. Choose the **Action** drop down, and select **Edit data**.

A screenshot of the AWS NoSQL Workbench Visualizer for the 'Songs' table. The table has a primary key of 'Id' and a sort key of 'Metadata'. A context menu is open over the table, with the 'Actions' dropdown showing options: 'Configure sample data', 'Add sample data', 'Edit data', and 'Import CSV file'.

4. Choose **Add new row**. Enter the sample data into the empty text boxes, and choose **Add new row** again to add additional rows. When done choose **Save changes**.

To delete sample data

1. In the navigation pane on the left side, choose the **visualizer** icon.

2. In the visualizer, select the data model and choose the table.
3. Choose the **Action** drop down, and select **Edit data**.

A screenshot of the NoSQL Workbench Visualizer interface for the Songs table. The table has a Primary key (Partition key: Id) and Sort key: Metadata. The Attributes section shows a list of attributes. An 'Actions' dropdown menu is open on the right, listing: Configure sample data, Add sample data, Edit data, and Import CSV file.

4. Select the delete icon next to each row of data you want to delete.

Importing sample data from a CSV file

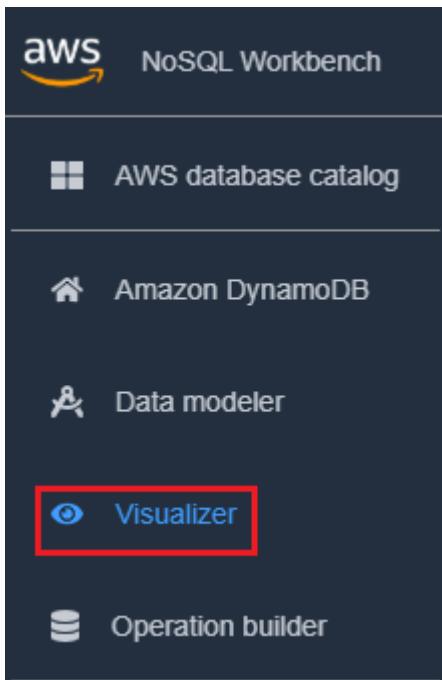

If you have preexisting sample data in a CSV file, you can import it into NoSQL Workbench. This enables you to quickly populate your model with sample data without having to enter it line by line.

The column names in the CSV file must match the attribute names in your data model, but they do not need to be in the same order. For example, if your data model has attributes called LoginAlias, FirstName, and LastName, your CSV columns could be LastName, FirstName, and LoginAlias.

Data import from a CSV file is limited to 150 rows at a time.

To import data from a CSV file into NoSQL Workbench

1. In the navigation pane on the left side, choose the **visualizer** icon.

2. In the visualizer, select the data model and choose the table.
3. Choose the **Action** drop down, and select **Edit Data**.
4. Choose the **Action** drop down again, and select **Import CSV file**.
5. Select your CSV file and choose **Open**. The data in the CSV file will be appended to your table.

Note

If your CSV file contains one or more rows that have the same keys as items already in your table, you will have the option of overwriting the existing items or appending them to the end of the table. If you choose to append the items, the suffix "-Copy" will be added to each duplicate item's key to differentiate the duplicate items from the items that were already in the table.

Viewing data access patterns

In NoSQL Workbench, *facets* represent an application's different data access patterns for Amazon DynamoDB. Facets can help you visualize your data model when multiple data types are represented by a sort key. Facets give you a way to view a subset of the data in a table, without

having to see records that don't meet the constraints of the facet. Facets are considered a visual data modeling tool, and don't exist as a usable construct in DynamoDB, as they are purely an aid to modeling of access patterns.

To see an example of facets, you can import one of our sample data models with facets as part of the data model template.

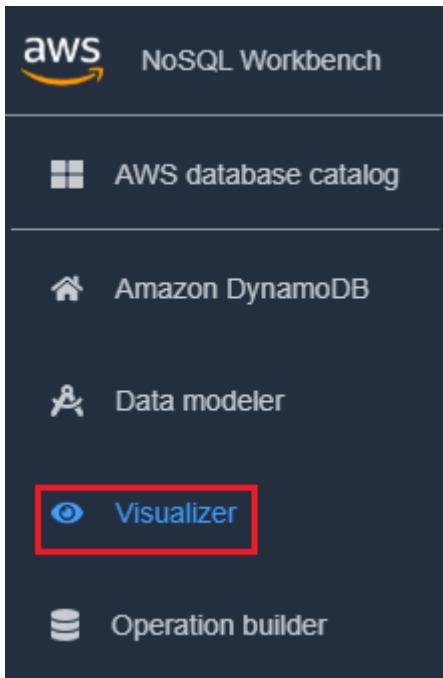

Import sample data model

1. On the left, choose **Amazon DynamoDB**.
2. In the Sample data models section, hover your pointer over Music Library Data Model and choose **Import**.

The screenshot shows the AWS NoSQL Workbench interface. On the left, there's a navigation pane with icons for NoSQL Workbench, AWS database catalog, Amazon DynamoDB (which is highlighted with a red box), Data modeler, Visualizer, Operation builder, Documentation (with a dropdown arrow), and Email us. The main area has two sections: 'Sample data models' and 'Recent data models'. The 'Sample data models' section lists several data models with their names, authors, and last modified dates. The 'Music Library Data Model' by 'Bobby' is selected and shown in more detail. An 'Import' button is highlighted with a red box at the bottom right of its row. The 'Recent data models' section shows two entries: 'Employee Data Model' by 'Amazon Web Services, Inc.' and 'Music' by 'Bobby'.

Data model name	Skill level
AWS Discussion Forum Data Model	Introductory
Bookmarks Data Model	Introductory
Employee Data Model	Introductory
Ski Resort Data Model	Introductory
Credit Card Offers Data Model	Advanced
Music Library Data Model	Advanced

3. In the navigation pane on the left side, choose the **visualizer** icon.

- Choose the Songs table to expand it. You'll be shown an aggregate view of your data.

The screenshot shows the Visualizer interface. On the left, the "Data model" dropdown is set to "Music Library Data Model". The "Songs" table is selected and highlighted with a red box. The main area displays an "Aggregate view" of the "Songs" table, specifically the "GS: DownloadsByMonth" facet. The data is presented in a table with columns: Primary key (Partition key: Id, Sort key: Metadata), Details (Title, Artist, TotalDownloads), DownloadTimestamp, and DownloadTimestamp.

Primary key	Attributes
Partition key: Id	Sort key: Metadata
Details	Title: Wild Love, Artist: Argyboots, TotalDownloads: 3
DId-9349823681	DownloadTimestamp: 2018-01-01T00:00:07
DId-9349823682	DownloadTimestamp: 2018-01-01T00:01:08

- Choose **Facets** drop-down arrow to expand the available facets.
- Choose the SongDetails facet to visualize the data with the SongDetails facet applied.

The screenshot shows the Visualizer interface with the "Facets" dropdown expanded. The "SongDetails" facet is selected and highlighted with a red box. The main area displays the "SongDetails" facet data for the "Songs" table. The data is presented in a table with columns: SongId (Partition key), Metadata (Sort key), Title, Artist, and TotalDownloads.

SongId (Partition key) : String	Metadata (Sort key) : String	Title : String	Artist : String	TotalDownloads : String
1	Details	Wild Love	Argyboots	3
2	Details	Example Song Title	Jorge Souza	4
12	ACME Album	ACME Best Song	ACME	4

You can also edit the facet definitions using the Data Modeler. For more information, see [Editing an existing data model](#).

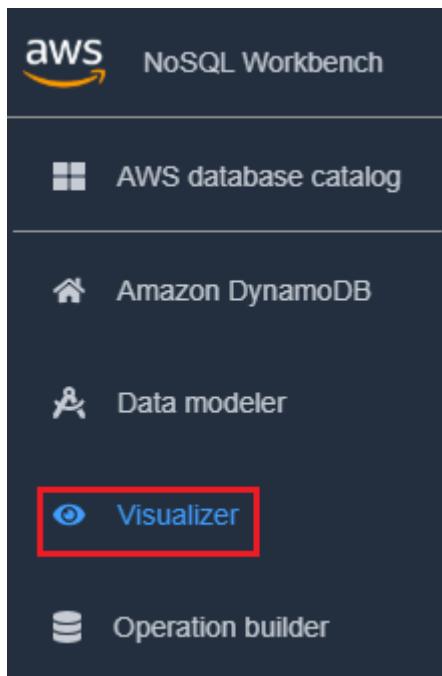

Viewing all tables in a data model using aggregate view

The aggregate view in NoSQL Workbench for Amazon DynamoDB represents all the tables in a data model. For each table, the following information appears:

- Table column names
- Sample data
- All global secondary indexes that are associated with the table. The following information is displayed for each index:
 - Index column names
 - Sample data

To view all table information

1. In the navigation pane on the left side, choose the **visualizer** icon.

2. In the visualizer, choose **Aggregate view**.

The screenshot shows the AWS NoSQL Workbench Visualizer interface. On the left, a navigation pane lists various tools: AWS database catalog, Amazon DynamoDB (selected), Data modeler, Visualizer (selected), Operation builder, Documentation, and Share feedback. A status bar at the bottom indicates "DDB local". The main area is titled "Visualizer" and contains a "Data model" section with a dropdown menu set to "Discussion Forum". Below this are sections for "Forum", "Thread", and "Reply". Under "Aggregate view", there is a table for "Forum" with the following data:

Primary key	Attributes			
	Partition key: ForumName	Category	Threads	Messages
Amazon DynamoDB	Amazon Web Services	2	4	1000
Amazon Simple Notification Service	Category	Threads	Messages	Views
Amazon Simple Queue Service	Amazon Web Services	5	5	1200
Amazon MQ	Category	Threads	Messages	Views
Amazon EMR	Amazon Web Services	9	6	1300
AWS Data Pipeline	Category	Threads	Messages	Views
Amazon Athena	Amazon Web Services	22	7	1400
AWS Step Functions	Category	Threads	Messages	Views
	Amazon Web Services	15	8	600
	Category	Threads	Messages	Views
	Amazon Web Services	19	9	500
	Category	Threads	Messages	Views
	Amazon Web Services	43	10	55
	Category	Threads	Messages	Views
	Amazon Web Services	30	11	99

Below the "Forum" table is a "Thread" section with a table header:

Primary key	Attributes			
-------------	------------	--	--	--

At the bottom of the main area, there are buttons for "Commit to Amazon DynamoDB" and "Share feedback".

Committing a data model to DynamoDB

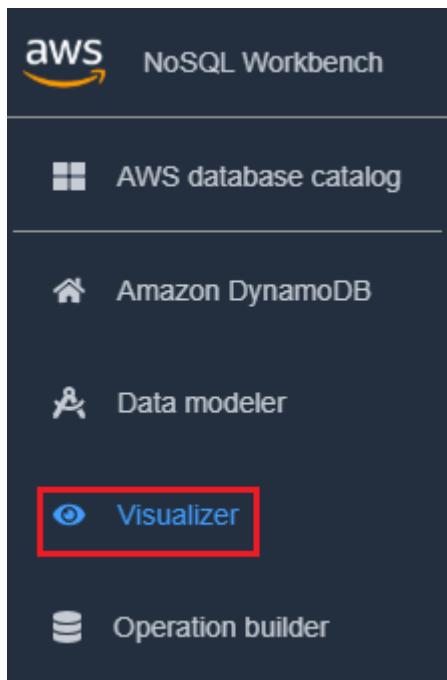

When you are satisfied with your data model, you can commit the model to Amazon DynamoDB.

Note

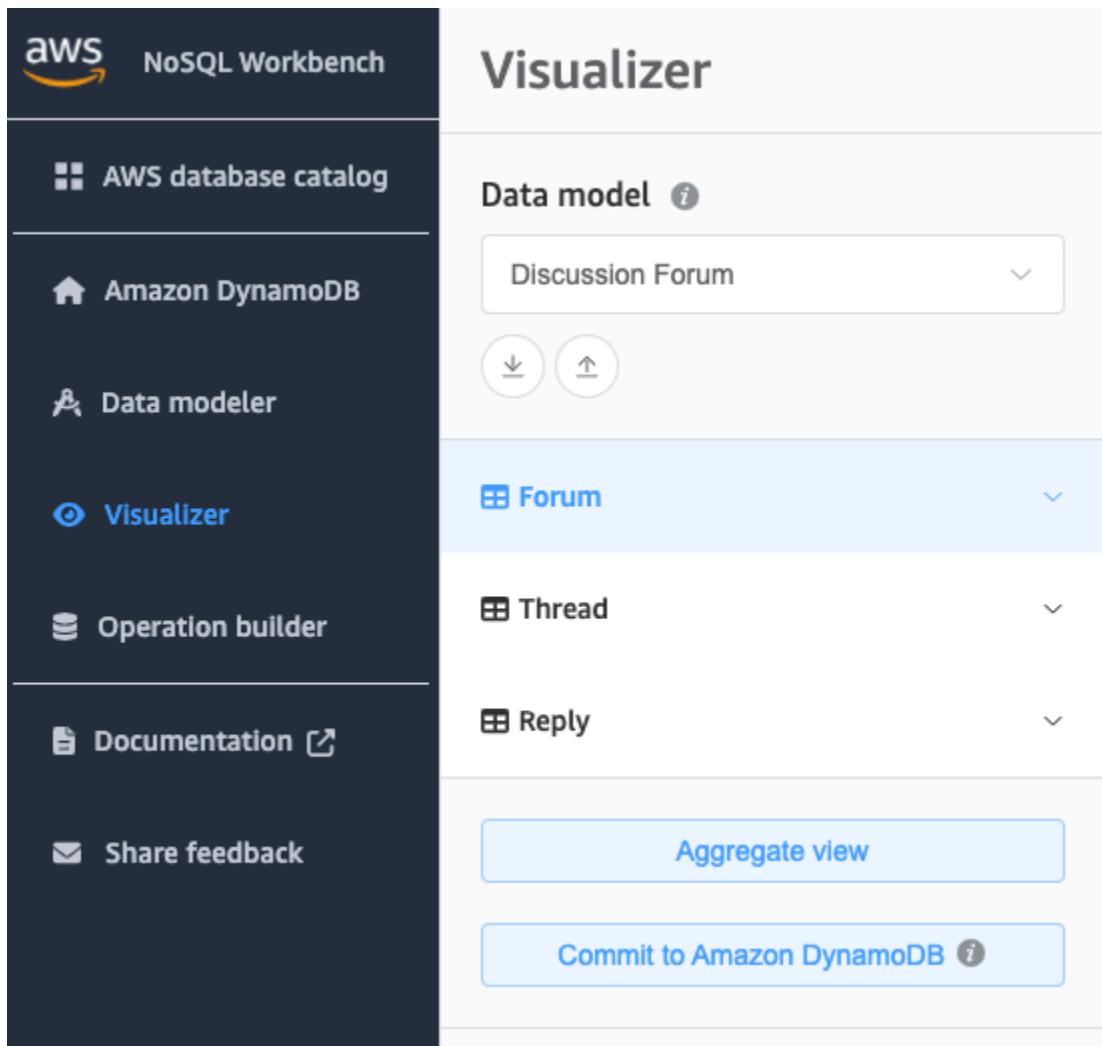

- This action results in the creation of server-side resources in AWS for the tables and global secondary indexes represented in the data model.
- Tables are created with the following characteristics:
 - Auto scaling is set to 70 percent target utilization.
 - Provisioned capacity is set to 5 read capacity units and 5 write capacity units.
 - Global secondary indexes are created with provisioned capacity of 10 read capacity units and 5 write capacity units.

To commit the data model to DynamoDB

- In the navigation pane on the left side, choose the **visualizer** icon.

2. Choose **Commit to DynamoDB**.

3. Choose an already existing connection, or create a new connection by choosing the **Add new remote connection** tab.

- To add a new connection, specify the following information:
 - **Account Alias**
 - **AWS Region**
 - **Access key ID**
 - **Secret access key**

For more information about how to obtain the access keys, see [Getting an AWS access key](#).

- You can optionally specify the following:
 - [**Session token**](#)
 - [**IAM role ARN**](#)

- If you don't want to sign up for a free tier account, and prefer to use [DynamoDB local \(downloadable version\)](#):
 1. Choose the **Add a new DynamoDB local connection** tab.
 2. Specify the **Connection name** and **Port**.

4. Choose **Commit**.

 **Note**

If you installed DynamoDB local as part of the NoSQL Workbench setup, you'll need to turn DynamoDB local on by using the **DynamoDB local Server** toggle at the bottom left of the NoSQL Workbench screen. See [Install NoSQL Workbench for DynamoDB](#) for more information on this toggle.

Exploring datasets and building operations with NoSQL Workbench

NoSQL Workbench for Amazon DynamoDB provides a rich graphical user interface for developing and testing queries. You can use the operation builder in NoSQL Workbench to view, explore, and query live datasets. The structured operation builder supports projection expression, condition expression, and generates sample code in multiple languages. You can directly clone tables from one Amazon DynamoDB account to another one in different Regions. You can also directly clone tables between DynamoDB local and an Amazon DynamoDB account for faster copying of your table's key schema (and optionally GSI schema and items) between your development environments. You can save as many as 50 DynamoDB data operations in the operation builder.

Topics

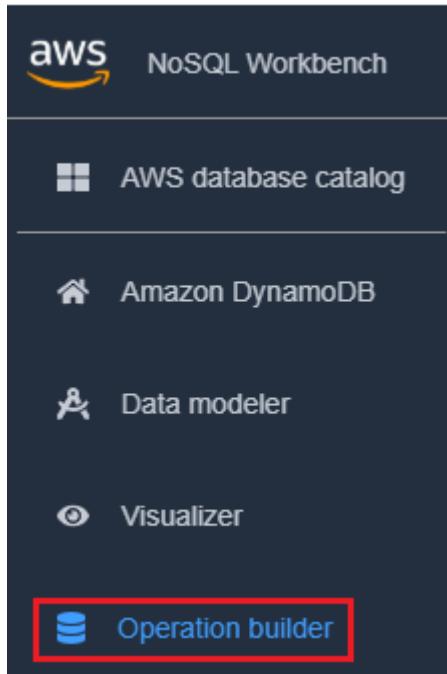

- [Connecting to live datasets](#)
- [Building complex operations](#)
- [Cloning tables with NoSQL Workbench](#)
- [Exporting data to a CSV file](#)

Connecting to live datasets

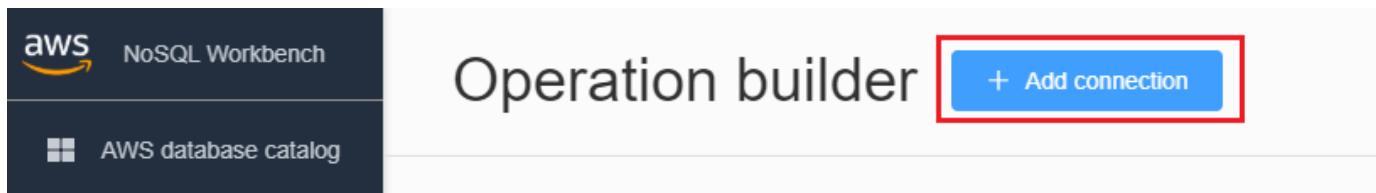

To connect to your Amazon DynamoDB tables with NoSQL Workbench, you must first connect to your AWS account.

To add a connection to your database

1. In NoSQL Workbench, in the navigation pane on the left side, choose the **Operation builder** icon.

2. Choose **Add connection**.

3. Specify the following information:

- **Account alias**
- **AWS Region**
- **Access key ID**
- **Secret access key**

For more information about how to obtain the access keys, see [Getting an AWS access key](#).

You can optionally, specify the following:

- [**Session token**](#)
- [**IAM role ARN**](#)

4. Choose **Connect**.

Add a new database connection

A remote connection lets you access the DynamoDB web service in different AWS Regions.

A DynamoDB local connection lets you access the DynamoDB local server running on your computer.

Remote

Connect

If you don't want to sign up for a free tier account, and prefer to use [DynamoDB local \(downloadable version\)](#):

- a. Choose the **Local** tab on the connection screen.
- b. Specify the following information:
 - **Connection name**
 - **Port**
- c. Choose the **connect** button.

Add a new database connection

i A remote connection can let you interact with DynamoDB servers in different regions.
A local connection can let you interact with the DynamoDB Local server on your machine.

Remote **Local**

i Please setup the dynamoDB local server on your machine before adding a connection.
[Setting Up DynamoDB Local](#)

* Connection name	Connection 1
* Hostname	localhost
* Port	8000

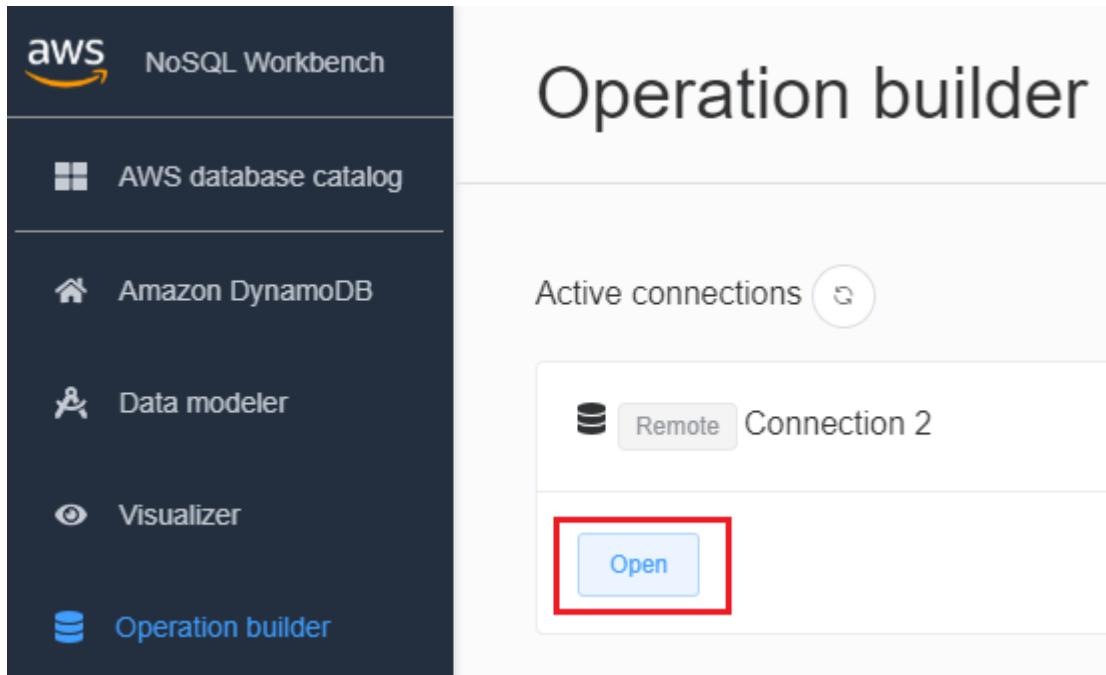

Cancel **Reset** **Connect**

i **Note**

To connect to DynamoDB local, either manually launch DynamoDB local using your terminal (see [deploying DynamoDB local on your computer](#)) or launch DynamoDB local

directly using the DDB local toggle in the NoSQL Workbench navigation menu. Ensure the connection port is the same as your DynamoDB local port.

5. On the created connection, choose **Open**.

After connecting to your DynamoDB database, the list of available tables appears in the left pane. Choose one of the tables to return a sample of the data stored in the table.

You can now run queries against the selected table.

To run queries on a table

1. In the **Attribute name** list, choose the attribute that you want to query on.
2. Specify the comparison operator.
3. Specify the data type of the value.
4. Specify the value to query for.
5. Choose **Scan**.

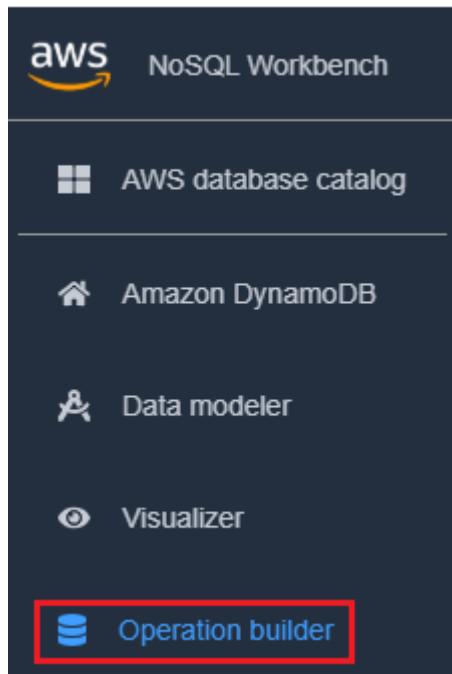

For more information about this operation, see [Scan](#) in the *Amazon DynamoDB API Reference*.

Building complex operations

The operation builder in NoSQL Workbench for Amazon DynamoDB provides a visual interface where you can perform complex data plane operations. It includes support for projection expressions and condition expressions. Once you've built an operation, you can save it for later use (up to 50 operations can be saved). You can then browse a list of your frequently used data-plane operations in the **Saved Operations** menu, and use them to automatically populate and build a new operation. You can also generate sample code for these operations, in multiple languages.

NoSQL Workbench supports building [PartiQL](#) for DynamoDB statements, which allows you to interact with DynamoDB using a SQL-compatible query language. NoSQL Workbench also supports building DynamoDB CRUD API operations.

To use NoSQL Workbench to build operations, in the navigation pane on the left side, choose the **Operation builder** icon.

Topics

- [Building PartiQL statements](#)
- [Building API operations](#)

Building PartiQL statements

To use NoSQL Workbench to build [PartiQL for DynamoDB](#) statements choose **PartiQL operations** at the top right corner of NoSQL Workbench.

You can build the following PartiQL statement types in the operation builder.

Topics

- [Singleton statements](#)
- [Transactions](#)
- [Batch](#)

Singleton statements

To run or generate code for a PartiQL statement, do the following.

● PartiQL statement ○ PartiQL transaction ○ PartiQL batch

1

Statement

```
1 SELECT *
2 FROM Music
3 WHERE Artist=? and SongTitle=?
```

Optional request parameters 3.a

Enable strongly consistent reads ⓘ

Parameters ⓘ

Attribute type	Attribute value
String	Acme Band 3.c
String	PartiQL Rocks

+ Add new parameter 3.b

5 4 6

Clear form Run Generate code Save operation

▲ Hide operation

1. Choose **PartiQL statement**.
2. Enter a valid [PartiQL statement](#).
3. If your statement uses parameters:
 - a. Choose **Optional request parameters**.
 - b. Choose **Add new parameters**.
 - c. Enter the attribute type and value.
 - d. If you want to add additional parameters, repeat steps b and c.
4. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

5. If you want the operation to be run immediately, choose **Run**.
6. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Transactions

To run or generate code for a PartiQL transaction, do the following.

○ PartiQL statement **○ PartiQL transaction** ○ PartiQL batch
1

Delete all statements Collapse all statements Run Generate code Save operation
7 6 8

i Read and write operations are not supported in the same PartiQL transaction request. A SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements.

⊕ 1. Choose and then enter a title

Statement

```
1 SELECT * FROM Music WHERE Artist=? AND SongTitle=? 3
```

Optional request parameters 4.a

Parameters **i**

Attribute type	Attribute value
String	Acme Band 4.c
String	PartiQL Rocks 4.b

+ Add new parameter

Clear Delete

+ Add a new statement 2

▲ Hide operation

The screenshot shows the Amazon DynamoDB PartiQL transaction editor interface. At the top, there are three radio button options: 'PartiQL statement' (unchecked), 'PartiQL transaction' (checked, highlighted with a red box), and 'PartiQL batch' (unchecked). Below the radio buttons are four buttons: 'Delete all statements', 'Collapse all statements', 'Run' (highlighted with a red box), 'Generate code', and 'Save operation'. A note below the buttons states: 'Read and write operations are not supported in the same PartiQL transaction request. A SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements.' A numbered callout '1' is placed over the 'PartiQL transaction' radio button. A numbered callout '2' is placed over the '+ Add a new statement' button. A numbered callout '3' is placed over the first parameter value 'Acme Band'. A numbered callout '4.a' is placed over the 'Optional request parameters' section. A numbered callout '4.b' is placed over the second parameter value 'PartiQL Rocks'. A numbered callout '5' is placed over the 'Run' button. A numbered callout '6' is placed over the 'Generate code' button. A numbered callout '7' is placed over the 'Delete all statements' button. A numbered callout '8' is placed over the 'Save operation' button. A numbered callout '9' is placed over the 'Save operation' button.

1. Choose **PartiQL transaction**.
2. Choose **Add a new statement**.
3. Enter a valid PartiQL statement.

Note

Read and write operations are not supported in the same PartiQL transaction request. A SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. See [Performing transactions with PartiQL for DynamoDB](#) for more details.

4. If your statement uses parameters
 - a. Choose **Optional request parameters**.
 - b. Choose **Add new parameters**.
 - c. Enter the attribute type and value.
 - d. If you want to add additional parameters, repeat steps b and c.
5. If you want to add more statements, repeat steps 2 to 4.
6. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.
8. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Batch

To run or generate code for a PartiQL batch, do the following.

1 PartiQL statement PartiQL transaction PartiQL batch

Delete all statements Collapse all statements Run Generate code Save operation

7 6 8

Read and write operations are not supported in the same PartiQL batch request, which means a SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. Write operations to the same item are not allowed. As with the BatchGetItem operation, only singleton read operations are supported. Scan and query operations are not supported.

⊕ 1. Choose and then enter a title

Statement

1 `SELECT * FROM Music WHERE Artist=? AND SongTitle=?` 3

Optional request parameters 4.a

Enable strongly consistent reads i

Parameters i

Attribute type	Attribute value
String	Acme Band 4.c
String	PartiQL Rocks

+ Add new parameter 4.b

Clear Delete

+ Add a new statement 2

▲ Hide operation

The screenshot shows the PartiQL batch editor interface. At the top, there are three radio buttons: 'PartiQL statement' (unchecked), 'PartiQL transaction' (unchecked), and 'PartiQL batch' (checked). Below the radio buttons are four buttons: 'Delete all statements', 'Collapse all statements', 'Run' (highlighted with a red box), 'Generate code', and 'Save operation'. A note below the buttons states: 'Read and write operations are not supported in the same PartiQL batch request, which means a SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. Write operations to the same item are not allowed. As with the BatchGetItem operation, only singleton read operations are supported. Scan and query operations are not supported.' A numbered callout '1' is placed over the 'PartiQL batch' radio button. A numbered callout '2' is placed over the '+ Add a new statement' button. A numbered callout '3' is placed over the question marks in the SELECT statement. A numbered callout '4.a' is placed over the 'Optional request parameters' section. A numbered callout '4.b' is placed over the '+ Add new parameter' button. A numbered callout '4.c' is placed over the 'Attribute value' field for the first parameter. A numbered callout '5' is placed over the 'Run' button. A numbered callout '6' is placed over the 'Generate code' button. A numbered callout '7' is placed over the 'Delete all statements' button. A numbered callout '8' is placed over the 'Save operation' button.

1. Choose **PartiQL batch**.
2. Choose **Add a new statement**.

3. Enter a valid [PartiQL statement](#).

Note

Read and write operations are not supported in the same PartiQL batch request, which means a SELECT statement cannot be in the same request with INSERT, UPDATE, and DELETE statements. Write operations to the same item are not allowed. As with the BatchGetItem operation, only singleton read operations are supported. Scan and query operations are not supported. See [Running batch operations with PartiQL for DynamoDB](#) for more details.

4. If your statement uses parameters:

- a. Choose **Optional request parameters**.
- b. Choose **Add new parameters**.
- c. Enter the attribute type and value.
- d. If you want to add additional parameters, repeat steps b and c.

5. If you want to add more statements, repeat steps 2 to 4.

6. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.

8. If you want to save this operation for later use, choose **Save operation**. Then enter a name for your operation and choose **Save**.

Building API operations

To use NoSQL Workbench to build DynamoDB CRUD APIs, select **Interface-based operations** at the top right corner of NoSQL Workbench.

Then go to the **Operations** drop-down and choose the operation that you want to build.

The screenshot shows the AWS NoSQL Workbench interface with the 'Operation builder' selected in the sidebar. The main area displays connection settings (Name: user1, Region: us-east-1) and a search bar for tables. A dropdown menu titled 'Build operations' is open, showing a list of operations categorized into 'Control plane operations' and 'Data plane operations'. The 'UpdateTable' operation is currently selected.

Build operations ⓘ

Operations

Choose an operation

Control plane operations

- DeleteTable
- CreateTable
- UpdateTable

Data plane operations

- UpdateItem
- PutItem

Choose a table from the navigation bar

You can perform the following operations in the operation builder.

Table operations

- [Delete Table](#)
- [Create Table](#)
- [Update Table](#)

Item operations

- [Get Item](#)
- [Put Item](#)
- [Update Item](#)
- [Delete Item](#)
- [Query](#)
- [Scan](#)

- [Transact Get Items](#)
- [Transact Write Items](#)

Table operations

Delete table

To run or generate code for a Delete Table operation, do the following.

1. Select **Delete Table** from the Operations dropdown list.
2. Select the table from the **Table name** dropdown list.
3. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

4. If you want the operation to be run immediately, choose **Run**.

In the confirmation window that appears, confirm by entering the table name and selecting **Delete**.

The screenshot shows the AWS Lambda Operation builder interface. On the left, there's a sidebar titled 'Operation builder' with sections for 'Connection' (set to 'user1' and 'us-east-1'), 'Tables' (with a search bar), and a bottom navigation bar with icons for 'Building operations', 'Logs', and 'Metrics'. The main area is titled 'Build operations' with tabs for 'PartiQL operations' (selected) and 'Interface-based operations'. It has dropdowns for 'Operations' (set to 'DeleteTable') and 'Table name' (set to 'NoSQLTest1'). At the bottom right are 'Run' and 'Generate code' buttons. Below these buttons is a 'Results' section with a message: 'No result to display. Choose a table from the navigation pane to view all table data, or build an operation and view operation results.'

Results of the operation will appear in the results tab at the bottom of the screen.

For more information about this operation, see [Delete table](#) in the *Amazon DynamoDB API Reference*.

Create table

To run or generate code for a `Create Table` operation, do the following.

1. Select **Create Table** from the Operations dropdown list.
2. Enter the table name desired.
3. Create a partition key.
4. Configure the table as desired. You can create a Global Secondary Index, enable autoscaling, and other options.
5. To customize capacity settings, go to **Capacity Settings** and uncheck the box next to **Default settings**.
 - You can now select either **Provisioned** or **On-demand capacity**.

With Provisioned selected, you can set minimum and maximum read and write capacity units. You can also enable or disable auto scaling.

- If the table is currently set to OnDemand, you will be unable to specify a provisioned throughput.
 - If you switch from OnDemand to Provisioned throughput, then Autoscaling will automatically be applied to all GSIs with: min: 1, max: 10; target: 70%.
6. If you want to clear all new settings you've made and start over, select **Clear form**.
 7. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

8. If you want the operation to be run immediately, choose **Run**.

Results of the operation will appear in the results tab at the bottom of the screen.

9. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

The screenshot shows the 'Operation builder' interface for creating a new table. The 'Operations' dropdown is set to 'CreateTable'. The 'Table name' field is set to 'Music'. The 'Partition key' is defined as 'pk1' of type 'String'. There is an unchecked checkbox for 'Add sort key'. The 'Capacity settings' section has 'Default settings' checked. A note states: 'The default settings use provisioned capacity mode with auto scaling enabled on both read and write capacity.' At the bottom are buttons for 'Clear form', 'Run', 'Generate code', and 'Save operation'.

For more information about this operation, see [Create table](#) in the *Amazon DynamoDB API Reference*.

Update table

To run or generate code for an Update Table operation, do the following.

1. Select **Update Table** from the Operations dropdown list.
2. Select the desired operation from the **Update operations** dropdown list.
3. Select the table from the **Table name** dropdown list.
4. Update the selected table as desired. You can create a GSI, update provisioned throughputs and other options.

5. If you select Create GSI, Update Provisioned Throughput or Update Provisioned Throughput for GSI the Capacity settings option will appear.
6. To customize capacity settings, go to **Capacity Settings**. Then uncheck the option for either **Inherit capacity settings from base table** or **On-demand**.
 - You can now select either **Provisioned** or **On-demand capacity**.

With Provisioned selected, you can set minimum and maximum read and write capacity units. You can also enable or disable auto scaling.

- If the table is currently set to OnDemand, you will be unable to specify a provisioned throughput.
 - If you switch from OnDemand to Provisioned throughput, then Autoscaling will automatically be applied to all GSIs with: min: 1, max: 10; target: 70%.
7. If you want to clear the settings you've just entered and start over, **Clear form**.
 8. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

9. If you want the operation to be run immediately, choose **Run**.

Results of the operation will appear in the results tab at the bottom of the screen.

10. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

The screenshot shows the 'Operation builder' interface for 'Interface-based operations'. On the left sidebar, there are sections for 'Connection' (set to 'user1' and 'us-east-1'), 'Tables' (listing 'DeleteMe1' and 'NoSQLTest1'), and 'Saved operations' (empty). The main area is titled 'Build operations' and shows the configuration for an 'UpdateTable' operation on the 'NoSQLTest1' table, specifically for creating a Global Secondary Index (GSI) named 'GSI1'. The 'GSI1' configuration includes a 'Partition key' of 'pk2' and a 'Projection type' of 'ALL'. Under 'Capacity settings', there is a checked checkbox for 'Inherit capacity settings from base table', with a note explaining that global secondary indexes inherit the capacity settings of the base table unless the base table is using provisioned capacity mode. At the bottom right are buttons for 'Clear form', 'Run', 'Generate code', and 'Save operation'.

For more information about this operation, see [Update table](#) in the *Amazon DynamoDB API Reference*.

Item operations

Get item

To run or generate code for a Get Item operation, do the following.

1. Specify the partition key value.
2. If you want to add a projection expression , do the following:

- a. Choose **Projection expression**.
- b. Choose the + (plus sign) next to **Projection expression**.
- c. Specify the **Attribute name**.

The screenshot shows the 'GetItem' operation configuration page. At the top, 'Data plane operations' dropdown is set to 'GetItem' and 'Table' dropdown is set to 'Music'. Below these, there are two input fields: 'Partition key' with value 'Artist' and 'Sort key' with value 'SongTitle'. A checked checkbox labeled 'Projection expression' has a '+' button next to it, which is highlighted in blue. Below this, a 'Projected attribute' field contains 'Attribute name' with a delete icon. At the bottom right, there are four buttons: 'Clear form', 'Run' (blue), 'Generate code' (blue), and 'Save operation'.

3. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

4. If you want the operation to be run immediately, choose **Run**.
5. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see [GetItem](#) in the *Amazon DynamoDB API Reference*.

Put item

To run or generate code for a Put Item operation, do the following.

1. Specify the partition key value.

2. Specify the sort key value, if one exists.
3. If you want to add non-key attributes, do the following:
 - a. Choose the + (plus sign) next to **Other attributes**.
 - b. Specify the **Attribute name, Type, and Value**.
4. If a condition expression must be satisfied for the Put Item operation to succeed, do the following:
 - a. Choose **Condition**.
 - b. Specify the attribute name, comparison operator, attribute type, and attribute value.
 - c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition expressions](#).

And Or Negate (checkbox)

* Condition Negate i

Attribute name	=	Attribute type	Attribute value
Attribute name	=	Attribute type	Attribute value

Clear form Run Generate code Save operation

5. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

6. If you want the operation to be run immediately, choose **Run**.
7. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see [PutItem](#) in the *Amazon DynamoDB API Reference*.

Update item

To run or generate code for an Update Item operation, do the following:

1. Enter the partition key value.
2. Enter the sort key value, if one exists.
3. In **Update expression**, choose the expression in the list.
4. Choose the + (plus sign) for the expression.
5. Enter the attribute name and attribute value for the selected expression.
6. If you want to add more expressions, choose another expression in the **Update Expression** drop-down list, and then select the +.
7. If a condition expression must be satisfied for the Update Item operation to succeed, do the following:
 - a. Choose **Condition**.
 - b. Specify the attribute name, comparison operator, attribute type, and attribute value.
 - c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition expressions](#).

Clear form Run Generate code Save operation

8. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

9. If you want the operation to be run immediately, choose **Run**.

10. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see [UpdateItem](#) in the *Amazon DynamoDB API Reference*.

Delete item

To run or generate code for a Delete Item operation, do the following.

1. Enter the partition key value.

2. Enter the sort key value, if one exists.
3. If a condition expression must be satisfied for the Delete Item operation to succeed, do the following:
 - a. Choose **Condition**.
 - b. Specify the attribute name, comparison operator, attribute type, and attribute value.
 - c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition expressions](#).

The screenshot shows the 'DeleteItem' form in the Amazon DynamoDB Data Plane Operations interface. At the top, there are dropdown menus for 'Data plane operations' (set to 'DeleteItem') and 'Table' (set to 'Music'). Below these are fields for specifying the partition key ('Artist') and sort key ('SongTitle'). Under the 'Condition expression' section, there are buttons for '+ Condition' and '+ Child expression'. A 'And' button is selected. There is also a 'Negate' toggle switch. Below this, there are fields for 'Attribute name' (with a dropdown menu), 'Comparison operator' (set to '='), 'Attribute type' (dropdown menu), and 'Attribute value' (input field). At the bottom right are buttons for 'Clear form', 'Run', 'Generate code', and 'Save operation'.

4. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

5. If you want the operation to be run immediately, choose **Run**.
6. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see [DeleteItem](#) in the *Amazon DynamoDB API Reference*.

Query

To run or generate code for a Query operation, do the following.

1. Specify the partition key value.
2. If a sort key is needed for the Query operation:
 - a. Select **Sort key**.
 - b. Specify the comparison operator, attribute type, and attribute value.
3. If not all the attributes should be returned with the operation result, select **Projection expression**.
4. Choose the + (plus sign).
5. Enter the attribute to return with the query result.
6. If more attributes are needed, choose the + .
7. If a condition expression must be satisfied for the Query operation to succeed, do the following:
 - a. Choose **Condition**.
 - b. Specify the attribute name, comparison operator, attribute type, and attribute value.
 - c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition expressions](#).

Clear form Run Generate code Save operation

8. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

9. If you want the operation to be run immediately, choose **Run**.

10. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about this operation, see [Query](#) in the *Amazon DynamoDB API Reference*.

Scan

To run or generate code for a Scan operation, do the following.

1. If not all the attributes should be returned with the operation result, select **Projection expression**.
2. Choose the + (plus sign).
3. Specify the attribute to return with the query result.
4. If more attributes are needed, choose the + again.
5. If a condition expression must be satisfied for the scan operation to succeed, do the following:
 - a. Choose **Condition**.
 - b. Specify the attribute name, comparison operator, attribute type, and attribute value.
 - c. If other conditions are needed, choose **Condition** again.

For more information, see [Condition expressions](#).

6. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

7. If you want the operation to be run immediately, choose **Run**.
8. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

TransactGetItems

To run or generate code for a TransactGetItems operation, do the following.

1. Choose the + (plus sign).
2. Follow the instructions for the [Get item](#) operation.

When you are done specifying the details of the operation, choose the + (plus sign) if you want to add more operations.

The screenshot shows the Amazon DynamoDB Data plane operations interface. At the top, there's a dropdown menu labeled "TransactGetItems". Below it, a sidebar lists actions: "TransactGetItem" (selected), "1. GetItem", and "1. GetItem" again. The main area is titled "1. GetItem". It has fields for "Table Name" (set to "Music"), "Partition key" (set to "Attribute value for partition key: Artist"), and "Sort key" (set to "Attribute value for sort key: SongTitle"). There's also a checked checkbox for "Projection expression" with a plus sign icon, and a field for "Projected attribute" with a placeholder "Attribute name" and a delete icon. At the bottom, there are three buttons: "Run", "Generate code", and "Save operation".

To change the order of actions, choose an action in the list on the left side, and then choose the up or down arrows to move it up or down in the list.

To delete an action, choose the action in the list, and then choose the **Delete** (trash can) icon.

3. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

4. If you want the operation to be run immediately, choose **Run**.
5. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about transactions, see [Amazon DynamoDB transactions](#).

TransactWriteItems

To run or generate code for a TransactWriteItems operation, do the following.

1. In the **Actions** drop-down list, choose the operation that you want.

- For DeleteItem, follow the instructions for the [Delete item](#) operation.
- For PutItem, follow the instructions for the [Put item](#) operation.
- For UpdateItem, follow the instructions for the [Update item](#) operation.

When you are done specifying the details of the operation, choose the **+** button.

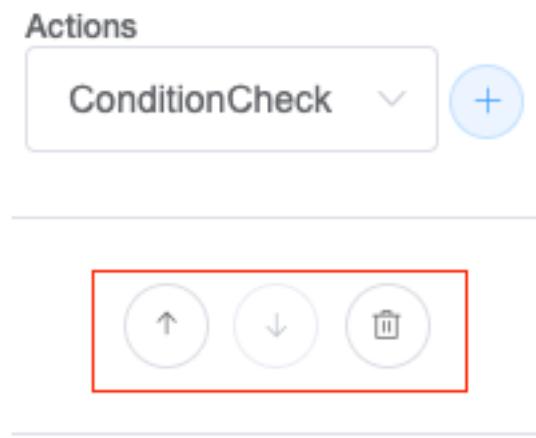

The screenshot shows the AWS Lambda Function Builder interface. On the left, there's a sidebar titled "Data plane operations" with a dropdown menu set to "TransactWriteItems". Below it is a list of actions: "DeleteItem", "PutItem" (which is selected and highlighted in blue), "UpdateItem", and "ConditionCheck". Under "PutItem", there's a sub-section titled "1. PutItem". The main workspace is titled "PutItem" and contains the following fields:

- "Table name": "Music"
- "* Partition key": "Attribute value for partition key: Artist" (with an info icon)
- "* Sort key": "Attribute value for sort key: SongTitle" (with an info icon)
- "Other attributes": A section with a "+" button and an info icon.
- "Condition expression": Buttons for "+ Condition" and "+ Child expression" (both with info icons).

At the bottom right of the workspace are three buttons: "Run", "Generate code", and "Save operation".

To change the order of actions, choose an action in the list on the left side, and then choose the up or down arrows to move it up or down in the list.

To delete an action, choose the action in the list, and then choose the **Delete** (trash can) icon.

1. DeleteItem

2. PutItem

3. ConditionCheck

2. If you want to generate code, choose **Generate code**.

Choose the tab for the language that you want. You can now copy this code and use it in your application.

3. If you want the operation to be run immediately, choose **Run**.
4. If you want to save this operation for later use, choose **Save operation**, then enter a name for your operation and choose **Save**.

For more information about transactions, see [Amazon DynamoDB transactions](#).

Cloning tables with NoSQL Workbench

Cloning tables will copy a table's key schema (and optionally GSI schema and items) between your development environments. You can clone a table between DynamoDB local to an Amazon

DynamoDB account, and even clone a table from one account to another in different Regions for faster experimentation.

To clone a table

1. In the **Operation Builder**, select your connection and Region (Region selection is not available for DynamoDB local).
2. Once you are connected to DynamoDB, browse your tables and select the table you want to clone.
3. Select the **Clone** button.

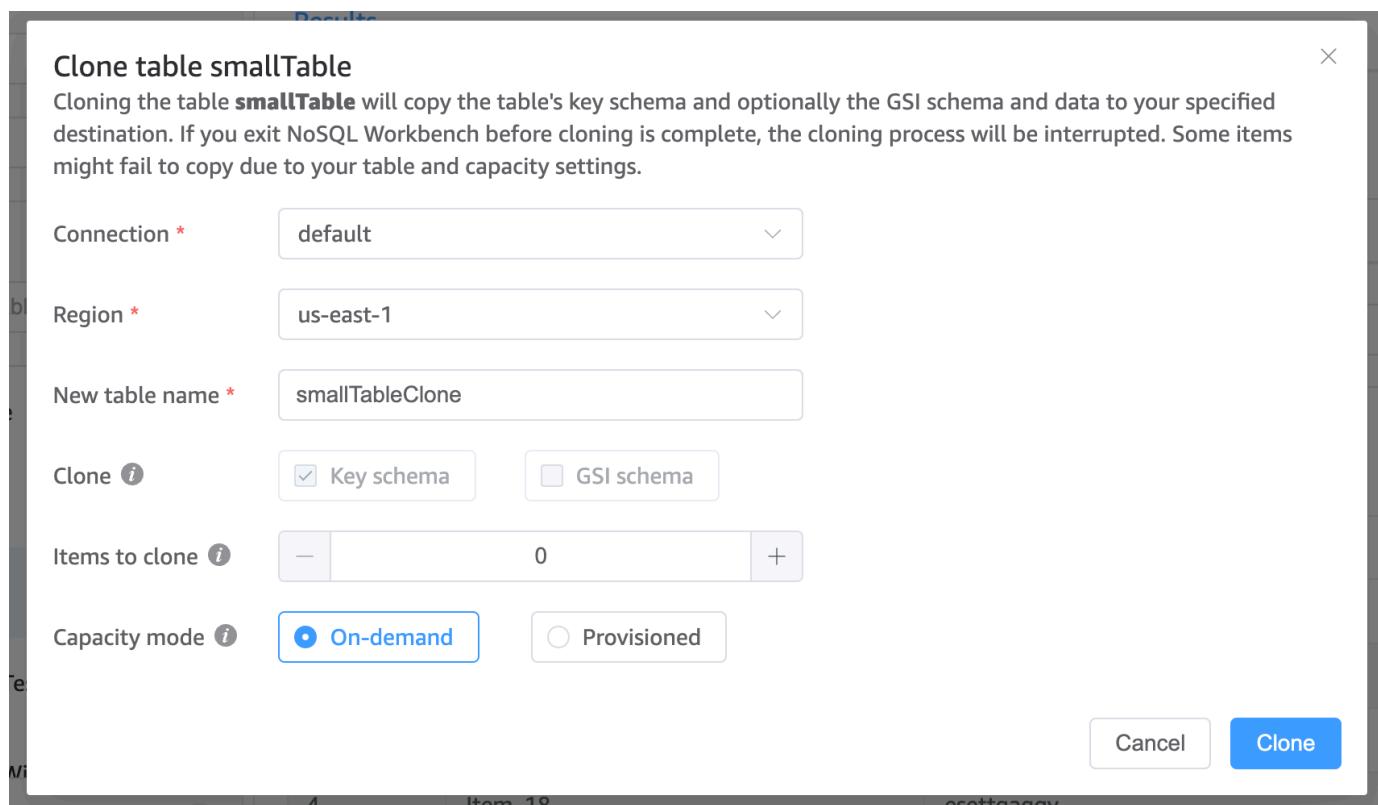

Items returned (15)
Consumed 1 RCU.

[Clone](#) [Export to CSV](#)

#	PrimaryKey ⓘ	Attribute1	Attribute2
1	Item_39	ggdqztcaw	61
2	Item_32	wljiouytoj	42
3	Item_3	aniqhpznsb	86
4	Item_18	esettqagqv	67

4. Input your clone destination details:
 - a. Select a connection.
 - b. Select a Region (Region is not available for DynamoDB local).
 - c. Enter a new table name.
 - d. Choose a clone options:
 - i. **Key schema** is selected by default and cannot be unselected. By default, cloning a table will copy your primary key and sort key if they are available.
 - ii. **GSI schema** is selected by default if your table to be cloned has a GSI. Cloning a table will copy your GSI primary key and sort key if they are available. You have the option to deselect GSI schema to skip cloning the GSI schema. Cloning a table will copy your base table's capacity settings as the GSI's capacity settings. You can use the `UpdateTable` operation in Operation Builder to update the table's GSI capacity setting after cloning is complete.

5. Enter the number of items to clone. To only clone the key schema and optionally the GSI schema, you can keep the **Items to clone** value at 0. The maximum number of items that can be cloned is 5000.
6. Choose a capacity mode:
 - a. **On-demand mode** is selected by default. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use. To learn more, see [DynamoDB On-demand mode](#).
 - b. **Provisioned mode** lets you specify the number of reads and writes per second that you require for your application. You can use auto scaling to adjust your table's provisioned capacity automatically in response to traffic changes. To learn more, see [DynamoDB Provisioned mode](#).
7. Select **Clone** to begin cloning.

8. The cloning process will run in the background. The **Operation builder** tab will show a notification when there is a change in the cloning table status. You can access this status by selecting the **Operation builder** tab and then selecting the arrow button. The arrow button is located on the cloning table status widget located near the bottom of the menu sidebar.

The screenshot shows the Amazon DynamoDB Operation Builder interface. At the top, a progress bar indicates a cloning operation is in progress. Below it, a modal window displays the completion of a cloning job from a table named **smallTable** to a new table named **smallTableTest**. The summary shows 50 items read, 50 items cloned successfully, 0 items cloned failed, and 0 items cloned in progress. RCU and WRU consumed were 0.5 RCU / 50 WCU. There are "Close" and "See new table" buttons at the bottom of the modal.

Cloning table

... In progress

Clone table job completed

Table **smallTable** was successfully cloned to **smallTableTest** in the connection **default** and region **us-east-1**

Summary

Number of items read	50
Items cloned successfully	50
Items cloned failed	0
Items clone in progress	0
RCU and WRU consumed	0.5 RCU / 50 WCU

Close See new table

Exporting data to a CSV file

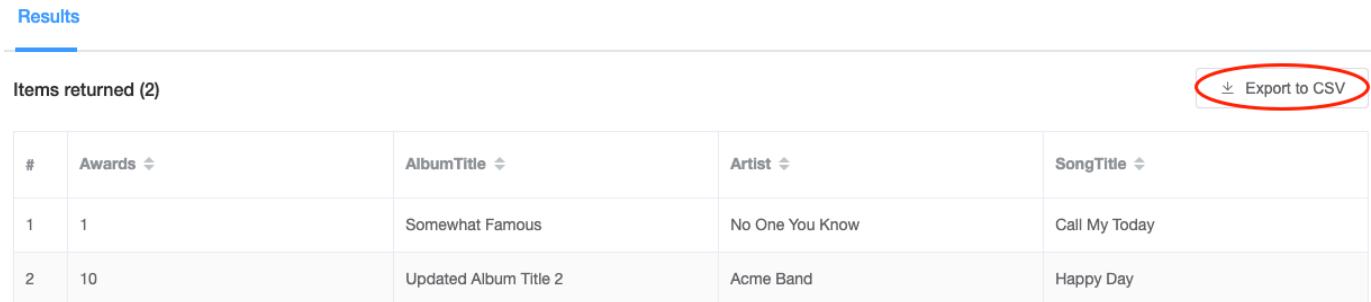

You can export the results of a query from Operation Builder to a CSV file. This enables you to load the data into a spreadsheet or process it using your preferred programming language.

Exporting to CSV

1. In the Operation Builder, run an operation of your choice, such as a Scan or Query.

Note

- You can only export results from read API operations and PartiQL statements to a CSV file. You can't export results from transaction read statements.
- Currently, you can export results one page at a time to a CSV file. If there are multiple pages of results, you must export each page individually.

2. In the Results panel, choose Export to CSV.

Items returned (2)				
#	Awards	AlbumTitle	Artist	SongTitle
1	1	Somewhat Famous	No One You Know	Call My Today
2	10	Updated Album Title 2	Acme Band	Happy Day

3. Choose a filename and location for your CSV file and select Save.

Sample data models for NoSQL Workbench

The home page for the modeler and visualizer display a number of sample models that ship with the NoSQL Workbench. This section describes these models and their potential uses.

Topics

- [Employee data model](#)
- [Discussion forum data model](#)
- [Music library data model](#)
- [Ski resort data model](#)
- [Credit card offers data model](#)
- [Bookmarks data model](#)

Employee data model

This data model is an introductory model. It represents an employee's basic details such as a unique alias, first name, last name, designation, manager, and skills.

This data model depicts a few techniques such as handling complex attribute such as having more than one skill. This model is also an example of one-to-many relationship through the manager and their reporting employees that has been achieved by the secondary index DirectReports.

The access patterns facilitated by this data model are:

- Retrieval of an employee record using the employee's login alias, facilitated by a table called Employee.
- Search for employees by name, facilitated by the Employee table's global secondary index called Name.
- Retrieval of all direct reports of a manager using the manager's login alias, facilitated by the Employee table's global secondary index called DirectReports.

Discussion forum data model

This data model represents a discussion forums. Using this model customers can engage with the developer community, ask questions, and respond to other customers' posts. Each AWS service has a dedicated forum. Anyone can start a new discussion thread by posting a message in a forum, and each thread receives any number of replies.

The access patterns facilitated by this data model are:

- Retrieval of a forum record using the forum's name, facilitated by a table called Forum.
- Retrieval of a specific thread or all threads for a forum, facilitated by a table called Thread.
- Search for replies using the posting user's email address, facilitated by the Reply table's global secondary index called PostedBy-Message-Index.

Music library data model

This data model represents a music library that has a large collection of songs and showcases its most downloaded songs in near-real time.

The access patterns facilitated by this data model are:

- Retrieval of a song record, facilitated by a table called Songs.
- Retrieval of a specific download record or all download records for a song, facilitated by a table called Songs.

- Retrieval of a specific monthly download count record or all monthly download count records for a song, facilitated by a table called Song.
- Retrieval of all records (including song record, download records, and monthly download count records) for a song, facilitated by a table called Songs.
- Search for most downloaded songs, facilitated by the Songs table's global secondary index called DownloadsByMonth.

Ski resort data model

This data model represents a ski resort that has a large collection of data for each ski lift collected daily.

The access patterns facilitated by this data model are:

- Retrieval of all data for a given ski lift or overall resort, dynamic and static, facilitated by a table called SkiLifts.
- Retrieval of all dynamic data (including unique lift riders, snow coverage, avalanche danger, and lift status) for a ski lift or the overall resort on a specific date, facilitated by a table called SkiLifts.
- Retrieval of all static data (including if the lift is for experienced riders only, vertical feet the lift rises, and lift riding time) for a specific ski lift, facilitated by a table called SkiLifts.
- Retrieval of date of data recorded for a specific ski lift or the overall resort sorted by total unique riders, facilitated by the SkiLifts table's global secondary index called SkiLiftsByRiders.

Credit card offers data model

This data model is used by a Credit Card Offers Application.

A credit card provider produces offers over time. These offers include balance transfers without fees, increased credit limits, lower interest rates, cash back, and airline miles. After a customer accepts or declines these offers, the respective offer status is updated accordingly.

The access patterns facilitated by this data model are:

- Retrieval of account records using AccountId, as facilitated by the main table.
- Retrieval of all the accounts with few projected items, as facilitated by the secondary index AccountIndex.

- Retrieval of accounts and all the offer records associated with those accounts by using AccountId, as facilitated by the main table.
- Retrieval of accounts and specific offer records associated with those accounts by using AccountId and OfferId, as facilitated by the main table.
- Retrieval of all ACCEPTED/DECLINED offer records of specific OfferType associated with accounts using AccountId, OfferType, and Status, as facilitated by the secondary index GSI1.
- Retrieval of offers and associated offer item records using OfferId, as facilitated by the main table.

Bookmarks data model

This data model is used store bookmarks for customers.

A customer can have many bookmarks and a bookmark can belong to many customers. This data model represents a many-to-many relationship.

The access patterns facilitated by this data model are:

- A single query by customerId can now return customer data as well as bookmarks.
- A query ByEmail index returns customer data by email address. Note that bookmarks are not retrieved by this index.
- A queryByUrl index gets bookmarks data by URL. Note that we have customerId as the sort key for the index because the same URL can be bookmarked by multiple customers.
- A query ByCustomerFolder index gets bookmarks by folder for each customer.

Release history for NoSQL Workbench

The following table describes the important changes in each release of the *NoSQL Workbench* client tool.

Version	Change	Description	Date
3.12.0	Cloning tables with NoSQL Workbench	You can now clone tables between DynamoDB local and	February 26, 2024

Version	Change	Description	Date
	and returning capacity consumed	a DynamoDB web service account or between DynamoDB web service accounts for faster development iterations. View RCU or WCU consumed after running an operation using the Operations Builder. We fixed the overwrite data issue when importing from a CSV file.	
3.11.0	DynamoDB local improvements	You can now specify port when launching the built-in DynamoDB local instance. NoSQL Workbench can now be installed on Windows without admin rights. We have updated the data model templates.	January 17, 2024

Version	Change	Description	Date
3.10.0	Native support for Apple silicon	NoSQL Workbench now includes native support for Mac with Apple silicon. You can now configure sample data generation format for attributes of type Number.	December 5, 2023
3.9.0	Data modeler improvements	Visualizer now supports committing data models to DynamoDB local with the option to overwrite existing tables.	November 3, 2023
3.8.0	Sample data generation	NoSQL Workbench now supports generating sample data for your DynamoDB data models.	September 25, 2023
3.6.0	Improvements in the Operations builder	Connections management improvements in the Operations builder. Attribute names in Data Modeler can now be changed without deleting data. Other bug fixes.	April 11, 2023

Version	Change	Description	Date
3.5.0	Support for new AWS Regions	NoSQL Workbench now supports the ap-south-2, ap-southeast-3, ap-southeast-4, eu-central-2, eu-south-2, me-central-1, and me-west-1 regions.	February 23, 2023
3.4.0	Support for DynamoDB local	NoSQL Workbench now supports installing DynamoDB local as part of the installation process.	December 6, 2022
3.3.0	Support for control plane operations	Operation Builder now supports control plane operations.	June 1, 2022
3.2.0	CSV import and export	You can now import sample data from a CSV file in the Visualizer tool, and also export the results of an Operation Builder query to a CSV file.	October 11, 2021
3.1.0	Save operations	The Operation Builder in NoSQL Workbench now supports saving operations for later use.	July 12, 2021

Version	Change	Description	Date
3.0.0	Capacity settings and CloudFormation import/export	NoSQL Workbench for Amazon DynamoDB now supports specifying a read/write capacity mode for tables, and can now import and export data models in AWS CloudFormation format.	April 21, 2021
2.2.0	Support for PartiQL	NoSQL Workbench for Amazon DynamoDB adds support for building PartiQL statements for DynamoDB.	December 4, 2020
1.1.0	Support for Linux.	NoSQL Workbench for Amazon DynamoDB is supported on Linux—Ubuntu, Fedora, and Debian.	May 4, 2020
1.0.0	NoSQL Workbench for Amazon DynamoDB – GA.	NoSQL Workbench for Amazon DynamoDB is generally available.	March 2, 2020

Version	Change	Description	Date
0.4.1	Support for IAM roles and temporary security credentials.	NoSQL Workbench for Amazon DynamoDB adds support for AWS Identity and Access Management (IAM) roles and temporary security credentials.	December 19, 2019
0.3.1	Support for DynamoDB local (Downloadable Version) .	The NoSQL Workbench now supports connecting to DynamoDB local (Downloadable Version) to design, create, query, and manage DynamoDB tables.	November 8, 2019
0.2.1	NoSQL Workbench preview released.	This is the initial release of NoSQL Workbench for DynamoDB. Use NoSQL Workbench to design, create, query, and manage DynamoDB tables.	September 16, 2019

Code examples for DynamoDB using AWS SDKs

The following code examples show how to use DynamoDB with an AWS software development kit (SDK).

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

Scenarios are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

Cross-service examples are sample applications that work across multiple AWS services.

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello DynamoDB

The following code examples show how to get started using DynamoDB.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

namespace DynamoDB_Actions;

public static class HelloDynamoDB
```

```
{  
    static async Task Main(string[] args)  
    {  
        var dynamoDbClient = new AmazonDynamoDBClient();  
  
        Console.WriteLine($"Hello Amazon Dynamo DB! Following are some of your  
tables:");  
        Console.WriteLine();  
  
        // You can use await and any of the async methods to get a response.  
        // Let's get the first five tables.  
        var response = await dynamoDbClient.ListTablesAsync(  
            new ListTablesRequest()  
            {  
                Limit = 5  
            });  
  
        foreach (var table in response.TableNames)  
        {  
            Console.WriteLine($"\\tTable: {table}");  
            Console.WriteLine();  
        }  
    }  
}
```

- For API details, see [ListTables](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
```

```
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS dynamodb)

# Set this project's name.
project("hello_dynamodb")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
libraries for the AWS SDK.

endif ()

add_executable(${PROJECT_NAME}
    hello_dynamodb.cpp)

target_link_libraries(${PROJECT_NAME}
    ${AWSSDK_LINK_LIBRARIES})
```

Code for the hello_dynamodb.cpp source file.

```
#include <aws/core/Aws.h>
#include <aws/dynamodb/DynamoDBClient.h>
#include <aws/dynamodb/model/ListTablesRequest.h>
#include <iostream>

/*
 * A "Hello DynamoDB" starter application which initializes an Amazon DynamoDB
(DynamoDB) client and lists the
 * DynamoDB tables.
 *
 * main function
 *
 * Usage: 'hello_dynamodb'
 *
 */

int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
//    options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.

    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

        Aws::DynamoDB::DynamoDBClient dynamodbClient(clientConfig);
        Aws::DynamoDB::Model::ListTablesRequest listTablesRequest;
        listTablesRequest.SetLimit(50);
        do {
            const Aws::DynamoDB::Model::ListTablesOutcome &outcome =
dynamodbClient.ListTables(
                listTablesRequest);
            if (!outcome.IsSuccess()) {
                std::cout << "Error: " << outcome.GetError().GetMessage() <<
std::endl;
                result = 1;
            }
        } while (!outcome.IsSuccess());
    }
}
```

```
        break;
    }

    for (const auto &tableName: outcome.GetResult().GetTableNames()) {
        std::cout << tableName << std::endl;
    }

    listTablesRequest.SetExclusiveStartTableName(
        outcome.GetResult().GetLastEvaluatedTableName());
}

} while (!listTablesRequest.GetExclusiveStartTableName().empty());
}

Aws::ShutdownAPI(options); // Should only be called once.
return result;
}
```

- For API details, see [ListTables](#) in *AWS SDK for C++ API Reference*.

Actions for DynamoDB using AWS SDKs

The following code examples demonstrate how to perform individual DynamoDB actions with AWS SDKs. These excerpts call the DynamoDB API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the [Amazon DynamoDB API Reference](#).

Examples

- [Create a DynamoDB table using an AWS SDK](#)
- [Delete a DynamoDB table using an AWS SDK](#)
- [Delete an item from a DynamoDB table using an AWS SDK](#)
- [Get a batch of DynamoDB items using an AWS SDK](#)
- [Get an item from a DynamoDB table using an AWS SDK](#)
- [Get information about a DynamoDB table](#)
- [List DynamoDB tables using an AWS SDK](#)
- [Put an item in a DynamoDB table using an AWS SDK](#)
- [Query a DynamoDB table using an AWS SDK](#)
- [Run a PartiQL statement on a DynamoDB table using an AWS SDK](#)
- [Run batches of PartiQL statements on a DynamoDB table using an AWS SDK](#)
- [Scan a DynamoDB table using an AWS SDK](#)
- [Update an item in a DynamoDB table using an AWS SDK](#)
- [Write a batch of DynamoDB items using an AWS SDK](#)

Create a DynamoDB table using an AWS SDK

The following code examples show how to create a DynamoDB table.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Accelerate reads with DAX](#)
- [Get started with tables, items, and queries](#)

```
#####
# function dynamodb_create_table
#
# This function creates an Amazon DynamoDB table.
#
# Parameters:
#     -n table_name -- The name of the table to create.
#     -a attribute_definitions -- JSON file path of a list of attributes and
#                               their types.
#     -k key_schema -- JSON file path of a list of attributes and their key
#                     types.
#     -p provisioned_throughput -- Provisioned throughput settings for the
#                                table.
#
# Returns:
#     0 - If successful.
#     1 - If it fails.
```

CLI

AWS CLI

Example 1: To create a table with tags

The following `create-table` example uses the specified attributes and key schema to create a table named `MusicCollection`. This table uses provisioned throughput and is encrypted at rest using the default AWS owned CMK. The command also applies a tag to the table, with a key of `Owner` and a value of `blueTeam`.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --tags Key=Owner,Value=blueTeam
```

Output:

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "ReadCapacityUnits": 5,  
            "WriteCapacityUnits": 5  
        }  
    }  
}
```

```
        "WriteCapacityUnits": 5,
        "ReadCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "TableName": "MusicCollection",
    "TableStatus": "CREATING",
    "KeySchema": [
        {
            "KeyType": "HASH",
            "AttributeName": "Artist"
        },
        {
            "KeyType": "RANGE",
            "AttributeName": "SongTitle"
        }
    ],
    "ItemCount": 0,
    "CreationDateTime": "2020-05-26T16:04:41.627000-07:00",
    "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",
    "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
}
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To create a table in On-Demand Mode

The following example creates a table called MusicCollection using on-demand mode, rather than provisioned throughput mode. This is useful for tables with unpredictable workloads.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST
```

Output:

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "MusicCollection",  
        "KeySchema": [  
            {  
                "AttributeName": "Artist",  
                "KeyType": "HASH"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "KeyType": "RANGE"  
            }  
        ],  
        "TableStatus": "CREATING",  
        "CreationDateTime": "2020-05-27T11:44:10.807000-07:00",  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "ReadCapacityUnits": 0,  
            "WriteCapacityUnits": 0  
        },  
        "TableSizeBytes": 0,  
        "ItemCount": 0,  
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/  
MusicCollection",  
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  
        "BillingModeSummary": {  
            "BillingMode": "PAY_PER_REQUEST"  
        }  
    }  
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To create a table and encrypt it with a Customer Managed CMK

The following example creates a table named MusicCollection and encrypts it using a customer managed CMK.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-\
abcd-1234-a123-ab1234a1b234
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2020-05-27T11:12:16.431000-07:00",
        "ProvisionedThroughput": {
```

```
        "NumberOfDecreasesToday": 0,
        "ReadCapacityUnits": 5,
        "WriteCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "ItemCount": 0,
    "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
MusicCollection",
    "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "SSEDescription": {
        "Status": "ENABLED",
        "SSEType": "KMS",
        "KMSMasterKeyArn": "arn:aws:kms:us-west-2:123456789012:key/abcd1234-
abcd-1234-a123-ab1234a1b234"
    }
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 4: To create a table with a Local Secondary Index

The following example uses the specified attributes and key schema to create a table named MusicCollection with a Local Secondary Index named AlbumTitleIndex.

```
aws dynamodb create-table \
--table-name MusicCollection \
--attribute-definitions AttributeName=Artist,AttributeType=S
AttributeName=SongTitle,AttributeType=S AttributeName=AlbumTitle,AttributeType=S \
\
--key-schema AttributeName=Artist,KeyType=HASH
AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--local-secondary-indexes \
"[
{
    \"IndexName\": \"AlbumTitleIndex\",
    \"KeySchema\": [
        {\"AttributeName\": \"Artist\", \"KeyType\": \"HASH\"},
        {\"AttributeName\": \"AlbumTitle\", \"KeyType\": \"RANGE\"}
    ],
    \"Projection\": {
```

```
\\"ProjectionType\\": \\"INCLUDE\",
\\"NonKeyAttributes\\": [\\"Genre\\", \\"Year\\"]
}
]
]"
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "AlbumTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
                "KeyType": "RANGE"
            }
        ],

            }
        ]
    }
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 5: To create a table with a Global Secondary Index

The following example creates a table named GameScores with a Global Secondary Index called GameTitleIndex. The base table has a partition key of UserId and a sort key of GameTitle, allowing you to find an individual user's best score for a specific game efficiently, whereas the GSI has a partition key of GameTitle and a sort key of TopScore, allowing you to quickly find the overall highest score for a particular game.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S
    AttributeName=GameTitle,AttributeType=S AttributeName=TopScore,AttributeType=N \
    --key-schema AttributeName=UserId,KeyType=HASH \
        AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --global-secondary-indexes \
    "[
        {
            \"IndexName\": \"GameTitleIndex\",
            \"KeySchema\": [
                {\"AttributeName\": \"GameTitle\", \"KeyType\": \"HASH\"},
                {\"AttributeName\": \"TopScore\", \"KeyType\": \"RANGE\"}
            ],
            \"Projection\": {
                \"ProjectionType\": \"INCLUDE\",
                \"NonKeyAttributes\": [\"UserId\"]
            },
            \"ProvisionedThroughput\": {
                \"ReadCapacityUnits\": 10,
                \"WriteCapacityUnits\": 5
            }
        }
    ]"
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",

Example 6: To create a table with multiple Global Secondary Indexes at once

The following example creates a table named GameScores with two Global Secondary Indexes. The GSI schemas are passed via a file, rather than on the command line.

```
aws dynamodb create-table \
--table-name GameScores \
--attribute-definitions AttributeName=UserId,AttributeType=S
AttributeName=GameTitle,AttributeType=S AttributeName=TopScore,AttributeType=N
AttributeName=Date,AttributeType=S \
--key-schema AttributeName=UserId,KeyType=HASH
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--global-secondary-indexes file://gsi.json
```

Contents of gsi.json:

```
[
{
    "IndexName": "GameTitleIndex",
    "KeySchema": [
        {
            "AttributeName": "GameTitle",
            "KeyType": "HASH"
        },
        {
            "AttributeName": "UserId",
            "KeyType": "RANGE"
        }
    ],
    "ProvisionedThroughput": {
        "ReadCapacityUnits": 10,
        "WriteCapacityUnits": 5
    }
}
```

```
        "AttributeName": "TopScore",
        "KeyType": "RANGE"
    },
],
"Projection": {
    "ProjectionType": "ALL"
},
"ProvisionedThroughput": {
    "ReadCapacityUnits": 10,
    "WriteCapacityUnits": 5
}
},
{
    "IndexName": "GameDateIndex",
    "KeySchema": [
        {
            "AttributeName": "GameTitle",
            "KeyType": "HASH"
        },
        {
            "AttributeName": "Date",
            "KeyType": "RANGE"
        }
    ],
    "Projection": {
        "ProjectionType": "ALL"
    },
    "ProvisionedThroughput": {
        "ReadCapacityUnits": 5,
        "WriteCapacityUnits": 5
    }
}
]
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Date",

```
        ]  
    }  
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 7: To create a table with Streams enabled

The following example creates a table called GameScores with DynamoDB Streams enabled. Both new and old images of each item will be written to the stream.

```
aws dynamodb create-table \  
  --table-name GameScores \  
  --attribute-definitions AttributeName=UserId,AttributeType=S  
  AttributeName=GameTitle,AttributeType=S \  
  --key-schema AttributeName=UserId,KeyType=HASH  
  AttributeName=GameTitle,KeyType=RANGE \  
  --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \  
  --stream-specification StreamEnabled=TRUE,StreamViewType=NEW_AND_OLD_IMAGES
```

Output:

```
{  
  "TableDescription": {  
    "AttributeDefinitions": [  
      {  
        "AttributeName": "GameTitle",  
        "AttributeType": "S"  
      },  
      {  
        "AttributeName": "UserId",  
        "AttributeType": "S"  
      }  
    ],  
    "TableName": "GameScores",  
    "KeySchema": [  
      {  
        "AttributeName": "UserId",  
        "KeyType": "HASH"  
      },  
      {  
        "AttributeName": "GameTitle",  
        "KeyType": "RANGE"  
      }  
    ]  
  }  
}
```

```
        "AttributeName": "GameTitle",
        "KeyType": "RANGE"
    },
],
"TableStatus": "CREATING",
"CreationDateTime": "2020-05-27T10:49:34.056000-07:00",
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "ReadCapacityUnits": 10,
    "WriteCapacityUnits": 5
},
"TableSizeBytes": 0,
"ItemCount": 0,
"TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
"TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
"StreamSpecification": {
    "StreamEnabled": true,
    "StreamViewType": "NEW_AND_OLD_IMAGES"
},
"LatestStreamLabel": "2020-05-27T17:49:34.056",
"LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/2020-05-27T17:49:34.056"
}
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 8: To create a table with Keys-Only Stream enabled

The following example creates a table called GameScores with DynamoDB Streams enabled. Only the key attributes of modified items are written to the stream.

```
aws dynamodb create-table \
--table-name GameScores \
--attribute-definitions AttributeName=UserId,AttributeType=S \
AttributeName=GameTitle,AttributeType=S \
--key-schema AttributeName=UserId,KeyType=HASH \
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--stream-specification StreamEnabled=TRUE,StreamViewType=KEYS_ONLY
```

Output:

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "GameTitle",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "UserId",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "GameScores",  
        "KeySchema": [  
            {  
                "AttributeName": "UserId",  
                "KeyType": "HASH"  
            },  
            {  
                "AttributeName": "GameTitle",  
                "KeyType": "RANGE"  
            }  
        ],  
        "TableStatus": "CREATING",  
        "CreationDateTime": "2023-05-25T18:45:34.140000+00:00",  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "ReadCapacityUnits": 10,  
            "WriteCapacityUnits": 5  
        },  
        "TableSizeBytes": 0,  
        "ItemCount": 0,  
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",  
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  
        "StreamSpecification": {  
            "StreamEnabled": true,  
            "StreamViewType": "KEYS_ONLY"  
        },  
        "LatestStreamLabel": "2023-05-25T18:45:34.140",  
        "LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/  
GameScores/stream/2023-05-25T18:45:34.140",  
        "DeletionProtectionEnabled": false  
    }  
}
```

{

For more information, see [Change data capture for DynamoDB Streams](#) in the *Amazon DynamoDB Developer Guide*.

Example 9: To create a table with the Standard Infrequent Access class

The following example creates a table called GameScores and assigns the Standard-Infrequent Access (DynamoDB Standard-IA) table class. This table class is optimized for storage being the dominant cost.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S
    AttributeName=GameTitle,AttributeType=S \
    --key-schema AttributeName=UserId,KeyType=HASH
    AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --table-class STANDARD_INFREQUENT_ACCESS
```

Output:

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "GameTitle",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "UserId",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "GameScores",  
        "KeySchema": [  
            {  
                "AttributeName": "UserId",  
                "KeyType": "HASH"  
            },  
            {  
                "AttributeName": "GameTitle",  
                "KeyType": "RANGE"  
            }  
        ]  
    }  
}
```

```
        "KeyType": "RANGE"
    },
],
"TableStatus": "CREATING",
"CreationDateTime": "2023-05-25T18:33:07.581000+00:00",
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "ReadCapacityUnits": 10,
    "WriteCapacityUnits": 5
},
"TableSizeBytes": 0,
"ItemCount": 0,
"TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
"TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
"TableClassSummary": {
    "TableClass": "STANDARD_INFREQUENT_ACCESS"
},
"DeletionProtectionEnabled": false
}
}
```

For more information, see [Table classes](#) in the *Amazon DynamoDB Developer Guide*.

Example 10: To Create a table with Delete Protection enabled

The following example creates a table called GameScores and enables deletion protection.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S
    AttributeName=GameTitle,AttributeType=S \
    --key-schema AttributeName=UserId,KeyType=HASH
    AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --deletion-protection-enabled
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
```

```
        "AttributeName": "GameTitle",
        "AttributeType": "S"
    },
    {
        "AttributeName": "UserId",
        "AttributeType": "S"
    }
],
"TableName": "GameScores",
"KeySchema": [
    {
        "AttributeName": "UserId",
        "KeyType": "HASH"
    },
    {
        "AttributeName": "GameTitle",
        "KeyType": "RANGE"
    }
],
"TableStatus": "CREATING",
"CreationDateTime": "2023-05-25T23:02:17.093000+00:00",
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "ReadCapacityUnits": 10,
    "WriteCapacityUnits": 5
},
"TableSizeBytes": 0,
"ItemCount": 0,
"TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
"TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
"DeletionProtectionEnabled": true
}
}
```

For more information, see [Using deletion protection](#) in the *Amazon DynamoDB Developer Guide*.

```
#!/ Delete an Amazon DynamoDB table.
<太后
    \sa deleteTable()
    \param tableName: The DynamoDB table name.
    \param clientConfiguration: AWS client configuration.
    \return bool: Function succeeded.
*/
bool AwsDoc::DynamoDB::deleteTable(const Aws::String &tableName,
                                    const Aws::Client::ClientConfiguration
&clientConfiguration) {
    Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

    Aws::DynamoDB::Model::DeleteTableRequest request;
    request.SetTableName(tableName);

    const Aws::DynamoDB::Model::DeleteTableOutcome &result =
dynamoClient.DeleteTable(
```

```
        request);
if (result.IsSuccess()) {
    std::cout << "Your table \""
        << result.GetResult().GetTableDescription().GetTableName()
        << " was deleted.\n";
}
else {
    std::cerr << "Failed to delete table: " << result.GetError().GetMessage()
        << std::endl;
}

return result.IsSuccess();
}
```

- For API details, see [DeleteTable](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

To delete a table

The following `delete-table` example deletes the `MusicCollection` table.

```
aws dynamodb delete-table \
--table-name MusicCollection
```

Output:

```
{
    "TableDescription": {
        "TableStatus": "DELETING",
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableName": "MusicCollection",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "WriteCapacityUnits": 5,
            "ReadCapacityUnits": 5
        }
    }
}
```

{}

CLI

AWS CLI

Example 1: To delete an item

The following `delete-item` example deletes an item from the `MusicCollection` table and requests details about the item that was deleted and the capacity used by the request.

```
aws dynamodb delete-item \
    --table-name MusicCollection \
    --key file://key.json \
    --return-values ALL_OLD \
    --return-consumed-capacity TOTAL \
    --return-item-collection-metrics SIZE
```

Contents of `key.json`:

```
{  
    "Artist": {"S": "No One You Know"},  
    "SongTitle": {"S": "Scared of My Shadow"}  
}
```

Output:

```
{  
    "Attributes": {  
        "AlbumTitle": {  
            "S": "Blue Sky Blues"  
        },  
        "Artist": {  
            "S": "No One You Know"  
        },  
        "SongTitle": {  
            "S": "Scared of My Shadow"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 2.0  
    },  
    "ItemCollectionMetrics": {  
        "ItemCollectionKey": {  
            "Artist": {  
                "S": "No One You Know"  
            }  
        },  
        "SizeEstimateRangeGB": [  
    }
```

```
    0.0,  
    1.0  
]  
}  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To delete an item conditionally

The following example deletes an item from the ProductCatalog table only if its ProductCategory is either Sporting Goods or Gardening Supplies and its price is between 500 and 600. It returns details about the item that was deleted.

```
aws dynamodb delete-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"456"}}' \  
  --condition-expression "(ProductCategory IN (:cat1, :cat2)) and (#P  
between :lo and :hi)" \  
  --expression-attribute-names file://names.json \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_OLD
```

Contents of names.json:

```
{  
  "#P": "Price"  
}
```

Contents of values.json:

```
{  
  ":cat1": {"S": "Sporting Goods"},  
  ":cat2": {"S": "Gardening Supplies"},  
  ":lo": {"N": "500"},  
  ":hi": {"N": "600"}  
}
```

Output:

```
{  
  "Attributes": {
```

```
    "Id": {
        "N": "456"
    },
    "Price": {
        "N": "550"
    },
    "ProductCategory": {
        "S": "Sporting Goods"
    }
}
}
```

JavaScript

SDK for JavaScript (v3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

This example uses the document client to simplify working with items in DynamoDB. For API details see [DeleteCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, DeleteCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new DeleteCommand({
    TableName: "Sodas",
    Key: {
      Flavor: "Cola",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For more information, see [AWS SDK for JavaScript Developer Guide](#).
- For API details, see [DeleteItem in AWS SDK for JavaScript API Reference](#).

SDK for JavaScript (v2)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Delete an item from a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Key: {
    KEY_NAME: { N: "VALUE" },
  },
};

// Call DynamoDB to delete the item from the table
ddb.deleteItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Delete an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });
```

```
// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  Key: {
    HASH_KEY: VALUE,
  },
  TableName: "TABLE",
};

docClient.delete(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

- For more information, see [AWS SDK for JavaScript Developer Guide](#).
- For API details, see [DeleteItem](#) in *AWS SDK for JavaScript API Reference*.

CLI

AWS CLI

To retrieve multiple items from a table

The following batch-get-items example reads multiple items from the MusicCollection table using a batch of three GetItem requests, and requests the

number of read capacity units consumed by the operation. The command returns only the `AlbumTitle` attribute.

```
aws dynamodb batch-get-item \  
  --request-items file://request-items.json \  
  --return-consumed-capacity TOTAL
```

Contents of `request-items.json`:

```
{  
    "MusicCollection": {  
        "Keys": [  
            {  
                "Artist": {"S": "No One You Know"},  
                "SongTitle": {"S": "Call Me Today"}  
            },  
            {  
                "Artist": {"S": "Acme Band"},  
                "SongTitle": {"S": "Happy Day"}  
            },  
            {  
                "Artist": {"S": "No One You Know"},  
                "SongTitle": {"S": "Scared of My Shadow"}  
            }  
        ],  
        "ProjectionExpression": "AlbumTitle"  
    }  
}
```

Output:

```
{  
    "Responses": {  
        "MusicCollection": [  
            {  
                "AlbumTitle": {  
                    "S": "Somewhat Famous"  
                }  
            },  
            {  
                "AlbumTitle": {  
                    "S": "Blue Sky Blues"  
                }  
            }  
        ]  
    }  
}
```

```
        }
    },
    {
        "AlbumTitle": {
            "S": "Louder Than Ever"
        }
    }
],
{
    "UnprocessedKeys": {},
    "ConsumedCapacity": [
        {
            "TableName": "MusicCollection",
            "CapacityUnits": 1.5
        }
    ]
}
```

Get an item from a DynamoDB table using an AWS SDK

The following code examples show how to get an item from a DynamoDB table.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Accelerate reads with DAX](#)
- [Get started with tables, items, and queries](#)

.NET

AWS SDK for .NET

Note

#####
# function dynamodb_get_item
#
# This function gets an item from a DynamoDB table.
#
# Parameters:
#     -n table_name -- The name of the table.
#     -k keys   -- Path to json file containing the keys that identify the item
#                  to get.
#     [-q query] -- Optional JMESPath query expression.
#
# Returns:
#     The item as text output.
# And:
#     0 - If successful.
#     1 - If it fails.
#####
function dynamodb_get_item() {
    local table_name keys query response
    local option OPTARG # Required to use getopt command in a function.

    # #####
    # Function usage explanation
    #####
    function usage() {
        echo "function dynamodb_get_item"
        echo "Get an item from a DynamoDB table."

                << std::endl;
        }
        else {
            std::cout << "No item found with the key " << partitionKey <<
std::endl;
        }
    }
    else {
        std::cerr << "Failed to get item: " << outcome.GetError().GetMessage();
```

```
    }

    return outcome.IsSuccess();
}
```

- For API details, see [GetItem](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To read an item in a table

The following get-item example retrieves an item from the MusicCollection table. The table has a hash-and-range primary key (Artist and SongTitle), so you must specify both of these attributes. The command also requests information about the read capacity consumed by the operation.

```
aws dynamodb get-item \
  --table-name MusicCollection \
  --key file://key.json \
  --return-consumed-capacity TOTAL
```

Contents of key.json:

```
{
  "Artist": {"S": "Acme Band"},
  "SongTitle": {"S": "Happy Day"}
}
```

Output:

```
{
  "Item": {
    "AlbumTitle": {
      "S": "Songs About Life"
    },
    "SongTitle": {
      "S": "Happy Day"
    },
  }
}
```

```
        "Artist": {  
            "S": "Acme Band"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 0.5  
    }  
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To read an item using a consistent read

The following example retrieves an item from the MusicCollection table using strongly consistent reads.

```
aws dynamodb get-item \  
  --table-name MusicCollection \  
  --key file://key.json \  
  --consistent-read \  
  --return-consumed-capacity TOTAL
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Output:

```
{  
    "Item": {  
        "AlbumTitle": {  
            "S": "Songs About Life"  
        },  
        "SongTitle": {  
            "S": "Happy Day"  
        },  
        "Artist": {  
            "S": "Acme Band"  
        }  
    }  
}
```

```
        },
    },
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    }
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To retrieve specific attributes of an item

The following example uses a projection expression to retrieve only three attributes of the desired item.

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id": {"N": "102"}}' \
--projection-expression "#T, #C, #P" \
--expression-attribute-names file://names.json
```

Contents of names.json:

```
{
    "#T": "Title",
    "#C": "ProductCategory",
    "#P": "Price"
}
```

Output:

```
{
    "Item": {
        "Price": {
            "N": "20"
        },
        "Title": {
            "S": "Book 102 Title"
        },
        "ProductCategory": {
            "S": "Book"
        }
    }
}
```

```
    }  
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

- For API details, see [GetItem](#) in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

This example uses the document client to simplify working with items in DynamoDB. For API details see [GetCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, GetCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
    const command = new GetCommand({
        TableName: "AngryAnimals",
        Key: {
            id: "1"
        }
    });
    const data = await docClient.send(command);
    console.log(data.Item);
}
```

```
Key: {  
    CommonName: "Shoebill",  
},  
});  
  
const response = await docClient.send(command);  
console.log(response);  
return response;  
};
```

- For API details, see [GetItem](#) in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Get an item from a table.

```
// Load the AWS SDK for Node.js  
var AWS = require("aws-sdk");  
// Set the region  
AWS.config.update({ region: "REGION" });  
  
// Create the DynamoDB service object  
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });  
  
var params = {  
    TableName: "TABLE",  
    Key: {  
        KEY_NAME: { N: "001" },  
    },  
    ProjectionExpression: "ATTRIBUTE_NAME",  
};  
  
// Call DynamoDB to read the item from the table  
ddb.getItem(params, function (err, data) {  
    if (err) {  
        console.log("Error", err);  
    } else {  
        console.log(data.Item);  
    }  
});
```

```
    } else {
      console.log("Success", data.Item);
    }
});
```

Get an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  TableName: "EPISODES_TABLE",
  Key: { KEY_NAME: VALUE },
};

docClient.get(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data.Item);
  }
});
```

CLI

AWS CLI

To describe a table

The following `describe-table` example describes the `MusicCollection` table.

```
aws dynamodb describe-table \
--table-name MusicCollection
```

Output:

```
{
  "Table": {
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 5,
      "ReadCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "TableName": "MusicCollection",
    "TableStatus": "ACTIVE",
    "KeySchema": [
      {
        "KeyType": "HASH",
        "AttributeName": "Artist"
      },
      {
        "KeyType": "RANGE",
        "AttributeName": "SongTitle"
      }
    ]
  }
}
```

```
        },
    ],
    "ItemCount": 0,
    "CreationDateTime": 1421866952.062
}
}
```

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

List DynamoDB tables using an AWS SDK

The following code examples show how to list DynamoDB tables.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
private static async Task ListMyTables()  
{  
    Console.WriteLine("\n*** Listing tables ***");  
  
    string lastTableNameEvaluated = null;  
    do  
    {  
        var response = await Client.ListTablesAsync(new ListTablesRequest  
        {  
            Limit = 2,  
            ExclusiveStartTableName = lastTableNameEvaluated  
        });  
    }  
}
```

```
        foreach (var name in response.TableNames)
        {
            Console.WriteLine(name);
        }

        lastTableNameEvaluated = response.LastEvaluatedTableName;
    } while (lastTableNameEvaluated != null);
}
```

- For API details, see [ListTables](#) in *AWS SDK for .NET API Reference*.

Bash

AWS CLI with Bash script

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
#####
# function dynamodb_list_tables
#
# This function lists all the tables in a DynamoDB.
#
# Returns:
#     0 - If successful.
#     1 - If it fails.
#####
function dynamodb_list_tables() {
    response=$(aws dynamodb list-tables \
        --output text \
        --query "TableNames")

    local error_code=${?}

    if [[ $error_code -ne 0 ]]; then
        aws_cli_error_log $error_code
        errecho "ERROR: AWS reports batch-write-item operation failed.$response"
        return 1
    fi
}
```

```
fi

echo "$response" | tr -s "[[:space:]]" "\n"

return 0
}
```

The utility functions used in this example.

```
#####
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
#####
function errecho() {
    printf "%s\n" "$*" 1>&2
}

#####
# function aws_cli_error_log()
#
# This function is used to log the error messages from the AWS CLI.
#
# See https://docs.aws.amazon.com/cli/latest/topic/return-codes.html#cli-aws-help-return-codes.
#
# The function expects the following argument:
#     $1 - The error code returned by the AWS CLI.
#
# Returns:
#     0: - Success.
#
#####
function aws_cli_error_log() {
    local err_code=$1
    errecho "Error code : $err_code"
    if [ "$err_code" == 1 ]; then
        errecho " One or more S3 transfers failed."
    elif [ "$err_code" == 2 ]; then
        errecho " Command line failed to parse."
    elif [ "$err_code" == 130 ]; then
        errecho " Process received SIGINT."
```

```
        elif [ "$err_code" == 252 ]; then
            errecho " Command syntax invalid."
        elif [ "$err_code" == 253 ]; then
            errecho " The system environment or configuration was invalid."
        elif [ "$err_code" == 254 ]; then
            errecho " The service returned an error."
        elif [ "$err_code" == 255 ]; then
            errecho " 255 is a catch-all error."
    fi

    return 0
}
```

```
#!/ List the Amazon DynamoDB tables for the current AWS account.
/*
\sa listTables()
\param clientConfiguration: AWS client configuration.
\return bool: Function succeeded.
*/

bool AwsDoc::DynamoDB::listTables(
    const Aws::Client::ClientConfiguration &clientConfiguration) {
    Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

    Aws::DynamoDB::Model::ListTablesRequest listTablesRequest;
    listTablesRequest.SetLimit(50);
    do {
        const Aws::DynamoDB::Model::ListTablesOutcome &outcome =
            dynamoClient.ListTables(
```

```
        listTablesRequest);
    if (!outcome.IsSuccess()) {
        std::cout << "Error: " << outcome.GetError().GetMessage() <<
std::endl;
        return false;
    }

    for (const auto &tableName: outcome.GetResult().GetTableNames())
        std::cout << tableName << std::endl;
    listTablesRequest.SetExclusiveStartTableName(
        outcome.GetResult().GetLastEvaluatedTableName());

} while (!listTablesRequest.GetExclusiveStartTableName().empty());

return true;
}
```

- For API details, see [ListTables](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To list tables

The following `list-tables` example lists all of the tables associated with the current AWS account and Region.

```
aws dynamodb list-tables
```

Output:

```
{
    "TableNames": [
        "Forum",
        "ProductCatalog",
        "Reply",
        "Thread"
    ]
}
```

For more information, see [Listing Table Names](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To limit page size

The following example returns a list of all existing tables, but retrieves only one item in each call, performing multiple calls if necessary to get the entire list. Limiting the page size is useful when running list commands on a large number of resources, which can result in a "timed out" error when using the default page size of 1000.

```
aws dynamodb list-tables \
--page-size 1
```

Output:

```
{
  "TableNames": [
    "Forum",
    "ProductCatalog",
    "Reply",
    "Thread"
  ]
}
```

For more information, see [Listing Table Names](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To limit the number of items returned

The following example limits the number of items returned to 2. The response includes a NextToken value with which to retrieve the next page of results.

```
aws dynamodb list-tables \
--max-items 2
```

Output:

```
{
  "TableNames": [
    "Forum",
    "ProductCatalog"
  ],
  "NextToken":
    "abCDeFGhiJKlmnOPqrSTuvwxyzYZ1aBCdEFghijK7LM51n0pqRSTuv3WxY3ZabC5dEFGhI2Jk3LmnoPQ6RST9"
```

{

For more information, see [Listing Table Names](#) in the *Amazon DynamoDB Developer Guide*.

Example 4: To retrieve the next page of results

The following command uses the NextToken value from a previous call to the list-tables command to retrieve another page of results. Since the response in this case does not include a NextToken value, we know that we have reached the end of the results.

```
aws dynamodb list-tables \
    --starting-token
    aBCDeFGhiJKLMNOPqrstuvwxyz1aBCdEFghijK7LM51n0pqRSTuv3WxY3ZabC5dEFGhI2Jk3LmnoPQ6RST9
```

Output:

```
{
  "TableNames": [
    "Reply",
    "Thread"
  ]
}
```

For more information, see [Listing Table Names](#) in the *Amazon DynamoDB Developer Guide*.

- For API details, see [ListTables](#) in *AWS CLI Command Reference*.

The utility functions used in this example.

```
#####
# function iecho
#
# This function enables the script to display the specified text only if
# the global variable $VERBOSE is set to true.
#####
function iecho() {
    if [[ $VERBOSE == true ]]; then
        echo "$@"
    fi
}
```

```
#####
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
#####
function errecho() {
    printf "%s\n" "$*" 1>&2
}

#####
# function aws_cli_error_log()
#
# This function is used to log the error messages from the AWS CLI.
#
# See https://docs.aws.amazon.com/cli/latest/topic/return-codes.html#cli-aws-help-return-codes.
#
# The function expects the following argument:
#       $1 - The error code returned by the AWS CLI.
#
# Returns:
#       0: - Success.
#
#####
function aws_cli_error_log() {
    local err_code=$1

}

return outcome.IsSuccess();
}
```

- For API details, see [PutItem](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To add an item to a table

The following `put-item` example adds a new item to the *MusicCollection* table.

```
aws dynamodb put-item \
--table-name MusicCollection \
```

```
--item file://item.json \
--return-consumed-capacity TOTAL \
--return-item-collection-metrics SIZE
```

Contents of item.json:

```
{
    "Artist": {"S": "No One You Know"},
    "SongTitle": {"S": "Call Me Today"},
    "AlbumTitle": {"S": "Greatest Hits"}
}
```

Output:

```
{
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    },
    "ItemCollectionMetrics": {
        "ItemCollectionKey": {
            "Artist": {
                "S": "No One You Know"
            }
        },
        "SizeEstimateRangeGB": [
            0.0,
            1.0
        ]
    }
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To conditionally overwrite an item in a table

The following put-item example overwrites an existing item in the MusicCollection table only if that existing item has an AlbumTitle attribute with a value of Greatest Hits. The command returns the previous value of the item.

```
aws dynamodb put-item \
```

```
--table-name MusicCollection \
--item file://item.json \
--condition-expression "#A = :A" \
--expression-attribute-names file://names.json \
--expression-attribute-values file://values.json \
--return-values ALL_OLD
```

Contents of item.json:

```
{
    "Artist": {"S": "No One You Know"},
    "SongTitle": {"S": "Call Me Today"},
    "AlbumTitle": {"S": "Somewhat Famous"}
}
```

Contents of names.json:

```
{
    "#A": "AlbumTitle"
}
```

Contents of values.json:

```
{
    ":A": {"S": "Greatest Hits"}
}
```

Output:

```
{
    "Attributes": {
        "AlbumTitle": {
            "S": "Greatest Hits"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Call Me Today"
        }
    }
}
```

{}

If the key already exists, you should see the following output:

A client error (ConditionalCheckFailedException) occurred when calling the PutItem operation: The conditional request failed.

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

This example uses the document client to simplify working with items in DynamoDB. For API details see [PutCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { PutCommand, DynamoDBDocumentClient } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new PutCommand({
    TableName: "HappyAnimals",
    Item: {
      CommonName: "Shiba Inu",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For API details, see [PutItem](#) in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Put an item in a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "CUSTOMER_LIST",
  Item: {
    CUSTOMER_ID: { N: "001" },
    CUSTOMER_NAME: { S: "Richard Roe" },
  },
};

// Call DynamoDB to add the item to the table
ddb.putItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Put an item in a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });
```

```
// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Item: {
    HASHKEY: VALUE,
    ATTRIBUTE_1: "STRING_VALUE",
    ATTRIBUTE_2: VALUE_2,
  },
};

docClient.put(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Query a DynamoDB table using an AWS SDK

The following code examples show how to query a DynamoDB table.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- [Accelerate reads with DAX](#)
- [Get started with tables, items, and queries](#)

    } while (!exclusiveStartKey.empty());

    return result;
}
```

- For API details, see [Query](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To query a table

The following query example queries items in the MusicCollection table. The table has a hash-and-range primary key (Artist and SongTitle), but this query only specifies the hash key value. It returns song titles by the artist named "No One You Know".

```
aws dynamodb query \
--table-name MusicCollection \
--projection-expression "SongTitle" \
--key-condition-expression "Artist = :v1" \
--expression-attribute-values file://expression-attributes.json \
--return-consumed-capacity TOTAL
```

Contents of expression-attributes.json:

```
{
  ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
  "Items": [
    {
      "SongTitle": {
        "S": "Call Me Today"
      },
      "SongTitle": {
        "S": "Scared of My Shadow"
      }
    }
  ]
}
```

```
        }
    ],
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5
    }
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To query a table using strongly consistent reads and traverse the index in descending order

The following example performs the same query as the first example, but returns results in reverse order and uses strongly consistent reads.

```
aws dynamodb query \
--table-name MusicCollection \
--projection-expression "SongTitle" \
--key-condition-expression "Artist = :v1" \
--expression-attribute-values file://expression-attributes.json \
--consistent-read \
--no-scan-index-forward \
--return-consumed-capacity TOTAL
```

Contents of expression-attributes.json:

```
{
    ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
    "Items": [
        {
            "SongTitle": {
                "S": "Scared of My Shadow"
            }
        }
    ]
}
```

```
        }
    },
    {
        "SongTitle": {
            "S": "Call Me Today"
        }
    }
],
"Count": 2,
"ScannedCount": 2,
"ConsumedCapacity": {
    "TableName": "MusicCollection",
    "CapacityUnits": 1.0
}
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To filter out specific results

The following example queries the MusicCollection but excludes results with specific values in the AlbumTitle attribute. Note that this does not affect the ScannedCount or ConsumedCapacity, because the filter is applied after the items have been read.

```
aws dynamodb query \
--table-name MusicCollection \
--key-condition-expression "#n1 = :v1" \
--filter-expression "NOT (#n2 IN (:v2, :v3))" \
--expression-attribute-names file://names.json \
--expression-attribute-values file://values.json \
--return-consumed-capacity TOTAL
```

Contents of values.json:

```
{
    ":v1": {"S": "No One You Know"},
    ":v2": {"S": "Blue Sky Blues"},
    ":v3": {"S": "Greatest Hits"}
}
```

Contents of names.json:

```
{  
    "#n1": "Artist",  
    "#n2": "AlbumTitle"  
}
```

Output:

```
{  
    "Items": [  
        {  
            "AlbumTitle": {  
                "S": "Somewhat Famous"  
            },  
            "Artist": {  
                "S": "No One You Know"  
            },  
            "SongTitle": {  
                "S": "Call Me Today"  
            }  
        }  
    ],  
    "Count": 1,  
    "ScannedCount": 2,  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 0.5  
    }  
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 4: To retrieve only an item count

The following example retrieves a count of items matching the query, but does not retrieve any of the items themselves.

```
aws dynamodb query \  
    --table-name MusicCollection \  
    --select COUNT \  
    --key-condition-expression "Artist = :v1" \  
    --expression-attribute-values file://expression-attributes.json
```

Contents of expression-attributes.json:

```
{  
    ":v1": {"S": "No One You Know"}  
}
```

Output:

```
{  
    "Count": 2,  
    "ScannedCount": 2,  
    "ConsumedCapacity": null  
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 5: To query an index

The following example queries the local secondary index `AlbumTitleIndex`. The query returns all attributes from the base table that have been projected into the local secondary index. Note that when querying a local secondary index or global secondary index, you must also provide the name of the base table using the `table-name` parameter.

```
aws dynamodb query \  
    --table-name MusicCollection \  
    --index-name AlbumTitleIndex \  
    --key-condition-expression "Artist = :v1" \  
    --expression-attribute-values file://expression-attributes.json \  
    --select ALL_PROJECTED_ATTRIBUTES \  
    --return-consumed-capacity INDEXES
```

Contents of expression-attributes.json:

```
{  
    ":v1": {"S": "No One You Know"}  
}
```

Output:

```
{
```

```
"Items": [
    {
        "AlbumTitle": {
            "S": "Blue Sky Blues"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Scared of My Shadow"
        }
    },
    {
        "AlbumTitle": {
            "S": "Somewhat Famous"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Call Me Today"
        }
    }
],
"Count": 2,
"ScannedCount": 2,
"ConsumedCapacity": {
    "TableName": "MusicCollection",
    "CapacityUnits": 0.5,
    "Table": {
        "CapacityUnits": 0.0
    },
    "LocalSecondaryIndexes": {
        "AlbumTitleIndex": {
            "CapacityUnits": 0.5
        }
    }
}
}

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Run a PartiQL statement on a DynamoDB table using an AWS SDK

The following code examples show how to run a PartiQL statement on a DynamoDB table.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Query a table using PartiQL](#)

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use an INSERT statement to add an item.

```
/// <summary>
/// Inserts a single movie into the movies table.
/// </summary>
/// <param name="tableName">The name of the table.</param>
/// <param name="movieTitle">The title of the movie to insert.</param>
/// <param name="year">The year that the movie was released.</param>
/// <returns>A Boolean value that indicates the success or failure of
/// the INSERT operation.</returns>
public static async Task<bool> InsertSingleMovie(string tableName, string
movieTitle, int year)
{
    string insertBatch = $"INSERT INTO {tableName} VALUE {{'title': ?, 'year': ?}}";

    var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
{
    Statement = insertBatch,
    Parameters = new List<AttributeValue>
    {
        new AttributeValue { S = movieTitle },
        new AttributeValue { N = year.ToString() },
    },
});
}

return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

Use a SELECT statement to get an item.

```
/// <summary>
/// Uses a PartiQL SELECT statement to retrieve a single movie from the
/// movie database.
/// </summary>
/// <param name="tableName">The name of the movie table.</param>
/// <param name="movieTitle">The title of the movie to retrieve.</param>
/// <returns>A list of movie data. If no movie matches the supplied
/// title, the list is empty.</returns>
```

```
public static async Task<List<Dictionary<string, AttributeValue>>>
GetSingleMovie(string tableName, string movieTitle)
{
    string selectSingle = $"SELECT * FROM {tableName} WHERE title = ?";
    var parameters = new List<AttributeValue>
    {
        new AttributeValue { S = movieTitle },
    };

    var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
    {
        Statement = selectSingle,
        Parameters = parameters,
    });

    return response.Items;
}
```

Use a SELECT statement to get a list of items.

```
/// <summary>
/// Retrieve multiple movies by year using a SELECT statement.
/// </summary>
/// <param name="tableName">The name of the movie table.</param>
/// <param name="year">The year the movies were released.</param>
/// <returns></returns>
public static async Task<List<Dictionary<string, AttributeValue>>>
GetMovies(string tableName, int year)
{
    string selectSingle = $"SELECT * FROM {tableName} WHERE year = ?";
    var parameters = new List<AttributeValue>
    {
        new AttributeValue { N = year.ToString() },
    };

    var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
    {
        Statement = selectSingle,
```

```
        Parameters = parameters,
    });

    return response.Items;
}
```

Use an UPDATE statement to update an item.

```
/// <summary>
/// Updates a single movie in the table, adding information for the
/// producer.
/// </summary>
/// <param name="tableName">the name of the table.</param>
/// <param name="producer">The name of the producer.</param>
/// <param name="movieTitle">The movie title.</param>
/// <param name="year">The year the movie was released.</param>
/// <returns>A Boolean value that indicates the success of the
/// UPDATE operation.</returns>
public static async Task<bool> UpdateSingleMovie(string tableName, string
producer, string movieTitle, int year)
{
    string insertSingle = $"UPDATE {tableName} SET Producer=? WHERE title
= ? AND year = ?";

    var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
{
    Statement = insertSingle,
    Parameters = new List<AttributeValue>
    {
        new AttributeValue { S = producer },
        new AttributeValue { S = movieTitle },
        new AttributeValue { N = year.ToString() },
    },
});

    return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

Use a DELETE statement to delete a single movie.

```
/// <summary>
/// Deletes a single movie from the table.
/// </summary>
/// <param name="tableName">The name of the table.</param>
/// <param name="movieTitle">The title of the movie to delete.</param>
/// <param name="year">The year that the movie was released.</param>
/// <returns>A Boolean value that indicates the success of the
/// DELETE operation.</returns>
public static async Task<bool> DeleteSingleMovie(string tableName, string
movieTitle, int year)
{
    var deleteSingle = $"DELETE FROM {tableName} WHERE title = ? AND year
= ?";

    var response = await Client.ExecuteStatementAsync(new
ExecuteStatementRequest
{
    Statement = deleteSingle,
    Parameters = new List<AttributeValue>
    {
        new AttributeValue { S = movieTitle },
        new AttributeValue { N = year.ToString() },
    },
});
    return response.HttpStatusCode == System.Net.HttpStatusCode.OK;
}
```

- For API details, see [ExecuteStatement](#) in *AWS SDK for .NET API Reference*.

C++

SDK for C++**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use an INSERT statement to add an item.

```
Aws::DynamoDB::DynamoDBClient dynamoClient(clientConfiguration);

// 2. Add a new movie using an "Insert" statement. (ExecuteStatement)
Aws::String title;
float rating;
int year;
Aws::String plot;
{
    title = askQuestion(
        "Enter the title of a movie you want to add to the table: ");
    year = askQuestionForInt("What year was it released? ");
    rating = askQuestionForFloatRange("On a scale of 1 - 10, how do you rate
it? ",
                                    1, 10);
    plot = askQuestion("Summarize the plot for me: ");

    Aws::DynamoDB::Model::ExecuteStatementRequest request;
    std::stringstream sqlStream;
    sqlStream << "INSERT INTO \""
    << MOVIE_TABLE_NAME << "\" VALUE {\""
    << TITLE_KEY << "': ?, '" << YEAR_KEY << "': ?, '"
    << INFO_KEY << "': ?}";

    request.SetStatement(sqlStream.str());

    // Create the parameter attributes.
    Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetS(title));
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(year));

    Aws::DynamoDB::Model::AttributeValue infoMapAttribute;
```

```
    std::shared_ptr<Aws::DynamoDB::Model::AttributeValue> ratingAttribute =
        Aws::MakeShared<Aws::DynamoDB::Model::AttributeValue>(
            ALLOCATION_TAG.c_str());
    ratingAttribute->SetN(rating);
    infoMapAttribute.AddMEntry(RATING_KEY, ratingAttribute);

    std::shared_ptr<Aws::DynamoDB::Model::AttributeValue> plotAttribute =
        Aws::MakeShared<Aws::DynamoDB::Model::AttributeValue>(
            ALLOCATION_TAG.c_str());
    plotAttribute->SetS(plot);
    infoMapAttribute.AddMEntry(PLOT_KEY, plotAttribute);
    attributes.push_back(infoMapAttribute);
    request.SetParameters(attributes);

    Aws::DynamoDB::Model::ExecuteStatementOutcome outcome =
        dynamoClient.ExecuteStatement(
            request);

    if (!outcome.IsSuccess()) {
        std::cerr << "Failed to add a movie: " <<
        outcome.GetError().GetMessage()
        << std::endl;
        return false;
    }
}
```

Use a SELECT statement to get an item.

```
// 3. Get the data for the movie using a "Select" statement.
(ExecuteStatement)
{
    Aws::DynamoDB::Model::ExecuteStatementRequest request;
    std::stringstream sqlStream;
    sqlStream << "SELECT * FROM \\" " << MOVIE_TABLE_NAME << "\\ WHERE "
        << TITLE_KEY << "=?" and " << YEAR_KEY << "=?";

    request.SetStatement(sqlStream.str());

    Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetS(title));
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(year));
    request.SetParameters(attributes);
```

```
Aws::DynamoDB::Model::ExecuteStatementOutcome outcome =
dynamoClient.ExecuteStatement(
    request);

if (!outcome.IsSuccess()) {
    std::cerr << "Failed to retrieve movie information: "
        << outcome.GetError().GetMessage() << std::endl;
    return false;
}
else {
    // Print the retrieved movie information.
    const Aws::DynamoDB::Model::ExecuteStatementResult &result =
outcome.GetResult();

    const Aws::Vector<Aws::Map<Aws::String,
Aws::DynamoDB::Model::AttributeValue>> &items = result.GetItems();

    if (items.size() == 1) {
        printMovieInfo(items[0]);
    }
    else {
        std::cerr << "Error: " << items.size() << " movies were
retrieved. "
            << " There should be only one movie." << std::endl;
    }
}
}
```

Use an UPDATE statement to update an item.

```
// 4. Update the data for the movie using an "Update" statement.
(ExecuteStatement)
{
    rating = askQuestionForFloatRange(
        Aws::String("\nLet's update your movie.\nYou rated it  ") +
        std::to_string(rating)
        + ", what new rating would you give it? ", 1, 10);

    Aws::DynamoDB::Model::ExecuteStatementRequest request;
    std::stringstream sqlStream;
    sqlStream << "UPDATE \""
        << MOVIE_TABLE_NAME << "\" SET "
```

```
<< INFO_KEY << "." << RATING_KEY << "=? WHERE "
<< TITLE_KEY << "=? AND " << YEAR_KEY << "=?";

request.SetStatement(sqlStream.str());

Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;

attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(rating));
attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetS(title));
attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(year));

request.SetParameters(attributes);

Aws::DynamoDB::Model::ExecuteStatementOutcome outcome =
dynamoClient.ExecuteStatement(
    request);

if (!outcome.IsSuccess()) {
    std::cerr << "Failed to update a movie: "
        << outcome.GetError().GetMessage();
    return false;
}
}
```

Use a DELETE statement to delete an item.

```
// 6. Delete the movie using a "Delete" statement. (ExecuteStatement)
{
    Aws::DynamoDB::Model::ExecuteStatementRequest request;
    std::stringstream sqlStream;
    sqlStream << "DELETE FROM  \"\" << MOVIE_TABLE_NAME << "\" WHERE "
        << TITLE_KEY << "=? and " << YEAR_KEY << "=?";

    request.SetStatement(sqlStream.str());

    Aws::Vector<Aws::DynamoDB::Model::AttributeValue> attributes;
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetS(title));
    attributes.push_back(Aws::DynamoDB::Model::AttributeValue().SetN(year));
    request.SetParameters(attributes);

    Aws::DynamoDB::Model::ExecuteStatementOutcome outcome =
dynamoClient.ExecuteStatement(
```

```
        request);
    if (!outcome.IsSuccess()) {
        std::cerr << "Failed to delete the movie: "
            << outcome.GetError().GetMessage() << std::endl;
        return false;
    }
}
```

- For API details, see [ExecuteStatement](#) in *AWS SDK for C++ API Reference*.

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use an INSERT statement to add an item.

```
// AddMovie runs a PartiQL INSERT statement to add a movie to the DynamoDB table.
func (runner PartiQLRunner) AddMovie(movie Movie) error {
    params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year,
        movie.Info})
    if err != nil {
        panic(err)
    }
    _, err = runner.DynamoDbClient.ExecuteStatement(context.TODO(),
        &dynamodb.ExecuteStatementInput{
            Statement: aws.String(
                fmt.Sprintf("INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
                    runner.TableName)),
            Parameters: params,
        })
    if err != nil {
        log.Printf("Couldn't insert an item with PartiQL. Here's why: %v\n", err)
    }
    return err
}
```

```
}
```

Use a SELECT statement to get an item.

```
// GetMovie runs a PartiQL SELECT statement to get a movie from the DynamoDB
// table by
// title and year.
func (runner PartiQLRunner) GetMovie(title string, year int) (Movie, error) {
    var movie Movie
    params, err := attributevalue.MarshalList([]interface{}{title, year})
    if err != nil {
        panic(err)
    }
    response, err := runner.DynamoDbClient.ExecuteStatement(context.TODO(),
        &dynamodb.ExecuteStatementInput{
            Statement: aws.String(
                fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?",
                    runner.TableName)),
            Parameters: params,
        })
    if err != nil {
        log.Printf("Couldn't get info about %v. Here's why: %v\n", title, err)
    } else {
        err = attributevalue.UnmarshalMap(response.Items[0], &movie)
        if err != nil {
            log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
        }
    }
    return movie, err
}
```

Use a SELECT statement to get a list of items and project the results.

```
// GetAllMovies runs a PartiQL SELECT statement to get all movies from the
// DynamoDB table.
// pageSize is not typically required and is used to show how to paginate the
// results.
```

```
// The results are projected to return only the title and rating of each movie.
func (runner PartiQLRunner) GetAllMovies(pageSize int32)
    ([]map[string]interface{}, error) {
    var output []map[string]interface{}
    var response *dynamodb.ExecuteStatementOutput
    var err error
    var nextToken *string
    for moreData := true; moreData; {
        response, err = runner.DynamoDbClient.ExecuteStatement(context.TODO(),
        &dynamodb.ExecuteStatementInput{
            Statement: aws.String(
                fmt.Sprintf("SELECT title, info.rating FROM \"%v\"", runner.TableName)),
            Limit:     aws.Int32(pageSize),
            NextToken: nextToken,
        })
        if err != nil {
            log.Printf("Couldn't get movies. Here's why: %v\n", err)
            moreData = false
        } else {
            var pageOutput []map[string]interface{}
            err = attributevalue.UnmarshalListOfMaps(response.Items, &pageOutput)
            if err != nil {
                log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
            } else {
                log.Printf("Got a page of length %v.\n", len(response.Items))
                output = append(output, pageOutput...)
            }
            nextToken = response.NextToken
            moreData = nextToken != nil
        }
    }
    return output, err
}
```

Use an UPDATE statement to update an item.

```
// UpdateMovie runs a PartiQL UPDATE statement to update the rating of a movie
// that
// already exists in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovie(movie Movie, rating float64) error {
```

```
params, err := attributevalue.MarshalList([]interface{}{rating, movie.Title,
    movie.Year})
if err != nil {
    panic(err)
}
_, err = runner.DynamoDbClient.ExecuteStatement(context.TODO(),
&dynamodb.ExecuteStatementInput{
    Statement: aws.String(
        fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
            runner.TableName)),
    Parameters: params,
})
if err != nil {
    log.Printf("Couldn't update movie %v. Here's why: %v\n", movie.Title, err)
}
return err
}
```

Use a DELETE statement to delete an item.

```
// DeleteMovie runs a PartiQL DELETE statement to remove a movie from the
// DynamoDB table.
func (runner PartiQLRunner) DeleteMovie(movie Movie) error {
    params, err := attributevalue.MarshalList([]interface{}{movie.Title,
        movie.Year})
    if err != nil {
        panic(err)
    }
    _, err = runner.DynamoDbClient.ExecuteStatement(context.TODO(),
        &dynamodb.ExecuteStatementInput{
            Statement: aws.String(
                fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?",
                    runner.TableName)),
            Parameters: params,
        })
    if err != nil {
        log.Printf("Couldn't delete %v from the table. Here's why: %v\n", movie.Title,
            err)
    }
    return err
}
```

```
}
```

Define a Movie struct that is used in this example.

```
// Movie encapsulates data about a movie. Title and Year are the composite
// primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
// key,
// and Info is additional data.
type Movie struct {
    Title string           `dynamodbav:"title"`
    Year  int              `dynamodbav:"year"`
    Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
    title, err := attributevalue.Marshal(movie.Title)
    if err != nil {
        panic(err)
    }
    year, err := attributevalue.Marshal(movie.Year)
    if err != nil {
        panic(err)
    }
    return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
// example.
func (movie Movie) String() string {
    return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
        movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Select a single item using PartiQL.

```
class DynamoDBPartiQLSingle

    attr_reader :dynamo_resource
    attr_reader :table

    def initialize(table_name)
        client = Aws::DynamoDB::Client.new(region: "us-east-1")
        @dynamodb = Aws::DynamoDB::Resource.new(client: client)
        @table = @dynamodb.table(table_name)
    end

    # Gets a single record from a table using PartiQL.
    # Note: To perform more fine-grained selects,
    # use the Client.query instance method instead.
    #
    # @param title [String] The title of the movie to search.
    # @return [Aws::DynamoDB::Types::ExecuteStatementOutput]
    def select_item_by_title(title)
        request = {
            statement: "SELECT * FROM #{@table.name} WHERE title=?",
            parameters: [title]
```

```
    }
    @dynamodb.client.execute_statement(request)
end
```

Update a single item using PartiQL.

```
class DynamoDBPartiQLSingle

  attr_reader :dynamo_resource
  attr_reader :table

  def initialize(table_name)
    client = Aws::DynamoDB::Client.new(region: "us-east-1")
    @dynamodb = Aws::DynamoDB::Resource.new(client: client)
    @table = @dynamodb.table(table_name)
  end

  # Updates a single record from a table using PartiQL.
  #
  # @param title [String] The title of the movie to update.

Run batches of PartiQL statements on a DynamoDB table using an AWS SDK

The following code examples show how to run batches of PartiQL statements on a DynamoDB table.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Query a table by using batches of PartiQL statements](#)

.NET

AWS SDK for .NET

Note

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Use batches of INSERT statements to add items.

```
// AddMovieBatch runs a batch of PartiQL INSERT statements to add multiple movies
// to the
// DynamoDB table.
func (runner PartiQLRunner) AddMovieBatch(movies []Movie) error {
    statementRequests := make([]types.BatchStatementRequest, len(movies))
    for index, movie := range movies {
        params, err := attributevalue.MarshalList([]interface{}{movie.Title,
            movie.Year, movie.Info})
        if err != nil {
            panic(err)
        }
        statementRequests[index] = types.BatchStatementRequest{
            Statement: aws.String(fmt.Sprintf(
                "INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
                runner.TableName)),
            Parameters: params,
        }
    }
}
```

```
_ , err := runner.DynamoDbClient.BatchExecuteStatement(context.TODO(),
&dynamodb.BatchExecuteStatementInput{
    Statements: statementRequests,
})
if err != nil {
    log.Printf("Couldn't insert a batch of items with PartiQL. Here's why: %v\n",
err)
}
return err
}
```

Use batches of SELECT statements to get items.

```
// GetMovieBatch runs a batch of PartiQL SELECT statements to get multiple movies
// from
// the DynamoDB table by title and year.
func (runner PartiQLRunner) GetMovieBatch(movies []Movie) ([]Movie, error) {
    statementRequests := make([]types.BatchStatementRequest, len(movies))
    for index, movie := range movies {
        params, err := attributevalue.MarshalList([]interface{}{movie.Title,
        movie.Year})
        if err != nil {
            panic(err)
        }
        statementRequests[index] = types.BatchStatementRequest{
            Statement: aws.String(
                fmt.Sprintf("SELECT * FROM \"%v\" WHERE title=? AND year=?",
runner.TableName)),
            Parameters: params,
        }
    }

    output, err := runner.DynamoDbClient.BatchExecuteStatement(context.TODO(),
&dynamodb.BatchExecuteStatementInput{
    Statements: statementRequests,
})
    var outMovies []Movie
    if err != nil {
        log.Printf("Couldn't get a batch of items with PartiQL. Here's why: %v\n", err)
    }
}
```

```
    } else {
        for _, response := range output.Responses {
            var movie Movie
            err = attributevalue.UnmarshalMap(response.Item, &movie)
            if err != nil {
                log.Printf("Couldn't unmarshal response. Here's why: %v\n", err)
            } else {
                outMovies = append(outMovies, movie)
            }
        }
    }
    return outMovies, err
}
```

Use batches of UPDATE statements to update items.

```
// UpdateMovieBatch runs a batch of PartiQL UPDATE statements to update the
// rating of
// multiple movies that already exist in the DynamoDB table.
func (runner PartiQLRunner) UpdateMovieBatch(movies []Movie, ratings []float64)
    error {
    statementRequests := make([]types.BatchStatementRequest, len(movies))
    for index, movie := range movies {
        params, err := attributevalue.MarshalList([]interface{}{ratings[index],
            movie.Title, movie.Year})
        if err != nil {
            panic(err)
        }
        statementRequests[index] = types.BatchStatementRequest{
            Statement: aws.String(
                fmt.Sprintf("UPDATE \"%v\" SET info.rating=? WHERE title=? AND year=?",
                    runner.TableName)),
            Parameters: params,
        }
    }

    _, err := runner.DynamoDbClient.BatchExecuteStatement(context.TODO(),
        &dynamodb.BatchExecuteStatementInput{
            Statements: statementRequests,
        })
}
```

```
if err != nil {
    log.Printf("Couldn't update the batch of movies. Here's why: %v\n", err)
}
return err
}
```

Use batches of DELETE statements to delete items.

```
// DeleteMovieBatch runs a batch of PartiQL DELETE statements to remove multiple
// movies
// from the DynamoDB table.
func (runner PartiQLRunner) DeleteMovieBatch(movies []Movie) error {
    statementRequests := make([]types.BatchStatementRequest, len(movies))
    for index, movie := range movies {
        params, err := attributevalue.MarshalList([]interface{}{movie.Title,
            movie.Year})
        if err != nil {
            panic(err)
        }
        statementRequests[index] = types.BatchStatementRequest{
            Statement: aws.String(
                fmt.Sprintf("DELETE FROM \"%v\" WHERE title=? AND year=?", runner.TableName)),
            Parameters: params,
        }
    }

    _, err := runner.DynamoDbClient.BatchExecuteStatement(context.TODO(),
        &dynamodb.BatchExecuteStatementInput{
            Statements: statementRequests,
        })
    if err != nil {
        log.Printf("Couldn't delete the batch of movies. Here's why: %v\n", err)
    }
    return err
}
```

Define a Movie struct that is used in this example.

```
// Movie encapsulates data about a movie. Title and Year are the composite
// primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
// key,
// and Info is additional data.
type Movie struct {
    Title string           `dynamodbav:"title"`
    Year  int               `dynamodbav:"year"`
    Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
    title, err := attributevalue.Marshal(movie.Title)
    if err != nil {
        panic(err)
    }
    year, err := attributevalue.Marshal(movie.Year)
    if err != nil {
        panic(err)
    }
    return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
// example.
func (movie Movie) String() string {
    return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
        movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

```
public static async Task<int> ScanTableAsync(
    AmazonDynamoDBClient client,
    string tableName,
    int startYear,
    int endYear)
{
    var request = new ScanRequest
    {
        TableName = tableName,
        ExpressionAttributeNames = new Dictionary<string, string>
        {
            { "#yr", "year" },
        },
        ExpressionAttributeValues = new Dictionary<string,
        AttributeValue>
        {
            { ":y_a", new AttributeValue { N = startYear.ToString() } },
        }
    };
    var response = await client.ScanAsync(request);
    return response.Count;
}
```

```
        { ":y_z", new AttributeValue { N = endYear.ToString() } },
    },
    FilterExpression = "#yr between :y_a and :y_z",
    ProjectionExpression = "#yr, title, info.actors[0],
info.directors, info.running_time_secs",
    Limit = 10 // Set a limit to demonstrate using the
LastEvaluatedKey.
};

// Keep track of how many movies were found.
int foundCount = 0;

var response = new ScanResponse();
do
{
    response = await client.ScanAsync(request);
    foundCount += response.Items.Count;
    response.Items.ForEach(i => DisplayItem(i));
    request.ExclusiveStartKey = response.LastEvaluatedKey;
}
while (response.LastEvaluatedKey.Count > 0);
return foundCount;
}
```

CLI

AWS CLI

To scan a table

The following scan example scans the entire MusicCollection table, and then narrows the results to songs by the artist "No One You Know". For each item, only the album title and song title are returned.

```
aws dynamodb scan \
--table-name MusicCollection \
--filter-expression "Artist = :a" \
--projection-expression "#ST, #AT" \
--expression-attribute-names file://expression-attribute-names.json \
--expression-attribute-values file://expression-attribute-values.json
```

Contents of expression-attribute-names.json:

```
{
    "#ST": "SongTitle",
    "#AT": "AlbumTitle"
}
```

Contents of expression-attribute-values.json:

```
{  
    ":a": {"S": "No One You Know"}  
}
```

Output:

```
{  
    "Count": 2,  
    "Items": [  
        {  
            "SongTitle": {  
                "S": "Call Me Today"  
            },  
            "AlbumTitle": {  
                "S": "Somewhat Famous"  
            }  
        },  
        {  
            "SongTitle": {  
                "S": "Scared of My Shadow"  
            },  
            "AlbumTitle": {  
                "S": "Blue Sky Blues"  
            }  
        }  
    "ScannedCount": 3,  
    "ConsumedCapacity": null  
}
```

CLI

AWS CLI

Example 1: To update an item in a table

The following update-item example updates an item in the MusicCollection table. It adds a new attribute (Year) and modifies the AlbumTitle attribute. All of the attributes in the item, as they appear after the update, are returned in the response.

```
aws dynamodb update-item \  
  --table-name MusicCollection \  
  --key file://key.json \  
  --update-expression "SET #Y = :y, #AT = :t" \  
  --expression-attribute-names file://expression-attribute-names.json \  
  --expression-attribute-values file://expression-attribute-values.json \  
  --return-values ALL_NEW \  
  --return-consumed-capacity TOTAL \  
  --return-item-collection-metrics SIZE
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Contents of expression-attribute-names.json:

```
{  
    "#Y":"Year", "#AT":"AlbumTitle"  
}
```

Contents of expression-attribute-values.json:

```
{  
    ":y":{"N": "2015"},  
    ":t":{"S": "Louder Than Ever"}  
}
```

Output:

```
{  
    "Attributes": {  
        "AlbumTitle": {  
            "S": "Louder Than Ever"  
        },  
        "Awards": {  
            "N": "10"  
        },  
        "Artist": {  
            "S": "Acme Band"  
        },  
        "Year": {  
            "N": "2015"  
        },  
        "SongTitle": {  
            "S": "Happy Day"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 3.0  
    },  
    "ItemCollectionMetrics": {  
        "ItemCollectionKey": {  
            "Artist": {  
                "S": "Acme Band"  
            }  
        },  
        "SizeEstimateRangeGB": [  
            0.0,  
            1.0  
        ]  
    }  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To update an item conditionally

The following example updates an item in the MusicCollection table, but only if the existing item does not already have a Year attribute.

```
aws dynamodb update-item \
```

```
--table-name MusicCollection \
--key file://key.json \
--update-expression "SET #Y = :y, #AT = :t" \
--expression-attribute-names file://expression-attribute-names.json \
--expression-attribute-values file://expression-attribute-values.json \
--condition-expression "attribute_not_exists(#Y)"
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Contents of expression-attribute-names.json:

```
{  
    "#Y": "Year",  
    "#AT": "AlbumTitle"  
}
```

Contents of expression-attribute-values.json:

```
{  
    ":y": {"N": "2015"},  
    ":t": {"S": "Louder Than Ever"}  
}
```

If the item already has a Year attribute, DynamoDB returns the following output.

An error occurred (ConditionalCheckFailedException) when calling the UpdateItem operation: The conditional request failed

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

 * To update an Amazon DynamoDB table using the AWS SDK for Java V2, its better
```

```
* practice to use the
* Enhanced Client, See the EnhancedModifyItem example.
*/
public class UpdateItem {
    public static void main(String[] args) {
        final String usage = """
            Usage:
            <tableName> <key> <keyVal> <name> <updateVal>
            Where:
            tableName - The Amazon DynamoDB table (for example, Music3).
            key - The name of the key in the table (for example, Artist).
            keyVal - The value of the key (for example, Famous Band).
            name - The name of the column where the value is updated (for
example, Awards).
            updateVal - The value used to update an item (for example,
14).

        Example:
            UpdateItem Music3 Artist Famous Band Awards 14
            """;
        if (args.length != 5) {
            System.out.println(usage);
            System.exit(1);

Write a batch of DynamoDB items using an AWS SDK

The following code examples show how to write a batch of DynamoDB items.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with tables, items, and queries](#)

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Writes a batch of items to the movie table.

```
/// <summary>
/// Loads the contents of a JSON file into a list of movies to be
/// added to the DynamoDB table.
/// </summary>
/// <param name="movieFileName">The full path to the JSON file.</param>
/// <returns>A generic list of movie objects.</returns>
public static List<Movie> ImportMovies(string movieFileName)
{
    if (!File.Exists(movieFileName))
    {
        return null;
    }

    using var sr = new StreamReader(movieFileName);
    string json = sr.ReadToEnd();
    var allMovies = JsonSerializer.Deserialize<List<Movie>>(
        json,
        new JsonSerializerOptions
    {
```

```
        PropertyNameCaseInsensitive = true
    });

    // Now return the first 250 entries.
    return allMovies.GetRange(0, 250);
}

/// <summary>
/// Writes 250 items to the movie table.
/// </summary>
/// <param name="client">The initialized DynamoDB client object.</param>
/// <param name="movieFileName">A string containing the full path to
/// the JSON file containing movie data.</param>
/// <returns>A long integer value representing the number of movies
/// imported from the JSON file.</returns>
public static async Task<long> BatchWriteItemsAsync(
    AmazonDynamoDBClient client,
    string movieFileName)
{
    var movies = ImportMovies(movieFileName);
    if (movies is null)
    {
        Console.WriteLine("Couldn't find the JSON file with movie
data.");
        return 0;
    }

    var context = new DynamoDBContext(client);

    var movieBatch = context.CreateBatchWrite<Movie>();
    movieBatch.AddPutItems(movies);

    Console.WriteLine("Adding imported movies to the table.");
    await movieBatch.ExecuteAsync();

    return movies.Count;
}
```

```
#!/ Batch write items from a JSON file.
/*
\sa batchWriteItem()
\param jsonFilePath: JSON file path.
\param clientConfiguration: AWS client configuration.
\return bool: Function succeeded.
*/

/*
 * The input for this routine is a JSON file that you can download from the
following URL:
 * https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/
SampleData.html.
 *
 * The JSON data uses the BatchWriteItem API request syntax. The JSON strings are
 * converted toAttributeValue objects. These AttributeValue objects will then
generate
 * JSON strings when constructing the BatchWriteItem request, essentially
outputting
 * their input.
 *
```

```
* This is perhaps an artificial example, but it demonstrates the APIs.  
*/

CLI

AWS CLI

To add multiple items to a table

The following batch-write-item example adds three new items to the MusicCollection table using a batch of three PutItem requests. It also requests information about the number of write capacity units consumed by the operation and any item collections modified by the operation.

```
aws dynamodb batch-write-item \  
--request-items file://request-items.json \  
--return-consumed-capacity INDEXES \  
--return-item-collection-metrics SIZE
```

Contents of request-items.json:

```
{
```

```
"MusicCollection": [
    {
        "PutRequest": {
            "Item": {
                "Artist": {"S": "No One You Know"},
                "SongTitle": {"S": "Call Me Today"},
                "AlbumTitle": {"S": "Somewhat Famous"}
            }
        }
    },
    {
        "PutRequest": {
            "Item": {
                "Artist": {"S": "Acme Band"},
                "SongTitle": {"S": "Happy Day"},
                "AlbumTitle": {"S": "Songs About Life"}
            }
        }
    },
    {
        "PutRequest": {
            "Item": {
                "Artist": {"S": "No One You Know"},
                "SongTitle": {"S": "Scared of My Shadow"},
                "AlbumTitle": {"S": "Blue Sky Blues"}
            }
        }
    }
]
```

Output:

```
{
    "UnprocessedItems": {},
    "ItemCollectionMetrics": {
        "MusicCollection": [
            {
                "ItemCollectionKey": {
                    "Artist": {
                        "S": "No One You Know"
                    }
                },
                ...
            }
        ]
    }
}
```

```
        "SizeEstimateRangeGB": [
            0.0,
            1.0
        ],
    },
    {
        "ItemCollectionKey": {
            "Artist": {
                "S": "Acme Band"
            }
        },
        "SizeEstimateRangeGB": [
            0.0,
            1.0
        ]
    }
],
"ConsumedCapacity": [
{
    "TableName": "MusicCollection",
    "CapacityUnits": 6.0,
    "Table": {
        "CapacityUnits": 3.0
    },
    "LocalSecondaryIndexes": {
        "AlbumTitleIndex": {
            "CapacityUnits": 3.0
        }
    }
}
]
```

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Scenarios for DynamoDB using AWS SDKs

The following code examples show you how to implement common scenarios in DynamoDB with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within DynamoDB. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

- [Accelerate DynamoDB reads with DAX using an AWS SDK](#)
- [Get started with DynamoDB tables, items, and queries using an AWS SDK](#)
- [Query a DynamoDB table by using batches of PartiQL statements and an AWS SDK](#)
- [Query a DynamoDB table using PartiQL and an AWS SDK](#)
- [Use a document model for DynamoDB using an AWS SDK](#)
- [Use a high-level object persistence model for DynamoDB using an AWS SDK](#)

Accelerate DynamoDB reads with DAX using an AWS SDK

The following code example shows how to:

- Create and write data to a table with both the DAX and SDK clients.
- Get, query, and scan the table with both clients and compare their performance.

For more information, see [Developing with the DynamoDB Accelerator Client](#).

Python

SDK for Python (Boto3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a table with either the DAX or Boto3 client.

```
import boto3

def create_dax_table(dyn_resource=None):
    """
    Creates a DynamoDB table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The newly created table.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table_name = "TryDaxTable"
    params = {
        "TableName": table_name,
        "KeySchema": [
            {"AttributeName": "partition_key", "KeyType": "HASH"},
            {"AttributeName": "sort_key", "KeyType": "RANGE"},
        ],
    }
```

```
        "AttributeDefinitions": [
            {"AttributeName": "partition_key", "AttributeType": "N"},
            {"AttributeName": "sort_key", "AttributeType": "N"},
        ],
        "ProvisionedThroughput": {"ReadCapacityUnits": 10, "WriteCapacityUnits": 10},
    }
}

table = dyn_resource.create_table(**params)
print(f"Creating {table_name}...")
table.wait_until_exists()
return table

if __name__ == "__main__":
    dax_table = create_dax_table()
    print(f"Created table.")
```

Write test data to the table.

```
import boto3

def write_data_to_dax_table(key_count, item_size, dyn_resource=None):
    """
    Writes test data to the demonstration table.

    :param key_count: The number of partition and sort keys to use to populate
    the
                    table. The total number of items is key_count * key_count.
    :param item_size: The size of non-key data for each test item.
    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    some_data = "X" * item_size

    for partition_key in range(1, key_count + 1):
        for sort_key in range(1, key_count + 1):
            table.put_item(
                Item={
```

```
        "partition_key": partition_key,
        "sort_key": sort_key,
        "some_data": some_data,
    }
)
print(f"Put item ({partition_key}, {sort_key}) succeeded.")

if __name__ == "__main__":
    write_key_count = 10
    write_item_size = 1000
    print(
        f"Writing {write_key_count*write_key_count} items to the table."
        f"Each item is {write_item_size} characters."
    )
    write_data_to_dax_table(write_key_count, write_item_size)
```

Get items for a number of iterations for both the DAX client and the Boto3 client and report the time spent for each.

```
import argparse
import sys
import time
import amazonadax
import boto3

def get_item_test(key_count, iterations, dyn_resource=None):
    """
    Gets items from the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param key_count: The number of items to get from the table in each
                      iteration.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.

 - [CreateTable](#)
 - [DeleteTable](#)
 - [GetItem](#)
 - [PutItem](#)
 - [Query](#)
 - [Scan](#)

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Get started with DynamoDB tables, items, and queries using an AWS SDK

The following code examples show how to:

- Create a table that can hold movie data.
- Put, get, and update a single movie in the table.
- Write movie data to the table from a sample JSON file.
- Query for movies that were released in a given year.
- Scan for movies that were released in a range of years.
- Delete a movie from the table, then delete the table.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// This example application performs the following basic Amazon DynamoDB
// functions:
//
//      CreateTableAsync
//      PutItemAsync
//      UpdateItemAsync
//      BatchWriteItemAsync
//      GetItemAsync
//      DeleteItemAsync
//      Query
//      Scan
//      DeleteItemAsync
//

The DynamoDB functions used in this scenario.

```
#####
# function dynamodb_create_table
#
# This function creates an Amazon DynamoDB table.
#
# Parameters:
#     -n table_name -- The name of the table to create.
#     -a attribute_definitions -- JSON file path of a list of attributes and
#       their types.
#     -k key_schema -- JSON file path of a list of attributes and their key
#       types.
#     -p provisioned_throughput -- Provisioned throughput settings for the
#       table.
#
# Returns:
#     0 - If successful.
#     1 - If it fails.
#####
```

```

Go

SDK for Go V2

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run an interactive scenario to create the table and perform actions on it.

```
// RunMovieScenario is an interactive example that shows you how to use the AWS  
// SDK for Go  
// to create and use an Amazon DynamoDB table that stores data about movies.  
//  
// 1. Create a table that can hold movie data.  
// 2. Put, get, and update a single movie in the table.  
// 3. Write movie data to the table from a sample JSON file.
```

```
// 4. Query for movies that were released in a given year.  
// 5. Scan for movies that were released in a range of years.  
// 6. Delete a movie from the table.  
// 7. Delete the table.  
  
//  
// This example creates a DynamoDB service client from the specified sdkConfig so  
// that  
// you can replace it with a mocked or stubbed config for unit testing.  
//  
// It uses a questioner from the `demotools` package to get input during the  
// example.  
// This package can be found in the ..\..\demotools folder of this repo.  
//  
// The specified movie sampler is used to get sample data from a URL that is  
// loaded  
// into the named table.

```

Define a Movie struct that is used in this example.

```
// Movie encapsulates data about a movie. Title and Year are the composite
// primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
// key,
// and Info is additional data.
type Movie struct {
    Title string           `dynamodbav:"title"`
    Year  int              `dynamodbav:"year"`
    Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
    title, err := attributevalue.Marshal(movie.Title)
    if err != nil {
        panic(err)
    }
    year, err := attributevalue.Marshal(movie.Year)
    if err != nil {
        panic(err)
    }
    return map[string]types.AttributeValue{"title": title, "year": year}
}
```

```
// String returns the title, year, rating, and plot of a movie, formatted for the
// example.
func (movie Movie) String() string {
    return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
        movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

Create a struct and methods that call DynamoDB actions.

```
// TableBasics encapsulates the Amazon DynamoDB service actions used in the
// examples.
// It contains a DynamoDB service client that is used to act on the specified
// table.
type TableBasics struct {
    DynamoDbClient *dynamodb.Client
    TableName       string
}

// TableExists determines whether a DynamoDB table exists.
func (basics TableBasics) TableExists() (bool, error) {
    exists := true
    _, err := basics.DynamoDbClient.DescribeTable(
        context.TODO(), &dynamodb.DescribeTableInput{TableName:
            aws.String(basics.TableName),
    )
    if err != nil {
        var notFoundEx *types.ResourceNotFoundException
        if errors.As(err, &notFoundEx) {
            log.Printf("Table %v does not exist.\n", basics.TableName)
            err = nil
        } else {
            log.Printf("Couldn't determine existence of table %v. Here's why: %v\n",
                basics.TableName, err)
        }
        exists = false
    }
    return exists, err
}
```

```
// CreateMovieTable creates a DynamoDB table with a composite primary key defined
// as
// a string sort key named `title`, and a numeric partition key named `year`.
// This function uses NewTableExistsWaiter to wait for the table to be created by
// DynamoDB before it returns.

Java

SDK for Java 2.x

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a DynamoDB table.

```
// Create a table with a Sort key.  
public static void createTable(DynamoDbClient ddb, String tableName) {  
    DynamoDbWaiter dbWaiter = ddb.waiter();  
    ArrayList<AttributeDefinition> attributeDefinitions = new ArrayList<>();
```

```
// Define attributes.
attributeDefinitions.add(AttributeDefinition.builder()
    .attributeName("year")
    .attributeType("N")
    .build());

attributeDefinitions.add(AttributeDefinition.builder()
    .attributeName("title")
    .attributeType("S")
    .build());

ArrayList<KeySchemaElement> tableKey = new ArrayList<>();
KeySchemaElement key = KeySchemaElement.builder()
    .attributeName("year")
    .keyType(KeyType.HASH)
    .build();

KeySchemaElement key2 = KeySchemaElement.builder()
    .attributeName("title")
    .keyType(KeyType.RANGE)
    .build();

// Add KeySchemaElement objects to the list.
tableKey.add(key);
tableKey.add(key2);

CreateTableRequest request = CreateTableRequest.builder()
    .keySchema(tableKey)
    .provisionedThroughput(ProvisionedThroughput.builder()
        .readCapacityUnits(10L)
        .writeCapacityUnits(10L)
        .build())
    .attributeDefinitions(attributeDefinitions)
    .tableName(tableName)
    .build();

try {
    CreateTableResponse response = ddb.createTable(request);
    DescribeTableRequest tableRequest = DescribeTableRequest.builder()
        .tableName(tableName)
        .build();

    // Wait until the Amazon DynamoDB table is created.
```

```
        WaiterResponse<DescribeTableResponse> waiterResponse =
    dbWaiter.waitUntilTableExists(tableRequest);
    waiterResponse.matched().response().ifPresent(System.out::println);
    String newTable = response.tableDescription().tableName();
    System.out.println("The " + newTable + " was successfully created.");

} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}
```

Create a helper function to download and extract the sample JSON file.

```
// Load data into the table.
public static void loadData(DynamoDbClient ddb, String tableName, String
fileName) throws IOException {
    DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
        .dynamoDbClient(ddb)
        .build();

    DynamoDbTable<Movies> mappedTable = enhancedClient.table("Movies",
TableSchema.fromBean(Movies.class));
    JsonParser parser = new JsonFactory().createParser(new File(fileName));
    com.fasterxml.jackson.databind.JsonNode rootNode = new
ObjectMapper().readTree(parser);
    Iterator<JsonNode> iter = rootNode.iterator();
    ObjectNode currentNode;
    int t = 0;
    while (iter.hasNext()) {
        // Only add 200 Movies to the table.
        if (t == 200)
            break;
        currentNode = (ObjectNode) iter.next();

        int year = currentNode.path("year").asInt();
        String title = currentNode.path("title").asText();
        String info = currentNode.path("info").toString();

        Movies movies = new Movies();
        movies.setYear(year);
        movies.setTitle(title);
```

```
        movies.setInfo(info);

        // Put the data into the Amazon DynamoDB Movie table.
        mappedTable.putItem(movies);
        t++;
    }
}
```

Get an item from a table.

```
public static void getItem(DynamoDbClient ddb) {

    HashMap<String, AttributeValue> keyToGet = new HashMap<>();
    keyToGet.put("year", AttributeValue.builder()
        .n("1933")
        .build());

    keyToGet.put("title", AttributeValue.builder()
        .s("King Kong")
        .build());

    GetItemRequest request = GetItemRequest.builder()
        .key(keyToGet)
        .tableName("Movies")
        .build();

    try {
        Map<String, AttributeValue> returnedItem =
ddb.getItem(request).item();

        if (returnedItem != null) {
            Set<String> keys = returnedItem.keySet();
            System.out.println("Amazon DynamoDB table attributes: \n");

            for (String key1 : keys) {
                System.out.format("%s: %s\n", key1,
returnedItem.get(key1).toString());
            }
        } else {
            System.out.format("No item found with the key %s!\n", "year");
        }
    }
}
```

```
        } catch (DynamoDbException e) {
            System.err.println(e.getMessage());
            System.exit(1);
        }
    }
```

Full example.

```
/**  
 * Before running this Java V2 code example, set up your development  
 * environment, including your credentials.  
 *  
 * For more information, see the following documentation topic:  
 *  
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html  
 *  
 * This Java example performs these tasks:  
 *  
 * 1. Creates the Amazon DynamoDB Movie table with partition and sort key.  
 * 2. Puts data into the Amazon DynamoDB table from a JSON document using the  
 * Enhanced client.  
 * 3. Gets data from the Movie table.  
 * 4. Adds a new item.  
 * 5. Updates an item.  
 * 6. Uses a Scan to query items using the Enhanced client.  
 * 7. Queries all items where the year is 2013 using the Enhanced Client.  
 * 8. Deletes the table.

    ddb.waitUntilTableExists { // suspend call
        tableName = tableNameVal
    }
    println("The table was successfully created
${response.tableDescription?.tableArn}")
}
}
```

Create a helper function to download and extract the sample JSON file.

```
// Load data into the table.
suspend fun loadData(tableName: String, fileName: String) {
    val parser = JsonFactory().createParser(File(fileName))
    val rootNode = ObjectMapper().readTree<JsonNode>(parser)
    val iter: Iterator<JsonNode> = rootNode.iterator()
    var currentNode: ObjectNode

    var t = 0
    while (iter.hasNext()) {
        if (t == 50) {
            break
        }

        currentNode = iter.next() as ObjectNode
        val year = currentNode.path("year").asInt()
        val title = currentNode.path("title").asText()
        val info = currentNode.path("info").toString()
        putMovie(tableName, year, title, info)
        t++
    }
}

suspend fun putMovie(
    tableNameVal: String,
    year: Int,
    title: String,
    info: String
```

```
) {  
    val itemValues = mutableMapOf<String, AttributeValue>()  
    val strVal = year.toString()  
    // Add all content to the table.  
    itemValues["year"] = AttributeValue.N(strVal)  
    itemValues["title"] = AttributeValue.S(title)  
    itemValues["info"] = AttributeValue.S(info)  
  
    val request = PutItemRequest {  
        tableName = tableNameVal  
        item = itemValues  
    }  
  
    DynamoDbClient { region = "us-east-1" }.use { ddb ->  
        ddb.putItem(request)  
        println("Added $title to the Movie table.")  
    }  
}
```

Get an item from a table.

```
suspend fun getMovie(tableNameVal: String, keyName: String, keyVal: String) {  
    val keyToGet = mutableMapOf<String, AttributeValue>()  
    keyToGet[keyName] = AttributeValue.N(keyVal)  
    keyToGet["title"] = AttributeValue.S("King Kong")  
  
    val request = GetItemRequest {  
        key = keyToGet  
        tableName = tableNameVal  
    }  
  
    DynamoDbClient { region = "us-east-1" }.use { ddb ->  
        val returnedItem = ddb.getItem(request)  
        val numbersMap = returnedItem.item  
        numbersMap?.forEach { key1 ->  
            println(key1.key)  
            println(key1.value)  
        }  
    }  
}
```

Full example.

```
suspend fun main(args: Array<String>) {
    val usage = """
        Usage:
        <fileName>

        Where:

Ruby

SDK for Ruby

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a class that encapsulates a DynamoDB table.

```
# Creates an Amazon DynamoDB table that can be used to store movie data.  
# The table uses the release year of the movie as the partition key and the  
# title as the sort key.  
  
#  
# @param table_name [String] The name of the table to create.  
# @return [Aws::DynamoDB::Table] The newly created table.  
def create_table(table_name)  
    @table = @dynamo_resource.create_table(  
        table_name: table_name,  
        key_schema: [  
            {attribute_name: "year", key_type: "HASH"}, # Partition key  
            {attribute_name: "title", key_type: "RANGE"} # Sort key  
        ],  
        attribute_definitions: [  
            {attribute_name: "year", attribute_type: "N"},  
            {attribute_name: "title", attribute_type: "S"}  
        ],
```

```
provisioned_throughput: {read_capacity_units: 10, write_capacity_units: 10})  
  @dynamo_resource.client.wait_until(:table_exists, table_name: table_name)  
  @table  
rescue Aws::DynamoDB::Errors::ServiceError => e  
  @logger.error("Failed create table #{table_name}:\n#{e.code}: #{e.message}")  
  raise  
end
```

Create a helper function to download and extract the sample JSON file.

```
# Gets sample movie data, either from a local file or by first downloading it  
from  
# the Amazon DynamoDB Developer Guide.  
#  
# @param movie_file_name [String] The local file name where the movie data is  
stored in JSON format.  
# @return [Hash] The movie data as a Hash.

Swift

SDK for Swift

 **Note**

This is prerelease documentation for an SDK in preview release. It is subject to change.

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

A Swift class that handles DynamoDB calls to the SDK for Swift.

```
import Foundation
import AWSDynamoDB

/// An enumeration of error codes representing issues that can arise when using
/// the `MovieTable` class.
enum MoviesError: Error {
    /// The specified table wasn't found or couldn't be created.
    case TableNotFound
    /// The specified item wasn't found or couldn't be created.
    case ItemNotFound
    /// The Amazon DynamoDB client is not properly initialized.
    case UninitializedClient
    /// The table status reported by Amazon DynamoDB is not recognized.
    case StatusUnknown
    /// One or more specified attribute values are invalid or missing.
    case InvalidAttributes
}

/// A class representing an Amazon DynamoDB table containing movie
/// information.
public class MovieTable {
    var ddbClient: DynamoDBClient? = nil
    let tableName: String

    /// Create an object representing a movie table in an Amazon DynamoDB
    /// database.
    ///
    /// - Parameters:
    ///   - region: The Amazon Region to create the database in.
    ///   - tableName: The name to assign to the table. If not specified, a
    ///     random table name is generated automatically.
    ///
    /// > Note: The table is not necessarily available when this function
    /// returns. Use `tableExists()` to check for its availability, or
    /// `awaitTableActive()` to wait until the table's status is reported as
    /// ready to use by Amazon DynamoDB.

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Query a DynamoDB table by using batches of PartiQL statements and an AWS SDK

The following code examples show how to:

- Get a batch of items by running multiple SELECT statements.
- Add a batch of items by running multiple INSERT statements.
- Update a batch of items by running multiple UPDATE statements.
- Delete a batch of items by running multiple DELETE statements.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
// Before you run this example, download 'movies.json' from
// https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/
GettingStarted.Js.02.html,
// and put it in the same folder as the example.

[Go](#)

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run a scenario that creates a table and runs batches of PartiQL queries.

```
// RunPartiQLBatchScenario shows you how to use the AWS SDK for Go
// to run batches of PartiQL statements to query a table that stores data about
// movies.
//
//   - Use batches of PartiQL statements to add, get, update, and delete data for
//     individual movies.
//
// This example creates an Amazon DynamoDB service client from the specified
// sdkConfig so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// This example creates and deletes a DynamoDB table to use during the scenario.
func RunPartiQLBatchScenario(sdkConfig aws.Config, tableName string) {
    defer func() {
        if r := recover(); r != nil {
            fmt.Printf("Something went wrong with the demo.")
        }
    }()
}

log.Println(strings.Repeat("-", 88))
log.Println("Welcome to the Amazon DynamoDB PartiQL batch demo.")

    log.Println(strings.Repeat("-", 88))
}
```

Define a Movie struct that is used in this example.

```
// Movie encapsulates data about a movie. Title and Year are the composite
// primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
// key,
// and Info is additional data.
type Movie struct {
    Title string           `dynamodbav:"title"`
    Year  int              `dynamodbav:"year"`
    Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
    title, err := attributevalue.Marshal(movie.Title)
    if err != nil {
        panic(err)
    }
    year, err := attributevalue.Marshal(movie.Year)
    if err != nil {
        panic(err)
    }
    return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
// example.
func (movie Movie) String() string {
    return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
        movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

Create a struct and methods that run PartiQL statements.

```
// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
// PartiQL examples. It contains a DynamoDB service client that is used to act on
// the
// specified table.
type PartiQLRunner struct {
    DynamoDbClient *dynamodb.Client
    TableName       string
}

// AddMovieBatch runs a batch of PartiQL INSERT statements to add multiple movies
// to the
// DynamoDB table.

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Query a DynamoDB table using PartiQL and an AWS SDK

The following code examples show how to:

- Get an item by running a SELECT statement.
- Add an item by running an INSERT statement.
- Update an item by running an UPDATE statement.
- Delete an item by running a DELETE statement.

.NET

AWS SDK for .NET

Go

SDK for Go V2

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Run a scenario that creates a table and runs PartiQL queries.

```
// RunPartiQLSingleScenario shows you how to use the AWS SDK for Go
// to use PartiQL to query a table that stores data about movies.
//
// * Use PartiQL statements to add, get, update, and delete data for individual
//   movies.
//
// This example creates an Amazon DynamoDB service client from the specified
// sdkConfig so that
// you can replace it with a mocked or stubbed config for unit testing.
//
// This example creates and deletes a DynamoDB table to use during the scenario.
func RunPartiQLSingleScenario(sdkConfig aws.Config, tableName string) {
    defer func() {
        if r := recover(); r != nil {
            fmt.Printf("Something went wrong with the demo.")
        }
    }()
}

log.Println(strings.Repeat("-", 88))
log.Println("Welcome to the Amazon DynamoDB PartiQL single action demo.")
log.Println(strings.Repeat("-", 88))

tableBasics := actions.TableBasics{
    DynamoDbClient: dynamodb.NewFromConfig(sdkConfig),
    TableName:      tableName,
```

```
}

log.Println("Thanks for watching!")
log.Println(strings.Repeat("-", 88))
}
```

Define a Movie struct that is used in this example.

```
// Movie encapsulates data about a movie. Title and Year are the composite
// primary key
// of the movie in Amazon DynamoDB. Title is the sort key, Year is the partition
// key,
// and Info is additional data.
type Movie struct {
    Title string            `dynamodbav:"title"`
    Year  int               `dynamodbav:"year"`
    Info  map[string]interface{} `dynamodbav:"info"`
}

// GetKey returns the composite primary key of the movie in a format that can be
// sent to DynamoDB.
func (movie Movie) GetKey() map[string]types.AttributeValue {
    title, err := attributevalue.Marshal(movie.Title)
    if err != nil {
        panic(err)
    }
    year, err := attributevalue.Marshal(movie.Year)
    if err != nil {
        panic(err)
    }
    return map[string]types.AttributeValue{"title": title, "year": year}
}

// String returns the title, year, rating, and plot of a movie, formatted for the
// example.
func (movie Movie) String() string {
    return fmt.Sprintf("%v\n\tReleased: %v\n\tRating: %v\n\tPlot: %v\n",
        movie.Title, movie.Year, movie.Info["rating"], movie.Info["plot"])
}
```

Create a struct and methods that run PartiQL statements.

```
// PartiQLRunner encapsulates the Amazon DynamoDB service actions used in the
// PartiQL examples. It contains a DynamoDB service client that is used to act on
// the
// specified table.
type PartiQLRunner struct {
    DynamoDbClient *dynamodb.Client
```

```
TableName      string
}

// AddMovie runs a PartiQL INSERT statement to add a movie to the DynamoDB table.
func (runner PartiQLRunner) AddMovie(movie Movie) error {
    params, err := attributevalue.MarshalList([]interface{}{movie.Title, movie.Year,
    movie.Info})
    if err != nil {
        panic(err)
    }
    _, err = runner.DynamoDbClient.ExecuteStatement(context.TODO(),
    &dynamodb.ExecuteStatementInput{
        Statement: aws.String(
            fmt.Sprintf("INSERT INTO \"%v\" VALUE {'title': ?, 'year': ?, 'info': ?}",
            runner.TableName)),
        Parameters: params,
    })
    if err != nil {
        log.Printf("Couldn't insert an item with PartiQL. Here's why: %v\n", err)
    }
    return err
}

// GetMovie runs a PartiQL SELECT statement to get a movie from the DynamoDB
// table by
// title and year.
func (runner PartiQLRunner) GetMovie(title string, year int) (Movie, error) {
    var movie Movie
    params, err := attributevalue.MarshalList([]interface{}{title, year})
    if err != nil {
        panic(err)
    }
    response, err := runner.DynamoDbClient.ExecuteStatement(context.TODO(),
    &dynamodb.ExecuteStatementInput{

Python

SDK for Python (Boto3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Create a class that can run PartiQL statements.

```
from datetime import datetime  
from decimal import Decimal  
import logging  
from pprint import pprint  
  
import boto3  
from botocore.exceptions import ClientError  
  
from scaffold import Scaffold  
  
logger = logging.getLogger(__name__)  
  
class PartiQLWrapper:  
    """  
    Encapsulates a DynamoDB resource to run PartiQL statements.  
    """  
  
    def __init__(self, dyn_resource):  
        """  
        :param dyn_resource: A Boto3 DynamoDB resource.  
        """  
        self.dyn_resource = dyn_resource
```

```
def run_partiql(self, statement, params):
    """
    Runs a PartiQL statement. A Boto3 resource is used even though
    `execute_statement` is called on the underlying `client` object because
    the
        resource transforms input and output from plain old Python objects
    (POPOs) to
        the DynamoDB format. If you create the client directly, you must do these
    transforms yourself.

    :param statement: The PartiQL statement.
    :param params: The list of PartiQL parameters. These are applied to the
        statement in the order they are listed.
    :return: The items returned from the statement, if any.
    """
    try:
        output = self.dyn_resource.meta.client.execute_statement(
            Statement=statement, Parameters=params
        )

Use a document model for DynamoDB using an AWS SDK

The following code example shows how to perform Create, Read, Update, and Delete (CRUD) and batch operations using a document model for DynamoDB and an AWS SDK.

For more information, see [Document model](#).

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Perform CRUD operations using a document model.

```
/// <summary>
/// Performs CRUD operations on an Amazon DynamoDB table.
/// </summary>
public class MidlevelItemCRUD
{
    public static async Task Main()
    {
        var tableName = "ProductCatalog";
        var sampleBookId = 555;

        var client = new AmazonDynamoDBClient();
        var productCatalog = LoadTable(client, tableName);

        await CreateBookItem(productCatalog, sampleBookId);
        RetrieveBook(productCatalog, sampleBookId);

        // Couple of sample updates.
        UpdateMultipleAttributes(productCatalog, sampleBookId);
        UpdateBookPriceConditionally(productCatalog, sampleBookId);

        // Delete.
        await DeleteBook(productCatalog, sampleBookId);
    }

    /// <summary>
    /// Loads the contents of a DynamoDB table.
    /// </summary>
    /// <param name="client">An initialized DynamoDB client object.</param>
    /// <param name="tableName">The name of the table to load.</param>

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use a high-level object persistence model for DynamoDB using an AWS SDK

The following code example shows how to perform Create, Read, Update, and Delete (CRUD) and batch operations using an object persistence model for DynamoDB and an AWS SDK.

For more information, see [Object persistence model](#).

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Perform CRUD operations using a high-level object persistence model.

```
/// <summary>
/// Shows how to perform high-level CRUD operations on an Amazon DynamoDB
/// table.
/// </summary>
public class HighLevelItemCrud

Cross-service examples for DynamoDB using AWS SDKs

The following sample applications use AWS SDKs to combine DynamoDB with other AWS services. Each example includes a link to GitHub, where you can find instructions on how to set up and run the application.

Examples

- [Build an application to submit data to a DynamoDB table](#)
- [Create an API Gateway REST API to track COVID-19 data](#)
- [Create a messenger application with Step Functions](#)
- [Create a photo asset management application that lets users manage photos using labels](#)
- [Create a web application to track DynamoDB data](#)
- [Create a websocket chat application with API Gateway](#)
- [Detect PPE in images with Amazon Rekognition using an AWS SDK](#)
- [Invoke a Lambda function from a browser](#)
- [Save EXIF and other image information using an AWS SDK](#)
- [Use API Gateway to invoke a Lambda function](#)
- [Use Step Functions to invoke Lambda functions](#)
- [Use scheduled events to invoke a Lambda function](#)

Build an application to submit data to a DynamoDB table

The following code examples show how to build an application that submits data to an Amazon DynamoDB table and notifies you when a user updates the table.

Java

SDK for Java 2.x

Shows how to create a dynamic web application that submits data using the Amazon DynamoDB Java API and sends a text message using the Amazon Simple Notification Service Java API.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

This example shows how to build an app that enables users to submit data to an Amazon DynamoDB table, and send a text message to the administrator using Amazon Simple Notification Service (Amazon SNS).

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- DynamoDB
- Amazon SNS

Kotlin

SDK for Kotlin

Shows how to create a native Android application that submits data using the Amazon DynamoDB Kotlin API and sends a text message using the Amazon SNS Kotlin API.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create an API Gateway REST API to track COVID-19 data

The following code example shows how to create a REST API that simulates a system to track daily cases of COVID-19 in the United States, using fictional data.

Python

SDK for Python (Boto3)

Shows how to use AWS Chalice with the AWS SDK for Python (Boto3) to create a serverless REST API that uses Amazon API Gateway, AWS Lambda, and Amazon DynamoDB. The REST API simulates a system that tracks daily cases of COVID-19 in the United States, using fictional data. Learn how to:

- Use AWS Chalice to define routes in Lambda functions that are called to handle REST requests that come through API Gateway.
- Use Lambda functions to retrieve and store data in a DynamoDB table to serve REST requests.
- Define table structure and security role resources in an AWS CloudFormation template.
- Use AWS Chalice and CloudFormation to package and deploy all necessary resources.
- Use CloudFormation to clean up all created resources.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- AWS CloudFormation
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a messenger application with Step Functions

The following code example shows how to create an AWS Step Functions messenger application that retrieves message records from a database table.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with AWS Step Functions to create a messenger application that retrieves message records from an Amazon DynamoDB table and sends them with Amazon Simple Queue Service (Amazon SQS). The state machine integrates with an AWS Lambda function to scan the database for unsent messages.

- Create a state machine that retrieves and updates message records from an Amazon DynamoDB table.
- Update the state machine definition to also send messages to Amazon Simple Queue Service (Amazon SQS).
- Start and stop state machine runs.
- Connect to Lambda, DynamoDB, and Amazon SQS from a state machine by using service integrations.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SQS
- Step Functions

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a photo asset management application that lets users manage photos using labels

The following code examples show how to create a serverless application that lets users manage photos using labels.

.NET

AWS SDK for .NET

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

C++

SDK for C++

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Java

SDK for Java 2.x

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Kotlin

SDK for Kotlin

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

PHP

SDK for PHP

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

Rust

SDK for Rust

Shows how to develop a photo asset management application that detects labels in images using Amazon Rekognition and stores them for later retrieval.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

For a deep dive into the origin of this example see the post on [AWS Community](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon Rekognition
- Amazon S3
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a web application to track DynamoDB data

The following code examples show how to create a web application that tracks work items in an Amazon DynamoDB table and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

AWS SDK for .NET

Shows how to use the Amazon DynamoDB .NET API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SES

Java

SDK for Java 2.x

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to use the Amazon DynamoDB API to create a dynamic web application that tracks DynamoDB work data.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) to create a REST service that tracks work items in Amazon DynamoDB and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with AWS services.
- Read, write, and update work items that are stored in a DynamoDB table.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example in the [AWS Code Examples Repository](#) on GitHub.

Services used in this example

- DynamoDB

- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Create a websocket chat application with API Gateway

The following code example shows how to create a chat application that is served by a websocket API built on Amazon API Gateway.

Python

SDK for Python (Boto3)

Shows how to use the AWS SDK for Python (Boto3) with Amazon API Gateway V2 to create a websocket API that integrates with AWS Lambda and Amazon DynamoDB.

- Create a websocket API served by API Gateway.
- Define a Lambda handler that stores connections in DynamoDB and posts messages to other chat participants.
- Connect to the websocket chat application and send messages with the Websockets package.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Detect PPE in images with Amazon Rekognition using an AWS SDK

The following code examples show how to build an app that uses Amazon Rekognition to detect Personal Protective Equipment (PPE) in images.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function that detects images with Personal Protective Equipment.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use Amazon Rekognition with the AWS SDK for JavaScript to create an application to detect personal protective equipment (PPE) in images located in an Amazon Simple Storage Service (Amazon S3) bucket. The app saves the results to an Amazon DynamoDB table, and sends the admin an email notification with the results using Amazon Simple Email Service (Amazon SES).

Learn how to:

- Create an unauthenticated user using Amazon Cognito.
- Analyze images for PPE using Amazon Rekognition.
- Verify an email address for Amazon SES.
- Update a DynamoDB table with results.

- Send an email notification using Amazon SES.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3
- Amazon SES

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Invoke a Lambda function from a browser

The following code example shows how to invoke an AWS Lambda function from a browser.

JavaScript

SDK for JavaScript (v2)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda

SDK for JavaScript (v3)

You can create a browser-based application that uses an AWS Lambda function to update an Amazon DynamoDB table with user selections. This app uses AWS SDK for JavaScript v3.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Save EXIF and other image information using an AWS SDK

The following code example shows how to:

- Get EXIF information from a a JPG, JPEG, or PNG file.
- Upload the image file to an Amazon S3 bucket.
- Use Amazon Rekognition to identify the three top attributes (*labels*) in the file.
- Add the EXIF and label information to an Amazon DynamoDB table in the Region.

Rust

SDK for Rust

Get EXIF information from a JPG, JPEG, or PNG file, upload the image file to an Amazon S3 bucket, use Amazon Rekognition to identify the three top attributes (*labels* in Amazon Rekognition) in the file, and add the EXIF and label information to a Amazon DynamoDB table in the Region.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Amazon Rekognition
- Amazon S3

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use API Gateway to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by Amazon API Gateway.

Java

SDK for Java 2.x

Shows how to create an AWS Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an AWS Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create a Lambda function invoked by Amazon API Gateway that scans an Amazon DynamoDB table for work anniversaries and uses Amazon Simple Notification

Service (Amazon SNS) to send a text message to your employees that congratulates them at their one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- API Gateway
- DynamoDB
- Lambda
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use Step Functions to invoke Lambda functions

The following code examples show how to create an AWS Step Functions state machine that invokes AWS Lambda functions in sequence.

Java

SDK for Java 2.x

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for Java 2.x. Each workflow step is implemented using an AWS Lambda function.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

JavaScript

SDK for JavaScript (v3)

Shows how to create an AWS serverless workflow by using AWS Step Functions and the AWS SDK for JavaScript. Each workflow step is implemented using an AWS Lambda function.

Lambda is a compute service that enables you to run code without provisioning or managing servers. Step Functions is a serverless orchestration service that lets you combine Lambda functions and other AWS services to build business-critical applications.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- DynamoDB
- Lambda
- Amazon SES
- Step Functions

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Use scheduled events to invoke a Lambda function

The following code examples show how to create an AWS Lambda function invoked by an Amazon EventBridge scheduled event.

Java

SDK for Java 2.x

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda Java runtime API. This example invokes different AWS services to perform a specific use case.

This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

Services used in this example

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

JavaScript

SDK for JavaScript (v3)

Shows how to create an Amazon EventBridge scheduled event that invokes an AWS Lambda function. Configure EventBridge to use a cron expression to schedule when the Lambda function is invoked. In this example, you create a Lambda function by using the Lambda JavaScript runtime API. This example invokes different AWS services to perform a specific use case. This example demonstrates how to create an app that sends a mobile text message to your employees that congratulates them at the one year anniversary date.

For complete source code and instructions on how to set up and run, see the full example on [GitHub](#).

This example is also available in the [AWS SDK for JavaScript v3 developer guide](#).

Services used in this example

- DynamoDB
- EventBridge
- Lambda
- Amazon SNS

For a complete list of AWS SDK developer guides and code examples, see [Using DynamoDB with an AWS SDK](#). This topic also includes information about getting started and details about previous SDK versions.

Security and compliance in Amazon DynamoDB

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The [shared responsibility model](#) describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. The effectiveness of our security is regularly tested and verified by third-party auditors as part of the [AWS compliance programs](#). To learn about the compliance programs that apply to DynamoDB, see [AWS Services in Scope by Compliance Program](#).
- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation will help you understand how to apply the shared responsibility model when using DynamoDB. The following topics show you how to configure DynamoDB to meet your security and compliance objectives. You'll also learn how to use other AWS services that can help you to monitor and secure your DynamoDB resources.

- [Security best practices for Amazon DynamoDB](#)

AWS managed policies for Amazon DynamoDB

DynamoDB uses AWS managed policies to define a set of permissions the service needs to perform specific actions. DynamoDB maintains and updates its AWS managed policies. You can't change the permissions in AWS managed policies. For more information about AWS managed policies, see [AWS managed policies](#) in the IAM User Guide.

DynamoDB may occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. An AWS managed policy is most likely to be updated when a new feature is launched or when new operations become available. DynamoDB will not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

AWS managed policy: `DynamoDBReplicationServiceRolePolicy`

You can't attach the `DynamoDBReplicationServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows DynamoDB to perform actions on your behalf. For more information, see [Using IAM with global tables](#).

This policy grants permissions that allow the service-linked role to perform data replication between global table replicas. It also grants administrative permissions to manage global table replicas on your behalf.

Permissions details

This policy grants permissions to do the following:

- `dynamodb` – Perform data replication and manage table replicas.
- `application-autoscaling` – Retrieve and manage table AutoScaling settings
- `account` – Retrieve region status for evaluating replica accessibility.
- `iam` – To create the service-linked role for application AutoScaling in the event that the service-linked role does not already exist.

The definition of this managed policy can be found [here](#).

AWS managed policy: `AmazonDynamoDBReadOnlyAccess`

You can attach the `AmazonDynamoDBReadOnlyAccess` policy to your IAM identities.

This policy grants read-only access to Amazon DynamoDB.

Permissions details

This policy includes the following permissions:

- Amazon DynamoDB – Provides read-only access to Amazon DynamoDB.
- Amazon DynamoDB Accelerator (DAX) – Provides read-only access to Amazon DynamoDB Accelerator (DAX).
- Application Auto Scaling – Allows principals to view configurations from Application Auto Scaling. This is required so that users can view automatic scaling policies that are attached to a table.
- CloudWatch – Allows principals to view metric data and alarms configured in CloudWatch. This is required so users can view the billable table size and CloudWatch alarms that have been configured for a table.
- AWS Data Pipeline – Allows principals to view AWS Data Pipeline and associated objects.
- Amazon EC2 – Allows principals to view Amazon EC2 VPCs, subnets, and security groups.
- IAM – Allows principals to view IAM roles.
- AWS KMS – Allows principals to view keys configured in AWS KMS. This is required so users can view AWS KMS keys that they create and manage in their account.
- Amazon SNS – Allows principals to list Amazon SNS topics and and subscriptions by topic.
- AWS Resource Groups – Allows principals to view resource groups and their queries.
- AWS Resource Groups Tagging – Allows principals to list all the tagged or previously tagged resources in a Region.
- Kinesis – Allows principals to view Kinesis data streams descriptions.
- Amazon CloudWatch Contributor Insights – Allow principals to view time series data collected by Contributor Insights rules.

To review the policy in JSON format, see [AmazonDynamoDBReadOnlyAccess](#).

DynamoDB updates to AWS managed policies

This table shows updates to the AWS access management policies for DynamoDB.

Change	Description	Date Changed
AmazonDynamoDBReadOnlyAccess update to an existing policy	AmazonDynamoDBReadOnlyAccess added the permission dynamodb:GetResourcePolicy . This permission provides access to read resource-based policies attached to DynamoDB resources.	March 20, 2024
DynamoDBReplicationServiceRolePolicy update to an existing policy	DynamoDBReplicationServiceRolePolicy added the permission dynamodb:GetResourcePolicy . This permission allows the service-linked role to read resource-based policies attached to DynamoDB resources.	December 15, 2023
DynamoDBReplicationServiceRolePolicy update to an existing policy	DynamoDBReplicationServiceRolePolicy added the permission account:ListRegions . This permission allows the service-linked role to evaluate replica accessibility	May 10, 2023
DynamoDBReplicationServiceRolePolicy added to list of managed policies	Added information about the managed policy DynamoDBReplicationServiceRolePolicy , which is used by the DynamoDB global tables service-linked role.	May 10, 2023
DynamoDB global tables started tracking changes	DynamoDB global tables started tracking changes for its AWS managed policies.	May 10, 2023

Using resource-based policies for DynamoDB

DynamoDB supports resource-based policies for tables, indexes, and streams. Resource-based policies let you define access permissions by specifying who has access to each resource, and the actions they are allowed to perform on each resource.

You can attach a resource-based policy to DynamoDB resources, such as a table or a stream. In this policy, you specify permissions for Identity and Access Management (IAM) [principals](#) that can perform specific actions on these DynamoDB resources. For example, the policy attached to a table will contain permissions for access to the table and its indexes. As a result, resource-based policies can help you simplify access control for your DynamoDB tables, indexes, and streams, by defining permissions at the resource level. The maximum size of a policy you can attach to a DynamoDB resource is 20 KB.

A significant benefit of using resource-based policies is to simplify cross-account access control for providing cross-account access to IAM principals in different AWS accounts. For more information, see [Resource-based policy for cross-account access](#).

Resource-based policies also support integrations with [IAM Access Analyzer](#) external access analyzer and [Block Public Access \(BPA\)](#) capabilities. IAM Access Analyzer reports cross-account access to external entities specified in resource-based policies. It also provides visibility to help you refine permissions and conform to the least privilege principle. BPA helps you prevent public access to your DynamoDB tables, indexes, and streams, and is automatically enabled in the resource-based policies creation and modification workflows.

Create a table with a resource-based policy

You can add a resource-based policy while you create a table by using the DynamoDB console, [CreateTable](#) API, AWS CLI, [AWS SDK](#), or an AWS CloudFormation template.

AWS CLI

The following example creates a table named *MusicCollection* using the `create-table` AWS CLI command. This command also includes the `resource-policy` parameter that adds a resource-based policy to the table. This policy allows the user *John* to perform the [RestoreTableToPointInTime](#), [GetItem](#), and [PutItem](#) API actions on the table.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --resource-policy \
    "{"
        \\"Version\\": \\"2012-10-17\",
        \\"Statement\\": [
            {
                \\"Effect\\": \\"Allow\",
                \\"Principal\\": {
                    \\"AWS\\": \\"arn:aws:iam::123456789012:user/John\"
                },
                \\"Action\\": [
                    \\"dynamodb:RestoreTableToPointInTime\",
                    \\"dynamodb:GetItem\",
                    \\"dynamodb:DescribeTable\"
                ],
                \\"Resource\\": \\"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
            }
        ]
    }"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. On the dashboard, choose **Create table**.
3. In **Table details**, enter the table name, partition key, and sort key details.
4. In **Table settings**, choose **Customize settings**.
5. (Optional) Specify your options for **Table class**, **Capacity calculator**, **Read/write capacity settings**, **Secondary indexes**, **Encryption at rest**, and **Deletion protection**.
6. In **Resource-based policy**, add a policy to define the access permissions for the table and its indexes. In this policy, you specify who has access to these resources, and the actions they are allowed to perform on each resource. To add a policy, do one of the following:
 - Type or paste a JSON policy document. For details about the IAM policy language, see [Creating policies using the JSON editor](#) in the *IAM User Guide*.

 **Tip**

To see examples of resource-based policies in the Amazon DynamoDB Developer Guide, choose **Policy examples**.

- Choose **Add new statement** to add a new statement and enter the information in the provided fields. Repeat this step for as many statements as you would like to add.

 **Important**

Make sure that you resolve any security warnings, errors, or suggestions before you save your policy.

The following IAM policy example allows the user *John* to perform the [RestoreTableToPointInTime](#), [GetItem](#), and [PutItem](#) API actions on the table *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/John"
        },
        "Action": [
            "dynamodb:RestoreTableToPointInTime",
            "dynamodb:GetItem",
            "dynamodb:PutItem"
        ],
        "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection"
    }
]
}
```

7. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to [create an account analyzer](#) in IAM Access Analyzer. For more information, see [Preview access](#).
8. Choose **Create table**.

AWS CloudFormation template

Using the AWS::DynamoDB::Table resource

The following CloudFormation template creates a table with a stream using the [AWS::DynamoDB::Table](#) resource. This template also includes resource-based policies that are attached to both the table and the stream.

```
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "MusicCollectionTable": {
            "Type": "AWS::DynamoDB::Table",
            "Properties": {
                "AttributeDefinitions": [
                    {
                        "AttributeName": "Artist",
                        "AttributeType": "S"
                    }
                ],
                "KeySchema": [
                    {
                        "AttributeName": "Artist",
                        "KeyType": "HASH"
                    }
                ],
                "ProvisionedThroughput": {
                    "ReadCapacityUnits": 5,
                    "WriteCapacityUnits": 5
                }
            }
        }
    }
}
```

```
        }
    ],
    "KeySchema": [
        {
            "AttributeName": "Artist",
            "KeyType": "HASH"
        }
    ],
    "BillingMode": "PROVISIONED",
    "ProvisionedThroughput": {
        "ReadCapacityUnits": 5,
        "WriteCapacityUnits": 5
    },
    "StreamSpecification": {
        "StreamViewType": "OLD_IMAGE",
        "ResourcePolicy": {
            "PolicyDocument": {
                "Version": "2012-10-17",
                "Statement": [
                    {
                        "Principal": {
                            "AWS": "arn:aws:iam::111122223333:user/John"
                        },
                        "Effect": "Allow",
                        "Action": [
                            "dynamodb:GetRecords",
                            "dynamodb:GetShardIterator",
                            "dynamodb:DescribeStream"
                        ],
                        "Resource": "*"
                    }
                ]
            }
        }
    },
    "TableName": "MusicCollection",
    "ResourcePolicy": {
        "PolicyDocument": {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Principal": {
                        "AWS": [
                            "arn:aws:iam::111122223333:user/John"
                        ]
                    }
                }
            ]
        }
    }
},
```

```
        ]
    },
    "Effect": "Allow",
    "Action": "dynamodb:GetItem",
    "Resource": "*"
}
]
}
}
}
}
}
```

Using the AWS::DynamoDB::GlobalTable resource

The following CloudFormation template creates a table with the [AWS::DynamoDB::GlobalTable](#) resource and attaches a resource-based policy to the table and its stream.

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "GlobalMusicCollection": {
      "Type": "AWS::DynamoDB::GlobalTable",
      "Properties": {
        "TableName": "MusicCollection",
        "AttributeDefinitions": [
          {
            "AttributeName": "Artist",
            "AttributeType": "S"
          }
        ],
        "KeySchema": [
          {
            "AttributeName": "Artist",
            "KeyType": "HASH"
          }
        ],
        "BillingMode": "PAY_PER_REQUEST",
        "StreamSpecification": {
          "StreamViewType": "NEW_AND_OLD_IMAGES"
        },
        "Replicas": [
          {
            "Region": "us-east-1",
            "ResourcePolicy": {

```

```
        "PolicyDocument": {
            "Version": "2012-10-17",
            "Statement": [
                {
                    "Principal": {
                        "AWS": [
                            "arn:aws:iam::111122223333:user/John"
                        ]
                    },
                    "Effect": "Allow",
                    "Action": "dynamodb:GetItem",
                    "Resource": "*"
                }
            ],
            "ReplicaStreamSpecification": {
                "ResourcePolicy": {
                    "PolicyDocument": {
                        "Version": "2012-10-17",
                        "Statement": [
                            {
                                "Principal": {
                                    "AWS": [
                                        "arn:aws:iam::111122223333:user/John"
                                    ],
                                    "Effect": "Allow",
                                    "Action": [
                                        "dynamodb:GetRecords",
                                        "dynamodb:GetShardIterator",
                                        "dynamodb:DescribeStream"
                                    ],
                                    "Resource": "*"
                                }
                            }
                        ]
                    }
                }
            }
        }
    }
}
```

Attach a policy to an existing table

You can attach a resource-based policy to an existing table or modify an existing policy by using the DynamoDB console, [PutResourcePolicy](#) API, the AWS CLI, AWS SDK, or an [AWS CloudFormation template](#).

AWS CLI example to attach a new policy

The following IAM policy example uses the `put-resource-policy` AWS CLI command to attach a resource-based policy to an existing table. This example allows the user *John* to perform the [GetItem](#), [PutItem](#), [UpdateItem](#), and [UpdateTable](#) API actions on an existing table named *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb put-resource-policy \
--resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
--policy \
"{
    \"Version\": \"2012-10-17\",
    \"Statement\": [
        {
            \"Effect\": \"Allow\",
            \"Principal\": {
                \"AWS\": \"arn:aws:iam::111122223333:user/John\"
            },
            \"Action\": [
                \"dynamodb:GetItem\",
                \"dynamodb:PutItem\",
                \"dynamodb:UpdateItem\",
                \"dynamodb:UpdateTable\"
            ],
            \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
        }
    ]
}"
```

AWS CLI example to conditionally update an existing policy

To conditionally update an existing resource-based policy of a table, you can use the optional `expected-revision-id` parameter. The following example will only update the policy if it

exists in DynamoDB and its current revision ID matches the provided `expected-revision-id` parameter.

```
aws dynamodb put-resource-policy \
--resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
--expected-revision-id 1709841168699 \
--policy \
{
    \"Version\": \"2012-10-17\",
    \"Statement\": [
        {
            \"Effect\": \"Allow\",
            \"Principal\": {
                \"AWS\": \"arn:aws:iam::111122223333:user/John\"
            },
            \"Action\": [
                \"dynamodb:GetItem\",
                \"dynamodb:UpdateItem\",
                \"dynamodb:UpdateTable\"
            ],
            \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection\"
        }
    ]
}"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. From the dashboard, choose an existing table.
3. Navigate to the **Permissions** tab, and choose **Create table policy**.
4. In the resource-based policy editor, add the policy you would like to attach and choose **Create policy**.

The following IAM policy example allows the user *John* to perform the [GetItem](#), [PutItem](#), [UpdateItem](#), and [UpdateTable](#) API actions on an existing table named *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

{

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:user/John"
        },
        "Action": [
            "dynamodb:GetItem",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:UpdateTable"
        ],
        "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
    }
]
```

AWS SDK for Java 2.x

The following IAM policy example uses the `putResourcePolicy` method to attach a resource-based policy to an existing table. This policy allows a user to perform the [GetItem](#) API action on an existing table.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.model.PutResourcePolicyRequest;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * Get started with the AWS SDK for Java 2.x
 */
public class PutResourcePolicy {

    public static void main(String[] args) {
        final String usage = """
```

```
Usage:  
    <tableArn> <allowedAWSPrincipal>  
  
Where:  
    tableArn - The Amazon DynamoDB table ARN to attach the policy to.  
For example, arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection.  
    allowedAWSPrincipal - Allowed AWS principal ARN that the example  
policy will give access to. For example, arn:aws:iam::123456789012:user/John.  
    """;  
  
if (args.length != 2) {

Attach a resource-based policy to a stream

You can attach a resource-based policy to an existing table's stream or modify an existing policy by using the DynamoDB console, [PutResourcePolicy](#) API, the AWS CLI, AWS SDK, or an [AWS CloudFormation template](#).

 **Note**

You can't attach a policy to a stream while creating it using the [CreateTable](#) or [UpdateTable](#) APIs. However, you can modify or delete a policy after a table is deleted. You can also modify or delete the policy of a disabled stream.

AWS CLI

The following IAM policy example uses the `put-resource-policy` AWS CLI command to attach a resource-based policy to the stream of a table named *MusicCollection*. This example allows the user *John* to perform the [GetRecords](#), [GetShardIterator](#), and [DescribeStream](#) API actions on the stream.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb put-resource-policy \
--resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/
stream/2024-02-12T18:57:26.492 \
--policy \
"{
    \"Version\": \"2012-10-17\",
    \"Statement\": [
        {
            \"Effect\": \"Allow\",
            \"Principal\": {
                \"AWS\": \"arn:aws:iam::111122223333:user/John\"
            },
            \"Action\": [
                \"dynamodb:GetRecords\",
                \"dynamodb:GetShardIterator\",
                \"dynamodb:DescribeStream\"
            ],
            \"Resource\": \"arn:aws:dynamodb:us-
west-2:123456789012:table/MusicCollection/stream/2024-02-12T18:57:26.492\"
        }
    ]
}"
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. On the DynamoDB console dashboard, choose **Tables** and then select an existing table.

Make sure the table you select has streams turned on. For information about turning on streams for a table, see [Enabling a stream](#).

3. Choose the **Permissions** tab.
4. In **Resource-based policy for active stream**, choose **Create stream policy**.
5. In the **Resource-based policy** editor, add a policy to define the access permissions for the stream. In this policy, you specify who has access to the stream and the actions they are allowed to perform on the stream. To add a policy, do one of the following:

- Type or paste a JSON policy document. For details about the IAM policy language, see [Creating policies using the JSON editor](#) in the *IAM User Guide*.

 **Tip**

To see examples of resource-based policies in the Amazon DynamoDB Developer Guide, choose **Policy examples**.

- Choose **Add new statement** to add a new statement and enter the information in the provided fields. Repeat this step for as many statements as you would like to add.

 **Important**

Make sure that you resolve any security warnings, errors, or suggestions before you save your policy.

6. (Optional) Choose **Preview external access** in the lower-right corner to preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to [create an account analyzer](#) in IAM Access Analyzer. For more information, see [Preview access](#).
7. Choose **Create policy**.

The following IAM policy example attaches a resource-based policy to the stream of a table named *MusicCollection*. This example allows the user *John* to perform the [GetRecords](#), [GetShardIterator](#), and [DescribeStream](#) API actions on the stream.

Remember to replace the *italicized* text with your resource-specific information.

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "arn:aws:iam::111122223333:user/John"  
      },  
      "Action": [  
        "kinesis:DescribeStream",  
        "kinesis:GetRecords",  
        "kinesis:GetShardIterator"  
      ]  
    }  
  ]  
}
```

```
        "dynamodb:GetRecords",
        "dynamodb:GetShardIterator",
        "dynamodb:DescribeStream"
    ],
    "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/
stream/2024-02-12T18:57:26.492"
    ]
}
]
```

Remove a resource-based policy from a table

You can delete a resource-based policy from an existing table by using the DynamoDB console, [DeleteResourcePolicy](#) API, the AWS CLI, AWS SDK, or an AWS CloudFormation template.

AWS CLI

The following example uses the `delete-resource-policy` AWS CLI command to remove a resource-based policy from a table named *MusicCollection*.

Remember to replace the *italicized* text with your resource-specific information.

```
aws dynamodb delete-resource-policy \
--resource-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection
```

AWS Management Console

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. On the DynamoDB console dashboard, choose **Tables** and then select an existing table.
3. Choose **Permissions**.
4. From the **Manage policy** dropdown, choose **Delete policy**.
5. In the **Delete resource-based policy for table** dialog box, type **confirm** to confirm the delete action.
6. Choose **Delete**.

Cross-account access with resource-based policies

Using a resource-based policy, you can provide cross-account access to resources available in different AWS accounts. All cross-account access allowed by the resource-based policies will be reported through IAM Access Analyzer external access findings if you have an analyzer in the same AWS Region as the resource. IAM Access Analyzer runs policy checks to validate your policy against IAM [policy grammar](#) and [best practices](#). These checks generate findings and provide actionable recommendations to help you author policies that are functional and conform to security best practices. You can view the active findings from IAM Access Analyzer in the **Permissions** tab of the [DynamoDB console](#).

For information about validating policies by using IAM Access Analyzer, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*. To view a list of the warnings, errors, and suggestions that are returned by IAM Access Analyzer, see [IAM Access Analyzer policy check reference](#).

To grant [GetItem](#) permission to a user A in account A for accessing a table B in account B, perform the following steps:

1. Attach a resource-based policy to table B that grants permission to user A for performing the [GetItem](#) action.
2. Attach an identity-based policy to user A that grants it permission to perform the [GetItem](#) action on table B.

Using the **Preview external access** option available in [DynamoDB console](#), you can preview how your new policy affects public and cross-account access to your resource. Before you save your policy, you can check whether it introduces new IAM Access Analyzer findings or resolves existing findings. If you don't see an active analyzer, choose **Go to Access Analyzer** to [create an account analyzer](#) in IAM Access Analyzer. For more information, see [Preview access](#).

The table name parameter in the DynamoDB data plane and control plane APIs accept complete Amazon Resource Name (ARN) of the table to support cross-account operations. If you only provide the table name parameter instead of a complete ARN, the API operation will be performed on the table in the account to which the requestor belongs. For an example of a policy that uses cross-account access, see [Resource-based policy for cross-account access](#).

The resource owner's account will be charged even when a principal from another account is reading from or writing to the DynamoDB table in the owner's account. If the table has provisioned throughput, the sum of all the requests from the owner accounts and the requestors in other

accounts will determine if the request will be throttled (if autoscaling is disabled) or scaled up/down if autoscaling is enabled.

The requests will be logged in the CloudTrail logs of both the owner and the requestor accounts so that each of the two accounts can track which account accessed what data.

 **Note**

The cross-account access of [control plane APIs](#) has a lower transactions per second (TPS) limit of 500 requests.

Blocking public access with resource-based policies

[Block Public Access \(BPA\)](#) is a feature that identifies and prevents the attaching of resource-based policies that grant public access to your DynamoDB tables, indexes, or streams across your [Amazon Web Services \(AWS\)](#) accounts. With BPA, you can prevent public access to your DynamoDB resources. BPA performs checks during the creation or modification of a resource-based policy and helps improve your security posture with DynamoDB.

BPA uses [automated reasoning](#) to analyze the access granted by your resource-based policy and alerts you if such permissions are found at the time of administering a resource-based policy. The analysis verifies access across all resource-based policy statements, actions, and the set of condition keys used in your policies.

 **Important**

BPA helps protect your resources by preventing public access from being granted through the resource-based policies that are directly attached to your DynamoDB resources, such as tables, indexes, and streams. In addition to using BPA, carefully inspect the following policies to confirm that they do not grant public access:

- Identity-based policies attached to associated AWS principals (for example, IAM roles)
- Resource-based policies attached to associated AWS resources (for example, AWS Key Management Service (KMS) keys)

You must ensure that the [principal](#) doesn't include a * entry or that one of the specified condition keys restrict access from principals to the resource. If the resource-based policy grants public access

to your table, indexes, or stream across AWS accounts, DynamoDB will block you from creating or modifying the policy until the specification within the policy is corrected and deemed non-public.

You can make a policy non-public by specifying one or more principals inside the Principal block. The following resource-based policy example blocks public access by specifying two principals.

```
{  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": [  
            "123456789012",  
            "111122223333"  
        ]  
    },  
    "Action": "dynamodb:*",  
    "Resource": "*"  
}
```

Policies that restrict access by specifying certain condition keys are also not considered public. Along with evaluation of the principal specified in the resource-based policy, the following [trusted condition keys](#) are used to complete the evaluation of a resource-based policy for non-public access:

- aws:PrincipalAccount
- aws:PrincipalArn
- aws:PrincipalOrgID
- aws:PrincipalOrgPaths
- aws:SourceAccount
- aws:SourceArn
- aws:SourceVpc
- aws:SourceVpce
- aws:UserId
- aws:PrincipalServiceName
- aws:PrincipalServiceNamesList
- aws:PrincipalIsAWSService
- aws:Ec2InstanceState
- aws:Ec2InstanceState

- aws:SourceOrgID
- aws:SourceOrgPaths

Additionally, for a resource-based policy to be non-public, the values for Amazon Resource Name (ARN) and string keys must not contain wildcards or variables. If your resource-based policy uses the aws:PrincipalIsAWSService key, you must make sure that you've set the key value to true.

The following policy limits access to the user John in the specified account. The condition makes the Principal constrained and not be considered as public.

```
{  
    "Effect": "Allow",  
    "Principal": {  
        "AWS": "*"  
    },  
    "Action": "dynamodb:*",  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:PrincipalArn": "arn:aws:iam::123456789012:user/John"  
        }  
    }  
}
```

The following example of a non-public resource-based policy constrains sourceVPC using the StringEquals operator.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "*"  
            },  
            "Action": "dynamodb:*",  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",  
            "Condition": {  
                "StringEquals": {  
                    "aws:SourceVpc": [  
                        "vpc-91237329"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

```
        ]
    }
}
]
}
```

IAM actions supported by resource-based policies

IAM actions and cross-account support through resource-based policies is restricted to a certain set of DynamoDB APIs. You can't attach resource-based policies to resource types, such as backups and imports. Also, APIs that operate on these resource types are excluded from the supported IAM actions in resource-based policies. Because table administrators configure internal table settings within the same account, APIs, such as [UpdateTimeToLive](#) and [DisableKinesisStreamingDestination](#), don't support cross-account access through resource-based policies.

The DynamoDB data plane and control plane APIs that support cross-account access also support table name overloading, which lets you specify the table ARN instead of the table name. You can specify table ARN in the `TableName` parameter of these APIs. However, not all of these APIs support cross-account access.

The following table lists the API-level support for resource-based policies and cross-account access.

API action	Resource-based policy support	Cross-account support
Data Plane - Tables/indexes		
DeleteItem	Yes	Yes
GetItem	Yes	Yes
PutItem	Yes	Yes

The following table lists the API-level support of DynamoDB Streams APIs for resource-based policies and cross-account access.

API action	Resource-based policy support	Cross-account support
DescribeStream	Yes	Yes
GetRecords	Yes	Yes
GetShardIterator	Yes	Yes
ListStreams	No	No

Authorization with IAM identity-based policies and DynamoDB resource-based policies

Identity-based policies are attached to an identity, such as IAM users, groups of users, and roles. These are IAM policy documents that control what actions an identity can perform, on which resources, and under what conditions. Identity-based policies can be [managed](#) or [inline](#) policies.

Resource-based policies are IAM policy documents that you attach to a resource, such as a DynamoDB table. These policies grant the specified principal permission to perform specific actions on that resource and defines under what conditions this applies. For example, the resource-based policy for a DynamoDB table also includes the index associated with the table. Resource-based policies are inline policies. There are no managed resource-based policies.

For more information about these policies, see [Identity-based policies and resource-based policies](#) in the *IAM User Guide*.

If the IAM principal is from the same account as the resource owner, a resource-based policy is sufficient to specify access permissions to the resource. You can still choose to have an IAM identity-based policy along with a resource-based policy. For cross-account access, you must explicitly allow access in both the identity and resource policies as specified in [Cross-account access with resource-based policies](#). When you use both types of policies, a policy is evaluated as described in [Determining whether a request is allowed or denied within an account](#).

Resource-based policy examples

When you specify an ARN in the Resource field of a resource-based policy, the policy takes effect only if the specified ARN matches the ARN of the DynamoDB resource to which it is attached.

 **Note**

Remember to replace the *italicized* text with your resource-specific information.

Resource-based policy for a table

The following resource-based policy attached to a DynamoDB table named *MusicCollection*, gives the IAM users *John* and *Jane* permission to perform [GetItem](#) and [BatchGetItem](#) actions on the *MusicCollection* resource.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "1111",  
            "Effect": "Allow",  
            "Action": "DynamoDB:PutItem",  
            "Resource": "arn:aws:dynamodb:Region:Account:table/MusicCollection/Primary Key Value"  
        }  
    ]  
}
```

```
    "Principal": {
        "AWS": [
            "arn:aws:iam::111122223333:user/John",
            "arn:aws:iam::111122223333:user/Jane"
        ]
    },
    "Action": [
        "dynamodb:GetItem",
        "dynamodb:BatchGetItem"
    ],
    "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
    ]
}
]
}
```

Resource-based policy for a stream

The following resource-based policy attached to a DynamoDB stream named 2024-02-12T18:57:26.492 gives the IAM users *John* and *Jane* permission to perform [GetRecords](#), [GetShardIterator](#), and [DescribeStream](#) API actions on the 2024-02-12T18:57:26.492 resource.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "1111",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "arn:aws:iam::111122223333:user/John",
                    "arn:aws:iam::111122223333:user/Jane"
                ]
            },
            "Action": [
                "dynamodb:DescribeStream",
                "dynamodb:GetRecords",
                "dynamodb:GetShardIterator"
            ],
        }
    ]
}
```

```
"Resource": [
    "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/
    stream/2024-02-12T18:57:26.492"
]
}
]
```

Resource-based policy for access to perform all actions on specified resources

To allow a user to perform all actions on a table and all associated indexes with a table, you can use a wildcard (*) to represent the actions and the resources associated with the table. Using a wild card character for the resources, will allow the user access to the DynamoDB table and all its associated indexes, including the ones that haven't yet been created. For example, the following policy will give the user **John** permission to perform any actions on the **MusicCollection** table and all of its indexes, including any indexes that will be created in the future.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "1111",
            "Effect": "Allow",
            "Principal": "arn:aws:iam::111122223333:user/John",
            "Action": "dynamodb:*",
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/index/*"
            ]
        }
    ]
}
```

Resource-based policy for cross-account access

You can specify permissions for a cross-account IAM identity to access DynamoDB resources. For example, you might need a user from a trusted account to get access to read the contents of your table, with the condition that they access only specific items and specific attributes in those items.

The following policy allows access to user *John* from a trusted AWS account ID **111111111111** to access data from a table in account **123456789012** by using the [GetItem](#) API. The policy ensures that the user can access only items with a primary key *Jane* and that the user can only retrieve the attributes *Artist* and *SongTitle*, but no other attributes.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CrossAccountTablePolicy",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::111111111111:user/John"  
            },  
            "Action": "dynamodb:GetItem",  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:LeadingKeys": "Jane",  
                    "dynamodb:Attributes": [  
                        "Artist",  
                        "SongTitle"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

In addition to the preceding resource-based policy, the identity-based policy attached to the user *John* also needs to allow the GetItem API action for the cross-account access to work. The following is an example of an identity-based policy that you must attach to the user *John*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "CrossAccountIdentityBasedPolicy",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:BatchWriteItem",  
                "dynamodb:ListTables",  
                "dynamodb:DescribeTable",  
                "dynamodb:UpdateTable",  
                "dynamodb:CreateTable",  
                "dynamodb:DeleteTable"  
            ]  
        }  
    ]  
}
```

```
        "dynamodb:GetItem"
    ],
    "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection"
    ],
    "Condition": {
        "ForAllValues:StringEquals": {
            "dynamodb:LeadingKeys": "Jane",
            "dynamodb:Attributes": [
                "Artist",
                "SongTitle"
            ]
        }
    }
}
]
```

The user John can make a GetItem request by specifying the table ARN in the table-name parameter for accessing the table *MusicCollection* in the account **123456789012**.

```
aws dynamodb get-item \
--table-name arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
--key '{"Artist": {"S": "Jane"}, "SongTitle": "Monsoon"}' \
--return-consumed-capacity TOTAL
```

Resource-based policy with IP address conditions

You can apply a condition to restrict source IP addresses, virtual private clouds (VPCs), and VPC endpoint (VPCE). You can specify permissions based on the source addresses of the originating request. For example, you might want to allow a user to access DynamoDB resources only if they are being accessed from a specific IP source, such as a corporate VPN endpoint. Specify these IP addresses in the Condition statement.

The following example allows the user *John* access to any DynamoDB resource when the source IPs are 54.240.143.0/24 and 2001:DB8:1234:5678::/64.

```
{
    "Id": "PolicyId2",
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Sid": "AllowIPmix",  
    "Effect": "Allow",  
    "Principal": "arn:aws:iam::111111111111:user/John",  
    "Action": "dynamodb:*",  
    "Resource": "*",  
    "Condition": {  
        "IpAddress": {  
            "aws:SourceIp": [  
                "54.240.143.0/24",  
                "2001:DB8:1234:5678::/64"  
            ]  
        }  
    }  
}  
]
```

You can also deny all access to DynamoDB resources except when the source is a specific VPC endpoint, for example *vpce-1a2b3c4d*.

```
{  
    "Id": "PolicyId",  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AccessToSpecificVPCEOnly",  
            "Principal": "*",  
            "Action": "dynamodb:*",  
            "Effect": "Deny",  
            "Resource": "*",  
            "Condition": {  
                "StringNotEquals": {  
                    "aws:sourceVpce": "vpce-1a2b3c4d"  
                }  
            }  
        }  
    ]  
}
```

Resource-based policy using an IAM role

You can also specify an IAM service role in the resource-based policy. IAM entities that assume this role are bounded by the permissible actions specified for the role and to the specific set of resources within the resource-based policy.

The following example allows an IAM entity to perform all DynamoDB actions on the *MusicCollection* and *MusicCollection* DynamoDB resources.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "1111",  
            "Effect": "Allow",  
            "Principal": { "AWS": "arn:aws:iam::111122223333:role/John" },  
            "Action": "dynamodb:*",  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",  
                "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/*"  
            ]  
        }  
    ]  
}
```

Resource-based policy considerations

When you define resource-based policies for your DynamoDB resources, the following considerations apply:

General considerations

- The maximum size supported for a resource-based policy document is 20 KB. DynamoDB counts whitespaces when calculating the size of a policy against this limit.
- Subsequent updates to a policy for a given resource are blocked for 15 seconds after a successful update of the policy for the same resource.
- Currently, you can only attach a resource-based policy to existing streams. You can't attach a policy to a stream while creating it.

Global table considerations

- Resource-based policies aren't supported for [Global table version 2017.11.29 \(Legacy\)](#) replicas.
- Within a resource-based policy, if the action for a DynamoDB service-linked role (SLR) to replicate data for a global table is denied, adding or deleting a replica will fail with an error.
- The [AWS::DynamoDB::GlobalTable](#) resource doesn't support creating a replica and adding a resource-based policy to that replica in the same stack update in Regions other than the Region where you deploy the stack update.

Cross-account considerations

- Cross-account access using resource-based policies doesn't support encrypted tables with AWS managed keys because you can't grant cross-account access to the AWS managed KMS policy.

AWS CloudFormation considerations

- Resource-based policies don't support [drift detection](#). If you update a resource-based policy outside of the AWS CloudFormation stack template, you'll need to update the CloudFormation stack with the changes.
- Resource-based policies don't support out of band changes. If you add, update, or delete a policy outside of the CloudFormation template, the change won't be overwritten if there're no changes to the policy within the template.

For example, say that your template contains a resource-based policy which you later update outside of the template. If you don't make any changes to the policy in the template, the updated policy in DynamoDB won't be synced with the policy in the template.

Conversely, say that your template doesn't contain a resource-based policy, but you add a policy outside of the template. This policy won't be removed from DynamoDB as long as you don't add it to the template. When you add a policy to the template and update the stack, the existing policy in DynamoDB will be updated to match the one defined in the template.

Resource-based policy best practices

This topic describes the best practices for defining access permissions for your DynamoDB resources and the actions allowed on these resources.

Simplify access control to DynamoDB resources

If the AWS Identity and Access Management principals that need access to a DynamoDB resource are part of the same AWS account as the resource owner, an IAM identity-based policy is not required for each principal. A resource-based policy that is attached to the given resources will suffice. This type of configuration simplifies access control.

Protect your DynamoDB resources with resource-based policies

For all DynamoDB tables and streams, create resource-based policies to enforce access control for these resources. Resource-based policies enable you to centralize permissions at the resource level, simplify access control to DynamoDB tables, indexes, and streams, and reduce administration overhead. If no resource-based policy is specified for a table or a stream, access to the table or stream will be implicitly denied, unless identity-based policies associated with the IAM principals allow access.

Apply least-privilege permissions

When you set permissions with resource-based policies for DynamoDB resources, grant only the permissions required to perform an action. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as least-privilege permissions. You might start with broad permissions while you explore the permissions that are required for your workload or use case. As your use case matures, you can work to reduce the permissions that you grant to work toward least privilege.

Analyze cross-account access activity for generating least-privilege policies

IAM Access Analyzer reports cross-account access to external entities specified in resource-based policies, and provides visibility to help you refine permissions and conform to least privilege. For more information about policy generation, see [IAM Access Analyzer policy generation](#).

Use IAM Access Analyzer to generate least-privilege policies

To grant only the permissions required to perform a task, you can generate policies based on your access activity that is logged in AWS CloudTrail. IAM Access Analyzer analyzes the services and actions that your policies use.

Data protection in DynamoDB

Amazon DynamoDB provides a highly durable storage infrastructure designed for mission-critical and primary data storage. Data is redundantly stored on multiple devices across multiple facilities in an Amazon DynamoDB Region.

DynamoDB protects user data stored at rest and also data in transit between on-premises clients and DynamoDB, and between DynamoDB and other AWS resources within the same AWS Region.

Topics

- [DynamoDB encryption at rest](#)
- [Data protection in DynamoDB Accelerator](#)
- [Internetwork traffic privacy](#)

DynamoDB encryption at rest

All user data stored in Amazon DynamoDB is fully encrypted at rest. DynamoDB encryption at rest provides enhanced security by encrypting all your data at rest using encryption keys stored in [AWS Key Management Service \(AWS KMS\)](#). This functionality helps reduce the operational burden and complexity involved in protecting sensitive data. With encryption at rest, you can build security-sensitive applications that meet strict encryption compliance and regulatory requirements.

DynamoDB encryption at rest provides an additional layer of data protection by always securing your data in an encrypted table—including its primary key, local and global secondary indexes, streams, global tables, backups, and DynamoDB Accelerator (DAX) clusters whenever the data is stored in durable media. Organizational policies, industry or government regulations, and compliance requirements often require the use of encryption at rest to increase the data security of your applications.

Encryption at rest integrates with AWS KMS for managing the encryption keys that are used to encrypt your tables. For more information on key types and states, see [AWS Key Management Service concepts](#) in the [AWS Key Management Service Developer Guide](#).

When creating a new table, you can choose one of the following AWS KMS key types to encrypt your table. You can switch between these key types at any time.

- **AWS owned key** – Default encryption type. The key is owned by DynamoDB (no additional charge).

- **AWS managed key** – The key is stored in your account and is managed by AWS KMS (AWS KMS charges apply).
- **Customer managed key** – The key is stored in your account and is created, owned, and managed by you. You have full control over the KMS key (AWS KMS charges apply).

For more information on key types, see [Customer keys and AWS keys](#).

 **Note**

- When creating a new DAX cluster with encryption at rest enabled, an AWS managed key will be used to encrypt data at rest in the cluster.
- If your table has a sort key, some of the sort keys that mark range boundaries are stored in plaintext in the table metadata.

When you access an encrypted table, DynamoDB decrypts the table data transparently. You don't have to change any code or applications to use or manage encrypted tables. DynamoDB continues to deliver the same single-digit millisecond latency that you have come to expect, and all DynamoDB queries work seamlessly on your encrypted data.

You can specify an encryption key when you create a new table or switch the encryption keys on an existing table by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API. To learn how, see [Managing encrypted tables in DynamoDB](#).

Encryption at rest using the AWS owned key is offered at no additional charge. However, AWS KMS charges apply for an AWS managed key and for a customer managed key. For more information about pricing, see [AWS KMS pricing](#).

DynamoDB encryption at rest is available in all AWS Regions, including the AWS China (Beijing) and AWS China (Ningxia) Regions and the AWS GovCloud (US) Regions. For more information, see [Encryption at rest: How it works](#) and [DynamoDB encryption at rest usage notes](#).

Encryption at rest: How it works

Amazon DynamoDB encryption at rest encrypts your data using 256-bit Advanced Encryption Standard (AES-256), which helps secure your data from unauthorized access to the underlying storage.

Encryption at rest integrates with AWS Key Management Service (AWS KMS) for managing the encryption keys that are used to encrypt your tables.

Note

In May 2022, AWS KMS changed the rotation schedule for AWS managed keys from every three years (approximately 1,095 days) to every year (approximately 365 days).

New AWS managed keys are automatically rotated one year after they are created, and approximately every year thereafter.

Existing AWS managed keys are automatically rotated one year after their most recent rotation, and every year thereafter.

AWS owned keys

AWS owned keys are not stored in your AWS account. They are part of a collection of KMS keys that AWS owns and manages for use in multiple AWS accounts. AWS services can use AWS owned keys to protect your data. AWS owned keys used by DynamoDB are rotated every year (approximately 365 days).

You cannot view, manage, or use AWS owned keys, or audit their use. However, you do not need to do any work or change any programs to protect the keys that encrypt your data.

You are not charged a monthly fee or a usage fee for use of AWS owned keys, and they do not count against AWS KMS quotas for your account.

AWS managed keys

AWS managed keys are KMS keys in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS. You can view the AWS managed keys in your account, view their key policies, and audit their use in AWS CloudTrail logs. However, you cannot manage these KMS keys or change their permissions.

Encryption at rest automatically integrates with AWS KMS for managing the AWS managed keys for DynamoDB (`aws/dynamodb`) that are used to encrypt your tables. If an AWS managed key doesn't exist when you create your encrypted DynamoDB table, AWS KMS automatically creates a new key for you. This key is used with encrypted tables that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

For more information about managing permissions of the AWS managed key, see [Authorizing use of the AWS managed key](#) in the *AWS Key Management Service Developer Guide*.

Customer managed keys

Customer managed keys are KMS keys in your AWS account that you create, own, and manage. You have full control over these KMS keys, including establishing and maintaining their key policies, IAM policies, and grants; enabling and disabling them; rotating their cryptographic material; adding tags; creating aliases that refer to them; and scheduling them for deletion. For more information about managing permissions of a customer managed key, see [Customer managed key policy](#).

When you specify a customer managed key as the table-level encryption key, the DynamoDB table, local and global secondary indexes, and streams are encrypted with the same customer managed key. On-demand backups are encrypted with the table-level encryption key that is specified at the time the backup is created. Updating the table-level encryption key does not change the encryption key that is associated with existing on-demand backups.

Setting the state of the customer managed key to disabled or scheduling it for deletion prevents all users and the DynamoDB service from being able to encrypt or decrypt data and to perform read and write operations on the table. DynamoDB must have access to your encryption key to ensure that you can continue to access your table and to prevent data loss.

If you disable your customer managed key or schedule it for deletion, your table status becomes **Inaccessible**. To ensure that you can continue working with the table, you must provide DynamoDB access to the specified encryption key within seven days. As soon as the service detects that your encryption key is inaccessible, DynamoDB sends you an email notification to alert you.

Note

- If your customer managed key remains inaccessible to the DynamoDB service for longer than seven days, the table is archived and can no longer be accessed. DynamoDB creates an on-demand backup of your table, and you are billed for it. You can use this on-demand backup to restore your data to a new table. To initiate the restore, the last customer managed key on the table must be enabled, and DynamoDB must have access to it.
- If your customer managed key that was used to encrypt a global table replica is inaccessible DynamoDB will remove this replica from the replication group. The replica

will not be deleted and replication will stop from and to this region, 20 hours after detecting the customer managed key as inaccessible.

For more information, see [enabling keys](#) and [deleting keys](#).

Notes on using AWS managed keys

Amazon DynamoDB can't read your table data unless it has access to the KMS key stored in your AWS KMS account. DynamoDB uses envelope encryption and key hierarchy to encrypt data. Your AWS KMS encryption key is used to encrypt the root key of this key hierarchy. For more information, see [Envelope encryption](#) in the *AWS Key Management Service Developer Guide*.

You can use AWS CloudTrail and Amazon CloudWatch Logs to track the requests that DynamoDB sends to AWS KMS on your behalf. For more information, see [Monitoring DynamoDB interaction with AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

DynamoDB doesn't call AWS KMS for every DynamoDB operation. The key is refreshed once every 5 minutes per caller with active traffic.

Ensure that you have configured the SDK to reuse connections. Otherwise, you will experience latencies from DynamoDB having to reestablish new AWS KMS cache entries for each DynamoDB operation. In addition, you might potentially have to face higher AWS KMS and CloudTrail costs. For example, to do this using the Node.js SDK, you can create a new HTTPS agent with `keepAlive` turned on. For more information, see [Configuring keepAlive in Node.js](#) in the *AWS SDK for JavaScript Developer Guide*.

DynamoDB encryption at rest usage notes

Consider the following when you are using encryption at rest in Amazon DynamoDB.

All table data is encrypted

Server-side encryption at rest is enabled on all DynamoDB table data and cannot be disabled. You cannot encrypt only a subset of items in a table.

Encryption at rest only encrypts data while it is static (at rest) on a persistent storage media. If data security is a concern for data in transit or data in use, you might need to take additional measures:

- Data in transit: All your data in DynamoDB is encrypted in transit. By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using Secure Sockets Layer (SSL)/Transport Layer Security (TLS) encryption.
- Data in use: Protect your data before sending it to DynamoDB using client-side encryption. For more information, see [Client-side and server-side encryption](#) in the *Amazon DynamoDB Encryption Client Developer Guide*.

You can use streams with encrypted tables. DynamoDB streams are always encrypted with a table-level encryption key. For more information, see [Change data capture for DynamoDB Streams](#).

DynamoDB backups are encrypted, and the table that is restored from a backup also has encryption enabled. You can use the AWS owned key, AWS managed key, or customer managed key to encrypt your backup data. For more information, see [Using On-Demand backup and restore for DynamoDB](#).

Local secondary indexes and global secondary indexes are encrypted using the same key as the base table.

Encryption types

Note

Customer managed keys are not supported in Global Table Version 2017. If you want to use a customer managed key in a DynamoDB Global Table, you need to upgrade the table to Global Table Version 2019 and then enable it.

On the AWS Management Console, the encryption type is KMS when you use the AWS managed key or customer managed key to encrypt your data. The encryption type is DEFAULT when you use the AWS owned key. In the Amazon DynamoDB API, the encryption type is KMS when you use the AWS managed key or customer managed key. In the absence of encryption type, your data is encrypted using the AWS owned key. You can switch between the AWS owned key, AWS managed key, and customer managed key at any given time. You can use the console, the AWS Command Line Interface (AWS CLI), or the Amazon DynamoDB API to switch the encryption keys.

Note the following limitations when using customer managed keys:

- You cannot use a customer managed key with DynamoDB Accelerator (DAX) clusters. For more information, see [DAX encryption at rest](#).

- You can use a customer managed key to encrypt tables that use transactions. However, to ensure durability for propagation of transactions, a copy of the transaction request is temporarily stored by the service and encrypted using an AWS owned key. Committed data in your tables and secondary indexes is always encrypted at rest using your customer managed key.
- You can use a customer managed key to encrypt tables that use Contributor Insights. However, data that is transmitted to Amazon CloudWatch is encrypted with an AWS owned key.
- When you transition to a new customer managed key, be sure to keep the original key enabled until the process is complete. AWS will still need the original key to decrypt the data before encrypting it with the new key. The process will be complete when the table's SSEDescription Status is ENABLED and the KMSMasterKeyArn of the new customer managed key is displayed. At this point the original key can be disabled or scheduled for deletion.
- Once the new customer managed key is displayed, the table and any new on-demand backups are encrypted with the new key.
- Any existing on-demand backups remain encrypted with the customer managed key that was used when those backups were created. You will need that same key to restore those backups. You can identify the key for the period when each backup was created by using the DescribeBackup API to view that backup's SSEDescription.
- If you disable your customer managed key or schedule it for deletion, any data in DynamoDB Streams is still subject to a 24-hour lifetime. Any unretrieved activity data is eligible for trimming when it is older than 24 hours.
- If you disable your customer managed key or schedule it for deletion, Time to Live (TTL) deletes continue for 30 minutes. These TTL deletes continue to be emitted to DynamoDB Streams and are subject to the standard trimming/retention interval.

For more information, see [enabling keys](#) and [deleting keys](#).

Using KMS keys and data keys

The DynamoDB encryption at rest feature uses an AWS KMS key and a hierarchy of data keys to protect your table data. DynamoDB uses the same key hierarchy to protect DynamoDB streams, global tables, and backups when they are written to durable media.

We recommend that you plan your encryption strategy before implementing your table in DynamoDB. If you store sensitive or confidential data in DynamoDB, consider including client-side encryption in your plan. This way you can encrypt data as close as possible to its origin, and ensure

its protection throughout its lifecycle. For more information see the [DynamoDB encryption client](#) documentation.

AWS KMS key

Encryption at rest protects your DynamoDB tables under an AWS KMS key. By default, DynamoDB uses an [AWS owned key](#), a multi-tenant encryption key that is created and managed in a DynamoDB service account. But you can encrypt your DynamoDB tables under a [customer managed key](#) for DynamoDB (aws/dynamodb) in your AWS account. You can select a different KMS key for each table. The KMS key you select for a table is also used to encrypt its local and global secondary indexes, streams, and backups.

You select the KMS key for a table when you create or update the table. You can change the KMS key for a table at any time, either in the DynamoDB console or by using the [UpdateTable](#) operation. The process of switching keys is seamless and does not require downtime or degrade service.

Important

DynamoDB supports only [symmetric KMS keys](#). You cannot use an [asymmetric KMS key](#) to encrypt your DynamoDB tables.

Use a customer managed key to get the following features:

- You create and manage the KMS key, including setting the [key policies](#), [IAM policies](#) and [grants](#) to control access to the KMS key. You can [enable and disable](#) the KMS key, enable and disable [automatic key rotation](#), and [delete the KMS key](#) when it is no longer in use.
- You can use a customer managed key with [imported key material](#) or a customer managed key in a [custom key store](#) that you own and manage.
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in [AWS CloudTrail logs](#).

Use the AWS managed key if you need any of the following features:

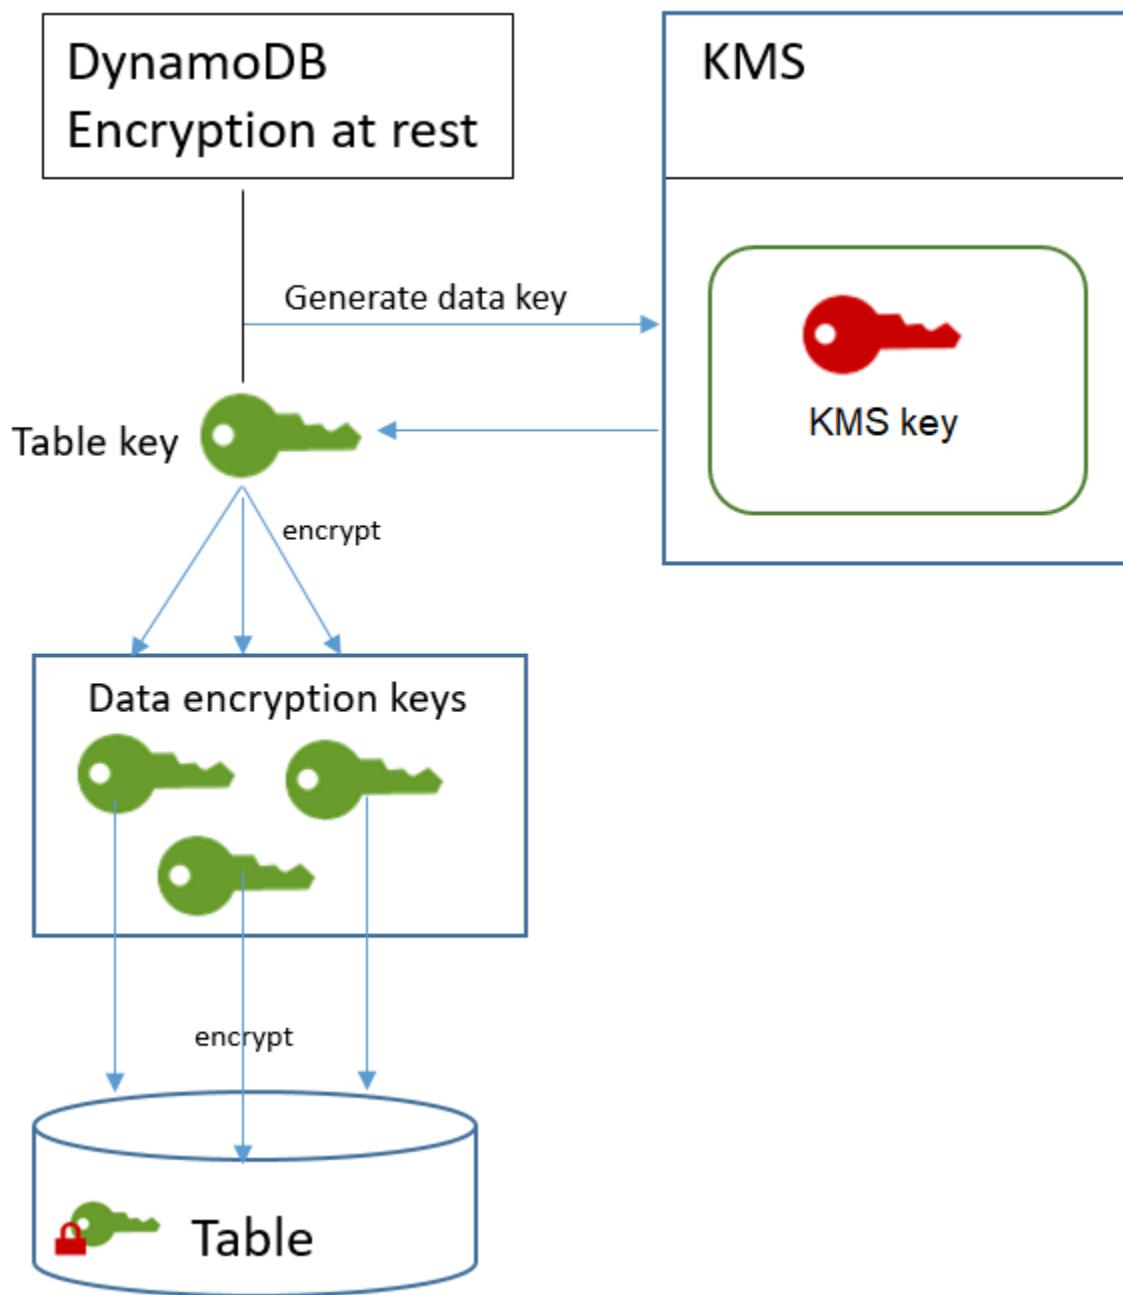

- You can [view the KMS key](#) and [view its key policy](#). (You cannot change the key policy.)
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in [AWS CloudTrail logs](#).

However, the AWS owned key is free of charge and its use does not count against [AWS KMS resource or request quotas](#). Customer managed keys and AWS managed keys [incur a charge](#) for each API call and AWS KMS quotas apply to these KMS keys.

Table keys

DynamoDB uses the KMS key for the table to [generate](#) and encrypt a unique [data key](#) for the table, known as the *table key*. The table key persists for the lifetime of the encrypted table.

The table key is used as a key encryption key. DynamoDB uses this table key to protect data encryption keys that are used to encrypt the table data. DynamoDB generates a unique data encryption key for each underlying structure in a table, but multiple table items might be protected by the same data encryption key.

When you first access an encrypted table, DynamoDB sends a request to AWS KMS to use the KMS key to decrypt the table key. Then, it uses the plaintext table key to decrypt the data encryption keys, and uses the plaintext data encryption keys to decrypt table data.

DynamoDB stores and uses the table key and data encryption keys outside of AWS KMS. It protects all keys with [Advanced Encryption Standard \(AES\)](#) encryption and 256-bit encryption

keys. Then, it stores the encrypted keys with the encrypted data so they are available to decrypt the table data on demand.

If you change the KMS key for your table, DynamoDB generates a new table key. Then, it uses the new table key to re-encrypt the data encryption keys.

Table key caching

To avoid calling AWS KMS for every DynamoDB operation, DynamoDB caches the plaintext table keys for each caller in memory. If DynamoDB gets a request for the cached table key after five minutes of inactivity, it sends a new request to AWS KMS to decrypt the table key. This call will capture any changes made to the access policies of the KMS key in AWS KMS or AWS Identity and Access Management (IAM) since the last request to decrypt the table key.

Authorizing use of your KMS key

If you use a [customer managed key](#) or the [AWS managed key](#) in your account to protect your DynamoDB table, the policies on that KMS key must give DynamoDB permission to use it on your behalf. The authorization context on the AWS managed key for DynamoDB includes its key policy and grants that delegate the permissions to use it.

You have full control over the policies and grants on a customer managed key. Because the AWS managed key is in your account, you can view its policies and grants. But, because it is managed by AWS, you cannot change the policies.

DynamoDB does not need additional authorization to use the default [AWS owned key](#) to protect the DynamoDB tables in your AWS account.

Topics

- [Key policy for an AWS managed key](#)
- [Key policy for a customer managed key](#)
- [Using grants to authorize DynamoDB](#)

Key policy for an AWS managed key

When DynamoDB uses the [AWS managed key](#) for DynamoDB (aws/dynamodb) in cryptographic operations, it does so on behalf of the user who is accessing the [DynamoDB resource](#). The key policy on the AWS managed key gives all users in the account permission to use the AWS managed key for specified operations. But permission is granted only when DynamoDB makes the request on

the user's behalf. The [ViaService condition](#) in the key policy does not allow any user to use the AWS managed key unless the request originates with the DynamoDB service.

This key policy, like the policies of all AWS managed keys, is established by AWS. You cannot change it, but you can view it at any time. For details, see [Viewing a key policy](#).

The policy statements in the key policy have the following effect:

- Allow users in the account to use the AWS managed key for DynamoDB in cryptographic operations when the request comes from DynamoDB on their behalf. The policy also allows users to [create grants](#) for the KMS key.
- Allows authorized IAM identities in the account to view the properties of the AWS managed key for DynamoDB and to [revoke the grant](#) that allows DynamoDB to use the KMS key. DynamoDB uses [grants](#) for ongoing maintenance operations.
- Allows DynamoDB to perform read-only operations to find the AWS managed key for DynamoDB in your account.

```

Key policy for a customer managed key

When you select a [customer managed key](#) to protect a DynamoDB table, DynamoDB gets permission to use the KMS key on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the KMS key that DynamoDB requires. You can provide these permissions in a [key policy](#), an [IAM policy](#), or a [grant](#).

At a minimum, DynamoDB requires the following permissions on a customer managed key:

- [kms:Encrypt](#)
- [kms:Decrypt](#)
- [kms:ReEncrypt*](#) (for kms:ReEncryptFrom and kms:ReEncryptTo)
- [kms:GenerateDataKey*](#) (for [kms:GenerateDataKey](#) and [kms:GenerateDataKeyWithoutPlaintext](#))
- [kms:DescribeKey](#)
- [kms>CreateGrant](#)

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows DynamoDB to use the KMS key in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use DynamoDB. If the principals specified in the policy statement don't have permission to use DynamoDB, the call fails, even when it comes from the DynamoDB service.

- The [kms:ViaService](#) condition key allows the permissions only when the request comes from DynamoDB on behalf of the principals listed in the policy statement. These principals can't call these operations directly. Note that the kms:ViaService value, dynamodb.*.amazonaws.com, has an asterisk (*) in the Region position. DynamoDB requires the permission to be independent of any particular AWS Region so it can make cross-Region calls to support [DynamoDB global tables](#).
- Gives the KMS key administrators (users who can assume the db-team role) read-only access to the KMS key and permission to revoke grants, including the [grants that DynamoDB requires](#) to protect the table.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```
{  
  "Id": "key-policy-dynamodb",

    },
    "Action": [
        "kms:Describe*",
        "kms:Get*",
        "kms>List*",
        "kms:RevokeGrant"
    ],
    "Resource": "*"
}
]
```

Using grants to authorize DynamoDB

In addition to key policies, DynamoDB uses grants to set permissions on a customer managed key or the AWS managed key for DynamoDB (aws/dynamodb). To view the grants on a KMS key in your account, use the [ListGrants](#) operation. DynamoDB does not need grants, or any additional permissions, to use the [AWS owned key](#) to protect your table.

DynamoDB uses the grant permissions when it performs background system maintenance and continuous data protection tasks. It also uses grants to generate [table keys](#).

Each grant is specific to a table. If the account includes multiple tables encrypted under the same KMS key, there is a grant of each type for each table. The grant is constrained by the [DynamoDB encryption context](#), which includes the table name and the AWS account ID, and it includes permission to the [retire the grant](#) if it is no longer needed.

To create the grants, DynamoDB must have permission to call `CreateGrant` on behalf of the user who created the encrypted table. For AWS managed keys, DynamoDB gets `kms:CreateGrant` permission from the [key policy](#), which allows account users to call [CreateGrant](#) on the KMS key only when DynamoDB makes the request on an authorized user's behalf.

The key policy can also allow the account to [revoke the grant](#) on the KMS key. However, if you revoke the grant on an active encrypted table, DynamoDB will not be able to protect and maintain the table.

DynamoDB encryption context

An [encryption context](#) is a set of key-value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds

the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

DynamoDB uses the same encryption context in all AWS KMS cryptographic operations. If you use a [customer managed key](#) or an [AWS managed key](#) to protect your DynamoDB table, you can use the encryption context to identify use of the KMS key in audit records and logs. It also appears in plaintext in logs, such as [AWS CloudTrail](#) and [Amazon CloudWatch Logs](#).

The encryption context can also be used as a condition for authorization in policies and grants. DynamoDB uses the encryption context to constrain the [grants](#) that allow access to the customer managed key or AWS managed key in your account and region.

In its requests to AWS KMS, DynamoDB uses an encryption context with two key–value pairs.

```
"encryptionContextSubset": {  
    "aws:dynamodb:tableName": "Books"  
    "aws:dynamodb:subscriberId": "111122223333"  
}
```

- **Table** – The first key–value pair identifies the table that DynamoDB is encrypting. The key is `aws:dynamodb:tableName`. The value is the name of the table.

```
"aws:dynamodb:tableName": "<table-name>"
```

For example:

```
"aws:dynamodb:tableName": "Books"
```

- **Account** – The second key–value pair identifies the AWS account. The key is `aws:dynamodb:subscriberId`. The value is the account ID.

```
"aws:dynamodb:subscriberId": "<account-id>"
```

For example:

```
"aws:dynamodb:subscriberId": "111122223333"
```

Monitoring DynamoDB interaction with AWS KMS

If you use a [customer managed key](#) or an [AWS managed key](#) to protect your DynamoDB tables, you can use AWS CloudTrail logs to track the requests that DynamoDB sends to AWS KMS on your behalf.

The `GenerateDataKey`, `Decrypt`, and `CreateGrant` requests are discussed in this section. In addition, DynamoDB uses a [DescribeKey](#) operation to determine whether the KMS key you selected exists in the account and region. It also uses a [RetireGrant](#) operation to remove a grant when you delete a table.

GenerateDataKey

When you enable encryption at rest on a table, DynamoDB creates a unique table key. It sends a [GenerateDataKey](#) request to AWS KMS that specifies the KMS key for the table.

The event that records the `GenerateDataKey` operation is similar to the following example event. The user is the DynamoDB service account. The parameters include the Amazon Resource Name (ARN) of the KMS key, a key specifier that requires a 256-bit key, and the [encryption context](#) that identifies the table and the AWS account.

```
{

"sharedEventID": "bf915fa6-6ceb-4659-8912-e36b69846aad"
}
```

Decrypt

When you access an encrypted DynamoDB table, DynamoDB needs to decrypt the table key so that it can decrypt the keys below it in the hierarchy. It then decrypts the data in the table. To decrypt the table key, DynamoDB sends a [Decrypt](#) request to AWS KMS that specifies the KMS key for the table.

The event that records the Decrypt operation is similar to the following example event. The user is the principal in your AWS account who is accessing the table. The parameters include the encrypted table key (as a ciphertext blob) and the [encryption context](#) that identifies the table and the AWS account. AWS KMS derives the ID of the KMS key from the ciphertext.

```

"recipientAccountId": "111122223333"
}
```

CreateGrant

When you use a [customer managed key](#) or an [AWS managed key](#) to protect your DynamoDB table, DynamoDB uses [grants](#) to allow the service to perform continuous data protection and maintenance and durability tasks. These grants are not required on [AWS owned key](#).

The grants that DynamoDB creates are specific to a table. The principal in the [CreateGrant](#) request is the user who created the table.

The event that records the CreateGrant operation is similar to the following example event. The parameters include the Amazon Resource Name (ARN) of the KMS key for the table, the grantee principal and retiring principal (the DynamoDB service), and the operations that the grant covers. It also includes a constraint that requires all encryption operation use the specified [encryption context](#).

```
        "encryptionContextSubset": {
            "aws:dynamodb:tableName": "Books",
            "aws:dynamodb:subscriberId": "111122223333"
        },
        "granteePrincipal": "dynamodb.us-west-2.amazonaws.com",
        "operations": [
            "DescribeKey",

            "Decrypt",
            "Encrypt",
            "ReEncryptFrom",
            "ReEncryptTo",
            "RetireGrant"
        ],
        "responseElements": {
            "grantId": "5c5cd4a3d68e65e77795f5ccc2516dff057308172b0cd107c85b5215c6e48bde"
        },
        "requestID": "2192b82a-111c-11e8-a528-f398979205d8",
        "eventID": "a03d65c3-9fee-4111-9816-8bf96b73df01",
        "readOnly": false,
        "resources": [
            {
                "ARN": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "accountId": "111122223333",
                "type": "AWS::KMS::Key"
            }
        ],
        "eventType": "AwsApiCall",
        "recipientAccountId": "111122223333"
    }
}
```

Managing encrypted tables in DynamoDB

You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to specify the encryption key on new tables and update the encryption keys on existing tables in Amazon DynamoDB.

Topics

- [Specifying the encryption key for a new table](#)
- [Updating an encryption key](#)

Specifying the encryption key for a new table

Follow these steps to specify the encryption key on a new table using the Amazon DynamoDB console or the AWS CLI.

Creating an encrypted table (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**. For the **Table name**, enter **Music**. For the primary key, enter **Artist**, and for the sort key, enter **SongTitle**, both as strings.
4. In **Settings**, make sure that **Customize settings** is selected.

 **Note**

If **Use default settings** is selected, tables are encrypted at rest with the AWS owned key at no additional cost.

5. Under **Encryption at rest**, choose an encryption type - AWS owned key, AWS managed key, or customer managed key.
 - **Owned by Amazon DynamoDB.** AWS owned key, specifically owned and managed by DynamoDB. You are not charged an additional fee for using this key.
 - **AWS managed key.** Key alias: aws/dynamodb. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.
 - **Stored in your account, and owned and managed by you.** Customer managed key. The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.

Note

If you select to own and manage your own key, make sure the KMS Key Policy is appropriately set. For more information including examples, see [Key policy for a customer managed key](#).

6. Choose **Create table** to create the encrypted table. To confirm the encryption type, select the table details on the **Overview** tab and review the **Additional details** section.

Creating an encrypted table (AWS CLI)

Use the AWS CLI to create a table with the default AWS owned key, the AWS managed key, or a customer managed key for Amazon DynamoDB.

To create an encrypted table with the default AWS owned key

- Create the encrypted Music table as follows.

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
  AttributeName=Artist,AttributeType=S \
  AttributeName=SongTitle,AttributeType=S \
--key-schema \
  AttributeName=Artist,KeyType=HASH \
  AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
  ReadCapacityUnits=10,WriteCapacityUnits=5
```

Note

This table is now encrypted using the default AWS owned key in the DynamoDB service account.

To create an encrypted table with the AWS managed key for DynamoDB

- Create the encrypted Music table as follows.

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
  AttributeName=Artist,AttributeType=S \
  AttributeName=SongTitle,AttributeType=S \
--key-schema \
  AttributeName=Artist,KeyType=HASH \
  AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
  ReadCapacityUnits=10,WriteCapacityUnits=5 \
--sse-specification Enabled=true,SSEType=KMS
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {
  "SSEType": "KMS",
  "Status": "ENABLED",
  "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-
a123-ab1234a1b234",
}
```

To create an encrypted table with a customer managed key for DynamoDB

- Create the encrypted Music table as follows.

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
  AttributeName=Artist,AttributeType=S \
  AttributeName=SongTitle,AttributeType=S \
--key-schema \
  AttributeName=Artist,KeyType=HASH \
  AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
  ReadCapacityUnits=10,WriteCapacityUnits=5 \
--sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-
a123-ab1234a1b234
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {  
    "SSEType": "KMS",  
    "Status": "ENABLED",  
    "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-a123-ab1234a1b234",  
}
```

Updating an encryption key

You can also use the DynamoDB console or the AWS CLI to update the encryption keys of an existing table between an AWS owned key, AWS managed key, and customer managed key at any time.

Updating an encryption key (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the table that you want to update.
4. Select the **Actions** dropdown, and then select the **Update settings** option.
5. Go to the **Additional settings** tab.
6. Under **Encryption**, choose **Manage encryption**.
7. Choose an encryption type:
 - **Owned by Amazon DynamoDB.** The AWS KMS key is owned and managed by DynamoDB. You are not charged an additional fee for using this key.
 - **AWS managed key** Key alias: aws/dynamodb. The key is stored in your account and is managed by AWS Key Management Service. (AWS KMS). AWS KMS charges apply.
 - **Stored in your account, and owned and managed by you.** The key is stored in your account and is managed by AWS Key Management Service. (AWS KMS). AWS KMS charges apply.

Note

If you select to own and manage your own key, make sure the KMS Key Policy is appropriately set. For more information see [Key policy for a customer managed key](#).

Then choose **Save** to update the encrypted table. To confirm the encryption type, check the table details under the **Overview** tab.

Updating an encryption key (AWS CLI)

The following examples show how to update an encrypted table using the AWS CLI.

To update an encrypted table with the default AWS owned key

- Update the encrypted Music table, as in the following example.

```
aws dynamodb update-table \
--table-name Music \
--sse-specification Enabled=false
```

Note

This table is now encrypted using the default AWS owned key in the DynamoDB service account.

To update an encrypted table with the AWS managed key for DynamoDB

- Update the encrypted Music table, as in the following example.

```
aws dynamodb update-table \
--table-name Music \
--sse-specification Enabled=true
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {  
    "SSEType": "KMS",  
    "Status": "ENABLED",  
    "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-  
a123-ab1234a1b234",  
}
```

To update an encrypted table with a customer managed key for DynamoDB

- Update the encrypted Music table, as in the following example.

```
aws dynamodb update-table \  
--table-name Music \  
--sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-  
a123-ab1234a1b234
```

The SSEDescription status of the table description is set to ENABLED and the SSEType is KMS.

```
"SSEDescription": {  
    "SSEType": "KMS",  
    "Status": "ENABLED",  
    "KMSMasterKeyArn": "arn:aws:kms:us-east-1:123456789012:key/abcd1234-abcd-1234-  
a123-ab1234a1b234",  
}
```

Data protection in DynamoDB Accelerator

Amazon DynamoDB Accelerator (DAX) encryption at rest provides an additional layer of data protection by helping secure your data from unauthorized access to the underlying storage. Organizational policies, industry or government regulations, and compliance requirements might require the use of encryption at rest to protect your data. You can use encryption to increase the data security of your applications that are deployed in the cloud.

For more information about data protection in DAX, see [DAX encryption at rest](#).

Internet network traffic privacy

Connections are protected both between Amazon DynamoDB and on-premises applications and between DynamoDB and other AWS resources within the same AWS Region.

Required policy for endpoints

Amazon DynamoDB provides a [DescribeEndpoints](#) API that enables you to enumerate regional endpoint information. For requests from a VPC endpoint, both the IAM and Virtual Private Cloud (VPC) endpoint policies must authorize the `DescribeEndpoints` API call for the requesting Identity and Access Management (IAM) principal(s) using the IAM `dynamodb:DescribeEndpoints` action. Otherwise, access to the `DescribeEndpoints` API will be denied. The IAM and VPC endpoint policy authorization steps for `DescribeEndpoints` API calls aren't applicable when you access public endpoints of DynamoDB.

The following is an example of an endpoints policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": "(Include IAM Principals)",  
            "Action": "dynamodb:DescribeEndpoints",  
            "Resource": "*"  
        }  
    ]  
}
```

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and AWS:

- An AWS Site-to-Site VPN connection. For more information, see [What is AWS Site-to-Site VPN?](#) in the [AWS Site-to-Site VPN User Guide](#).
- An AWS Direct Connect connection. For more information, see [What is AWS Direct Connect?](#) in the [AWS Direct Connect User Guide](#).

Access to DynamoDB via the network is through AWS published APIs. Clients must support Transport Layer Security (TLS) 1.2. We recommend TLS 1.3. Clients must also support cipher suites

with Perfect Forward Secrecy (PFS), such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, you must sign requests using an access key ID and a secret access key that are associated with an IAM principal, or you can use the [AWS Security Token Service \(STS\)](#) to generate temporary security credentials to sign requests.

Traffic between AWS resources in the same Region

An Amazon Virtual Private Cloud (Amazon VPC) endpoint for DynamoDB is a logical entity within a VPC that allows connectivity only to DynamoDB. The Amazon VPC routes requests to DynamoDB and routes responses back to the VPC. For more information, see [VPC endpoints](#) in the *Amazon VPC User Guide*. For example policies that you can use to control access from VPC endpoints, see [Using IAM policies to control access to DynamoDB](#).

 **Note**

Amazon VPC endpoints are not accessible via AWS Site-to-Site VPN or AWS Direct Connect.

AWS Identity and Access Management (IAM)

AWS Identity and Access Management is an AWS service that helps an administrator securely control access to AWS resources. Administrators control who can be authenticated (signed in) and authorized (have permissions) to use Amazon DynamoDB and DynamoDB Accelerator resources. You can use IAM to manage access permissions and implement security policies for both Amazon DynamoDB and DynamoDB Accelerator. IAM is an AWS service that you can use with no additional charge.

Identity and Access Management for Amazon DynamoDB

AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use DynamoDB resources. IAM is an AWS service that you can use with no additional charge.

Topics

- [Audience](#)
- [Authenticating with identities](#)
- [Managing access using policies](#)
- [How Amazon DynamoDB works with IAM](#)
- [Identity-based policy examples for Amazon DynamoDB](#)
- [Troubleshooting Amazon DynamoDB identity and access](#)
- [IAM policy to prevent the purchase of DynamoDB reserved capacity](#)

Audience

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in DynamoDB.

Service user – If you use the DynamoDB service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more DynamoDB features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in DynamoDB, see [Troubleshooting Amazon DynamoDB identity and access](#).

Service administrator – If you're in charge of DynamoDB resources at your company, you probably have full access to DynamoDB. It's your job to determine which DynamoDB features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with DynamoDB, see [How Amazon DynamoDB works with IAM](#).

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to DynamoDB. To view example DynamoDB identity-based policies that you can use in IAM, see [Identity-based policy examples for Amazon DynamoDB](#).

Authenticating with identities

Authentication is how you sign in to AWS using your identity credentials. You must be *authenticated* (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see [How to sign in to your AWS account](#) in the *AWS Sign-In User Guide*.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see [Signing AWS API requests](#) in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see [Multi-factor authentication](#) in the *AWS IAM Identity Center User Guide* and [Using multi-factor authentication \(MFA\) in AWS](#) in the *IAM User Guide*.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see [Tasks that require root user credentials](#) in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see [What is IAM Identity Center?](#) in the *AWS IAM Identity Center User Guide*.

IAM users and groups

An [*IAM user*](#) is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see [Rotate access keys regularly for use cases that require long-term credentials](#) in the *IAM User Guide*.

An [*IAM group*](#) is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see [When to create an IAM user \(instead of a role\)](#) in the *IAM User Guide*.

IAM roles

An [*IAM role*](#) is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in

the AWS Management Console by [switching roles](#). You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see [Using IAM roles](#) in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see [Creating a role for a third-party Identity Provider](#) in the *IAM User Guide*. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see [Permission sets](#) in the *AWS IAM Identity Center User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.
- **Cross-service access** – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
 - **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).
 - **Service role** – A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For

more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

To learn whether to use IAM roles or IAM users, see [When to create an IAM role \(instead of a user\)](#) in the *IAM User Guide*.

Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see [Overview of JSON policies](#) in the *IAM User Guide*.

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see [Choosing between managed policies and inline policies](#) in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see [Access control list \(ACL\) overview](#) in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see [Permissions boundaries for IAM entities](#) in the *IAM User Guide*.
- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see [How SCPs work](#) in the *AWS Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see [Session policies](#) in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see [Policy evaluation logic](#) in the *IAM User Guide*.

How Amazon DynamoDB works with IAM

Before you use IAM to manage access to DynamoDB, learn what IAM features are available to use with DynamoDB.

IAM features you can use with Amazon DynamoDB

IAM feature	DynamoDB support
Identity-based policies	Yes

IAM feature	DynamoDB support
Resource-based policies	Yes
Policy actions	Yes
Policy resources	Yes
Policy condition keys	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	Yes
Service-linked roles	No

To get a high-level view of how DynamoDB and other AWS services work with most IAM features, see [AWS services that work with IAM](#) in the *IAM User Guide*.

Identity-based policies for DynamoDB

Supports identity-based policies	Yes
----------------------------------	-----

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see [Creating IAM policies](#) in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

Identity-based policy examples for DynamoDB

To view examples of DynamoDB identity-based policies, see [Identity-based policy examples for Amazon DynamoDB](#).

Resource-based policies within DynamoDB

Supports resource-based policies	Yes
----------------------------------	-----

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must [specify a principal](#) in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

Policy actions for DynamoDB

Supports policy actions	Yes
-------------------------	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Action element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API

operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of DynamoDB actions, see [Actions defined by Amazon DynamoDB in the Service Authorization Reference](#).

Policy actions in DynamoDB use the following prefix before the action:

aws

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [  
    "aws:action1",  
    "aws:action2"  
]
```

To view examples of DynamoDB identity-based policies, see [Identity-based policy examples for Amazon DynamoDB](#).

Policy resources for DynamoDB

Supports policy resources	Yes
---------------------------	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name \(ARN\)](#). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of DynamoDB resource types and their ARNs, see [Resources defined by Amazon DynamoDB](#) in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see [Actions defined by Amazon DynamoDB](#).

To view examples of DynamoDB identity-based policies, see [Identity-based policy examples for Amazon DynamoDB](#).

Policy condition keys for DynamoDB

Supports service-specific policy condition keys	Yes
---	-----

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element (or Condition *block*) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use [condition operators](#), such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags](#) in the *IAM User Guide*.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see [AWS global condition context keys](#) in the *IAM User Guide*.

To see a list of DynamoDB condition keys, see [Condition keys for Amazon DynamoDB](#) in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions defined by Amazon DynamoDB](#).

To view examples of DynamoDB identity-based policies, see [Identity-based policy examples for Amazon DynamoDB](#).

Access control lists (ACLs) in DynamoDB

Supports ACLs	No
---------------	----

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) with DynamoDB

Supports ABAC (tags in policies)	Partial
----------------------------------	---------

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see [What is ABAC?](#) in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see [Use attribute-based access control \(ABAC\)](#) in the *IAM User Guide*.

Using Temporary credentials with DynamoDB

Supports temporary credentials	Yes
--------------------------------	-----

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see [AWS services that work with IAM](#) in the *IAM User Guide*.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switching to a role \(console\)](#) in the *IAM User Guide*.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](#).

Cross-service principal permissions for DynamoDB

Supports forward access sessions (FAS)	Yes
--	-----

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

Service roles for DynamoDB

Supports service roles	Yes
------------------------	-----

A service role is an [IAM role](#) that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

Warning

Changing the permissions for a service role might break DynamoDB functionality. Edit service roles only when DynamoDB provides guidance to do so.

Service-linked roles for DynamoDB

Supports service-linked roles	No
-------------------------------	----

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see [AWS services that work with IAM](#). Find a service in the table that includes a Yes in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Identity-based policy examples for Amazon DynamoDB

By default, users and roles don't have permission to create or modify DynamoDB resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see [Creating IAM policies](#) in the *IAM User Guide*.

For details about actions and resource types defined by DynamoDB, including the format of the ARNs for each of the resource types, see [Actions, resources, and condition keys for Amazon DynamoDB](#) in the *Service Authorization Reference*.

Topics

- [Policy best practices](#)
- [Using the DynamoDB console](#)

- [Allow users to view their own permissions](#)
- [Using identity-based policies with Amazon DynamoDB](#)

Policy best practices

Identity-based policies determine whether someone can create, access, or delete DynamoDB resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](#) or [AWS managed policies for job functions](#) in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](#) in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see [IAM Access Analyzer policy validation](#) in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see [Configuring MFA-protected API access](#) in the *IAM User Guide*.

For more information about best practices in IAM, see [Security best practices in IAM](#) in the *IAM User Guide*.

Using the DynamoDB console

To access the Amazon DynamoDB console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the DynamoDB resources in your AWS account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the AWS CLI or the AWS API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the DynamoDB console, also attach the DynamoDB `ConsoleAccess` or `ReadOnly` AWS managed policy to the entities. For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam>ListGroupsForUser",
                "iam>ListAttachedUserPolicies",
                "iam>ListUserPolicies",
                "iam GetUser"
            ],
            "Resource": ["arn:aws:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "execute-api:Invoke"
            ]
        }
    ]
}
```

```
        "iam:GetGroupPolicy",
        "iam:GetPolicyVersion",
        "iam:GetPolicy",
        "iam>ListAttachedGroupPolicies",
        "iam>ListGroupPolicies",
        "iam>ListPolicyVersions",
        "iam>ListPolicies",
        "iam>ListUsers"
    ],
    "Resource": "*"
}
]
}
```

Using identity-based policies with Amazon DynamoDB

This topic covers using identity-based AWS Identity and Access Management (IAM) policies with Amazon DynamoDB and provides examples. The examples show how an account administrator can attach permissions policies to IAM identities (users, groups, and roles) and thereby grant permissions to perform operations on Amazon DynamoDB resources.

The sections in this topic cover the following:

- [IAM permissions required to use the Amazon DynamoDB console](#)
- [AWS managed \(predefined\) IAM policies for Amazon DynamoDB](#)
- [Customer managed policy examples](#)

The following is an example of a permissions policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DescribeQueryScanBooksTable",
            "Effect": "Allow",
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:Query",
                "dynamodb:Scan"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:account-id:table/Books"
```

```
    }
]
}
```

The preceding policy has one statement that grants permissions for three DynamoDB actions (`dynamodb:DescribeTable`, `dynamodb:Query`, and `dynamodb:Scan`) on a table in the `us-west-2` AWS Region, which is owned by the AWS account specified by `account-id`. The *Amazon Resource Name (ARN)* in the `Resource` value specifies the table that the permissions apply to.

IAM permissions required to use the Amazon DynamoDB console

To work with the DynamoDB console, a user must have a minimum set of permissions that allow the user to work with their AWS account's DynamoDB resources. In addition to these DynamoDB permissions, the console requires permissions:

- Amazon CloudWatch permissions to display metrics and graphs.
- AWS Data Pipeline permissions to export and import DynamoDB data.
- AWS Identity and Access Management permissions to access roles necessary for exports and imports.
- Amazon Simple Notification Service permissions to notify you whenever a CloudWatch alarm is triggered.
- AWS Lambda permissions to process DynamoDB Streams records.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console won't function as intended for users with that IAM policy. To ensure that those users can still use the DynamoDB console, also attach the `AmazonDynamoDBReadOnlyAccess` AWS managed policy to the user, as described in [AWS managed \(predefined\) IAM policies for Amazon DynamoDB](#).

You don't need to allow minimum console permissions for users who are making calls only to the AWS CLI or the Amazon DynamoDB API.

Note

If you refer to a VPC endpoint, you will also need to authorize the `DescribeEndpoints` API call for the requesting IAM principal(s) with the IAM action (`dynamodb:DescribeEndpoints`). For more information see [Required policy for endpoints](#).

AWS managed (predefined) IAM policies for Amazon DynamoDB

AWS addresses some common use cases by providing standalone IAM policies that are created and administered by AWS. These AWS managed policies grant necessary permissions for common use cases so that you can avoid having to investigate which permissions are needed. For more information, see [AWS Managed Policies](#) in the *IAM User Guide*.

The following AWS managed policies, which you can attach to users in your account, are specific to DynamoDB and are grouped by use-case scenario:

- **AmazonDynamoDBReadOnlyAccess** – Grants read-only access to DynamoDB resources through the AWS Management Console.
- **AmazonDynamoDBFullAccess** – Grants full access to DynamoDB resources through the AWS Management Console.

You can review these AWS managed permissions policies by signing in to the IAM console and searching for specific policies there.

Important

The best practice is to create custom IAM policies that grant [least-privilege](#) to the users, roles, or groups that require them.

Customer managed policy examples

In this section, you can find policy examples that grant permissions for various DynamoDB actions. These policies work when you use AWS SDKs or the AWS CLI. When you use the console, you need to grant additional permissions that are specific to the console. For more information, see [IAM permissions required to use the Amazon DynamoDB console](#).

Note

All of the following policy examples use one of the AWS Regions and contain fictitious account IDs and table names.

Examples:

- [IAM policy to grant permissions to all DynamoDB actions on a table](#)
- [IAM policy to grant read-only permissions on items in a DynamoDB table](#)
- [IAM policy to grant access to a specific DynamoDB table and its indexes](#)
- [IAM policy to read, write, update, and delete access on a DynamoDB table](#)
- [IAM policy to separate DynamoDB environments in the same AWS account](#)
- [IAM policy to prevent the purchase of DynamoDB reserved capacity](#)
- [IAM policy to grant read access for a DynamoDB stream only \(not for the table\)](#)
- [IAM policy to allow an AWS Lambda function to access DynamoDB stream records](#)
- [IAM policy for read and write access to a DynamoDB Accelerator \(DAX\) cluster](#)

The *IAM User Guide*, includes [three additional DynamoDB examples](#):

- [Amazon DynamoDB: Allows Access to a Specific Table](#)
- [Amazon DynamoDB: Allows Access to Specific Columns](#)
- [Amazon DynamoDB: Allows Row-Level Access to DynamoDB Based on an Amazon Cognito ID](#)

IAM policy to grant permissions to all DynamoDB actions on a table

The following policy grants permissions for *all* DynamoDB actions on a table called Books. The resource ARN specified in the Resource identifies a table in a specific AWS Region. If you replace the table name Books in the Resource ARN with a wildcard character (*), *all* DynamoDB actions are allowed on *all* tables in the account. Carefully consider the possible security implications before using a wildcard character on this or any IAM policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllAPIActionsOnBooks",  
            "Effect": "Allow",  
            "Action": "dynamodb:*",  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        }  
    ]  
}
```

Note

This is an example of using a wildcard character (*) to allow *all* actions, including administration, data operations, monitoring, and purchase of DynamoDB reserved capacity. Instead, it is a best practice to explicitly specify each action to be granted and only what that user, role, or group needs.

IAM policy to grant read-only permissions on items in a DynamoDB table

The following permissions policy grants permissions for the GetItem, BatchGetItem, Scan, Query, and ConditionCheckItem DynamoDB actions only, and as a result, sets read-only access on the Books table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ReadOnlyAPIActionsOnBooks",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Scan",  
                "dynamodb:Query",  
                "dynamodb:ConditionCheckItem"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        }  
    ]  
}
```

IAM policy to grant access to a specific DynamoDB table and its indexes

The following policy grants permissions for data modification actions on a DynamoDB table called Books and all of that table's indexes. For more information about how indexes work, see [Improving data access with secondary indexes](#).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {
```

```
{  
    "Sid": "AccessTableAllIndexesOnBooks",  
    "Effect": "Allow",  
    "Action": [  
        "dynamodb:PutItem",  
        "dynamodb:UpdateItem",  
        "dynamodb:DeleteItem",  
        "dynamodb:BatchWriteItem",  
        "dynamodb:GetItem",  
        "dynamodb:BatchGetItem",  
        "dynamodb:Scan",  
        "dynamodb:Query",  
        "dynamodb:ConditionCheckItem"  
    ],  
    "Resource": [  
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books",  
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"  
    ]  
}  
}
```

IAM policy to read, write, update, and delete access on a DynamoDB table

Use this policy if you need to allow your application to create, read, update, and delete data in Amazon DynamoDB tables, indexes, and streams. Substitute the AWS Region name, your account ID, and the table name or wildcard character (*) where appropriate.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DynamoDBIndexAndStreamAccess",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetShardIterator",  
                "dynamodb:Scan",  
                "dynamodb:Query",  
                "dynamodb:DescribeStream",  
                "dynamodb:GetRecords",  
                "dynamodb>ListStreams"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:  
                    region:  
                    table/  
                    <table_name>  
            ]  
        }  
    ]  
}
```

```
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*",
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books/stream/*"
    ],
},
{
    "Sid": "DynamoDBTableAccess",
    "Effect": "Allow",
    "Action": [
        "dynamodb:BatchGetItem",
        "dynamodb:BatchWriteItem",
        "dynamodb:ConditionCheckItem",
        "dynamodb:PutItem",
        "dynamodb:DescribeTable",
        "dynamodb:DeleteItem",
        "dynamodb:GetItem",
        "dynamodb:Scan",
        "dynamodb:Query",
        "dynamodb:UpdateItem"
    ],
    "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
},
{
    "Sid": "DynamoDBDescribeLimitsAccess",
    "Effect": "Allow",
    "Action": "dynamodb:DescribeLimits",
    "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books",
        "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/*"
    ]
}
]
```

To expand this policy to cover all DynamoDB tables in all AWS Regions for this account, use a wildcard (*) for the Region and table name. For example:

```
"Resource": [
    "arn:aws:dynamodb:*:123456789012:table/*",
    "arn:aws:dynamodb:*:123456789012:table/*/*index/*"
]
```

IAM policy to separate DynamoDB environments in the same AWS account

Suppose that you have separate environments where each environment maintains its own version of a table named `ProductCatalog`. If you create two `ProductCatalog` tables in the same AWS account, work in one environment might affect the other environment because of the way that permissions are set up. For example, quotas on the number of concurrent control plane operations (such as `CreateTable`) are set at the AWS account level.

As a result, each action in one environment reduces the number of operations available in the other environment. There is also a risk that the code in one environment might accidentally access tables in the other environment.

Note

If you want to separate production and test workloads to help control an event's potential "blast radius," the best practice is to create separate AWS accounts for test and production workloads. For more information, see [AWS Account Management and Separation](#).

Suppose further that you have two developers, Amit and Alice, who are testing the `ProductCatalog` table. Instead of each developer requiring a separate AWS account, your developers can share the same test AWS account. In this test account, you can create a copy of the same table for each developer to work on, such as `Alice_ProductCatalog` and `Amit_ProductCatalog`. In this case, you can create users Alice and Amit in the AWS account that you created for the test environment. You then can grant permissions to these users to perform DynamoDB actions on the tables that they own.

To grant these IAM user permissions, you can do either of the following:

- Create a separate policy for each user, and then attach each policy to its user separately. For example, you can attach the following policy to user Alice to allow her access to DynamoDB actions on the `Alice_ProductCatalog` table:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllAPIActionsOnAliceTable",  
            "Effect": "Allow",  
            "Action": [
```

```
"dynamodb>DeleteItem",
"dynamodb>DescribeContributorInsights",
"dynamodb>RestoreTableToPointInTime",
"dynamodb>ListTagsOfResource",
"dynamodb>CreateTableReplica",
"dynamodb>UpdateContributorInsights",
"dynamodb>CreateBackup",
"dynamodb>DeleteTable",
"dynamodb>UpdateTableReplicaAutoScaling",
"dynamodb>UpdateContinuousBackups",
"dynamodb>TagResource",
"dynamodb>DescribeTable",
"dynamodb>GetItem",
"dynamodb>DescribeContinuousBackups",
"dynamodb>BatchGetItem",
"dynamodb>UpdateTimeToLive",
"dynamodb>BatchWriteItem",
"dynamodb>ConditionCheckItem",
"dynamodb>UntagResource",
"dynamodb>PutItem",
"dynamodb>Scan",
"dynamodb>Query",
"dynamodb>UpdateItem",
"dynamodb>DeleteTableReplica",
"dynamodb>DescribeTimeToLive",
"dynamodb>RestoreTableFromBackup",
"dynamodb>UpdateTable",
"dynamodb>DescribeTableReplicaAutoScaling",
"dynamodb>GetShardIterator",
"dynamodb>DescribeStream",
"dynamodb>GetRecords",
"dynamodb>DescribeLimits",
"dynamodb>ListStreams"
],
"Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/
Alice_ProductCatalog/*"
}
]
}
```

Then, you can create a similar policy with a different resource (the Amit_ProductCatalog table) for user Amit.

- Instead of attaching policies to individual users, you can use IAM policy variables to write a single policy and attach it to a group. You need to create a group and, for this example, add both users Alice and Amit to the group. The following example grants permissions to perform all DynamoDB actions on the \${aws:username}_ProductCatalog table. The policy variable \${aws:username} is replaced by the requester's user name when the policy is evaluated. For example, if Alice sends a request to add an item, the action is allowed only if Alice is adding items to the Alice_ProductCatalog table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ActionsOnUserSpecificTable",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem",  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Scan",  
                "dynamodb:Query",  
                "dynamodb:ConditionCheckItem"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/  
${aws:username}_ProductCatalog"  
        },  
        {  
            "Sid": "AdditionalPrivileges",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb>ListTables",  
                "dynamodb:DescribeTable",  
                "dynamodb:DescribeContributorInsights"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/*"  
        }  
    ]  
}
```

Note

When using IAM policy variables, you must explicitly specify the 2012-10-17 version of the IAM policy language in the policy. The default version of the IAM policy language (2008-10-17) does not support policy variables.

Instead of identifying a specific table as a resource as you normally would, you could use a wildcard character (*) to grant permissions on all tables where the table name is prefixed with the user that is making the request, as shown in the following example.

```
"Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/${aws:username}_*"
```

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see [Amazon DynamoDB pricing](#).

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- dynamodb:DescribeReservedCapacity – Returns the reserved capacity purchases that are currently in effect.
- dynamodb:DescribeReservedCapacityOfferings – Returns details about the reserved capacity plans that are currently offered by AWS.
- dynamodb:PurchaseReservedCapacityOfferings – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowReservedCapacityDescriptions",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:DescribeReservedCapacity",  
                "dynamodb:DescribeReservedCapacityOfferings"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:/*"  
        },  
        {  
            "Sid": "DenyReservedCapacityPurchases",  
            "Effect": "Deny",  
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:/*"  
        }  
    ]  
}
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

IAM policy to grant read access for a DynamoDB stream only (not for the table)

When you enable DynamoDB Streams on a table, information is captured about every modification to items in the table. For more information, see [Change data capture for DynamoDB Streams](#).

In some cases, you might want to prevent an application from reading data from a DynamoDB table, but still allow access to that table's streams. For example, you can configure AWS Lambda to poll a stream and invoke a Lambda function when item updates are detected, and then perform additional processing.

The following actions are available for controlling access to DynamoDB streams:

- dynamodb:DescribeStream
- dynamodb:GetRecords
- dynamodb:GetShardIterator
- dynamodb>ListStreams

The following example policy grants users permissions to access the streams of a table named GameScores. The wildcard character (*) in the ARN matches any stream associated with that table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AccessGameScoresStreamOnly",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:DescribeStream",  
                "dynamodb:GetRecords",  
                "dynamodb:GetShardIterator",  
                "dynamodb>ListStreams"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/  
stream/*"  
        }  
    ]  
}
```

Note that this policy grants access to the GameScores table's streams, but not to the table itself.

IAM policy to allow an AWS Lambda function to access DynamoDB stream records

If you want certain actions to be performed based on events in a DynamoDB stream, you can write an AWS Lambda function that is triggered by these events. A Lambda function such as this needs permissions to read data from a DynamoDB stream. For more information about using Lambda with DynamoDB Streams, see [DynamoDB Streams and AWS Lambda triggers](#).

To grant permissions to Lambda, use the permissions policy that is associated with the Lambda function's IAM role (also known as an execution role). Specify this policy when you create the Lambda function.

For example, you can associate the following permissions policy with an execution role to grant Lambda permissions to perform the DynamoDB Streams actions listed.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "APIAccessForDynamoDBStreams",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:DescribeStream",  
                "dynamodb:GetRecords",  
                "dynamodb:GetShardIterator",  
                "dynamodb>ListStreams"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/  
stream/*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Action": [
            "dynamodb:GetRecords",
            "dynamodb:GetShardIterator",
            "dynamodb:DescribeStream",
            "dynamodb>ListStreams"
        ],
        "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/
stream/*"
    }
]
```

For more information, see [AWS Lambda permissions](#) in the *AWS Lambda Developer Guide*.

IAM policy for read and write access to a DynamoDB Accelerator (DAX) cluster

The following policy allows read, write, update, and delete access to a DynamoDB Accelerator (DAX) cluster, but not to the associated DynamoDB table. To use this policy, substitute the AWS Region name, your account ID, and the name of your DAX cluster.

Note

This policy gives access to DAX cluster, but not to the associated DynamoDB table. Make sure that your DAX cluster has the correct policy to perform these same operations on the DynamoDB table on your behalf.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AmazonDynamoDBDAXDataOperations",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:PutItem",
                "dax:ConditionCheckItem",
                "dax:BatchGetItem",
                "dax:BatchWriteItem",
                "dax>DeleteItem",
                "dax:Query",
                "dax:Scan"
            ]
        }
    ]
}
```

```
        "dax:UpdateItem",
        "dax:Scan"
    ],
    "Resource": "arn:aws:dax:eu-west-1:123456789012:cache/MyDAXCluster"
}
]
```

To expand this policy to cover DAX access for all AWS Regions for an account, use a wildcard character (*) for the Region name.

```
"Resource": "arn:aws:dax:*:123456789012:cache/MyDAXCluster"
```

Troubleshooting Amazon DynamoDB identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with DynamoDB and IAM.

Topics

- [I am not authorized to perform an action in DynamoDB](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my DynamoDB resources](#)

I am not authorized to perform an action in DynamoDB

If the AWS Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your user name and password.

The following example error occurs when the mateojackson user tries to use the console to view details about a fictional *my-example-widget* resource but does not have the fictional aws:*GetWidget* permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform:
aws:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *my-example-widget* resource using the aws : *GetWidget* action.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to DynamoDB.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in DynamoDB. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform:  
    iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my AWS account to access my DynamoDB resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether DynamoDB supports these features, see [How Amazon DynamoDB works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the *IAM User Guide*.

- To learn how to provide access through identity federation, see [Providing access to externally authenticated users \(identity federation\)](#) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the *IAM User Guide*.

IAM policy to prevent the purchase of DynamoDB reserved capacity

With Amazon DynamoDB reserved capacity, you pay a one-time, upfront fee and commit to paying for a minimum usage level at significant savings over a period of time. You can use the AWS Management Console to view and purchase reserved capacity. However, you might not want all of the users in your organization to be able to purchase reserved capacity. For more information about reserved capacity, see [Amazon DynamoDB pricing](#).

DynamoDB provides the following API operations for controlling access to reserved capacity management:

- `dynamodb:DescribeReservedCapacity` – Returns the reserved capacity purchases that are currently in effect.
- `dynamodb:DescribeReservedCapacityOfferings` – Returns details about the reserved capacity plans that are currently offered by AWS.
- `dynamodb:PurchaseReservedCapacityOfferings` – Performs an actual purchase of reserved capacity.

The AWS Management Console uses these API actions to display reserved capacity information and make purchases. You cannot call these operations from an application program because they can be accessed only from the console. However, you can allow or deny access to these operations in an IAM permissions policy.

The following policy allows users to view reserved capacity purchases and offerings by using the AWS Management Console — but new purchases are denied.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowReservedCapacityDescriptions",  
            "Effect": "Allow",  
            "Action": "dynamodb:DescribeReservedCapacityOfferings",  
            "Resource": "*"  
        },  
        {  
            "Sid": "DenyPurchaseReservedCapacityOfferings",  
            "Effect": "Deny",  
            "Action": "dynamodb:PurchaseReservedCapacityOfferings",  
            "Resource": "*"  
        }  
    ]  
}
```

```
    "Action": [
        "dynamodb:DescribeReservedCapacity",
        "dynamodb:DescribeReservedCapacityOfferings"
    ],
    "Resource": "arn:aws:dynamodb:us-west-2:123456789012:/*"
},
{
    "Sid": "DenyReservedCapacityPurchases",
    "Effect": "Deny",
    "Action": "dynamodb:PurchaseReservedCapacityOfferings",
    "Resource": "arn:aws:dynamodb:us-west-2:123456789012:/*"
}
]
```

Note that this policy uses the wildcard character (*) to allow describe permissions for all, and to deny the purchase of DynamoDB reserved capacity for all.

Using IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect.

Overview

In DynamoDB, you have the option to specify conditions when granting permissions using an IAM policy (see [Identity and Access Management for Amazon DynamoDB](#)). For example, you can:

- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

In DynamoDB, you can specify conditions in an IAM policy using condition keys, as illustrated in the use case in the following section.

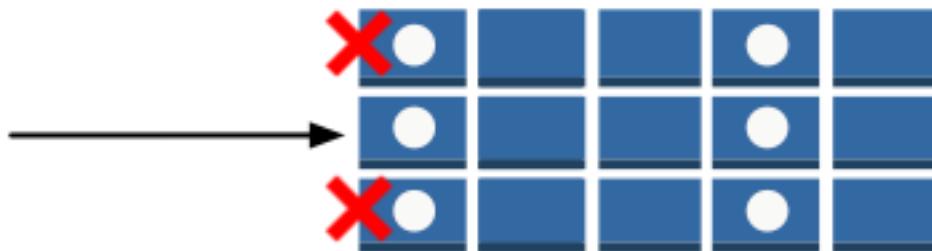

Note

Some AWS services also support tag-based conditions; however, DynamoDB does not.

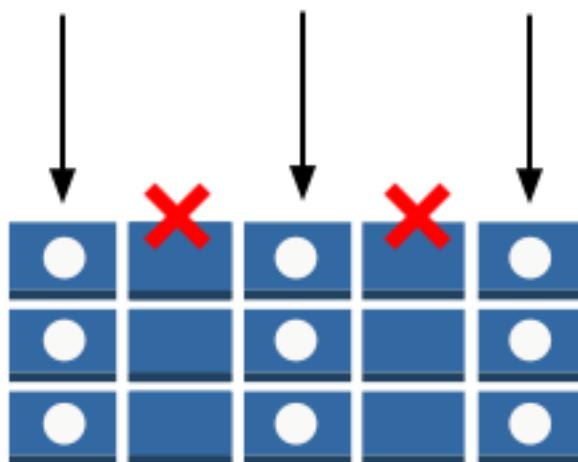

Permissions use case

In addition to controlling access to DynamoDB API actions, you can also control access to individual data items and attributes. For example, you can do the following:

- Grant permissions on a table, but restrict access to specific items in that table based on certain primary key values. An example might be a social networking app for games, where all users' saved game data is stored in a single table, but no users can access data items that they do not own, as shown in the following illustration:

- Hide information so that only a subset of attributes is visible to the user. An example might be an app that displays flight data for nearby airports, based on the user's location. Airline names, arrival and departure times, and flight numbers are all displayed. However, attributes such as pilot names or the number of passengers are hidden, as shown in the following illustration:

To implement this kind of fine-grained access control, you write an IAM permissions policy that specifies conditions for accessing security credentials and the associated permissions. You then apply the policy to users, groups, or roles that you create using the IAM console. Your IAM policy can restrict access to individual items in a table, access to the attributes in those items, or both at the same time.

You can optionally use web identity federation to control access by users who are authenticated by Login with Amazon, Facebook, or Google. For more information, see [Using web identity federation](#).

You use the IAM Condition element to implement a fine-grained access control policy. By adding a Condition element to a permissions policy, you can allow or deny access to items and attributes in DynamoDB tables and indexes, based upon your particular business requirements.

As an example, consider a mobile gaming app that lets players select from and play a variety of different games. The app uses a DynamoDB table named GameScores to keep track of high scores and other user data. Each item in the table is uniquely identified by a user ID and the name of the game that the user played. The GameScores table has a primary key consisting of a partition key (UserId) and sort key (GameTitle). Users only have access to game data associated with their user ID. A user who wants to play a game must belong to an IAM role named GameRole, which has a security policy attached to it.

To manage user permissions in this app, you could write a permissions policy such as the following:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToOnlyItemsMatchingUserID",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"  
            ],  
            "Condition": {}  
        }  
    ]  
}
```

```
"Condition":{  
    "ForAllValues:StringEquals":{  
        "dynamodb:LeadingKeys": [  
            "${www.amazon.com:user_id}"  
        ],  
        "dynamodb:Attributes": [  
            "UserId",  
            "GameTitle",  
            "Wins",  
            "Losses",  
            "TopScore",  
            "TopScoreDateTime"  
        ]  
    },  
    "StringEqualsIfExists":{  
        "dynamodb:Select":"SPECIFIC_ATTRIBUTES"  
    }  
}  
}  
]  
}
```

In addition to granting permissions for specific DynamoDB actions (Action element) on the GameScores table (Resource element), the Condition element uses the following condition keys specific to DynamoDB that limit the permissions as follows:

- dynamodb:LeadingKeys – This condition key allows users to access only the items where the partition key value matches their user ID. This ID, \${www.amazon.com:user_id}, is a substitution variable. For more information about substitution variables, see [Using web identity federation](#).
- dynamodb:Attributes – This condition key limits access to the specified attributes so that only the actions listed in the permissions policy can return values for these attributes. In addition, the StringEqualsIfExists clause ensures that the app must always provide a list of specific attributes to act upon and that the app can't request all attributes.

When an IAM policy is evaluated, the result is always either true (access is allowed) or false (access is denied). If any part of the Condition element is false, the entire policy evaluates to false and access is denied.

⚠ Important

If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

IAM policy documents can contain only the following Unicode characters: horizontal tab (U+0009), linefeed (U+000A), carriage return (U+000D), and characters in the range U+0020 to U+00FF.

Specifying conditions: Using condition keys

AWS provides a set of predefined condition keys (AWS-wide condition keys) for all AWS services that support IAM for access control. For example, you can use the `aws:SourceIp` condition key to check the requester's IP address before allowing an action to be performed. For more information and a list of the AWS-wide keys, see [Available Keys for Conditions](#) in the IAM User Guide.

The following table shows the DynamoDB service-specific condition keys that apply to DynamoDB.

DynamoDB Condition Key	Description
<code>dynamodb:LeadingKeys</code>	Represents the first key attribute of a table—in other words, the partition key. The key name <code>LeadingKeys</code> is plural, even if the key is used with single-item actions. In addition, you must use the <code>ForAllValues</code> modifier when using <code>LeadingKeys</code> in a condition.
<code>dynamodb:Select</code>	Represents the <code>Select</code> parameter of a <code>Query</code> or <code>Scan</code> request. <code>Select</code> can be any of the following values: <ul style="list-style-type: none">• <code>ALL_ATTRIBUTES</code>• <code>ALL_PROJECTED_ATTRIBUTES</code>• <code>SPECIFIC_ATTRIBUTES</code>• <code>COUNT</code>
<code>dynamodb:Attributes</code>	Represents a list of the attribute names in a request, or the attributes that are returned from a request. <code>Attributes</code> values are named the

DynamoDB Condition Key	Description
	<p>same way and have the same meaning as the parameters for certain DynamoDB API actions, as shown following:</p> <ul style="list-style-type: none">• AttributesToGet Used by: <code>BatchGetItem</code>, <code>.GetItem</code>, <code>Query</code>, <code>Scan</code>• AttributeUpdates Used by: <code>UpdateItem</code>• Expected Used by: <code>DeleteItem</code>, <code>PutItem</code>, <code>UpdateItem</code>• Item Used by: <code>PutItem</code>• ScanFilter Used by: <code>Scan</code>
<code>dynamodb:ReturnValues</code>	Represents the <code>ReturnValues</code> parameter of a request. <code>ReturnValues</code> can be any of the following values: <ul style="list-style-type: none">• <code>ALL_OLD</code>• <code>UPDATED_OLD</code>• <code>ALL_NEW</code>• <code>UPDATED_NEW</code>• <code>NONE</code>
<code>dynamodb:ReturnConsumedCapacity</code>	Represents the <code>ReturnConsumedCapacity</code> parameter of a request. <code>ReturnConsumedCapacity</code> can be one of the following values: <ul style="list-style-type: none">• <code>TOTAL</code>• <code>NONE</code>

Limiting user access

Many IAM permissions policies allow users to access only those items in a table where the partition key value matches the user identifier. For example, the game app preceding limits access in this way so that users can only access game data that is associated with their user ID. The IAM substitution variables \${www.amazon.com:user_id}, \${graph.facebook.com:id}, and \${accounts.google.com:sub} contain user identifiers for Login with Amazon, Facebook, and Google. To learn how an application logs in to one of these identity providers and obtains these identifiers, see [Using web identity federation](#).

Note

Each of the examples in the following section sets the Effect clause to Allow and specifies only the actions, resources, and parameters that are allowed. Access is permitted only to what is explicitly listed in the IAM policy.

In some cases, it is possible to rewrite these policies so that they are deny-based (that is, setting the Effect clause to Deny and inverting all of the logic in the policy). However, we recommend that you avoid using deny-based policies with DynamoDB because they are difficult to write correctly, compared to allow-based policies. In addition, future changes to the DynamoDB API (or changes to existing API inputs) can render a deny-based policy ineffective.

Example policies: Using conditions for fine-grained access control

This section shows several policies for implementing fine-grained access control on DynamoDB tables and indexes.

Note

All examples use the us-west-2 Region and contain fictitious account IDs.

1: Grant permissions that limit access to items with a specific partition key value

The following permissions policy grants permissions that allow a set of DynamoDB actions on the GamesScore table. It uses the dynamodb:LeadingKeys condition key to limit user actions only on the items whose UserID partition key value matches the Login with Amazon unique user ID for this app.

⚠ Important

The list of actions does not include permissions for Scan because Scan returns all items regardless of the leading keys.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "FullAccessToUserItems",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:LeadingKeys": [  
                        "${www.amazon.com:user_id}"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

ⓘ Note

When using policy variables, you must explicitly specify version 2012-10-17 in the policy. The default version of the access policy language, 2008-10-17, does not support policy variables.

To implement read-only access, you can remove any actions that can modify the data. In the following policy, only those actions that provide read-only access are included in the condition.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ReadOnlyAccessToUserItems",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:LeadingKeys": [  
                        "${www.amazon.com:user_id}"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Important

If you use `dynamodb:Attributes`, you must specify the names of all of the primary key and index key attributes, for the table and any secondary indexes that are listed in the policy. Otherwise, DynamoDB can't use these key attributes to perform the requested action.

2: Grant permissions that limit access to specific attributes in a table

The following permissions policy allows access to only two specific attributes in a table by adding the `dynamodb:Attributes` condition key. These attributes can be read, written, or evaluated in a conditional write or scan filter.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "LimitAccessToSpecificAttributes",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:UpdateItem",  
                "dynamodb:GetItem",  
                "dynamodb:Query",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Scan"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:Attributes": [  
                        "UserId",  
                        "TopScore"  
                    ]  
                },  
                "StringEqualsIfExists": {  
                    "dynamodb:Select": "SPECIFIC_ATTRIBUTES",  
                    "dynamodb:ReturnValues": [  
                        "NONE",  
                        "UPDATED_OLD",  
                        "UPDATED_NEW"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Note

The policy takes an *allow list* approach, which allows access to a named set of attributes. You can write an equivalent policy that denies access to other attributes instead. We don't recommend this *deny list* approach. Users can determine the names of these denied attributes by following the *principle of least privilege*, as explained in Wikipedia at <http://>

en.wikipedia.org/wiki/Principle_of_least_privilege, and use an *allow list* approach to enumerate all of the allowed values, rather than specifying the denied attributes.

This policy doesn't permit PutItem, DeleteItem, or BatchWriteItem. These actions always replace the entire previous item, which would allow users to delete the previous values for attributes that they are not allowed to access.

The `StringEqualsIfExists` clause in the permissions policy ensures the following:

- If the user specifies the `Select` parameter, then its value must be `SPECIFIC_ATTRIBUTES`. This requirement prevents the API action from returning any attributes that aren't allowed, such as from an index projection.
- If the user specifies the `ReturnValues` parameter, then its value must be `NONE`, `UPDATED_OLD`, or `UPDATED_NEW`. This is required because the `UpdateItem` action also performs implicit read operations to check whether an item exists before replacing it, and so that previous attribute values can be returned if requested. Restricting `ReturnValues` in this way ensures that users can only read or write the allowed attributes.
- The `StringEqualsIfExists` clause assures that only one of these parameters — `Select` or `ReturnValues` — can be used per request, in the context of the allowed actions.

The following are some variations on this policy:

- To allow only read actions, you can remove `UpdateItem` from the list of allowed actions. Because none of the remaining actions accept `ReturnValues`, you can remove `ReturnValues` from the condition. You can also change `StringEqualsIfExists` to `StringEquals` because the `Select` parameter always has a value (`ALL_ATTRIBUTES`, unless otherwise specified).
- To allow only write actions, you can remove everything except `UpdateItem` from the list of allowed actions. Because `UpdateItem` does not use the `Select` parameter, you can remove `Select` from the condition. You must also change `StringEqualsIfExists` to `StringEquals` because the `ReturnValues` parameter always has a value (`NONE` unless otherwise specified).
- To allow all attributes whose name matches a pattern, use `StringLike` instead of `StringEquals`, and use a multi-character pattern match wildcard character (*).

3: Grant permissions to prevent updates on certain attributes

The following permissions policy limits user access to updating only the specific attributes identified by the dynamodb:Attributes condition key. The StringNotLike condition prevents an application from updating the attributes specified using the dynamodb:Attributes condition key.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "PreventUpdatesOnCertainAttributes",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:UpdateItem"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",  
            "Condition": {  
                "ForAllValues:StringNotLike": {  
                    "dynamodb:Attributes": [  
                        "FreeGamesAvailable",  
                        "BossLevelUnlocked"  
                    ]  
                },  
                "StringEquals": {  
                    "dynamodb:ReturnValues": [  
                        "NONE",  
                        "UPDATED_OLD",  
                        "UPDATED_NEW"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

Note the following:

- The UpdateItem action, like other write actions, requires read access to the items so that it can return values before and after the update. In the policy, you limit the action to accessing only the attributes that are allowed to be updated by specifying the dynamodb:ReturnValues

condition key. The condition key restricts `ReturnValues` in the request to specify only `NONE`, `UPDATED_OLD`, or `UPDATED_NEW` and doesn't include `ALL_OLD` or `ALL_NEW`.

- The `PutItem` and `DeleteItem` actions replace an entire item, and thus allows applications to modify any attributes. So when limiting an application to updating only specific attributes, you should not grant permission for these APIs.

4: Grant permissions to query only projected attributes in an index

The following permissions policy allows queries on a secondary index (`TopScoreDateTimeIndex`) by using the `dynamodb:Attributes` condition key. The policy also limits queries to requesting only specific attributes that have been projected into the index.

To require the application to specify a list of attributes in the query, the policy also specifies the `dynamodb:Select` condition key to require that the `Select` parameter of the DynamoDB Query action is `SPECIFIC_ATTRIBUTES`. The list of attributes is limited to a specific list that is provided using the `dynamodb:Attributes` condition key.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "QueryOnlyProjectedIndexAttributes",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:Query"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/  
TopScoreDateTimeIndex"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:Attributes": [  
                        "TopScoreDateTime",  
                        "GameTitle",  
                        "Wins",  
                        "Losses",  
                        "Attempts"  
                    ]  
                },  
                "StringEquals": {  
                    "ConditionKey": "TopScoreDateTime"  
                }  
            }  
        }  
    ]  
}
```

```
        "dynamodb:Select":"SPECIFIC_ATTRIBUTES"
    }
}
]
}
```

The following permissions policy is similar, but the query must request all of the attributes that have been projected into the index.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "QueryAllIndexAttributes",
            "Effect": "Allow",
            "Action": [
                "dynamodb:Query"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/TopScoreDateTimeIndex"
            ],
            "Condition": {
                "StringEquals": {
                    "dynamodb:Select": "ALL_PROJECTED_ATTRIBUTES"
                }
            }
        }
    ]
}
```

5: Grant permissions to limit access to certain attributes and partition key values

The following permissions policy allows specific DynamoDB actions (specified in the Action element) on a table and a table index (specified in the Resource element). The policy uses the dynamodb:LeadingKeys condition key to restrict permissions to only the items whose partition key value matches the user's Facebook ID.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Sid": "LimitAccessToCertainAttributesAndKeyValues",  
    "Effect": "Allow",  
    "Action": [  
        "dynamodb:UpdateItem",  
        "dynamodb:GetItem",  
        "dynamodb:Query",  
        "dynamodb:BatchGetItem"  
    ],  
    "Resource": [  
        "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",  
        "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores/index/  
TopScoreDateTimeIndex"  
    ],  
    "Condition": {  
        "ForAllValues:StringEquals": {  
            "dynamodb:LeadingKeys": [  
                "${graph.facebook.com:id}"  
            ],  
            "dynamodb:Attributes": [  
                "attribute-A",  
                "attribute-B"  
            ]  
        },  
        "StringEqualsIfExists": {  
            "dynamodb:Select": "SPECIFIC_ATTRIBUTES",  
            "dynamodb:ReturnValues": [  
                "NONE",  
                "UPDATED_OLD",  
                "UPDATED_NEW"  
            ]  
        }  
    }  
}
```

Note the following:

- Write actions allowed by the policy (UpdateItem) can only modify attribute-A or attribute-B.
- Because the policy allows UpdateItem, an application can insert new items, and the hidden attributes will be null in the new items. If these attributes are projected into

TopScoreDateTimeIndex, the policy has the added benefit of preventing queries that cause fetches from the table.

- Applications cannot read any attributes other than those listed in dynamodb:Attributes. With this policy in place, an application must set the Select parameter to SPECIFIC_ATTRIBUTES in read requests, and only attributes in the allow list can be requested. For write requests, the application cannot set ReturnValue to ALL_OLD or ALL_NEW and it cannot perform conditional write operations based on any other attributes.

Using web identity federation

If you are writing an application targeted at large numbers of users, you can optionally use *web identity federation* for authentication and authorization. Web identity federation removes the need for creating individual users. Instead, users can sign in to an identity provider and then obtain temporary security credentials from AWS Security Token Service (AWS STS). The app can then use these credentials to access AWS services.

Web identity federation supports the following identity providers:

- Login with Amazon
- Facebook
- Google

Additional resources for web identity federation

The following resources can help you learn more about web identity federation:

- The post [Web Identity Federation using the AWS SDK for .NET](#) on the AWS Developer blog walks through how to use web identity federation with Facebook. It includes code snippets in C# that show how to assume an IAM role with web identity and how to use temporary security credentials to access an AWS resource.

- The [AWS Mobile SDK for iOS](#) and the [AWS Mobile SDK for Android](#) contain sample apps. They include code that shows how to invoke the identity providers, and then how to use the information from these providers to get and use temporary security credentials.
- The article [Web Identity Federation with Mobile Applications](#) discusses web identity federation and shows an example of how to use web identity federation to access an AWS resource.

Example policy for web identity federation

To show how you can use web identity federation with DynamoDB, revisit the *GameScores* table that was introduced in [Using IAM policy conditions for fine-grained access control](#). Here is the primary key for *GameScores*.

Table Name	Primary Key Type	Partition Key Name and Type	Sort Key Name and Type
GameScores (<u>UserId</u> , <u>GameTitle</u> , ...)	Composite	Attribute Name: UserId Type: String	Attribute Name: GameTitle Type: String

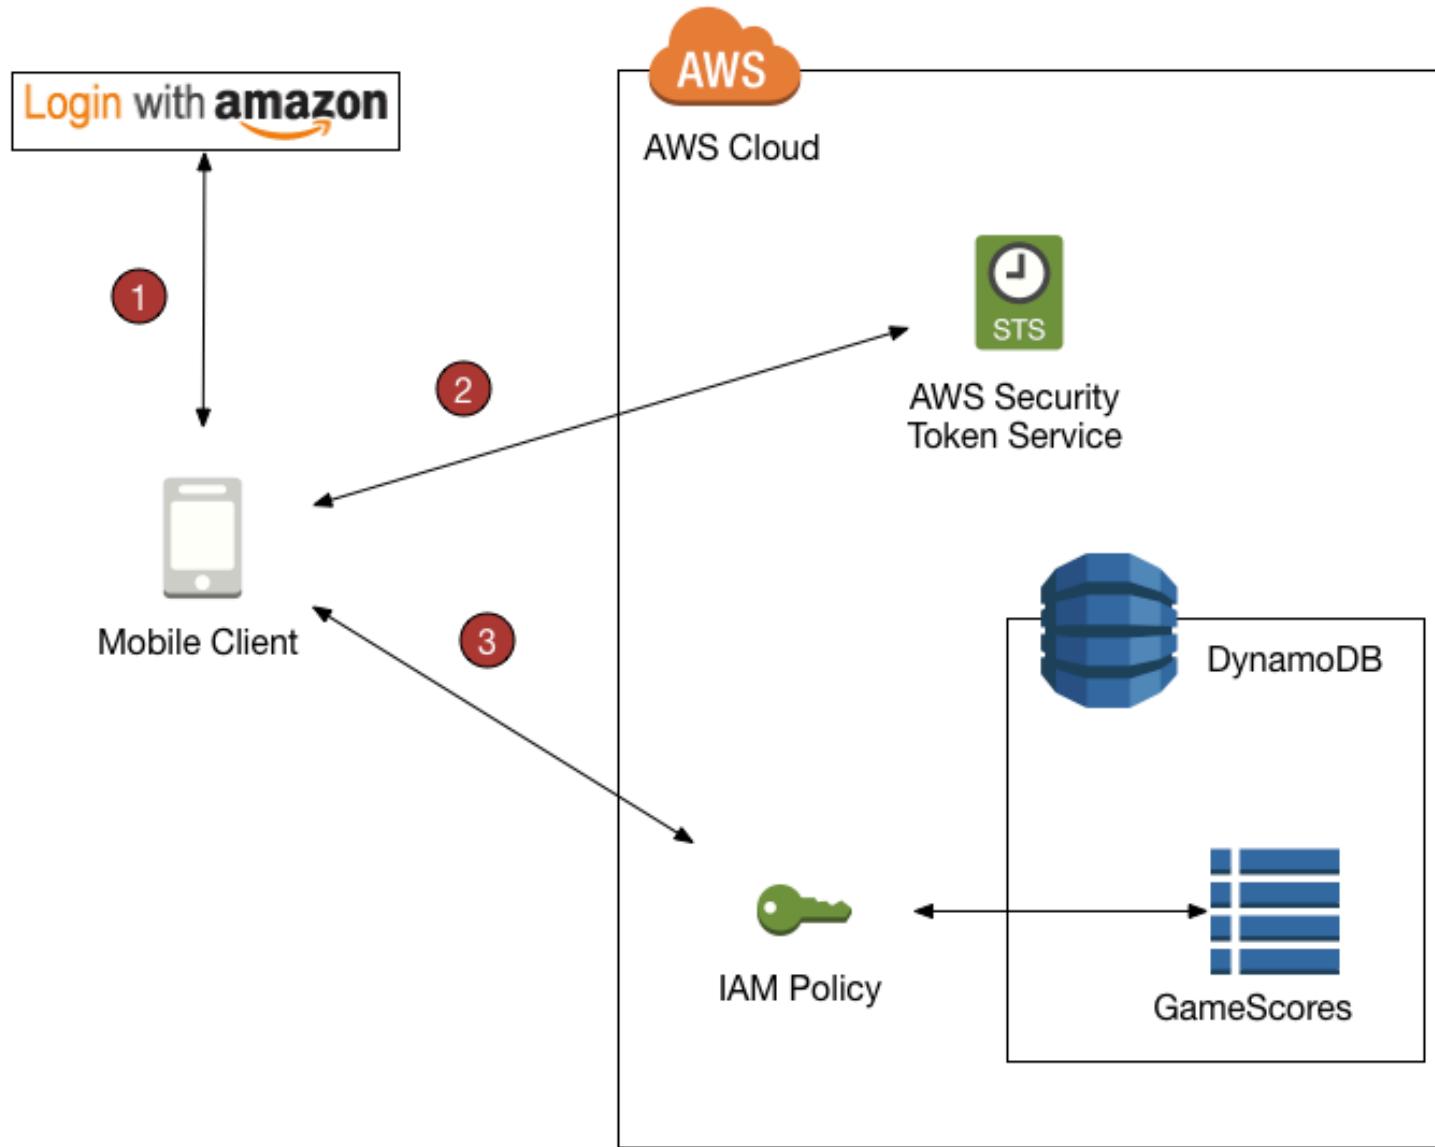

Now suppose that a mobile gaming app uses this table, and that app needs to support thousands, or even millions, of users. At this scale, it becomes very difficult to manage individual app users, and to guarantee that each user can only access their own data in the *GameScores* table. Fortunately, many users already have accounts with a third-party identity provider, such as Facebook, Google, or Login with Amazon. So it makes sense to use one of these providers for authentication tasks.

To do this using web identity federation, the app developer must register the app with an identity provider (such as Login with Amazon) and obtain a unique app ID. Next, the developer needs to create an IAM role. (For this example, this role is named *GameRole*.) The role must have an IAM policy document attached to it, specifying the conditions under which the app can access *GameScores* table.

When a user wants to play a game, they sign in to their Login with Amazon account from within the gaming app. The app then calls AWS Security Token Service (AWS STS), providing the Login with Amazon app ID and requesting membership in *GameRole*. AWS STS returns temporary AWS

credentials to the app and allows it to access the *GameScores* table, subject to the *GameRole* policy document.

The following diagram shows how these pieces fit together.

Web identity federation overview

1. The app calls a third-party identity provider to authenticate the user and the app. The identity provider returns a web identity token to the app.
2. The app calls AWS STS and passes the web identity token as input. AWS STS authorizes the app and gives it temporary AWS access credentials. The app is allowed to assume an IAM role (*GameRole*) and access AWS resources in accordance with the role's security policy.

3. The app calls DynamoDB to access the *GameScores* table. Because it has assumed the *GameRole*, the app is subject to the security policy associated with that role. The policy document prevents the app from accessing data that does not belong to the user.

Once again, here is the security policy for *GameRole* that was shown in [Using IAM policy conditions for fine-grained access control](#):

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowAccessToOnlyItemsMatchingUserID",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores"  
            ],  
            "Condition": {  
                "ForAllValues:StringEquals": {  
                    "dynamodb:LeadingKeys": [  
                        "${www.amazon.com:user_id}"  
                    ],  
                    "dynamodb:Attributes": [  
                        "UserId",  
                        "GameTitle",  
                        "Wins",  
                        "Losses",  
                        "TopScore",  
                        "TopScoreDateTime"  
                    ]  
                },  
                "StringEqualsIfExists": {  
                    "dynamodb:Select": "SPECIFIC_ATTRIBUTES"  
                }  
            }  
        }  
    ]  
}
```

```
        }
    }
]
}
```

The Condition clause determines which items in *GameScores* are visible to the app. It does this by comparing the Login with Amazon ID to the UserId partition key values in *GameScores*. Only the items belonging to the current user can be processed using one of DynamoDB actions that are listed in this policy. Other items in the table cannot be accessed. Furthermore, only the specific attributes listed in the policy can be accessed.

Preparing to use web identity federation

If you are an application developer and want to use web identity federation for your app, follow these steps:

- 1. Sign up as a developer with a third-party identity provider.** The following external links provide information about signing up with supported identity providers:
 - [Login with Amazon Developer Center](#)
 - [Registration on the Facebook site](#)
 - [Using OAuth 2.0 to Access Google APIs](#) on the Google site
- 2. Register your app with the identity provider.** When you do this, the provider gives you an ID that's unique to your app. If you want your app to work with multiple identity providers, you need to obtain an app ID from each provider.
- 3. Create one or more IAM roles.** You need one role for each identity provider for each app. For example, you might create a role that can be assumed by an app where the user signed in using Login with Amazon, a second role for the same app where the user has signed in using Facebook, and a third role for the app where users sign in using Google.

As part of the role creation process, you need to attach an IAM policy to the role. Your policy document should define the DynamoDB resources required by your app, and the permissions for accessing those resources.

For more information, see [About Web Identity Federation](#) in *IAM User Guide*.

Note

As an alternative to AWS Security Token Service, you can use Amazon Cognito. Amazon Cognito is the preferred service for managing temporary credentials for mobile apps. For more information, see [Getting credentials](#) in the *Amazon Cognito Developer Guide*.

Generating an IAM policy using the DynamoDB console

The DynamoDB console can help you create an IAM policy for use with web identity federation. To do this, you choose a DynamoDB table and specify the identity provider, actions, and attributes to be included in the policy. The DynamoDB console then generates a policy that you can attach to an IAM role.

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, choose **Tables**.
3. In the list of tables, choose the table for which you want to create the IAM policy.
4. Select the **Actions** button, and choose **Create Access Control Policy**.
5. Choose the identity provider, actions, and attributes for the policy.

When the settings are as you want them, choose **Generate Policy**. The generated policy appears.

6. Choose **See Documentation**, and follow the steps required to attach the generated policy to an IAM role.

Writing your app to use web identity federation

To use web identity federation, your app must assume the IAM role that you created. From that point on, the app honors the access policy that you attached to the role.

At runtime, if your app uses web identity federation, it must follow these steps:

1. **Authenticate with a third-party identity provider.** Your app must call the identity provider using an interface that they provide. The exact way in which you authenticate the user depends on the provider and on what platform your app is running. Typically, if the user is not already signed in, the identity provider takes care of displaying a sign-in page for that provider.

After the identity provider authenticates the user, the provider returns a web identity token to your app. The format of this token depends on the provider, but is typically a very long string of characters.

2. Obtain temporary AWS security credentials. To do this, your app sends a `AssumeRoleWithWebIdentity` request to AWS Security Token Service (AWS STS). This request contains the following:

- The web identity token from the previous step
- The app ID from the identity provider
- The Amazon Resource Name (ARN) of the IAM role that you created for this identity provider for this app

AWS STS returns a set of AWS security credentials that expire after a certain amount of time (3,600 seconds, by default).

The following is a sample request and response from a `AssumeRoleWithWebIdentity` action in AWS STS. The web identity token was obtained from the Login with Amazon identity provider.

```
GET / HTTP/1.1
Host: sts.amazonaws.com
Content-Type: application/json; charset=utf-8
URL: https://sts.amazonaws.com/?ProviderId=www.amazon.com
&DurationSeconds=900&Action=AssumeRoleWithWebIdentity
&Version=2011-06-15&RoleSessionName=web-identity-federation
&RoleArn=arn:aws:iam::123456789012:role/GameRole
&WebIdentityToken=Atza|IQEBLjAsAhQluyKqyBiYZ8-kclvGTYM81e... (remaining characters
omitted)
```

```
<AssumeRoleWithWebIdentityResponse
  xmlns="https://sts.amazonaws.com/doc/2011-06-15/">
  <AssumeRoleWithWebIdentityResult>
    <SubjectFromWebIdentityToken>amzn1.account.AGJZDKHJKAUUSW6C44CHPEXAMPLE</
    SubjectFromWebIdentityToken>
    <Credentials>
      <SessionToken>AQoDYXdzEMf//////////wEa8AP6nNDwcSLnf+cHupC... (remaining
      characters omitted)</SessionToken>
      <SecretAccessKey>8Jhi60+EWUUbbUShTEsjTxqQtM8UKvsM6XAjdA==</SecretAccessKey>
      <Expiration>2013-10-01T22:14:35Z</Expiration>
      <AccessKeyId>06198791C436IEXAMPLE</AccessKeyId>
```

```
</Credentials>
<AssumedRoleUser>
  <Arn>arn:aws:sts::123456789012:assumed-role/GameRole/web-identity-federation</Arn>
    <AssumedRoleId>AR0AJU4SA2VW5SZRF2YMG:web-identity-federation</AssumedRoleId>
  </AssumedRoleUser>
</AssumeRoleWithWebIdentityResult>
<ResponseMetadata>
  <RequestId>c265ac8e-2ae4-11e3-8775-6969323a932d</RequestId>
</ResponseMetadata>
</AssumeRoleWithWebIdentityResponse>
```

3. Access AWS resources. The response from AWS STS contains information that your app requires in order to access DynamoDB resources:

- The `AccessKeyId`, `SecretAccessKey`, and `SessionToken` fields contain security credentials that are valid for this user and this app only.
- The `Expiration` field signifies the time limit for these credentials, after which they are no longer valid.
- The `AssumedRoleId` field contains the name of a session-specific IAM role that has been assumed by the app. The app honors the access controls in the IAM policy document for the duration of this session.
- The `SubjectFromWebIdentityToken` field contains the unique ID that appears in an IAM policy variable for this particular identity provider. The following are the IAM policy variables for supported providers, and some example values for them:

Policy Variable	Example Value
<code> \${www.amazon.com:user_id}</code>	amzn1.account.AGJZDKHJKAUUS W6C44CHPEXAMPLE
<code> \${graph.facebook.com:id}</code>	123456789
<code> \${accounts.google.com:sub}</code>	123456789012345678901

For example IAM policies where these policy variables are used, see [Example policies: Using conditions for fine-grained access control](#).

For more information about how AWS STS generates temporary access credentials, see [Requesting Temporary Security Credentials](#) in *IAM User Guide*.

DynamoDB API permissions: Actions, resources, and conditions reference

When you are setting up [Identity and Access Management for Amazon DynamoDB](#) and writing a permissions policy that you can attach to an IAM identity (identity-based policies), you can use the list of [Actions, resources, and condition keys for Amazon DynamoDB](#) in the *IAM User Guide* as a reference. The page lists each DynamoDB API operation, the corresponding actions for which you can grant permissions to perform the action, and the AWS resource for which you can grant the permissions. You specify the actions in the policy's Action field, and you specify the resource value in the policy's Resource field.

You can use AWS-wide condition keys in your DynamoDB policies to express conditions. For a complete list of AWS-wide keys, see the [IAM JSON policy elements reference](#) in the *IAM User Guide*.

In addition to the AWS-wide condition keys, DynamoDB has its own specific keys that you can use in conditions. For more information, see [Using IAM policy conditions for fine-grained access control](#).

Identity and access management in DynamoDB Accelerator

DynamoDB Accelerator (DAX) is designed to work together with DynamoDB, to seamlessly add a caching layer to your applications. However, DAX and DynamoDB have separate access control mechanisms. Both services use AWS Identity and Access Management (IAM) to implement their respective security policies, but the security models for DAX and DynamoDB are different.

For more information about Identity and Access Management in DAX, see [DAX access control](#).

Compliance validation by industry for DynamoDB

To learn whether an AWS service is within the scope of specific compliance programs, see [AWS services in Scope by Compliance Program](#) and choose the compliance program that you are interested in. For general information, see [AWS Compliance Programs](#).

You can download third-party audit reports using AWS Artifact. For more information, see [Downloading Reports in AWS Artifact](#).

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- [Security and Compliance Quick Start Guides](#) – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- [Architecting for HIPAA Security and Compliance on Amazon Web Services](#) – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

 **Note**

Not all AWS services are HIPAA eligible. For more information, see the [HIPAA Eligible Services Reference](#).

- [AWS Compliance Resources](#) – This collection of workbooks and guides might apply to your industry and location.
- [AWS Customer Compliance Guides](#) – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
- [Evaluating Resources with Rules](#) in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- [AWS Security Hub](#) – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see [Security Hub controls reference](#).
- [AWS Audit Manager](#) – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

Resilience and disaster recovery in Amazon DynamoDB

The AWS global infrastructure is built around AWS Regions and Availability Zones. AWS Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Regions. An AWS Local Region is a single data center designed to complement an existing AWS Region. Like all AWS Regions, AWS Local Regions are completely isolated from other AWS Regions.

For more information about AWS Regions and Availability Zones, see [AWS global infrastructure](#).

In addition to the AWS global infrastructure, Amazon DynamoDB offers several features to help support your data resiliency and backup needs.

On-demand backup and restore

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival. For more information, see [On-Demand backup and restore for DynamoDB](#).

Point-in-time recovery

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For more information, see [Point-in-time recovery for DynamoDB](#).

Global tables that sync across AWS regions

DynamoDB automatically spreads the data and traffic for your tables over a sufficient number of servers to handle your throughput and storage requirements, while maintaining consistent and fast performance. All of your data is stored on solid-state disks (SSDs) and is automatically replicated across multiple Availability Zones in an AWS Region, providing built-in high availability and data durability. You can use global tables to keep DynamoDB tables in sync across AWS Regions.

Infrastructure security in Amazon DynamoDB

As a managed service, Amazon DynamoDB is protected by the AWS global network security procedures that are described in [Infrastructure protection](#) located in the AWS Well-Architected Framework.

You use AWS published API calls to access DynamoDB through the network. Clients can use TLS (Transport Layer Security) version 1.2 or 1.3. Clients must also support cipher suites with perfect forward secrecy (PFS) such as Ephemeral Diffie-Hellman (DHE) or Elliptic Curve Diffie-Hellman Ephemeral (ECDHE). Most modern systems such as Java 7 and later support these modes. Additionally, requests must be signed using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [AWS Security Token Service](#) (AWS STS) to generate temporary security credentials to sign requests.

You can also use a virtual private cloud (VPC) endpoint for DynamoDB to enable Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. For more information, see [Using Amazon VPC endpoints to access DynamoDB](#).

Using Amazon VPC endpoints to access DynamoDB

For security reasons, many AWS customers run their applications within an Amazon Virtual Private Cloud environment (Amazon VPC). With Amazon VPC, you can launch Amazon EC2 instances into a virtual private cloud, which is logically isolated from other networks—including the public internet. With an Amazon VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings.

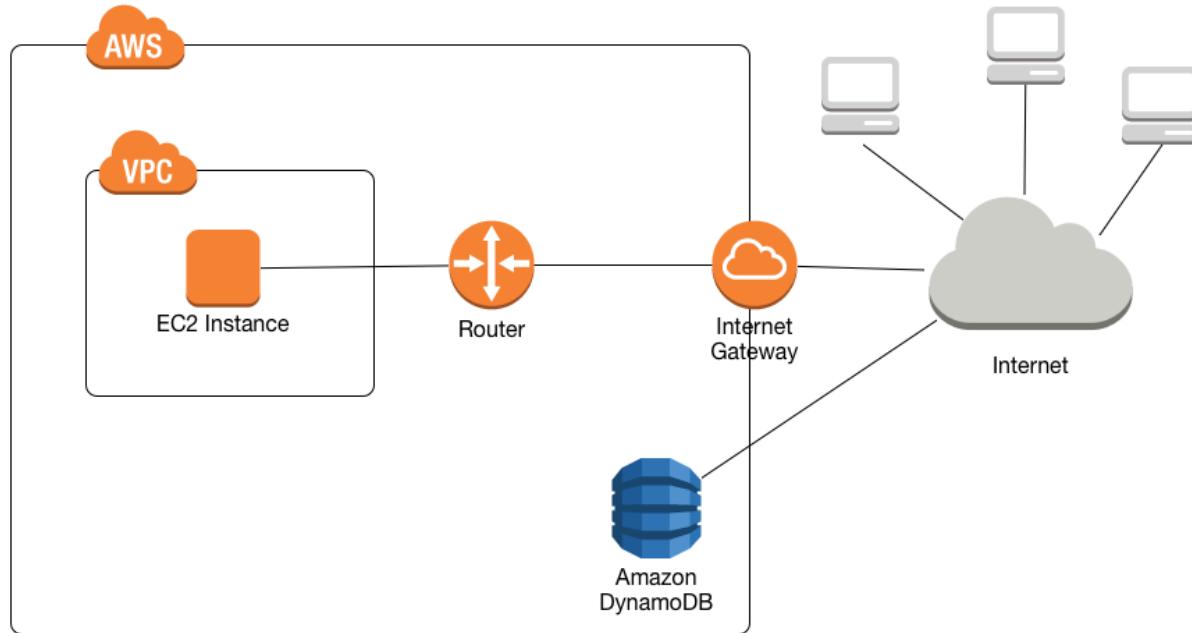

Note

If you created your AWS account after December 4, 2013, then you already have a default VPC in each AWS Region. A default VPC is ready for you to use—you can immediately start using it without having to perform any additional configuration steps.

For more information, see [Default VPC and Default Subnets](#) in the *Amazon VPC User Guide*.

To access the public internet, your VPC must have an internet gateway—a virtual router that connects your VPC to the internet. This allows applications running on Amazon EC2 in your VPC to access internet resources, such as Amazon DynamoDB.

By default, communications to and from DynamoDB use the HTTPS protocol, which protects network traffic by using SSL/TLS encryption. The following diagram shows an Amazon EC2 instance in a VPC accessing DynamoDB, by having DynamoDB use an internet gateway rather than VPC endpoints.

Many customers have legitimate privacy and security concerns about sending and receiving data across the public internet. You can address these concerns by using a virtual private network (VPN) to route all DynamoDB network traffic through your own corporate network infrastructure. However, this approach can introduce bandwidth and availability challenges.

VPC endpoints for DynamoDB can alleviate these challenges. A *VPC endpoint* for DynamoDB enables Amazon EC2 instances in your VPC to use their private IP addresses to access DynamoDB with no exposure to the public internet. Your EC2 instances do not require public IP addresses, and you don't need an internet gateway, a NAT device, or a virtual private gateway in your VPC. You use endpoint policies to control access to DynamoDB. Traffic between your VPC and the AWS service does not leave the Amazon network.

 **Note**

Even when you use public IP addresses, all VPC communication between instances and services hosted in AWS is kept private within the AWS network. Packets that originate from

the AWS network with a destination on the AWS network stay on the AWS global network, except traffic to or from AWS China Regions.

When you create a VPC endpoint for DynamoDB, any requests to a DynamoDB endpoint within the Region (for example, `dynamodb.us-west-2.amazonaws.com`) are routed to a private DynamoDB endpoint within the Amazon network. You don't need to modify your applications running on EC2 instances in your VPC. The endpoint name remains the same, but the route to DynamoDB stays entirely within the Amazon network, and does not access the public internet.

The following diagram shows how an EC2 instance in a VPC can use a VPC endpoint to access DynamoDB.

For more information, see [the section called “Tutorial: Using a VPC endpoint for DynamoDB”](#).

Sharing Amazon VPC endpoints and DynamoDB

In order to enable access to the DynamoDB service through a VPC subnet's gateway endpoint, you must have owner account permissions for that VPC subnet.

Once the VPC subnet's gateway endpoint has been granted access to DynamoDB, any AWS account with access to that subnet can use DynamoDB. This means all account users within the VPC

subnet can use any DynamoDB tables which they have access to. This includes DynamoDB tables associated with a different account than the VPC subnet. The VPC subnet owner can still restrict any particular user within the subnet from using the DynamoDB service through the gateway endpoint, at their discretion.

Tutorial: Using a VPC endpoint for DynamoDB

This section walks you through setting up and using a VPC endpoint for DynamoDB.

Topics

- [Step 1: Launch an Amazon EC2 instance](#)
- [Step 2: Configure your Amazon EC2 instance](#)
- [Step 3: Create a VPC endpoint for DynamoDB](#)
- [Step 4: \(Optional\) Clean up](#)

Step 1: Launch an Amazon EC2 instance

In this step, you launch an Amazon EC2 instance in your default Amazon VPC. You can then create and use a VPC endpoint for DynamoDB.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance** and do the following:

Step 1: Choose an Amazon Machine Image (AMI)

- At the top of the list of AMIs, go to **Amazon Linux AMI** and choose **Select**.

Step 2: Choose an Instance Type

- At the top of the list of instance types, choose **t2.micro**.
- Choose **Next: Configure Instance Details**.

Step 3: Configure Instance Details

- Go to **Network** and choose your default VPC.

Choose **Next: Add Storage**.

Step 4: Add Storage

- Skip this step by choosing **Next: Tag Instance**.

Step 5: Tag Instance

- Skip this step by choosing **Next: Configure Security Group**.

Step 6: Configure Security Group

- Choose **Select an existing security group**.
- In the list of security groups, choose **default**. This is the default security group for your VPC.
- Choose **Next: Review and Launch**.

Step 7: Review Instance Launch

- Choose **Launch**.

3. In the **Select an existing key pair or create a new key pair** window, do one of the following:
 - If you do not have an Amazon EC2 key pair, choose **Create a new key pair** and follow the instructions. You will be asked to download a private key file (*.pem* file); you will need this file later when you log in to your Amazon EC2 instance.
 - If you already have an existing Amazon EC2 key pair, go to **Select a key pair** and choose your key pair from the list. You must already have the private key file (*.pem* file) available in order to log in to your Amazon EC2 instance.
4. When you have configured your key pair, choose **Launch Instances**.
5. Return to the Amazon EC2 console home page and choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance. For example: `ec2-00-00-00-00.us-east-1.compute.amazonaws.com`.

Make a note of this public DNS name, because you will need it in the next step in this tutorial ([Step 2: Configure your Amazon EC2 instance](#)).

Note

It will take a few minutes for your Amazon EC2 instance to become available. Before you go on to the next step, ensure that the **Instance State** is running and that all of its **Status Checks** have passed.

Step 2: Configure your Amazon EC2 instance

When your Amazon EC2 instance is available, you will be able to log into it and prepare it for first use.

Note

The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see [Connect to Your Linux Instance](#) in the Amazon EC2 User Guide for Linux Instances.

1. You will need to authorize inbound SSH traffic to your Amazon EC2 instance. To do this, you will create a new EC2 security group, and then assign the security group to your EC2 instance.
 - a. In the navigation pane, choose **Security Groups**.
 - b. Choose **Create Security Group**. In the **Create Security Group** window, do the following:
 - **Security group name**—type a name for your security group. For example: my-ssh-access
 - **Description**—type a short description for the security group.
 - **VPC**—choose your default VPC.
 - In the **Security group rules** section, choose **Add Rule** and do the following:
 - **Type**—choose SSH.
 - **Source**—choose My IP.
- When the settings are as you want them, choose **Create**.
- c. In the navigation pane, choose **Instances**.

- d. Choose the Amazon EC2 instance that you launched in [Step 1: Launch an Amazon EC2 instance](#).
 - e. Choose **Actions --> Networking --> Change Security Groups**.
 - f. In the **Change Security Groups**, select the security group that you created earlier in this procedure (for example: my-ssh-access). The existing default security group should also be selected. When the settings are as you want them, choose **Assign Security Groups**.
2. Use the ssh command to log in to your Amazon EC2 instance, as in the following example.

```
ssh -i my-keypair.pem ec2-user@public-dns-name
```

You will need to specify your private key file (*.pem* file) and the public DNS name of your instance. (See [Step 1: Launch an Amazon EC2 instance](#)).

The login ID is ec2-user. No password is required.

3. Configure your AWS credentials, as shown following. Enter your AWS access key ID, secret key, and default Region name when prompted.

```
aws configure
```

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
Default region name [None]: us-east-1
Default output format [None]:
```

You are now ready to create a VPC endpoint for DynamoDB.

Step 3: Create a VPC endpoint for DynamoDB

In this step, you will create a VPC endpoint for DynamoDB and test it to make sure that it works.

1. Before you begin, verify that you can communicate with DynamoDB using its public endpoint.

```
aws dynamodb list-tables
```

The output will show a list of DynamoDB tables that you currently own. (If you don't have any tables, the list will be empty.).

- Verify that DynamoDB is an available service for creating VPC endpoints in the current AWS Region. (The command is shown in bold text, followed by example output.)

```
aws ec2 describe-vpc-endpoint-services

{
    "ServiceNames": [
        "com.amazonaws.us-east-1.s3",
        "com.amazonaws.us-east-1.dynamodb"
    ]
}
```

In the example output, DynamoDB is one of the services available, so you can proceed with creating a VPC endpoint for it.

- Determine your VPC identifier.

```
aws ec2 describe-vpcs

{
    "Vpcs": [
        {
            "VpcId": "vpc-0bbc736e",
            "InstanceTenancy": "default",
            "State": "available",
            "DhcpOptionsId": "dopt-8454b7e1",
            "CidrBlock": "172.31.0.0/16",
            "IsDefault": true
        }
    ]
}
```

In the example output, the VPC ID is vpc-0bbc736e.

- Create the VPC endpoint. For the `--vpc-id` parameter, specify the VPC ID from the previous step. Use the `--route-table-ids` parameter to associate the endpoint with your route tables.

```
aws ec2 create-vpc-endpoint --vpc-id vpc-0bbc736e --service-name com.amazonaws.us-east-1.dynamodb --route-table-ids rtb-11aa22bb
```

```
"VpcEndpoint": {  
    "PolicyDocument": "{\"Version\":\"2008-10-17\", \"Statement\":[{\"Effect\": \"Allow\", \"Principal\":\"*\", \"Action\":\"*\", \"Resource\":\"*\"}]}",  
    "VpcId": "vpc-0bbc736e",  
    "State": "available",  
    "ServiceName": "com.amazonaws.us-east-1.dynamodb",  
    "RouteTableIds": [  
        "rtb-11aa22bb"  
    ],  
    "VpcEndpointId": "vpce-9b15e2f2",  
    "CreationTimestamp": "2017-07-26T22:00:14Z"  
}  
}
```

5. Verify that you can access DynamoDB through the VPC endpoint.

```
aws dynamodb list-tables
```

If you want, you can try some other AWS CLI commands for DynamoDB. For more information, see the [AWS CLI Command Reference](#).

Step 4: (Optional) Clean up

If you want to delete the resources you have created in this tutorial, follow these procedures:

To remove your VPC endpoint for DynamoDB

1. Log in to your Amazon EC2 instance.
2. Determine the VPC endpoint ID.

```
aws ec2 describe-vpc-endpoints
```

```
{  
    "VpcEndpoint": {  
        "PolicyDocument": "{\"Version\":\"2008-10-17\", \"Statement\":[{\"Effect\": \"Allow\", \"Principal\":\"*\", \"Action\":\"*\", \"Resource\":\"*\"}]}",  
        "VpcId": "vpc-0bbc736e",  
        "State": "available",  
        "ServiceName": "com.amazonaws.us-east-1.dynamodb",  
        "RouteTableIds": [],  
        "VpcEndpointId": "vpce-9b15e2f2",  
        "CreationTimestamp": "2017-07-26T22:00:14Z"
```

```
    }  
}
```

In the example output, the VPC endpoint ID is vpce-9b15e2f2.

3. Delete the VPC endpoint.

```
aws ec2 delete-vpc-endpoints --vpc-endpoint-ids vpce-9b15e2f2  
  
{  
    "Unsuccessful": []  
}
```

The empty array [] indicates success (there were no unsuccessful requests).

To terminate your Amazon EC2 instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Choose your Amazon EC2 instance.
4. Choose **Actions, Instance State, Terminate**.
5. In the confirmation window, choose **Yes, Terminate**.

AWS PrivateLink for DynamoDB

With AWS PrivateLink for DynamoDB, you can provision *interface Amazon VPC endpoints* (interface endpoints) in your virtual private cloud (Amazon VPC). These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over [Amazon VPC peering](#). Using AWS PrivateLink and interface endpoints, you can simplify private network connectivity from your applications to DynamoDB.

Applications in your VPC do not need public IP addresses to communicate with DynamoDB interface VPC endpoints for DynamoDB operations. Interface endpoints are represented by one or more elastic network interfaces (ENIs) that are assigned private IP addresses from subnets in your Amazon VPC. Requests to DynamoDB over interface endpoints stay on the Amazon network. You can also access interface endpoints in your Amazon VPC from on-premises applications through AWS Direct Connect or AWS Virtual Private Network (AWS VPN). For more information about how

to connect your Amazon VPC with your on-premises network, see the [AWS Direct Connect User Guide](#) and the [AWS Site-to-Site VPN User Guide](#).

For general information about interface endpoints, see [Interface Amazon VPC endpoints \(AWS PrivateLink\)](#) in the *AWS PrivateLink Guide*.

Topics

- [Types of Amazon VPC endpoints for Amazon DynamoDB](#)
- [Considerations when using AWS PrivateLink for Amazon DynamoDB](#)
- [Creating an Amazon VPC endpoint](#)
- [Accessing Amazon DynamoDB interface endpoints](#)
- [Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints](#)
- [Updating an on-premises DNS configuration](#)
- [Creating an Amazon VPC endpoint policy for DynamoDB](#)

Types of Amazon VPC endpoints for Amazon DynamoDB

You can use two types of Amazon VPC endpoints to access Amazon DynamoDB: *gateway endpoints* and *interface endpoints* (by using AWS PrivateLink). A *gateway endpoint* is a gateway that you specify in your route table to access DynamoDB from your Amazon VPC over the AWS network. *Interface endpoints* extend the functionality of gateway endpoints by using private IP addresses to route requests to DynamoDB from within your Amazon VPC, on premises, or from an Amazon VPC in another AWS Region by using Amazon VPC peering or AWS Transit Gateway. For more information, see [What is Amazon VPC peering?](#) and [Transit Gateway vs Amazon VPC peering](#).

Interface endpoints are compatible with gateway endpoints. If you have an existing gateway endpoint in the Amazon VPC, you can use both types of endpoints in the same Amazon VPC.

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
In both cases, your network traffic remains on the AWS network.	
Use Amazon DynamoDB public IP addresses	Use private IP addresses from your Amazon VPC to access Amazon DynamoDB
Do not allow access from on premises	Allow access from on premises

Gateway endpoints for DynamoDB	Interface endpoints for DynamoDB
Do not allow access from another AWS Region	Allow access from an Amazon VPC endpoint in another AWS Region by using Amazon VPC peering or AWS Transit Gateway
Not billed	Billed

For more information about gateway endpoints, see [Gateway Amazon VPC endpoints](#) in the *AWS PrivateLink Guide*.

Considerations when using AWS PrivateLink for Amazon DynamoDB

Amazon VPC considerations apply to AWS PrivateLink for Amazon DynamoDB. For more information, see [Interface endpoint considerations](#) and [AWS PrivateLink quotas](#) in the *AWS PrivateLink Guide*. In addition, the following restrictions apply.

AWS PrivateLink for Amazon DynamoDB does not support the following:

- [Federal Information Processing Standard \(FIPS\) endpoints](#)
- Transport Layer Security (TLS) 1.1
- Private and Hybrid Domain Name System (DNS) services

AWS PrivateLink is currently not supported for Amazon DynamoDB Streams endpoints.

You can submit up to 50,000 requests per second for each AWS PrivateLink endpoint that you enable.

 **Note**

Network connectivity timeouts to AWS PrivateLink endpoints are not within the scope of DynamoDB error responses and need to be appropriately handled by your applications connecting to the PrivateLink endpoints.

Creating an Amazon VPC endpoint

To create an Amazon VPC interface endpoint, see [Create an endpoint](#) in the *AWS PrivateLink Guide*.

Accessing Amazon DynamoDB interface endpoints

When you create an interface endpoint, DynamoDB generates two types of endpoint-specific, DynamoDB DNS names: *Regional* and *zonal*.

- A *Regional* DNS name includes a unique Amazon VPC endpoint ID, a service identifier, the AWS Region, and `vpce.amazonaws.com` in its name. For example, for Amazon VPC endpoint ID `vpce-1a2b3c4d`, the DNS name generated might be similar to `vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com`.
- A *Zonal* DNS name includes the Availability Zone—for example, `vpce-1a2b3c4d-5e6f-us-east-1a.dynamodb.us-east-1.vpce.amazonaws.com`. You might use this option if your architecture isolates Availability Zones. For example, you could use it for fault containment or to reduce Regional data transfer costs.

Endpoint-specific DynamoDB DNS names can be resolved from the DynamoDB public DNS domain.

Accessing DynamoDB tables and control API operations from DynamoDB interface endpoints

You can use the AWS CLI or AWS SDKs to access DynamoDB tables and control API operations through DynamoDB interface endpoints.

AWS CLI examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints in AWS CLI commands, use the `--region` and `--endpoint-url` parameters.

Example: Create a VPC endpoint

```
aws ec2 create-vpc-endpoint \
--region us-east-1 \
--service-name dynamodb-service-name \
--vpc-id client-vpc-id \
--subnet-ids client-subnet-id \
--vpc-endpoint-type Interface \
--security-group-ids client-sg-id
```

Example: Modify a VPC endpoint

```
aws ec2 modify-vpc-endpoint \
--region us-east-1 \
--vpc-endpoint-id client-vpc-endpoint-id \
--policy-document policy-document \ #example optional parameter
--add-security-group-ids security-group-ids \ #example optional parameter
# any additional parameters needed, see PrivateLink documentation for more details
```

Example: List tables using an endpoint URL

In the following example, replace the Region `us-east-1` and the DNS name of the VPC endpoint ID `vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
aws dynamodb --region us-east-1 --endpoint https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com list-tables
```

AWS SDK examples

To access DynamoDB tables or DynamoDB control API operations through DynamoDB interface endpoints when using the AWS SDKs, update your SDKs to the latest version. Then, configure your clients to use an endpoint URL for accessing a table or DynamoDB control API operation through DynamoDB interface endpoints.

SDK for Python (Boto3)

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region `us-east-1` and VPC endpoint ID `https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com` with your own information.

```
ddb_client = session.client(
    service_name='dynamodb',
    region_name='us-east-1',
    endpoint_url='https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com'
)
```

SDK for Java 1.x

Example: Use an endpoint URL to access a DynamoDB table

In the following example, replace the Region us-east-1 and VPC endpoint ID https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com with your own information.

```
//client build with endpoint config
final AmazonDynamoDB dynamodb =
    AmazonDynamoDBClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration(
            "https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com",
            Regions.DEFAULT_REGION.getName()
        )
    ).build();
```

SDK for Java 2.x

Example: Use an endpoint URL to access an S3 bucket

In the following example, replace the Region us-east-1 and VPC endpoint ID https://vpce-1a2b3c4d-5e6f.dynamodb.us-east-1.vpce.amazonaws.com with your own information.

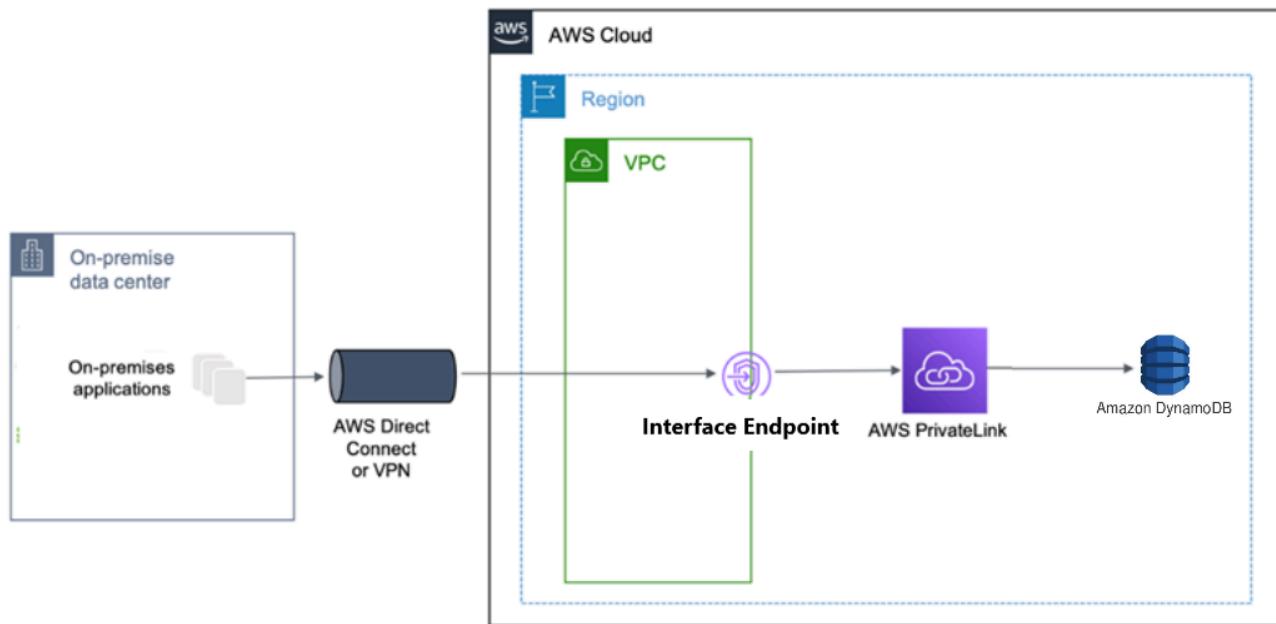

```
Region region = Region.US_EAST_1;
dynamoDbClient = DynamoDbClient.builder().region(region)
    .endpointOverride(URI.create("https://vpce-1a2b3c4d-5e6f.dynamodb.us-
east-1.vpce.amazonaws.com"))
    .build()
```

Updating an on-premises DNS configuration

When using endpoint-specific DNS names to access the interface endpoints for DynamoDB, you don't have to update your on-premises DNS resolver. You can resolve the endpoint-specific DNS name with the private IP address of the interface endpoint from the public DynamoDB DNS domain.

Using interface endpoints to access DynamoDB without a gateway endpoint or an internet gateway in the Amazon VPC

Interface endpoints in your Amazon VPC can route both in-Amazon VPC applications and on-premises applications to DynamoDB over the Amazon network, as illustrated in the following diagram.

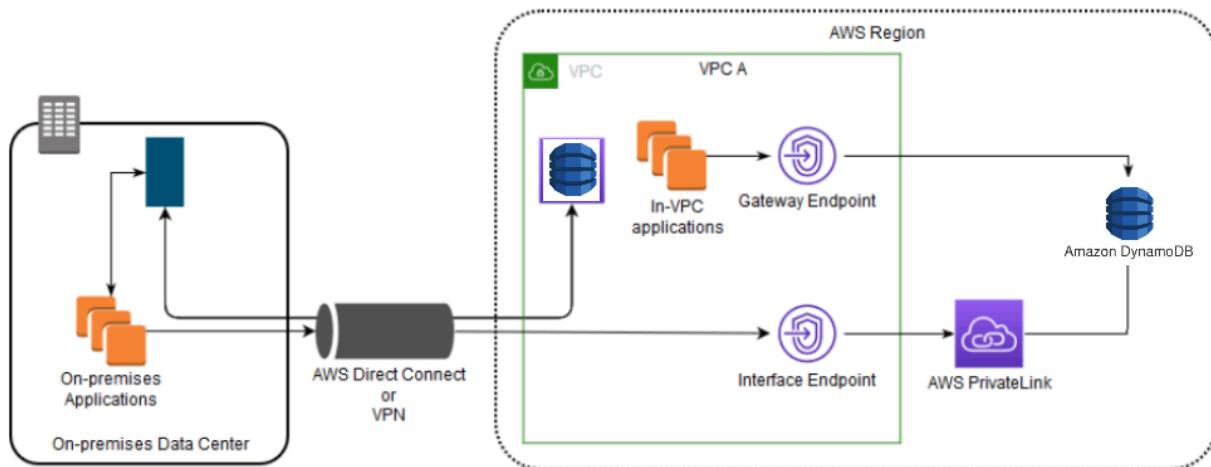

The diagram illustrates the following:

- Your on-premises network uses AWS Direct Connect or AWS VPN to connect to Amazon VPC A.
- Your applications on-premises and in Amazon VPC A use endpoint-specific DNS names to access DynamoDB through the DynamoDB interface endpoint.
- On-premises applications send data to the interface endpoint in the Amazon VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- In-Amazon VPC applications also send traffic to the interface endpoint. AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.

Using gateway endpoints and interface endpoints together in the same Amazon VPC to access DynamoDB

You can create interface endpoints and retain the existing gateway endpoint in the same Amazon VPC, as the following diagram shows. By taking this approach, you allow in-Amazon VPC applications to continue accessing DynamoDB through the gateway endpoint, which is not billed. Then, only your on-premises applications would use interface endpoints to access DynamoDB. To access DynamoDB this way, you must update your on-premises applications to use endpoint-specific DNS names for DynamoDB.

The diagram illustrates the following:

- On-premises applications use endpoint-specific DNS names to send data to the interface endpoint within the Amazon VPC through AWS Direct Connect (or AWS VPN). AWS PrivateLink moves the data from the interface endpoint to DynamoDB over the AWS network.
- Using default Regional DynamoDB names, in-Amazon VPC applications send data to the gateway endpoint that connects to DynamoDB over the AWS network.

For more information about gateway endpoints, see [Gateway Amazon VPC endpoints](#) in the *Amazon VPC User Guide*.

Creating an Amazon VPC endpoint policy for DynamoDB

You can attach an endpoint policy to your Amazon VPC endpoint that controls access to DynamoDB. The policy specifies the following information:

- The AWS Identity and Access Management (IAM) principal that can perform actions
- The actions that can be performed
- The resources on which actions can be performed

Topics

- [Example: Restricting access to a specific table from an Amazon VPC endpoint](#)

Example: Restricting access to a specific table from an Amazon VPC endpoint

You can create an endpoint policy that restricts access to only specific DynamoDB tables. This type of policy is useful if you have other AWS services in your Amazon VPC that use tables. The following table policy restricts access to only the *DOC-EXAMPLE-TABLE*. To use this endpoint policy, replace *DOC-EXAMPLE-TABLE* with the name of your table.

```
{  
    "Version": "2012-10-17",  
    "Id": "Policy1216114807515",  
    "Statement": [  
        { "Sid": "Access-to-specific-table-only",  
          "Principal": "*",  
          "Action": [  
              "dynamodb:GetItem",  
              "dynamodb:PutItem"  
          ],  
          "Effect": "Allow",  
          "Resource": ["arn:aws:dynamodb:::DOC-EXAMPLE-TABLE",  
                      "arn:aws:dynamodb:::DOC-EXAMPLE-TABLE/*"]  
        }  
    ]  
}
```

Configuration and vulnerability analysis in Amazon DynamoDB

AWS handles basic security tasks like guest operating system (OS) and database patching, firewall configuration, and disaster recovery. These procedures have been reviewed and certified by the appropriate third parties. For more details, see the following resources:

- [Compliance validation for Amazon DynamoDB](#)
- [Shared responsibility model](#)
- [Amazon Web Services: Overview of security processes](#)(whitepaper)

The following security best practices also address configuration and vulnerability analysis in Amazon DynamoDB:

- [Monitor DynamoDB compliance with AWS Config Rules](#)
- [Monitor DynamoDB configuration with AWS Config](#)

Security best practices for Amazon DynamoDB

Amazon DynamoDB provides a number of security features to consider as you develop and implement your own security policies. The following best practices are general guidelines and don't represent a complete security solution. Because these best practices might not be appropriate or sufficient for your environment, treat them as helpful considerations rather than prescriptions.

Topics

- [DynamoDB preventative security best practices](#)
- [DynamoDB detective security best practices](#)

DynamoDB preventative security best practices

The following best practices can help you anticipate and prevent security incidents in Amazon DynamoDB.

Encryption at rest

DynamoDB encrypts at rest all user data stored in tables, indexes, streams, and backups using encryption keys stored in [AWS Key Management Service \(AWS KMS\)](#). This provides an additional layer of data protection by securing your data from unauthorized access to the underlying storage .

You can specify whether DynamoDB should use an AWS owned key (default encryption type), an AWS managed key, or a customer managed key to encrypt user data. For more information, see [Amazon DynamoDB Encryption at Rest](#).

Use IAM roles to authenticate access to DynamoDB

For users, applications, and other AWS services to access DynamoDB, they must include valid AWS credentials in their AWS API requests. You should not store AWS credentials directly in the application or EC2 instance. These are long-term credentials that are not automatically rotated, and therefore could have significant business impact if they are compromised. An IAM role enables you to obtain temporary access keys that can be used to access AWS services and resources.

For more information, see [Identity and Access Management for Amazon DynamoDB](#).

Use IAM policies for DynamoDB base authorization

When granting permissions, you decide who is getting them, which DynamoDB APIs they are getting permissions for, and the specific actions you want to allow on those resources. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

Attach permissions policies to IAM identities (that is, users, groups, and roles) and thereby grant permissions to perform operations on DynamoDB resources.

You can do this by using the following:

- [AWS Managed \(predefined\) policies](#)
- [Customer managed policies](#)

Use IAM policy conditions for fine-grained access control

When you grant permissions in DynamoDB, you can specify conditions that determine how a permissions policy takes effect. Implementing least privilege is key in reducing security risk and the impact that can result from errors or malicious intent.

You can specify conditions when granting permissions using an IAM policy. For example, you can do the following:

- Grant permissions to allow users read-only access to certain items and attributes in a table or a secondary index.
- Grant permissions to allow users write-only access to certain attributes in a table, based upon the identity of that user.

For more information, see [Using IAM Policy Conditions for Fine-Grained Access Control](#).

Use a VPC endpoint and policies to access DynamoDB

If you only require access to DynamoDB from within a virtual private cloud (VPC), you should use a VPC endpoint to limit access from only the required VPC. Doing this prevents that traffic from traversing the open internet and being subject to that environment.

Using a VPC endpoint for DynamoDB allows you to control and limit access using the following:

- VPC endpoint policies – These policies are applied on the DynamoDB VPC endpoint. They allow you to control and limit API access to the DynamoDB table.
- IAM policies – By using the `aws:sourceVpce` condition on policies attached to users, groups, or roles, you can enforce that all access to the DynamoDB table is via the specified VPC endpoint.

For more information, see [Endpoints for Amazon DynamoDB](#).

Consider client-side encryption

We recommend that you plan your encryption strategy before implementing your table in DynamoDB. If you store sensitive or confidential data in DynamoDB, consider including client-side encryption in your plan. This way you can encrypt data as close as possible to its origin, and ensure its protection throughout its lifecycle. Encrypting your sensitive data in transit and at rest helps ensure that your plaintext data isn't available to any third party.

The [AWS Database Encryption SDK for DynamoDB](#) is a software library that helps you protect your table data before you send it to DynamoDB. It encrypts, signs, verifies, and decrypts your DynamoDB table items. You control which attributes are encrypted and signed.

DynamoDB detective security best practices

The following best practices for Amazon DynamoDB can help you detect potential security weaknesses and incidents.

Use AWS CloudTrail to monitor AWS managed KMS key usage

If you are using an [AWS managed key](#) for encryption at rest, usage of this key is logged into AWS CloudTrail. CloudTrail provides visibility into user activity by recording actions taken on your account. CloudTrail records important information about each action, including who made the request, the services used, the actions performed, parameters for the actions, and the response elements returned by the AWS service. This information helps you track changes made to your AWS resources and troubleshoot operational issues. CloudTrail makes it easier to ensure compliance with internal policies and regulatory standards.

You can use CloudTrail to audit key usage. CloudTrail creates log files that contain a history of AWS API calls and related events for your account. These log files include all AWS KMS API requests made using the AWS Management Console, AWS SDKs, and command line tools, in addition to those made through integrated AWS services. You can use these log files to get information about when the KMS key was used, the operation that was requested, the identity of the requester, the IP address that the request came from, and so on. For more information, see [Logging AWS KMS API Calls with AWS CloudTrail](#) and the [AWS CloudTrail User Guide](#).

Monitor DynamoDB operations using CloudTrail

CloudTrail can monitor both control plane events and data plane events. Control plane operations let you create and manage DynamoDB tables. They also let you work with indexes,

streams, and other objects that are dependent on tables. Data plane operations let you perform create, read, update, and delete (also called *CRUD*) actions on data in a table. Some data plane operations also let you read data from a secondary index. To enable logging of data plane events in CloudTrail, you'll need to enable logging of data plane API activity in CloudTrail. See [Logging data events for trails](#) for more information.

When activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in the event history. For more information, see [Logging DynamoDB Operations by Using AWS CloudTrail](#). You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#) in the [AWS CloudTrail User Guide](#).

For an ongoing record of events in your AWS account, including events for DynamoDB, create a [trail](#). A trail enables CloudTrail to deliver log files to an Amazon Simple Storage Service (Amazon S3) bucket. By default, when you create a trail on the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs.

Use DynamoDB Streams to monitor data plane operations

DynamoDB is integrated with AWS Lambda so that you can create triggers—pieces of code that automatically respond to events in DynamoDB Streams. With triggers, you can build applications that react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN) with a Lambda function that you write. Immediately after an item in the table is modified, a new record appears in the table's stream. AWS Lambda polls the stream and invokes your Lambda function synchronously when it detects new stream records. The Lambda function can perform any actions that you specify, such as sending a notification or initiating a workflow.

For an example, see [Tutorial: Using AWS Lambda with Amazon DynamoDB Streams](#). This example receives a DynamoDB event input, processes the messages that it contains, and writes some of the incoming event data to Amazon CloudWatch Logs.

Monitor DynamoDB configuration with AWS Config

Using [AWS Config](#), you can continuously monitor and record configuration changes of your AWS resources. You can also use AWS Config to inventory your AWS resources. When a change from a previous state is detected, an Amazon Simple Notification Service (Amazon SNS) notification

can be delivered for you to review and take action. Follow the guidance in [Setting Up AWS Config with the Console](#), ensuring that DynamoDB resource types are included.

You can configure AWS Config to stream configuration changes and notifications to an Amazon SNS topic. For example, when a resource is updated, you can get a notification sent to your email, so that you can view the changes. You can also be notified when AWS Config evaluates your custom or managed rules against your resources.

For an example, see [Notifications that AWS Config Sends to an Amazon SNS topic](#) in the *AWS Config Developer Guide*.

Monitor DynamoDB compliance with AWS Config rules

AWS Config continuously tracks the configuration changes that occur among your resources. It checks whether these changes violate any of the conditions in your rules. If a resource violates a rule, AWS Config flags the resource and the rule as noncompliant.

By using AWS Config to evaluate your resource configurations, you can assess how well your resource configurations comply with internal practices, industry guidelines, and regulations. AWS Config provides [AWS managed rules](#), which are predefined, customizable rules that AWS Config uses to evaluate whether your AWS resources comply with common best practices.

Tag your DynamoDB resources for identification and automation

You can assign metadata to your AWS resources in the form of tags. Each tag is a simple label consisting of a customer-defined key and an optional value that can make it easier to manage, search for, and filter resources.

Tagging allows for grouped controls to be implemented. Although there are no inherent types of tags, they enable you to categorize resources by purpose, owner, environment, or other criteria. The following are some examples:

- Security – Used to determine requirements such as encryption.
- Confidentiality – An identifier for the specific data-confidentiality level a resource supports.
- Environment – Used to distinguish between development, test, and production infrastructure.

For more information, see [AWS Tagging Strategies](#) and [Tagging for DynamoDB](#).

Monitor your usage of Amazon DynamoDB as it relates to security best practices by using AWS Security Hub.

Security Hub uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks.

For more information about using Security Hub to evaluate DynamoDB resources, see [Amazon DynamoDB controls](#) in the *AWS Security Hub User Guide*.

Monitoring and logging

Monitoring is an important part of maintaining the reliability, availability, and performance of DynamoDB and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your DynamoDB resources and responding to potential incidents:

Topics

- [Logging and monitoring in DynamoDB](#)
- [Logging and monitoring in DynamoDB Accelerator](#)
- [Analyzing data access using CloudWatch contributor insights for DynamoDB](#)
- [Using AWS User Notifications User Notifications with Amazon DynamoDB](#)

Logging and monitoring in DynamoDB

Monitoring is an important part of maintaining the reliability, availability, and performance of DynamoDB and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs. Before you start monitoring DynamoDB, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

The next step is to establish a baseline for normal DynamoDB performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DynamoDB, you should consider storing historical monitoring data. This stored data will give you a baseline from which to compare current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline you should, at a minimum, monitor the following items:

- The number of read or write capacity units consumed over the specified time period, so you can track how much of your provisioned throughput is used.
- Requests that exceeded a table's provisioned write or read capacity during the specified time period, so you can determine which requests exceed the provisioned throughput quotas of a table.
- System errors, so you can determine if any requests resulted in an error.

Topics

- [Monitoring tools](#)
- [Monitoring with Amazon CloudWatch](#)
- [Logging DynamoDB operations by using AWS CloudTrail](#)

Monitoring tools

AWS provides tools that you can use to monitor DynamoDB. You can configure some of these tools to do the monitoring for you; some require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch DynamoDB and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring with Amazon CloudWatch](#).
- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see [Monitoring Log Files](#) in the *Amazon CloudWatch User Guide*.

- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see [What is Amazon CloudWatch Events](#) in the *Amazon CloudWatch User Guide*.
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Working with CloudTrail Log Files](#) in the *AWS CloudTrail User Guide*.

Manual monitoring tools

Another important part of monitoring DynamoDB involves manually monitoring those items that the CloudWatch alarms don't cover. The DynamoDB, CloudWatch, Trusted Advisor, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on Amazon DynamoDB.

- DynamoDB dashboard shows:
 - Recent alerts
 - Total capacity
 - Service health
- CloudWatch home page shows:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about
- Graph metric data to troubleshoot issues and discover trends
- Search and browse all of your AWS resource metrics
- Create and edit alarms to be notified of problems

Monitoring with Amazon CloudWatch

You can monitor Amazon DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so that you can access historical information for a better perspective on how your web

application or service is performing. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see [What is Amazon CloudWatch?](#) and [Metrics retention](#) in the *Amazon CloudWatch User Guide*.

Topics

- [DynamoDB Metrics and dimensions](#)
- [How do I use DynamoDB metrics?](#)
- [Understanding and analyzing DynamoDB response times](#)
- [Creating CloudWatch alarms to monitor DynamoDB](#)

DynamoDB Metrics and dimensions

When you interact with DynamoDB, it sends the following metrics and dimensions to CloudWatch. You can use the following procedures to view the metrics for DynamoDB.

To view metrics (console)

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Metrics**.

 **Note**

You can also select **Usage** namespace to view DynamoDB usage metrics. For more information about usage metrics, see [AWS usage metrics](#).

3. Select the **DynamoDB** namespace.

To view metrics (CLI)

- At a command prompt, use the following command:

```
aws cloudwatch list-metrics --namespace "AWS/DynamoDB"
```

Viewing metrics and dimensions

CloudWatch displays the following metrics for DynamoDB:

DynamoDB metrics

Note

Amazon CloudWatch aggregates these metrics at one-minute intervals:

- ConditionalCheckFailedRequests
- ConsumedReadCapacityUnits
- ConsumedWriteCapacityUnits
- ReadThrottleEvents
- ReturnedBytes
- ReturnedItemCount
- ReturnedRecordsCount
- SuccessfulRequestLatency
- SystemErrors
- TimeToLiveDeletedItemCount
- ThrottledRequests
- TransactionConflict
- UserErrors
- WriteThrottleEvents

For all other DynamoDB metrics, the aggregation granularity is five minutes.

Not all statistics, such as *Average* or *Sum*, are applicable for every metric. However, all of these values are available through the Amazon DynamoDB console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics.

In the following list, each metric has a set of valid statistics that are applicable to that metric.

List of Available Metrics

- [AccountMaxReads](#)

- [AccountMaxTableLevelReads](#)
- [AccountMaxTableLevelWrites](#)
- [AccountMaxWrites](#)
- [AccountProvisionedReadCapacityUtilization](#)
- [AccountProvisionedWriteCapacityUtilization](#)
- [AgeOfOldestUnreplicatedRecord](#)
- [ConditionalCheckFailedRequests](#)
- [ConsumedChangeDataCaptureUnits](#)
- [ConsumedReadCapacityUnits](#)
- [ConsumedWriteCapacityUnits](#)
- [FailedToReplicateRecordCount](#)
- [MaxProvisionedTableReadCapacityUtilization](#)
- [MaxProvisionedTableWriteCapacityUtilization](#)
- [OnlineIndexConsumedWriteCapacity](#)
- [OnlineIndexPercentageProgress](#)
- [OnlineIndexThrottleEvents](#)
- [PendingReplicationCount](#)
- [ProvisionedReadCapacityUnits](#)
- [ProvisionedWriteCapacityUnits](#)
- [ReadThrottleEvents](#)
- [ReplicationLatency](#)
- [ReturnedBytes](#)
- [ReturnedItemCount](#)
- [ReturnedRecordsCount](#)
- [SuccessfulRequestLatency](#)
- [SystemErrors](#)
- [TimeToLiveDeletedItemCount](#)
- [ThrottledPutRecordCount](#)
- [ThrottledRequests](#)
- [TransactionConflict](#)

- [UserErrors](#)
- [WriteThrottleEvents](#)

AccountMaxReads

The maximum number of read capacity units that can be used by an account. This limit does not apply to on-demand tables or global secondary indexes.

Units: Count

Valid Statistics:

- Maximum – The maximum number of read capacity units that can be used by an account.

AccountMaxTableLevelReads

The maximum number of read capacity units that can be used by a table or global secondary index of an account. For on-demand tables this limit caps the maximum read request units a table or a global secondary index can use.

Units: Count

Valid Statistics:

- Maximum – The maximum number of read capacity units that can be used by a table or global secondary index of the account.

AccountMaxTableLevelWrites

The maximum number of write capacity units that can be used by a table or global secondary index of an account. For on-demand tables this limit caps the maximum write request units a table or a global secondary index can use.

Units: Count

Valid Statistics:

- Maximum – The maximum number of write capacity units that can be used by a table or global secondary index of the account.

AccountMaxWrites

The maximum number of write capacity units that can be used by an account. This limit does not apply to on-demand tables or global secondary indexes.

Units: Count

Valid Statistics:

- Maximum – The maximum number of write capacity units that can be used by an account.

AccountProvisionedReadCapacityUtilization

The percentage of provisioned read capacity units utilized by an account.

Units: Percent

Valid Statistics:

- Maximum – The maximum percentage of provisioned read capacity units utilized by the account.
- Minimum – The minimum percentage of provisioned read capacity units utilized by the account.
- Average – The average percentage of provisioned read capacity units utilized by the account.
The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

AccountProvisionedWriteCapacityUtilization

The percentage of provisioned write capacity units utilized by an account.

Units: Percent

Valid Statistics:

- Maximum – The maximum percentage of provisioned write capacity units utilized by the account.
- Minimum – The minimum percentage of provisioned write capacity units utilized by the account.
- Average – The average percentage of provisioned write capacity units utilized by the account.
The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AgeOfOldestUnreplicatedRecord

The elapsed time since a record yet to be replicated to the Kinesis data stream first appeared in the DynamoDB table.

Units: Milliseconds

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- Maximum.
- Minimum.
- Average.

ConditionalCheckFailedRequests

The number of failed attempts to perform conditional writes. The PutItem, UpdateItem, and DeleteItem operations let you provide a logical condition that must evaluate to true before the operation can proceed. If this condition evaluates to false, ConditionalCheckFailedRequests is incremented by one. ConditionalCheckFailedRequests is also incremented by one for PartiQL Update and Delete statements where a logical condition is provided and that condition evaluates to false.

 **Note**

A failed conditional write will result in an HTTP 400 error (Bad Request). These events are reflected in the ConditionalCheckFailedRequests metric, but not in the UserErrors metric.

Units: Count

Dimensions: TableName

Valid Statistics:

- Minimum
- Maximum
- Average

- SampleCount
- Sum

ConsumedChangeDataCaptureUnits

The number of consumed change data capture units.

Units: Count

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- Minimum
- Maximum
- Average

ConsumedReadCapacityUnits

The number of read capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see [Read/Write Capacity Mode](#).

The TableName dimension returns the ConsumedReadCapacityUnits for the table, but not for any global secondary indexes. To view ConsumedReadCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Note

In Amazon DynamoDB, the consumed capacity metric is reported to CloudWatch at one-minute intervals as an average value. This means that short, intense spikes in capacity consumption lasting just a second may not be accurately reflected in the CloudWatch graph, potentially leading to a lower apparent consumption rate for that minute.

Use the Sum statistic to calculate the consumed throughput. For example, get the Sum value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average ConsumedReadCapacityUnits per second. You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The minimum number of read capacity units consumed by any individual request to the table or index.
- Maximum – The maximum number of read capacity units consumed by any individual request to the table or index.
- Average – The average per-request read capacity consumed.

 **Note**

The Average value is influenced by periods of inactivity where the sample value will be zero.

- Sum – The total read capacity units consumed. This is the most useful statistic for the ConsumedReadCapacityUnits metric.
- SampleCount – The number of read requests to DynamoDB, even if no read capacity was consumed.

 **Note**

The SampleCount value is influenced by periods of inactivity where the sample value will be zero.

ConsumedWriteCapacityUnits

The number of write capacity units consumed over the specified time period for both provisioned and on-demand capacity, so you can track how much of your throughput is used. You can retrieve the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index. For more information, see [Read/Write Capacity Mode](#).

The TableName dimension returns the ConsumedWriteCapacityUnits for the table, but not for any global secondary indexes. To view ConsumedWriteCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Note

Use the Sum statistic to calculate the consumed throughput. For example, get the Sum value over a span of one minute, and divide it by the number of seconds in a minute (60) to calculate the average ConsumedWriteCapacityUnits per second (recognizing that this average does not highlight any large but brief spikes in write activity that occurred during that minute). You can compare the calculated value to the provisioned throughput value that you provide DynamoDB.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The minimum number of write capacity units consumed by any individual request to the table or index.
- Maximum – The maximum number of write capacity units consumed by any individual request to the table or index.
- Average – The average per-request write capacity consumed.

Note

The Average value is influenced by periods of inactivity where the sample value will be zero.

- Sum – The total write capacity units consumed. This is the most useful statistic for the ConsumedWriteCapacityUnits metric.
- SampleCount – The number of write requests to DynamoDB, even if no write capacity was consumed.

Note

The SampleCount value is influenced by periods of inactivity where the sample value will be zero.

FailedToReplicateRecordCount

The number of records that DynamoDB failed to replicate to your Kinesis data stream.

Units: Count

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- Sum

MaxProvisionedTableReadCapacityUtilization

The percentage of provisioned read capacity utilized by the highest provisioned read table or global secondary index of an account.

Units: Percent

Valid Statistics:

- Maximum – The maximum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- Minimum – The minimum percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of an account.
- Average – The average percentage of provisioned read capacity units utilized by the highest provisioned read table or global secondary index of the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

MaxProvisionedTableWriteCapacityUtilization

The percentage of provisioned write capacity utilized by the highest provisioned write table or global secondary index of an account.

Units: Percent

Valid Statistics:

- Maximum – The maximum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.

- Minimum – The minimum percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of an account.
- Average – The average percentage of provisioned write capacity units utilized by the highest provisioned write table or global secondary index of the account. The metric is published for five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

OnlineIndexConsumedWriteCapacity

The number of write capacity units consumed when adding a new global secondary index to a table. If the write capacity of the index is too low, incoming write activity during the backfill phase might be throttled. This can increase the time it takes to create the index. You should monitor this statistic while the index is being built to determine whether the write capacity of the index is underprovisioned.

You can adjust the write capacity of the index using the `UpdateTable` operation, even while the index is still being built.

The `ConsumedWriteCapacityUnits` metric for the index does not include the write throughput consumed during index creation.

Note

This metric may not be emitted if the new global secondary index's backfill phase completes quickly (less than a few minutes), which may occur if the base table has few or no items to backfill in the index.

Units: Count

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount

- Sum

OnlineIndexPercentageProgress

The percentage of completion when a new global secondary index is being added to a table. DynamoDB must first allocate resources for the new index, and then backfill attributes from the table into the index. For large tables, this process might take a long time. You should monitor this statistic to view the relative progress as DynamoDB builds the index.

Units: Count

Dimensions: TableName , GlobalSecondaryIndexName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

OnlineIndexThrottleEvents

The number of write throttle events that occur when adding a new global secondary index to a table. These events indicate that the index creation will take longer to complete, because incoming write activity is exceeding the provisioned write throughput of the index.

You can adjust the write capacity of the index using the `UpdateTable` operation, even while the index is still being built.

The `WriteThrottleEvents` metric for the index does not include any throttle events that occur during index creation.

Units: Count

Dimensions: TableName , GlobalSecondaryIndexName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

PendingReplicationCount

Metric for [Global tables version 2017.11.29 \(Legacy\)](#) (global tables only). The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table.

Units: Count

Dimensions: TableName, ReceivingRegion

Valid Statistics:

- Average
- Sample Count
- Sum

ProvisionedReadCapacityUnits

The number of provisioned read capacity units for a table or a global secondary index. The TableName dimension returns the ProvisionedReadCapacityUnits for the table, but not for any global secondary indexes. To view ProvisionedReadCapacityUnits for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units:Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- Minimum – The lowest setting for provisioned read capacity. If you use UpdateTable to increase read capacity, this metric shows the lowest value of provisioned ReadCapacityUnits during this time period.

- Maximum – The highest setting for provisioned read capacity. If you use `UpdateTable` to decrease read capacity, this metric shows the highest value of provisioned `ReadCapacityUnits` during this time period.
- Average – The average provisioned read capacity. The `ProvisionedReadCapacityUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

ProvisionedWriteCapacityUnits

The number of provisioned write capacity units for a table or a global secondary index.

The `TableName` dimension returns the `ProvisionedWriteCapacityUnits` for the table, but not for any global secondary indexes. To view `ProvisionedWriteCapacityUnits` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: Count

Dimensions: `TableName`, `GlobalSecondaryIndexName`

Valid Statistics:

- Minimum – The lowest setting for provisioned write capacity. If you use `UpdateTable` to increase write capacity, this metric shows the lowest value of provisioned `WriteCapacityUnits` during this time period.
- Maximum – The highest setting for provisioned write capacity. If you use `UpdateTable` to decrease write capacity, this metric shows the highest value of provisioned `WriteCapacityUnits` during this time period.
- Average – The average provisioned write capacity. The `ProvisionedWriteCapacityUnits` metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

ReadThrottleEvents

Requests to DynamoDB that exceed the provisioned read capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a `BatchGetItem` that reads 10 items is processed as 10 `GetItem` events. For each event, `ReadThrottleEvents` is incremented by one

if that event is throttled. The ThrottledRequests metric for the entire BatchGetItem is not incremented unless *all 10* of the GetItem events are throttled.

The TableName dimension returns the ReadThrottleEvents for the table, but not for any global secondary indexes. To view ReadThrottleEvents for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- SampleCount
- Sum

ReplicationLatency

(This metric is for DynamoDB global tables.) The elapsed time between an updated item appearing in the DynamoDB stream for one replica table, and that item appearing in another replica in the global table.

Units: Milliseconds

Dimensions: TableName, ReceivingRegion

Valid Statistics:

- Average
- Minimum
- Maximum

ReturnedBytes

The number of bytes returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Bytes

Dimensions: Operation, StreamLabel, TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedItemCount

The number of items returned by Query, Scan or ExecuteStatement (select) operations during the specified time period.

The number of items *returned* is not necessarily the same as the number of items that were evaluated. For example, suppose that you requested a Scan on a table or an index that had 100 items, but specified a FilterExpression that narrowed the results so that only 15 items were returned. In this case, the response from Scan would contain a ScanCount of 100 and a Count of 15 returned items.

Units: Count

Dimensions: TableName, Operation

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

ReturnedRecordsCount

The number of stream records returned by GetRecords operations (Amazon DynamoDB Streams) during the specified time period.

Units: Count

Dimensions: Operation, StreamLabel, TableName

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount
- Sum

SuccessfulRequestLatency

The latency of successful requests to DynamoDB or Amazon DynamoDB Streams during the specified time period. SuccessfulRequestLatency can provide two different kinds of information:

- The elapsed time for successful requests (Minimum, Maximum, Sum, or Average).
- The number of successful requests (SampleCount).

SuccessfulRequestLatency reflects activity only within DynamoDB or Amazon DynamoDB Streams, and does not take into account network latency or client-side activity.

Units: Milliseconds

Dimensions: TableName, Operation, StreamLabel

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount

SystemErrors

The requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 500 status code during the specified time period. An HTTP 500 usually indicates an internal service error.

Units: Count

Dimensions: TableName, Operation

Valid Statistics:

- Sum
- SampleCount

TimeToLiveDeletedItemCount

The number of items deleted by Time to Live (TTL) during the specified time period. This metric helps you monitor the rate of TTL deletions on your table.

Units: Count

Dimensions: TableName

Valid Statistics:

- Sum

ThrottledPutRecordCount

The number of records that were throttled by your Kinesis data stream due to insufficient Kinesis Data Streams capacity.

Units: Count

Dimensions: TableName, DelegatedOperation

Valid Statistics:

- Minimum
- Maximum
- Average
- SampleCount

ThrottledRequests

Requests to DynamoDB that exceed the provisioned throughput limits on a resource (such as a table or an index).

ThrottledRequests is incremented by one if any event within a request exceeds a provisioned throughput limit. For example, if you update an item in a table with global secondary indexes, there are multiple events—a write to the table, and a write to each index. If one or more of these events are throttled, then ThrottledRequests is incremented by one.

Note

In a batch request (`BatchGetItem` or `BatchWriteItem`), ThrottledRequests is incremented only if *every* request in the batch is throttled.

If any individual request within the batch is throttled, one of the following metrics is incremented:

- `ReadThrottleEvents` – For a throttled `GetItem` event within `BatchGetItem`.
- `WriteThrottleEvents` – For a throttled `PutItem` or `DeleteItem` event within `BatchWriteItem`.

To gain insight into which event is throttling a request, compare ThrottledRequests with the `ReadThrottleEvents` and `WriteThrottleEvents` for the table and its indexes.

Note

A throttled request will result in an HTTP 400 status code. All such events are reflected in the ThrottledRequests metric, but not in the UserErrors metric.

Units: Count

Dimensions: TableName, Operation

Valid Statistics:

- Sum
- SampleCount

TransactionConflict

Rejected item-level requests due to transactional conflicts between concurrent requests on the same items. For more information, see [Transaction Conflict Handling in DynamoDB](#).

Units: Count

Dimensions: TableName

Valid Statistics:

- Sum – The number of rejected item-level requests due to transaction conflicts.

 **Note**

If multiple item-level requests within a call to `TransactWriteItems` or `TransactGetItems` were rejected, Sum is incremented by one for each item-level Put, Update, Delete, or Get request.

- SampleCount – The number of rejected requests due to transaction conflicts.

 **Note**

If multiple item-level requests within a call to `TransactWriteItems` or `TransactGetItems` are rejected, SampleCount is only incremented by one.

- Min – The minimum number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.
- Max – The maximum number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.
- Average – The average number of rejected item-level requests within a call to `TransactWriteItems`, `TransactGetItems`, `PutItem`, `UpdateItem`, or `DeleteItem`.

UserErrors

Requests to DynamoDB or Amazon DynamoDB Streams that generate an HTTP 400 status code during the specified time period. An HTTP 400 usually indicates a client-side error, such as an invalid combination of parameters, an attempt to update a nonexistent table, or an incorrect request signature.

Some examples of exceptions that will log metrics related to `UserErrors` would be:

- `ResourceNotFoundException`
- `ValidationException`
- `TransactionConflict`

All such events are reflected in the `UserErrors` metric, except for the following:

- *ProvisionedThroughputExceededException* – See the `ThrottledRequests` metric in this section.
- *ConditionalCheckFailedException* – See the `ConditionalCheckFailedRequests` metric in this section.

`UserErrors` represents the aggregate of HTTP 400 errors for DynamoDB or Amazon DynamoDB Streams requests for the current AWS Region and the current AWS account.

Units: Count

Valid Statistics:

- Sum
- SampleCount

WriteThrottleEvents

Requests to DynamoDB that exceed the provisioned write capacity units for a table or a global secondary index.

A single request can result in multiple events. For example, a `PutItem` request on a table with three global secondary indexes would result in four events—the table write, and each of the three index writes. For each event, the `WriteThrottleEvents` metric is incremented by one if that event is throttled. For single `PutItem` requests, if any of the events are throttled, `ThrottledRequests` is also incremented by one. For `BatchWriteItem`, the `ThrottledRequests` metric for the entire `BatchWriteItem` is not incremented unless all of the individual `PutItem` or `DeleteItem` events are throttled.

The `TableName` dimension returns the `WriteThrottleEvents` for the table, but not for any global secondary indexes. To view `WriteThrottleEvents` for a global secondary index, you must specify both `TableName` and `GlobalSecondaryIndexName`.

Units: Count

Dimensions: TableName, GlobalSecondaryIndexName

Valid Statistics:

- SampleCount

Usage metrics

Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert you when usage approaches a threshold.

DynamoDB also integrates these usage metrics with Service Quotas. You can use CloudWatch to manage your account's use of your service quotas. For more information, see [Visualizing your service quotas and setting alarms](#)

List of Available Usage Metrics

- [AccountProvisionedWriteCapacityUnits](#)
- [AccountProvisionedReadCapacityUnits](#)
- [TableCount](#)

AccountProvisionedWriteCapacityUnits

The sum of write capacity units provisioned for all tables and global secondary indexes of an account.

Units: Count

Valid Statistics:

- Minimum – The lowest number of provisioned write capacity units during a time period.
- Maximum – The highest number of provisioned write capacity units during a time period.
- Average - The average number provisioned write capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned write capacity units, this statistic might not reflect the true average.

AccountProvisionedReadCapacityUnits

The sum of read capacity units provisioned for all tables and global secondary indexes of an account.

Units: Count

Valid Statistics:

- Minimum – The lowest number of provisioned read capacity units during a time period.
- Maximum – The highest number of provisioned read capacity units during a time period.
- Average - The average number provisioned read capacity units account during a time period.

This metric is published at five-minute intervals. Therefore, if you rapidly adjust the provisioned read capacity units, this statistic might not reflect the true average.

TableCount

The number of active tables of an account.

Units: Count

Valid Statistics:

- Minimum – The lowest number of tables during a time period.
- Maximum – The highest number of tables during a time period.
- Average - The average number tables during a time period.

Understanding metrics and dimensions for DynamoDB

The metrics for DynamoDB are qualified by the values for the account, table name, global secondary index name, or operation. You can use the CloudWatch console to retrieve DynamoDB data along any of the dimensions in the table below.

List of Available Dimensions

- [DelegatedOperation](#)

- [GlobalSecondaryIndexName](#)
- [Operation](#)
- [OperationType](#)
- [Verb](#)
- [ReceivingRegion](#)
- [StreamLabel](#)
- [TableName](#)

DelegatedOperation

This dimension limits the data to operations DynamoDB performs on your behalf. The following operations are captured:

- Change data capture for Kinesis Data Streams.

GlobalSecondaryIndexName

This dimension limits the data to a global secondary index on a table. If you specify GlobalSecondaryIndexName, you must also specify TableName.

Operation

This dimension limits the data to one of the following DynamoDB operations:

- PutItem
- DeleteItem
- UpdateItem
- GetItem
- BatchGetItem
- Scan
- Query
- BatchWriteItem
- TransactWriteItems
- TransactGetItems

- `ExecuteTransaction`
- `BatchExecuteStatement`
- `ExecuteStatement`

In addition, you can limit the data to the following Amazon DynamoDB Streams operation:

- `GetRecords`

OperationType

This dimension limits the data to one of the following operation types:

- `Read`
- `Write`

This dimension is emitted for `ExecuteTransaction` and `BatchExecuteStatement` requests.

Verb

This dimension limits the data to one of the following DynamoDB PartiQL verbs:

- `Insert: PartiQLInsert`
- `Select: PartiQLSelect`
- `Update: PartiQLUpdate`
- `Delete: PartiQLDelete`

This dimension is emitted for the `ExecuteStatement` operation.

ReceivingRegion

This dimension limits the data to a particular AWS region. It is used with metrics originating from replica tables within a DynamoDB global table.

StreamLabel

This dimension limits the data to a specific stream label. It is used with metrics originating from Amazon DynamoDB Streams `GetRecords` operations.

TableName

This dimension limits the data to a specific table. This value can be any table name in the current region and the current AWS account.

How do I use DynamoDB metrics?

The metrics reported by DynamoDB provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, not a comprehensive list.

How can I?	Relevant metrics
How can I monitor the rate of TTL deletions on my table?	You can monitor <code>TimeToLiveDeletedItemCount</code> over the specified time period, to track the rate of TTL deletions on your table. For an example of a server-less application using the <code>TimeToLiveDeletedItemCount</code> metric, see Automatically archive items to S3 using DynamoDB time to live (TTL) with AWS Lambda and Amazon Data Firehose .
How can I determine how much of my provisioned throughput is being used?	You can monitor <code>ConsumedReadCapacityUnits</code> or <code>ConsumedWriteCapacityUnits</code> over the specified time period, to track how much of your provisioned throughput is being used.
How can I determine which requests exceed the provisioned throughput quotas of a table?	<code>ThrottledRequests</code> is incremented by one if any event within a request exceeds a provisioned throughput quota. Then, to gain insight into which event is throttling a request, compare <code>ThrottledRequests</code> with the <code>ReadThrottleEvents</code> and <code>WriteThrottleEvents</code> metrics for the table and its indexes.
How can I determine if any system errors occurred?	You can monitor <code>SystemErrors</code> to determine if any requests resulted in an HTTP 500 (server error) code. Typically, this metric should be equal to zero. If it isn't, then you might want to investigate.

How can I?	Relevant metrics
	<p>Note</p> <p>You might encounter internal server errors while working with items. These are expected during the lifetime of a table. Any failed requests can be retried immediately.</p>

Understanding and analyzing DynamoDB response times

When analyzing latency, it's generally best to check the average. Occasional spikes in latency aren't a cause for concern. However, if average latency is high then an underlying issue could be responsible.

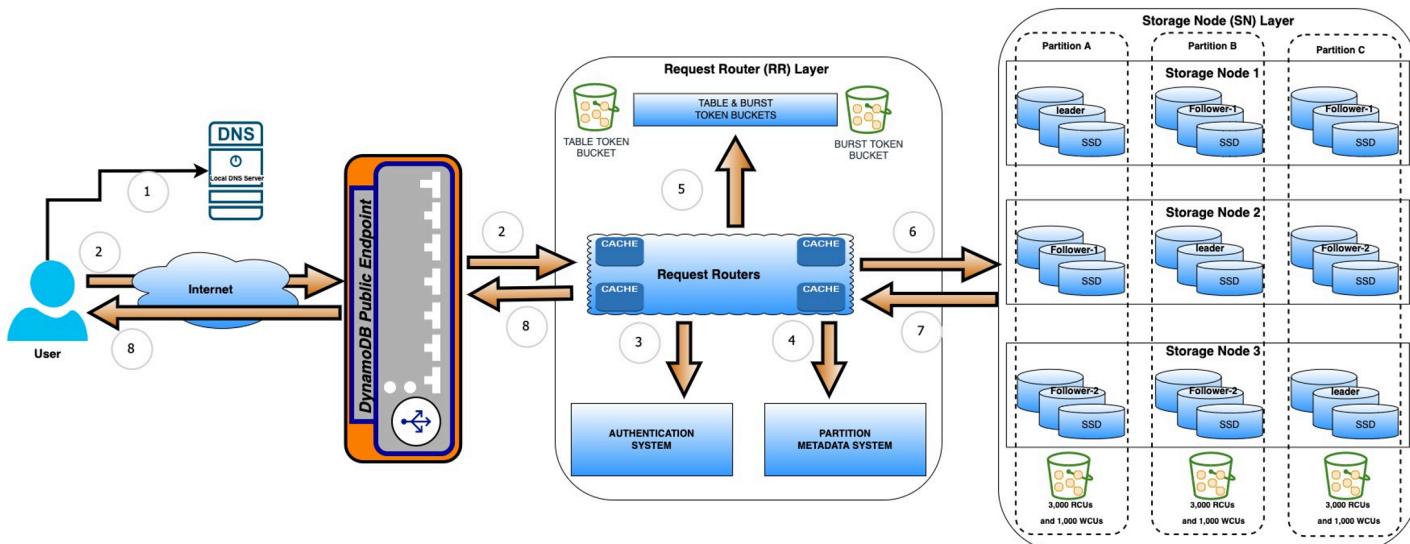

There are two categories of latency, API latency and service side latency. DynamoDB's API latency is measured from steps 1 through 11 in the process below. Service-side latency is measured from the moment an API reaches the Request Router (step 4) to the time the RR takes to send a result back to the application user (step 11). You can analyze service side latency with the Amazon CloudWatch metric `SuccessfulRequestLatency`.

When any application makes any DynamoDB API call to DynamoDB, such as issuing a `GetItem` operation to a DynamoDB table, the following steps occur.

1. The application resolves the DynamoDB public endpoint using local DNS server.
2. The application connects to the IP address resolved in step one, and makes an API call.
3. The DynamoDB public endpoint takes the request and forwards it to a component called Request Router (RR).
4. Once the API request reaches the Request Router (RR), RR does authentication and authorization of the API call. RR also does the throttling checks at this stage.
5. After completing all the checks Request Router (RR) creates the hash of the partition key value which it gets from the API request. Based upon hash value, Request Router (RR) finds the partition information (storage node) details.
6. The Storage Nodes represent the servers where customer table data is stored. A single partition (not to be confused with primary or partition key), consists of a set of 3 Storage

Nodes. Out of these three Storage Nodes, one node acts as a leader for that partition and the remaining two nodes act as follower.

7. If the API call is a write request or if it is strongly consistent read request, then Request Routers (RR) finds the leader node for that partition and forwards the API request to that specific node. In case of eventually consistent read request, Request Routers(RR) forwards the request to leader node or any of the follower nodes for that partition randomly.
8. In normal circumstances, the Request Router reaches the the Storage Node in first attempt. If this attempt fails, RR does multiple retries to reach the storage node. While connecting to storage node, RR always gives enough time to the existing attempt and then tries to connect to the different SN. This is an internal micro-service retry, and not a configurable SDK retry.
9. At this stage the API request reaches to Storage Node (SN) layer and SN starts processing it, reading or writing the data depending of the API call.
10. After successfully processing the API request, the Storage Node (SN) return the results or response code to the RR which originated the request.
11. Finally, Request Router forwards the results to the customer application.

Note

- For most atomic operations, such as `GetItem` and `PutItem`, you can expect an average latency in single-digit milliseconds. Latency for non-atomic operations such as `Query` and `Scan` depends on many factors, including the size of the result set and the complexity of the query conditions and filters.

- DynamoDB doesn't measure the amount of time an application takes to connect with the DynamoDB public endpoint, or the amount of time an application takes to download the results from the public endpoint.

Creating CloudWatch alarms to monitor DynamoDB

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period you specify, and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

Note

You must specify all the required dimensions when creating your CloudWatch alarm, since CloudWatch will not aggregate metrics for a missing dimension. Creating a CloudWatch alarm with a missing dimension will not result in an error, when creating the alarm.

For a list of supported metrics and their required dimensions in DynamoDB, see [Viewing metrics and dimensions](#).

How can I be notified before I consume my entire read capacity?

1. Create an Amazon SNS topic, `arn:aws:sns:us-east-1:123456789012:capacity-alarm`.

For more information, see [Set up Amazon Simple Notification Service](#).

2. Create the alarm. In this example, we assume a provisioned capacity of five read capacity units.

```
aws cloudwatch put-metric-alarm \
  --alarm-name ReadCapacityUnitsLimitAlarm \
  --alarm-description "Alarm when read capacity reaches 80% of my provisioned
  read capacity" \
  --namespace AWS/DynamoDB \
```

```
--metric-name ConsumedReadCapacityUnits \
--dimensions Name=TableName,Value=myTable \
--statistic Sum \
--threshold 240 \
--comparison-operator GreaterThanOrEqualToThreshold \
--period 60 \
--evaluation-periods 1 \
--alarm-actions arn:aws:sns:us-east-1:123456789012:capacity-alarm
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name ReadCapacityUnitsLimitAlarm --state-reason "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name ReadCapacityUnitsLimitAlarm --state-reason "initializing" --state-value ALARM
```

Note

The alarm is activated whenever the consumed read capacity is at least 4 units per second (80% of provisioned read capacity of 5) for 1 minute (60 seconds). So the threshold is 240 read capacity units (4 units/sec * 60 seconds). Any time the read capacity is updated you should update the alarm calculations appropriately. You can avoid this process by creating alarms through the DynamoDB Console. In this way, the alarms are automatically updated for you.

How can I be notified if any requests exceed the provisioned throughput quotas of a table?

1. Create an Amazon SNS topic, arn:aws:sns:us-east-1:123456789012:requests-exceeding-throughput.

For more information, see [Set up Amazon Simple Notification Service](#).

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
--alarm-name RequestsExceedingThroughputAlarm \
--alarm-description "Alarm when my requests are exceeding provisioned throughput quotas of a table" \
```

```
--namespace AWS/DynamoDB \
--metric-name ThrottledRequests \
--dimensions Name=TableName,Value=myTable
Name=Operation,Value=aDynamoDBOperation \
--statistic Sum \
--threshold 0 \
--comparison-operator GreaterThanThreshold \
--period 300 \
--unit Count \
--evaluation-periods 1 \
--treat-missing-data notBreaching \
--alarm-actions arn:aws:sns:us-east-1:123456789012:requests-exceeding-
throughput
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name RequestsExceedingThroughputAlarm --
state-reason "initializing" --state-value ALARM
```

How can I be notified if any system errors occurred?

1. Create an Amazon SNS topic, arn:aws:sns:us-east-1:123456789012:notify-on-system-errors.

For more information, see [Set up Amazon Simple Notification Service](#).

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
--alarm-name SystemErrorsAlarm \
--alarm-description "Alarm when system errors occur" \
--namespace AWS/DynamoDB \
--metric-name SystemErrors \
--dimensions Name=TableName,Value=myTable
Name=Operation,Value=aDynamoDBOperation \
--statistic Sum \
--threshold 0 \
--comparison-operator GreaterThanThreshold \
--period 60 \
```

```
--unit Count \
--evaluation-periods 1 \
--treat-missing-data breaching \
--alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
"initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name SystemErrorsAlarm --state-reason
"initializing" --state-value ALARM
```

Logging DynamoDB operations by using AWS CloudTrail

DynamoDB is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DynamoDB. CloudTrail captures all API calls for DynamoDB as events. The calls captured include calls from the DynamoDB console and code calls to the DynamoDB API operations, using both PartiQL and the classic API. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for DynamoDB. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to DynamoDB, the IP address from which the request was made, who made the request, when it was made, and additional details.

For robust monitoring and alerting, you can also integrate CloudTrail events with [Amazon CloudWatch Logs](#). To enhance your analysis of DynamoDB service activity and identify changes in activities for an AWS account, you can query AWS CloudTrail logs using [Amazon Athena](#). For example, you can use queries to identify trends and further isolate activity by attributes such as source IP address or user.

To learn more about CloudTrail, including how to configure and enable it, see the [AWS CloudTrail User Guide](#).

Topics

- [DynamoDB information in CloudTrail](#)
- [Understanding DynamoDB log file entries](#)

DynamoDB information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in DynamoDB, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail event history](#).

For an ongoing record of events in your AWS account, including events for DynamoDB, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for creating a trail](#)
- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)

DynamoDB data plane events in CloudTrail

To enable logging of the following API actions in CloudTrail files, you'll need to enable logging of data plane API activity in CloudTrail. See [Logging data events for trails](#) for more information.

Data plane events can be filtered by resource type, for granular control over which DynamoDB API calls you want to selectively log and pay for in CloudTrail. For example, by specifying AWS::DynamoDB::Stream as a resource type, you can log only calls to the DynamoDB streams APIs. For tables with streams enabled, the resource field in the data plane event contains both AWS::DynamoDB::Stream and AWS::DynamoDB::Table. If you specify AWS::DynamoDB::Table as a resource type, it will log both DynamoDB table and DynamoDB streams events by default. You can add an additional [filter](#) to exclude the streams events, if you don't want the streams events to be logged. For more information, see [DataResource](#) in the CloudTrail [AWS CloudTrail API reference](#).

Understanding DynamoDB log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

Note

Non key attribute values will be redacted in the CloudTrail logs of actions using the PartiQL API, and will not appear in logs of actions using the classic API.

For more information, see the [CloudTrail userIdentity element](#).

The following examples demonstrate CloudTrail logs of these event types:

Amazon DynamoDB

- [UpdateTable](#)

Logging and monitoring in DynamoDB Accelerator

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon DynamoDB Accelerator (DAX) and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs.

For more information about logging and monitoring in DAX, see [Monitoring DAX](#).

Analyzing data access using CloudWatch contributor insights for DynamoDB

Amazon CloudWatch Contributor Insights for Amazon DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your table or index at a glance. This tool uses [CloudWatch contributor insights](#).

By enabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, you can view the most accessed and throttled items in those resources.

Note

CloudWatch charges apply for Contributor Insights for DynamoDB. For more information about pricing, see [Amazon CloudWatch pricing](#).

Topics

- [CloudWatch contributor insights for DynamoDB: How it works](#)
- [Getting started with CloudWatch contributor insights for DynamoDB](#)
- [Using IAM with CloudWatch contributor insights for DynamoDB](#)

CloudWatch contributor insights for DynamoDB: How it works

Amazon DynamoDB integrates with [Amazon CloudWatch Contributor Insights](#) to provide information about the most accessed and throttled items in a table or global secondary index. DynamoDB delivers this information to you via CloudWatch Contributor Insights [rules](#), [reports](#), and graphs of report data.

For more information about CloudWatch Contributor Insights, see [Using Contributor Insights to Analyze High-Cardinality Data](#) in the *Amazon CloudWatch User Guide*.

The following sections describe the core concepts and behavior of CloudWatch Contributor Insights for DynamoDB.

Topics

- [CloudWatch contributor insights for DynamoDB rules](#)
- [Understanding CloudWatch contributor insights for DynamoDB graphs](#)

- [Interactions with other DynamoDB features](#)
- [CloudWatch contributor insights for DynamoDB billing](#)

CloudWatch contributor insights for DynamoDB rules

When you enable CloudWatch Contributor Insights for DynamoDB on a table or global secondary index, DynamoDB creates the following [rules](#) on your behalf:

- **Most accessed items (partition key)** — Identifies the partition keys of the most accessed items in your table or global secondary index.

CloudWatch rule name format: DynamoDBContributorInsights-PKC-[resource_name]-[creationtimestamp]

- **Most throttled keys (partition key)** — Identifies the partition keys of the most throttled items in your table or global secondary index.

CloudWatch rule name format: DynamoDBContributorInsights-PKT-[resource_name]-[creationtimestamp]

Note

When you enable Contributor Insights on your DynamoDB table, you're still subject to Contributor Insights rules limits. For more information, see [CloudWatch service quotas](#).

If your table or global secondary index has a sort key, DynamoDB also creates the following rules specific to sort keys:

- **Most accessed keys (partition and sort keys)** — Identifies the partition and sort keys of the most accessed items in your table or global secondary index.

CloudWatch rule name format: DynamoDBContributorInsights-SKC-[resource_name]-[creationtimestamp]

- **Most throttled keys (partition and sort keys)** — Identifies the partition and sort keys of the most throttled items in your table or global secondary index.

CloudWatch rule name format: DynamoDBContributorInsights-SKT-[resource_name]-[creationtimestamp]

Note

- You can't use the CloudWatch console or APIs to directly modify or delete the rules created by CloudWatch Contributor Insights for DynamoDB. Disabling CloudWatch Contributor Insights for DynamoDB on a table or global secondary index automatically deletes the rules created for that table or global secondary index.
- When you use the [GetInsightRuleReport](#) operation with CloudWatch Contributor Insights rules that are created by DynamoDB, only MaxContributorValue and Maximum return useful statistics. The other statistics in this list don't return meaningful values.
- CloudWatch Contributor Insights for DynamoDB has a limit of 25 contributors. Requesting more than 25 contributors will return an error.

You can create CloudWatch Alarms using the CloudWatch Contributor Insights for DynamoDB [rules](#). This allows you to be notified when any item exceed or meets a specific threshold for ConsumedThroughputUnits or ThrottleCount. For more information, see [Setting an Alarm on Contributor Insights Metric Data](#).

Understanding CloudWatch contributor insights for DynamoDB graphs

CloudWatch Contributor Insights for DynamoDB displays two types of graphs on both the DynamoDB and CloudWatch consoles: *Most Accessed Items* and *Most Throttled Items*.

Most accessed items

Use this graph to identify the most accessed items in the table or global secondary index. The graph displays ConsumedThroughputUnits on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures key access frequency by using ConsumedThroughputUnits, which measures combined read and write traffic. ConsumedThroughputUnits is defined as the following:

- Provisioned — $(3 \times \text{consumed write capacity units}) + \text{consumed read capacity units}$
- On-demand — $(3 \times \text{write request units}) + \text{read request units}$

On the DynamoDB console, each data point in the graph represents the maximum of ConsumedThroughputUnits over a 1-minute period. For example, a graph value of 180,000

`ConsumedThroughputUnits` indicates that the item was accessed continuously at the per-item maximum throughput of 1,000 write request units or 3,000 read request units for a 60-second span within that 1-minute period (3,000 x 60 seconds). In other words, the graphed values represent the highest-traffic minute within each 1-minute period. You can change the time granularity of the `ConsumedThroughputUnits` metric (for example, to view 5-minute metrics instead of 1-minute) on the CloudWatch console.

If you see several closely clustered lines without any obvious outliers, it indicates that your workload is relatively balanced across items over the given time window. If you see isolated points in the graph instead of connected lines, it indicates an item that was frequently accessed only for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for the most accessed partition keys and one for the most accessed partition + sort key pairs. You can see traffic at the partition key level in the partition key-only graph. You can see traffic at the item level in the partition + sort key graphs.

Most throttled items

Use this graph to identify the most throttled items in the table or global secondary index. The graph displays `ThrottleCount` on the y-axis and time on the x-axis. Each of the top N keys is displayed in its own color, with a legend displayed below the x-axis.

DynamoDB measures throttle frequency using `ThrottleCount`, which is the count of `ProvisionedThroughputExceededException`, `ThrottlingException`, and `RequestLimitExceeded` errors.

Write throttling caused by insufficient write capacity for a global secondary index is not measured. You can use the *Most Accessed Items* graph of the global secondary index to identify imbalanced access patterns that may cause write throttling. For more information, see [Provisioned Throughput Considerations for Global Secondary Indexes](#).

On the DynamoDB console, each data point in the graph represents the count of throttle events over a 1-minute period.

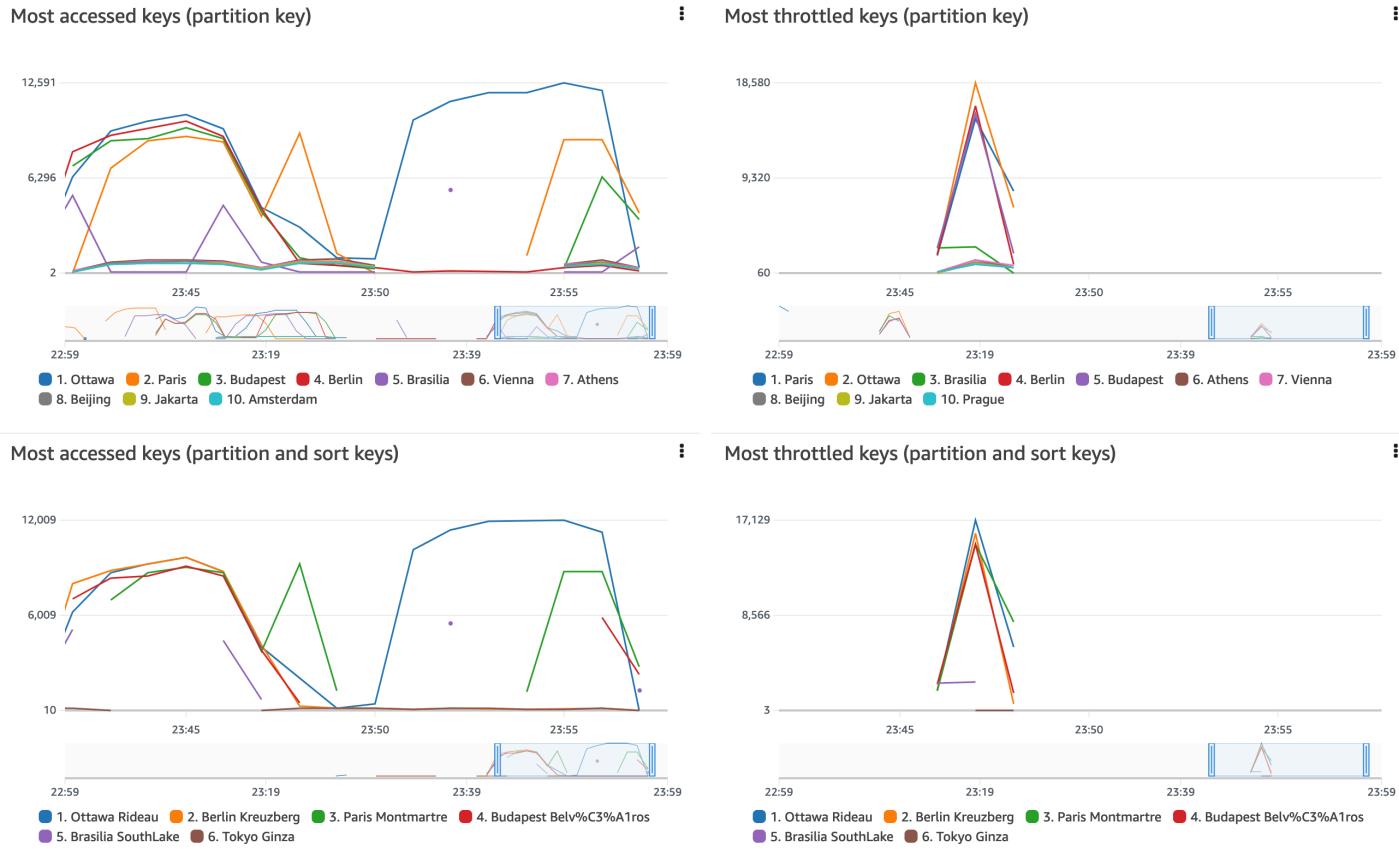

If you see no data in this graph, it indicates that your requests are not being throttled. If you see isolated points in the graph instead of connected lines, it indicates that an item was frequently throttled for a brief period.

If your table or global secondary index has a sort key, DynamoDB creates two graphs: one for most throttled partition keys and one for most throttled partition + sort key pairs. You can see throttle

count at the partition key level in the partition key-only graph, and throttle count at the item-level in the partition + sort key graphs.

Report examples

The following are examples of the reports generated for a table with both a partition key and sort key.

Interactions with other DynamoDB features

The following sections describe how CloudWatch Contributor Insights for DynamoDB behaves and interacts with several other features in DynamoDB.

Global tables

CloudWatch Contributor Insights for DynamoDB monitors global table replicas as distinct tables. The Contributor Insights graphs for a replica in one AWS Region might not show the same patterns as another Region. This is because write data is replicated across all replicas in a global table, but each replica can serve Region-bound read traffic.

DynamoDB Accelerator (DAX)

CloudWatch Contributor Insights for DynamoDB doesn't show DAX cache responses. It only shows responses to accessing a table or a global secondary index.

Note

DynamoDB CCI does not support PartiQL requests.

Encryption at rest

CloudWatch Contributor Insights for DynamoDB doesn't affect how encryption works in DynamoDB. The primary key data that is published in CloudWatch is encrypted with the AWS owned key. However, DynamoDB also supports the AWS managed key and a customer managed key.

CloudWatch Contributor Insights for DynamoDB graphs display the partition key and sort key (if applicable) of frequently accessed items and frequently throttled items in plaintext. If you require the use of AWS Key Management Service (KMS) to encrypt this table's partition key and sort key data with an AWS managed key or customer managed key, you should not enable CloudWatch Contributor Insights for DynamoDB for this table.

If you require your primary key data to be encrypted with the AWS managed key or a customer managed key, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.

Fine-grained access control

CloudWatch Contributor Insights for DynamoDB doesn't function differently for tables with fine-grained access control (FGAC). In other words, any user who has the appropriate CloudWatch permissions can view FGAC-protected primary keys in CloudWatch Contributor Insights graphs.

If the table's primary key contains FGAC-protected data that you don't want published to CloudWatch, you should not enable CloudWatch Contributor Insights for DynamoDB for that table.

Access control

You control access to CloudWatch Contributor Insights for DynamoDB using AWS Identity and Access Management (IAM) by limiting DynamoDB control plane permissions and CloudWatch data

plane permissions. For more information see, [Using IAM with CloudWatch Contributor Insights for DynamoDB](#).

CloudWatch contributor insights for DynamoDB billing

Charges for CloudWatch Contributor Insights for DynamoDB appear in the [CloudWatch](#) section of your monthly bill. These charges are calculated based on the number of DynamoDB events that are processed. For tables and global secondary indexes with CloudWatch Contributor Insights for DynamoDB enabled, each item that is written or read via a [data plane](#) operation represents one event.

If a table or global secondary index includes a sort key, each item that is read or written represents two events. This is because DynamoDB is identifying top contributors from separate time series: one for partitions keys only, and one for partition and sort key pairs.

For example, assume that your application performs the following DynamoDB operations: a `GetItem`, a `PutItem`, and a `BatchWriteItem` that puts five items

- If your table or global secondary index has only a partition key, it results in 7 events (1 for the `GetItem`, 1 for the `PutItem`, and 5 for the `BatchWriteItem`).
- If your table or global secondary index has a partition key and sort key, it results in 14 events (2 for the `GetItem`, 2 for the `PutItem`, and 10 for the `BatchWriteItem`).
- A `Query` operation always results in 1 event, regardless of the number of items returned.

Unlike other DynamoDB features, CloudWatch Contributor Insights for DynamoDB billing *does not* vary based on the following:

- The [capacity mode](#) (provisioned vs. on-demand)
- Whether you perform read or write requests
- The size (KB) of the items read or written

Getting started with CloudWatch contributor insights for DynamoDB

This section describes how to use Amazon CloudWatch Contributor Insights with the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

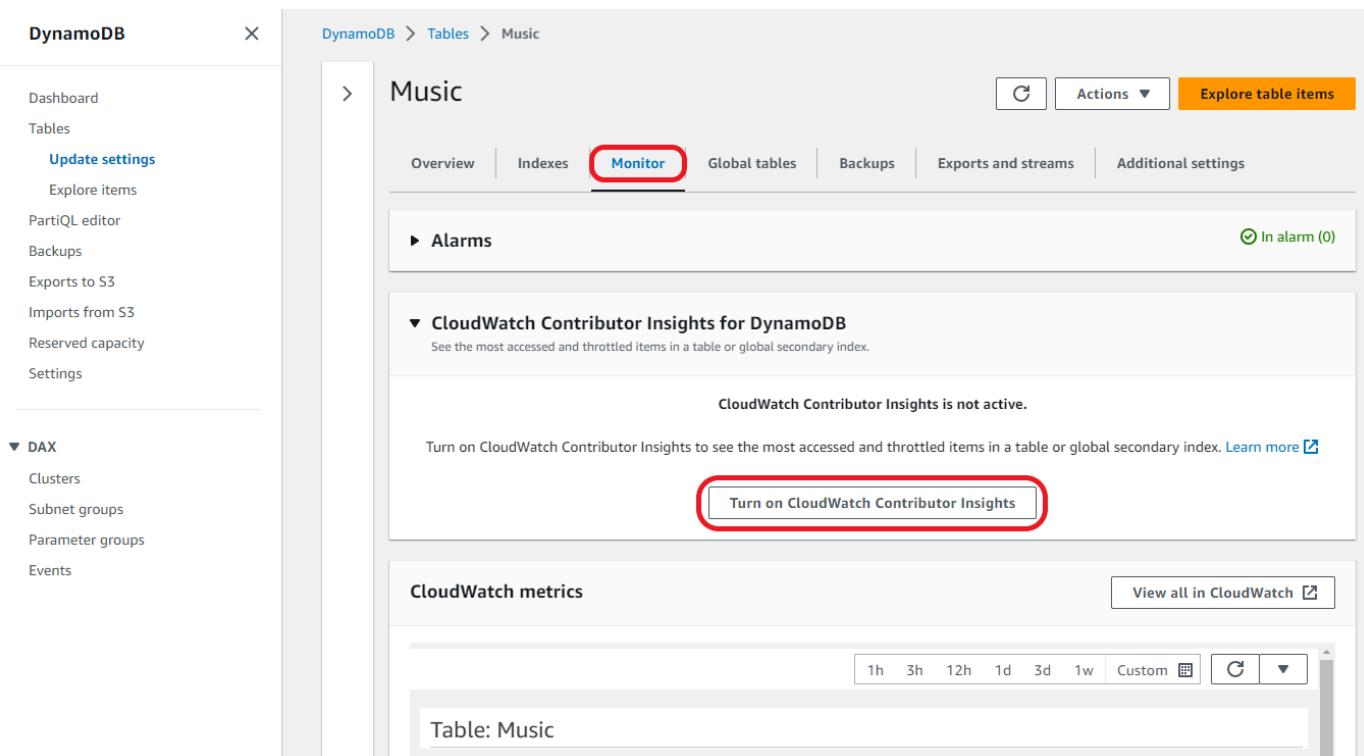

In the following examples, you use the DynamoDB table that is defined in the [Getting started with DynamoDB](#) tutorial.

Topics

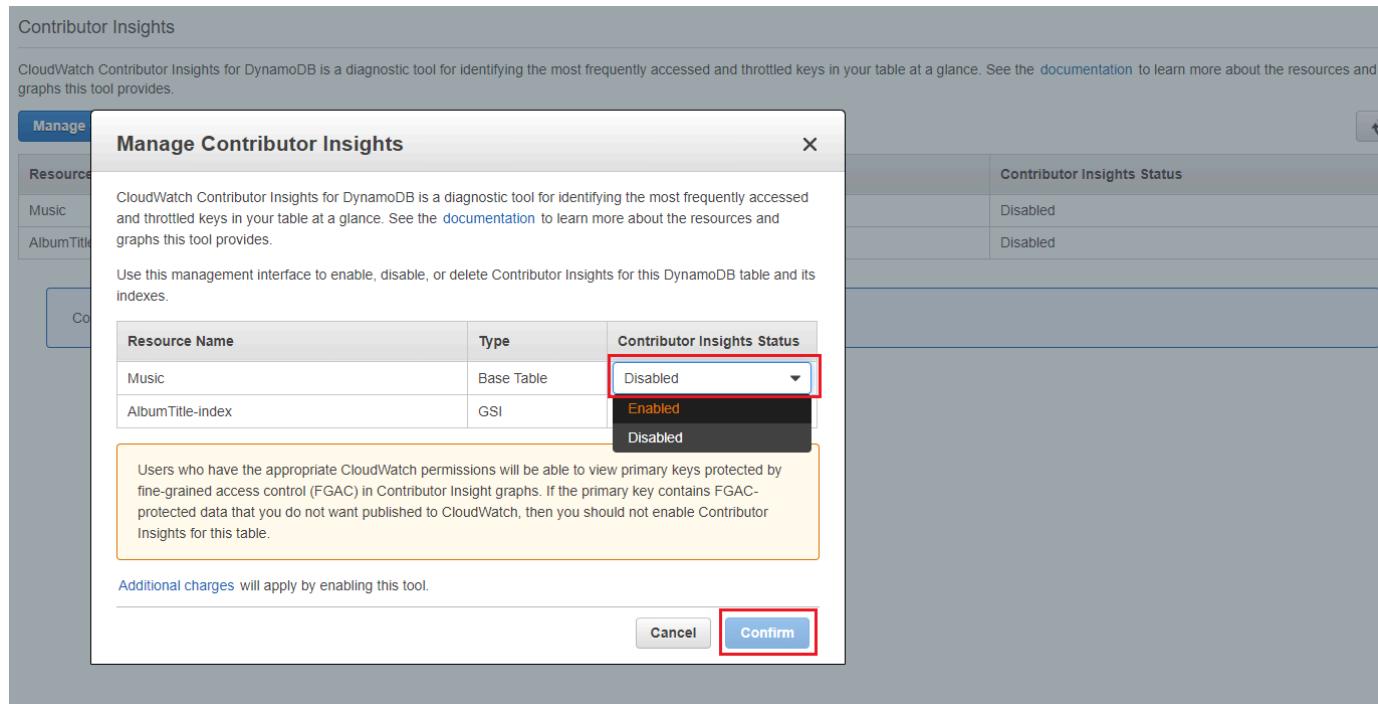

- [Using contributor insights \(console\)](#)
- [Using contributor insights \(AWS CLI\)](#)

Using contributor insights (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the Music table.
4. Choose the **Monitor** tab.
5. Choose **Turn on CloudWatch Contributor Insights**.

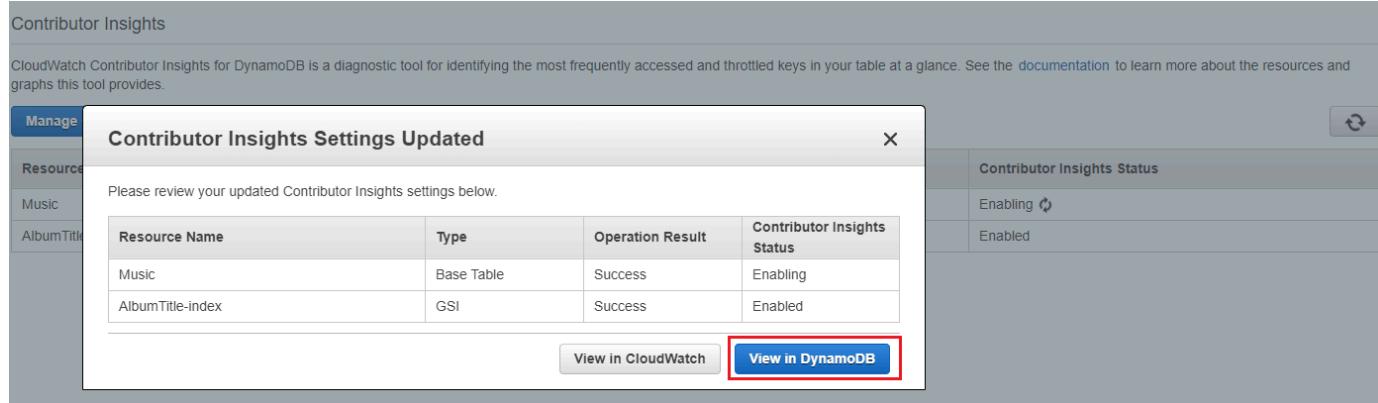

6. In the **Manage Contributor Insights** dialog box, under **Contributor Insights Status**, choose **Enabled** for both the Music base table and the AlbumTitle-index global secondary index. Then choose **Confirm**.

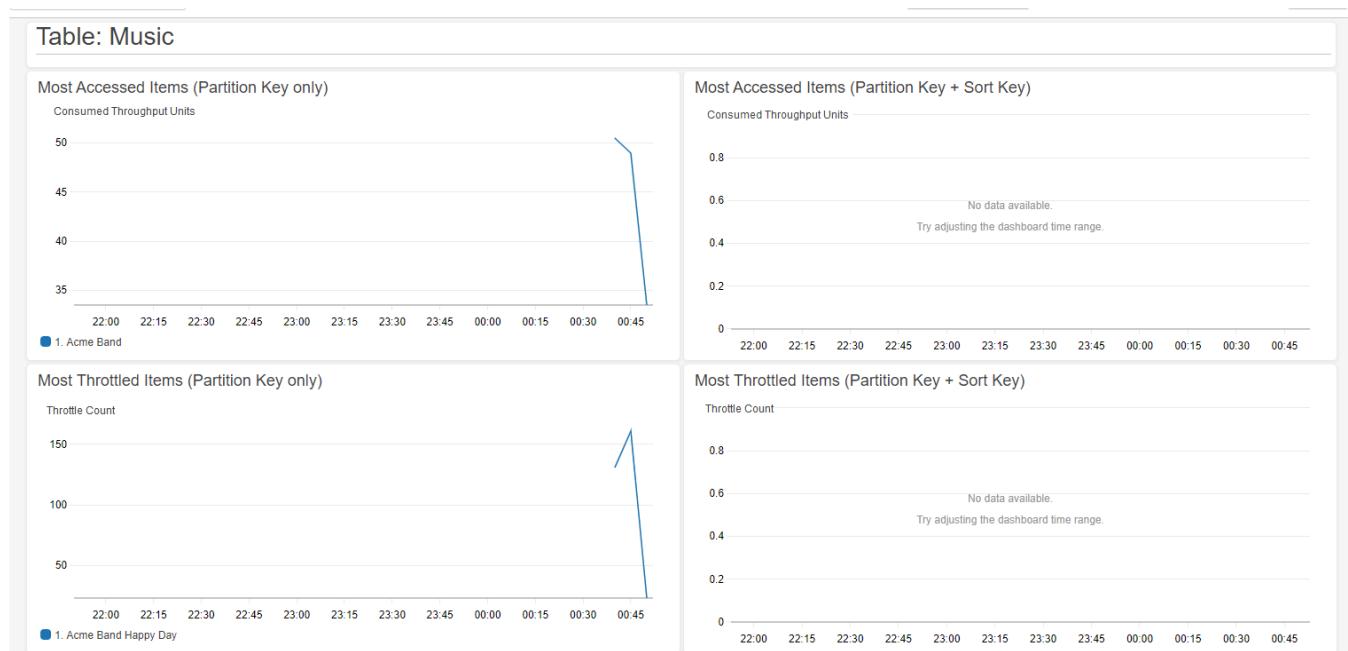

If the operation fails, see [DescribeContributorInsightsFailureException](#) in the *Amazon DynamoDB API Reference* for possible reasons.

7. Choose View in DynamoDB.

8. The Contributor Insights graphs are now visible on the **Contributor Insights** tab for the Music table.

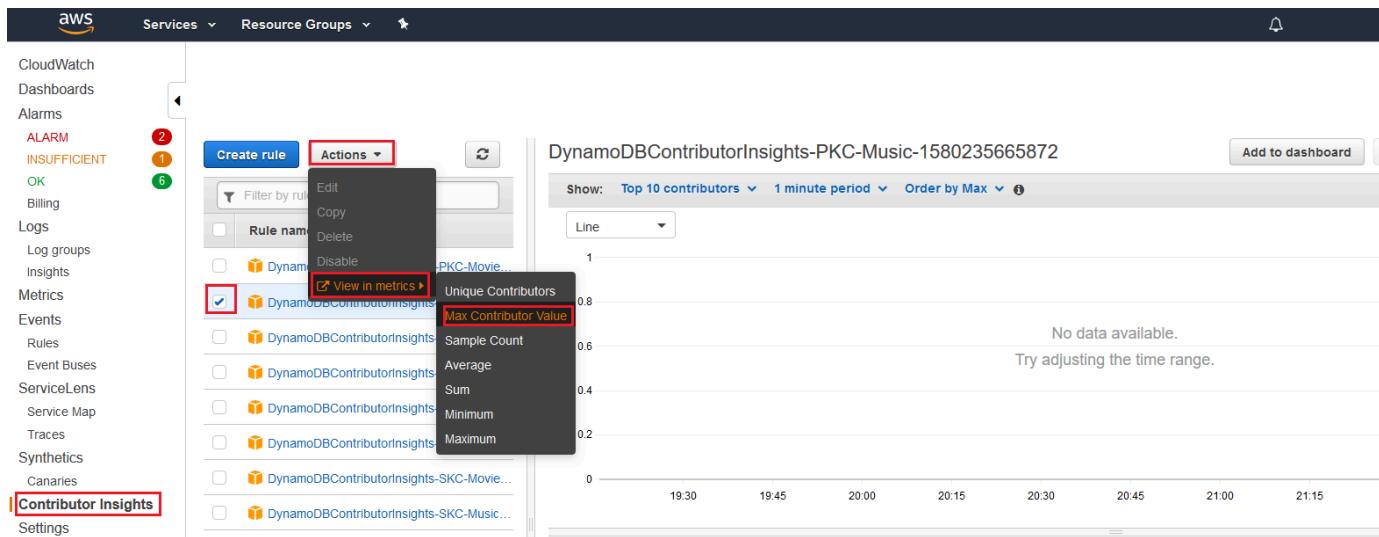

Creating CloudWatch alarms

Follow these steps to create a CloudWatch alarm and be notified when any partition key consumes more than 50,000 [ConsumedThroughputUnits](#).

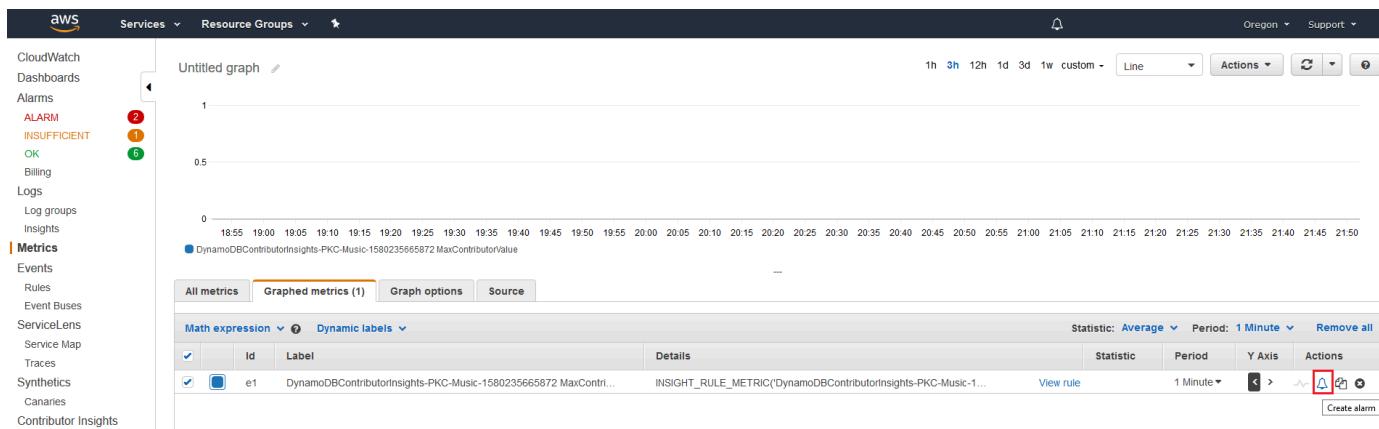

1. Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>
2. In the navigation pane on the left side of the console, choose **Contributor Insights**.
3. Choose the **DynamoDBContributorInsights-PKC-Music** rule.
4. Choose the **Actions** drop down.
5. Choose **View in metrics**.
6. Choose **Max Contributor Value**.

Note

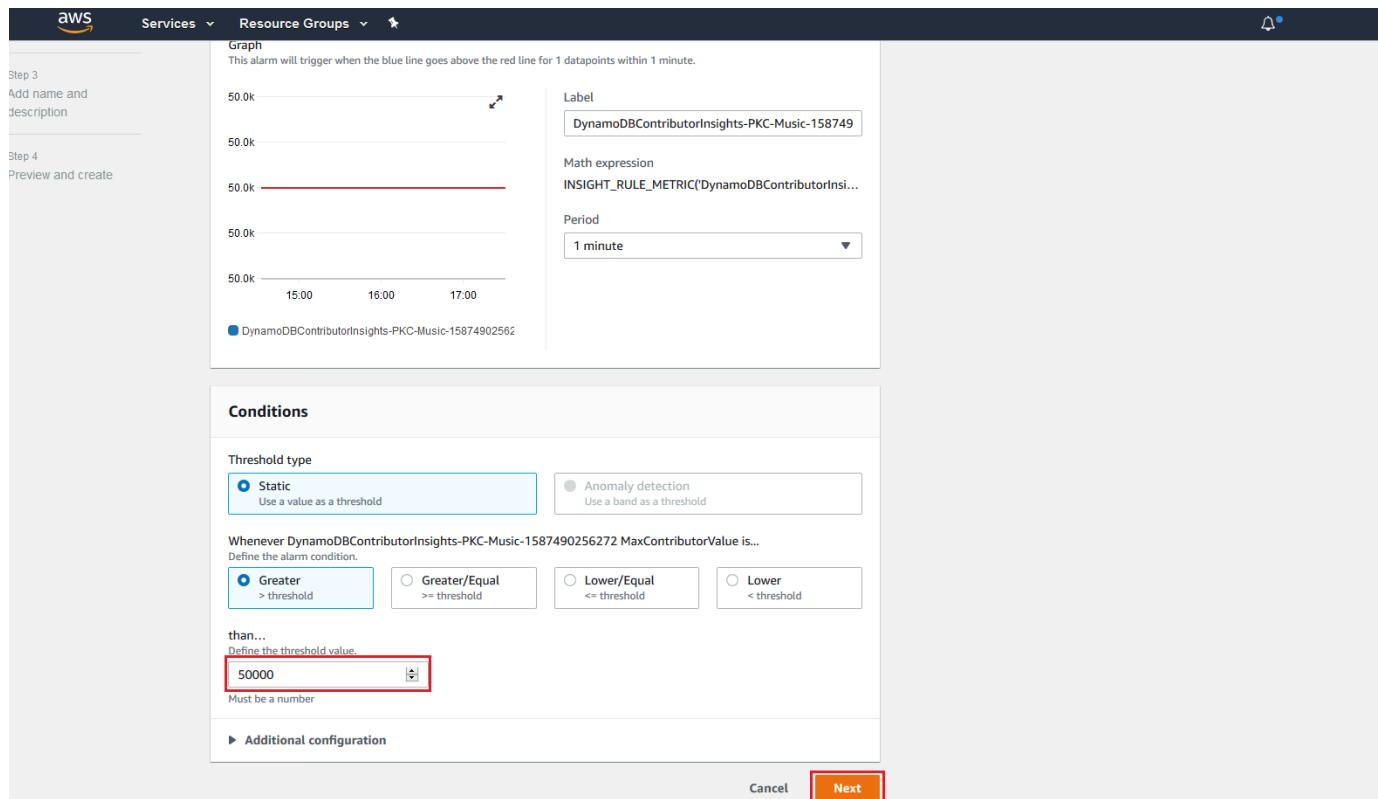

Only Max Contributor Value and Maximum return useful statistics. The other statistics in this list don't return meaningful values.

7. On the Actions column, Choose Create Alarm.

8. Enter a value of 50000 for threshold and choose Next.

- See [Using Amazon CloudWatch alarms](#) for details on how to configure the notification for the alarm.

Using contributor insights (AWS CLI)

- Enable CloudWatch Contributor Insights for DynamoDB on the Music base table.

```
aws dynamodb update-contributor-insights --table-name Music --contributor-insights-action=ENABLE
```

- Enable Contributor Insights for DynamoDB on the AlbumTitle-index global secondary index.

```
aws dynamodb update-contributor-insights --table-name Music --index-name AlbumTitle-index --contributor-insights-action=ENABLE
```

- Get the status and rules for the Music table and all its indexes.

```
aws dynamodb describe-contributor-insights --table-name Music
```

4. Disable CloudWatch Contributor Insights for DynamoDB on the AlbumTitle-index global secondary index.

```
aws dynamodb update-contributor-insights --table-name Music --index-name  
AlbumTitle-index --contributor-insights-action=DISABLE
```

5. Get the status of the Music table and all its indexes.

```
aws dynamodb list-contributor-insights --table-name Music
```

Using IAM with CloudWatch contributor insights for DynamoDB

The first time that you enable Amazon CloudWatch Contributor Insights for Amazon DynamoDB, DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role, `AWSServiceRoleForDynamoDBCloudWatchContributorInsights`, allows DynamoDB to manage CloudWatch Contributor Insights rules on your behalf. Don't delete this service-linked role. If you delete it, all your managed rules will no longer be cleaned up when you delete your table or global secondary index.

For more information about service-linked roles, see [Using service-linked roles in the IAM User Guide](#).

The following permissions are required:

- To enable or disable CloudWatch Contributor Insights for DynamoDB, you must have `dynamodb:UpdateContributorInsights` permission on the table or index.
- To view CloudWatch Contributor Insights for DynamoDB graphs, you must have `cloudwatch:GetInsightRuleReport` permission.
- To describe CloudWatch Contributor Insights for DynamoDB for a given DynamoDB table or index, you must have `dynamodb:DescribeContributorInsights` permission.
- To list CloudWatch Contributor Insights for DynamoDB statuses for each table and global secondary index, you must have `dynamodb>ListContributorInsights` permission.

Example: Enable or disable CloudWatch contributor insights for DynamoDB

The following IAM policy grants permissions to enable or disable CloudWatch Contributor Insights for DynamoDB.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "iam:CreateServiceLinkedRole",  
            "Resource": "arn:aws:iam::*:role/aws-service-role/  
contributorinsights.dynamodb.amazonaws.com/  
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",  
            "Condition": {"StringLike": {"iam:AWSPropertyName":  
"contributorinsights.dynamodb.amazonaws.com"}}  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:UpdateContributorInsights"  
            ],  
            "Resource": "arn:aws:dynamodb:*:*:table/*"  
        }  
    ]  
}
```

For tables encrypted by KMS key, the user needs to have kms:Decrypt permissions in order to update Contributor Insights.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "iam:CreateServiceLinkedRole",  
            "Resource": "arn:aws:iam::*:role/aws-service-role/  
contributorinsights.dynamodb.amazonaws.com/  
AWSServiceRoleForDynamoDBCloudWatchContributorInsights",  
            "Condition": {"StringLike": {"iam:AWSPropertyName":  
"contributorinsights.dynamodb.amazonaws.com"}}  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:UpdateContributorInsights"  
            ],  
            "Resource": "arn:aws:dynamodb:*:*:table/*"  
        }  
    ]  
}
```

```
        },
        {
            "Effect": "Allow",
            "Resource": "arn:aws:kms:*:*:key/*",
            "Action": [
                "kms:Decrypt"
            ],
        }
    ]
}
```

Example: Retrieve CloudWatch contributor insights rule report

The following IAM policy grants permissions to retrieve CloudWatch Contributor Insights rule report.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetInsightRuleReport"
            ],
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/
DynamoDBContributorInsights*"
        }
    ]
}
```

Example: Selectively apply CloudWatch contributor insights for DynamoDB permissions based on resource

The following IAM policy grants permissions to allow the `ListContributorInsights` and `DescribeContributorInsights` actions and denies the `UpdateContributorInsights` action for a specific global secondary index.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {

```

```
        "Effect": "Allow",
        "Action": [
            "dynamodb>ListContributorInsights",
            "dynamodb>DescribeContributorInsights"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Deny",
        "Action": [
            "dynamodb>UpdateContributorInsights"
        ],
        "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books/index/
Author-index"
    }
]
```

Using service-linked roles for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Contributor Insights for DynamoDB. Service-linked roles are predefined by CloudWatch Contributor Insights for DynamoDB and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up CloudWatch Contributor Insights for DynamoDB easier because you don't have to manually add the necessary permissions. CloudWatch Contributor Insights for DynamoDB defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Contributor Insights for DynamoDB can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB uses the service-linked role named **AWSServiceRoleForDynamoDBCloudWatchContributorInsights**. The purpose of the service-linked

role is to allow Amazon DynamoDB to manage Amazon CloudWatch Contributor Insights rules created for DynamoDB tables and global secondary indexes, on your behalf.

The `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role trusts the following services to assume the role:

- `contributorinsights.dynamodb.amazonaws.com`

The role permissions policy allows CloudWatch Contributor Insights for DynamoDB to complete the following actions on the specified resources:

- Action: Create and manage Insight Rules on `DynamoDBContributorInsights`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually create a service-linked role. When you enable Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Contributor Insights, CloudWatch Contributor Insights for DynamoDB creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Contributor Insights for DynamoDB

CloudWatch Contributor Insights for DynamoDB does not allow you to edit the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Contributor Insights for DynamoDB

You don't need to manually delete the `AWSServiceRoleForDynamoDBCloudWatchContributorInsights` role. When you disable

Contributor Insights in the AWS Management Console, the AWS CLI, or the AWS API, CloudWatch Contributor Insights for DynamoDB cleans up the resources.

You can also use the IAM console, the AWS CLI or the AWS API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role and then you can manually delete it.

 **Note**

If the CloudWatch Contributor Insights for DynamoDB service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForDynamoDBCloudWatchContributorInsights service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Using AWS User Notifications User Notifications with Amazon DynamoDB

You can use [User Notifications](#) to set up delivery channels to get notified about DynamoDB events. You receive a notification when an event matches a rule that you specify. You can receive notifications for events through multiple channels, including email, [AWS Chatbot](#) chat notifications, or [AWS Console Mobile Application](#) push notifications. You can also see notifications in the [Console Notifications Center](#). User Notifications supports aggregation, which can reduce the number of notifications you receive during specific events.

Best practices for designing and architecting with DynamoDB

Use this section to quickly find recommendations for maximizing performance and minimizing throughput costs when working with Amazon DynamoDB.

NoSQL design for DynamoDB

NoSQL database systems like Amazon DynamoDB use alternative models for data management, such as key-value pairs or document storage. When you switch from a relational database

management system to a NoSQL database system like DynamoDB, it's important to understand the key differences and specific design approaches.

Topics

- [Differences between relational data design and NoSQL](#)
- [Two key concepts for NoSQL design](#)
- [Approaching NoSQL design](#)
- [NoSQL Workbench for DynamoDB](#)

Differences between relational data design and NoSQL

Relational database systems (RDBMS) and NoSQL databases have different strengths and weaknesses:

- In RDBMS, data can be queried flexibly, but queries are relatively expensive and don't scale well in high-traffic situations (see [First steps for modeling relational data in DynamoDB](#)).
- In a NoSQL database such as DynamoDB, data can be queried efficiently in a limited number of ways, outside of which queries can be expensive and slow.

These differences make database design different between the two systems:

- In RDBMS, you design for flexibility without worrying about implementation details or performance. Query optimization generally doesn't affect schema design, but normalization is important.
- In DynamoDB, you design your schema specifically to make the most common and important queries as fast and as inexpensive as possible. Your data structures are tailored to the specific requirements of your business use cases.

Two key concepts for NoSQL design

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can go ahead and create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. You can organize each type of data into its own table.

How NoSQL design is different

- By contrast, you shouldn't start designing your schema for DynamoDB until you know the questions it will need to answer. Understanding the business problems and the application use cases up front is essential.
- You should maintain as few tables as possible in a DynamoDB application. Having fewer tables keeps things more scalable, requires less permissions management, and reduces overhead for your DynamoDB application. It can also help keep backup costs lower overall.

Approaching NoSQL design

The first step in designing your DynamoDB application is to identify the specific query patterns that the system must satisfy.

In particular, it is important to understand three fundamental properties of your application's access patterns before you begin:

- **Data size:** Knowing how much data will be stored and requested at one time will help determine the most effective way to partition the data.
- **Data shape:** Instead of reshaping data when a query is processed (as an RDBMS system does), a NoSQL database organizes data so that its shape in the database corresponds with what will be queried. This is a key factor in increasing speed and scalability.
- **Data velocity:** DynamoDB scales by increasing the number of physical partitions that are available to process queries, and by efficiently distributing data across those partitions. Knowing in advance what the peak query loads will be might help determine how to partition data to best use I/O capacity.

After you identify specific query requirements, you can organize data according to general principles that govern performance:

- **Keep related data together.** Research on routing-table optimization 20 years ago found that "locality of reference" was the single most important factor in speeding up response time: keeping related data together in one place. This is equally true in NoSQL systems today, where keeping related data in close proximity has a major impact on cost and performance. Instead of distributing related data items across multiple tables, you should keep related items in your NoSQL system as close together as possible.

As a general rule, you should maintain as few tables as possible in a DynamoDB application.

Exceptions are cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

- **Use sort order.** Related items can be grouped together and queried efficiently if their key design causes them to sort together. This is an important NoSQL design strategy.
- **Distribute queries.** It is also important that a high volume of queries not be focused on one part of the database, where they can exceed I/O capacity. Instead, you should design data keys to distribute traffic evenly across partitions as much as possible, avoiding "hot spots."
- **Use global secondary indexes.** By creating specific global secondary indexes, you can enable different queries than your main table can support, and that are still fast and relatively inexpensive.

These general principles translate into some common design patterns that you can use to model data efficiently in DynamoDB.

NoSQL Workbench for DynamoDB

[NoSQL Workbench for DynamoDB](#) is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench is a visual development tool that provides data modeling, data visualization, sample data generation, and query development features to help you design, create, query, and manage DynamoDB tables. With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see [Building data models with NoSQL Workbench](#)

Using deletion protection to protect your table

Deletion protection can keep your table from being accidentally deleted. This section describes some best practices for using deletion protection.

- For all active production tables, the best practice is to turn on the deletion protection setting and protect these tables from accidental deletion. This also applies to global replicas.

- When serving application development use cases, if the table management workflow includes frequently deleting and recreating development and staging tables then the deletion protection setting can be turned off. This will allow intentional deletion of such tables by authorized IAM principals.

For more information about deletion protection, see [Using deletion protection](#).

Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload

This section describes the Amazon DynamoDB Well-Architected Lens, a collection of design principles and guidance for designing well-architected DynamoDB workloads.

Optimizing costs on DynamoDB tables

This section covers best practices on how to optimize costs for your existing DynamoDB tables. You should look at the following strategies to see which cost optimization strategy best suits your needs and approach them iteratively. Each strategy will provide an overview of what might be impacting your costs, what signs to look for, and prescriptive guidance on how to reduce them.

Topics

- [Evaluate your costs at the table level](#)
- [Evaluate your table capacity mode](#)
- [Evaluate your table's auto scaling settings](#)
- [Evaluate your table class selection](#)
- [Identifying your unused resources](#)
- [Evaluate your table usage patterns](#)
- [Evaluate your Streams usage](#)
- [Evaluate your provisioned capacity for right-sized provisioning](#)

Evaluate your costs at the table level

The Cost Explorer tool found within the AWS Management Console allows you to see costs broken down by type, such as read, write, storage and backup charges. You can also see these costs summarized by period such as month or day.

One challenge administrators can face is when the costs of only one particular table need to be reviewed. Some of this data is available via the DynamoDB console or via calls to the `DescribeTable` API, however Cost Explorer does not, by default, allow you to filter or group by costs associated with a specific table. This section will show you how to use tagging to perform individual table cost analysis in Cost Explorer.

Topics

- [How to view the costs of a single DynamoDB table](#)
- [Cost Explorer's default view](#)
- [How to use and apply table tags in Cost Explorer](#)

How to view the costs of a single DynamoDB table

Both the Amazon DynamoDB AWS Management Console and the `DescribeTable` API will show you information about a single table, including the primary key schema, any indexes on the table, and the size and item count of the table and any indexes. The size of the table, plus the size of the indexes, can be used to calculate the monthly storage cost for your table. For example, \$0.25 per GB in the us-east-1 region.

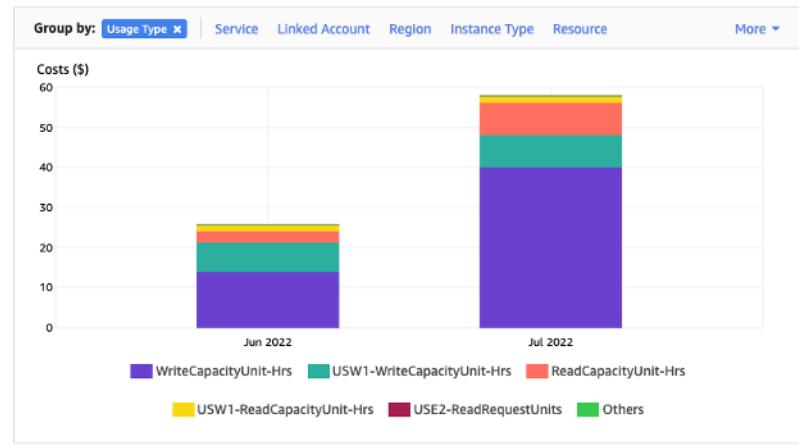

If the table is in provisioned capacity mode, the current RCU and WCU settings are returned as well. These could be used to calculate the current read and write costs for the table, but these costs could change, especially if the table has been configured with Auto Scaling.

Note

If the table is in on-demand capacity mode, then `DescribeTable` will not help estimate throughput costs, as these are billed based on actual, not provisioned usage in any one period.

Cost Explorer's default view

Cost Explorer's default view provides charts showing the cost of consumed resources such as throughput and storage. You can choose to group costs by period, such as totals by month or by day. The costs of storage, reads, writes, and other features can be broken out and compared as well.

How to use and apply table tags in Cost Explorer

By default, Cost Explorer does not provide a summary of the costs for any one specific table, as it will combine the costs of multiple tables into a total. However, you can use [AWS resource tagging](#) to identify each table by a metadata tag. Tags are key-value pairs you can use for a variety of purposes, such as to identify all resources belonging to a project or department. For this example, we'll assume you have a table named **MyTable**.

1. Set a tag with the key of **table_name** and the value of **MyTable**.
2. [Activate the tag within Cost Explorer](#) and then filter on the tag value to gain more visibility into each table's costs.

Note

It may take one or two days for the tag to start appearing in Cost Explorer

You can set metadata tags yourself in the console, or via automation such as the AWS CLI or AWS SDK. Consider requiring a **table_name** tag to be set as part of your organization's new table creation process. For existing tables, there is a Python utility available that will find and apply these tags to all existing tables in a certain region in your account. See [Eponymous Table Tagger on GitHub](#) for more details.

Evaluate your table capacity mode

This section provides an overview of how to select the appropriate capacity mode for your DynamoDB table. Each mode is tuned to meet the needs of a different workload in terms of

responsiveness to change in throughput, as well as how that usage is billed. You must balance these factors when making our decision.

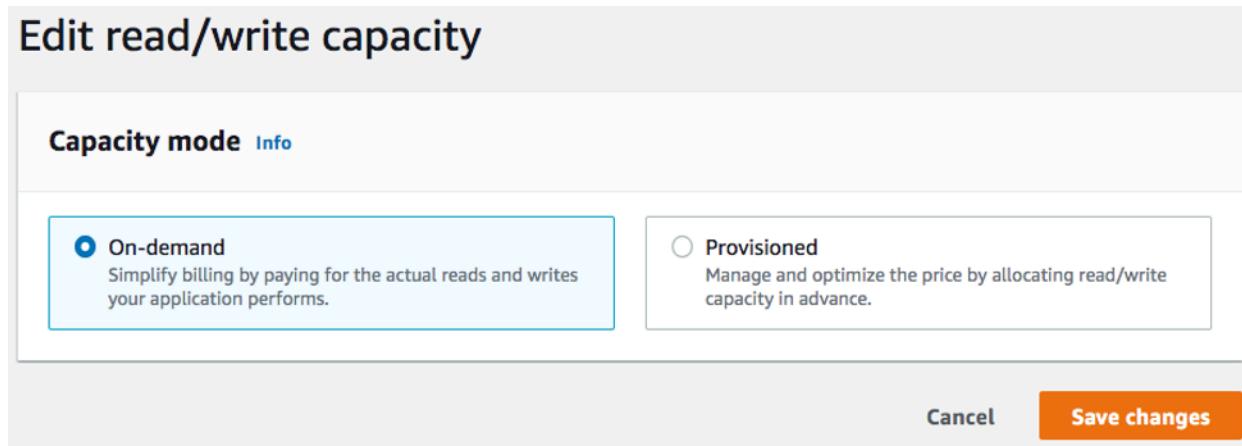

Topics

- [What table capacity modes are available](#)
- [When to select on-demand capacity mode](#)
- [When to select provisioned capacity mode](#)
- [Additional factors to consider when choosing a table capacity mode](#)

What table capacity modes are available

When you create a DynamoDB table, you must select either on-demand or provisioned capacity mode. You can switch between read/write capacity modes once every 24 hours. The only exception to this is if you switch a provisioned mode table to on-demand mode: you can switch back to provisioned mode in the same 24-hour period.

Edit read/write capacity

On-demand capacity mode

The on-demand capacity mode is designed to eliminate the need to plan or provision the capacity of your DynamoDB table. In this mode, your table will instantly accommodate requests to your table without the need to scale any resources up or down (up to twice the previous peak throughput of the table).

On-demand tables are billed by counting the number of actual requests against the table, so you will only pay for what you use rather than what has been provisioned.

Provisioned capacity mode

The provisioned capacity mode is a more traditional model where you can define how much capacity the table has available for requests either directly or with the assistance of auto scaling. Because a specific capacity is provisioned for the table at any given time, billing is based off of the capacity provisioned rather than the number of requests. Going over the allocated capacity can also cause the table to reject requests and reduce the experience of your applications users.

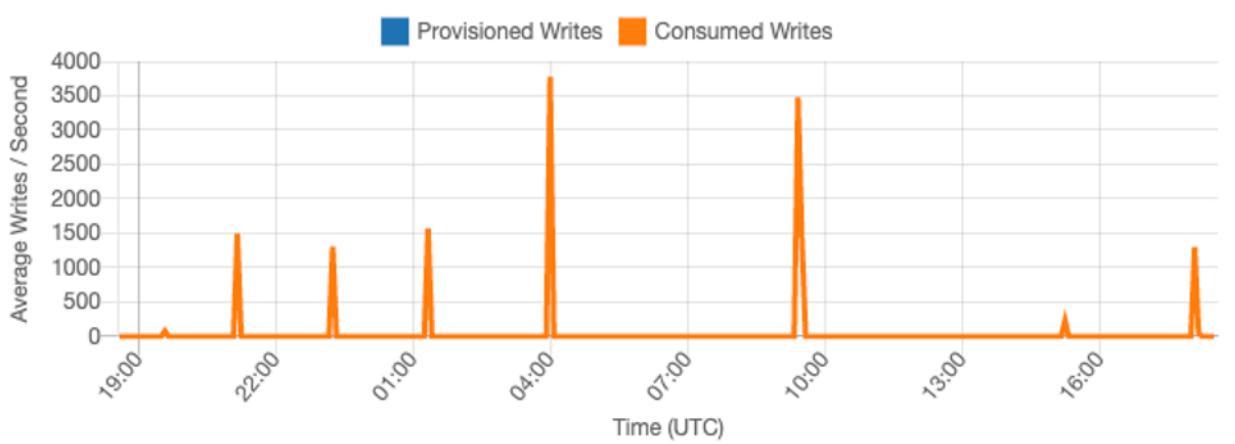

Provisioned capacity mode requires a balance between not overprovisioning or under provisioning the table to keep both throttling low and costs tuned.

When to select on-demand capacity mode

When optimizing for cost, on-demand mode is your best choice when you have a workload similar to the following graph.

The following factors contribute to this type of workload:

- Unpredictable request timing (resulting in traffic spikes)
- Variable volume of requests (resulting from batch workloads)
- Drops to zero or below 18% of the peak for a given hour (resulting from dev or test environments)

For workloads with the above factors, using auto scaling to maintain enough capacity on the table to respond to spikes in traffic will likely lead to the table being overprovisioned and costing more than necessary or the table being under provisioned and requests being unnecessarily throttled.

Because on-demand tables are billed by request, there is nothing further we need to do at the table level to optimize for cost. You should regularly evaluate your on-demand tables to verify

the workload still has the above factors. If the workload has stabilized, consider changing to provisioned mode to further optimize cost.

When to select provisioned capacity mode

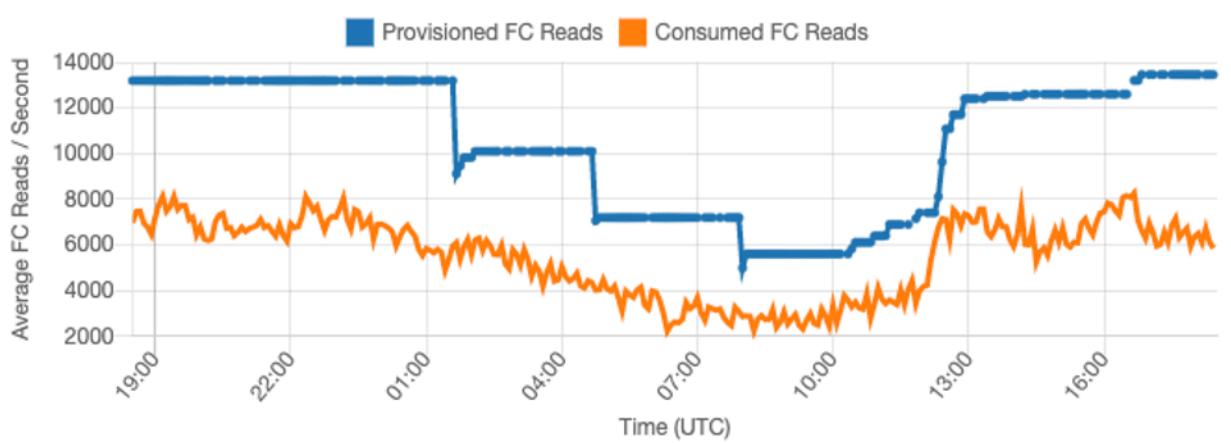

An ideal workload for provisioned capacity mode is one with a more predictable usage pattern like the graph below.

Note

We recommend reviewing metrics at a fine-grained period, such as 14 days or 24 hours, before taking action on your provisioned capacity.

The following factors contribute to this type of workload:

- Predictable/cyclical traffic for a given hour or day
- Limited short term bursts of traffic

Since the traffic volumes within a given hour or day are more stable, we can set the provisioned capacity of the table relatively close to the actual consumed capacity of the table. Cost optimizing a provisioned capacity table is ultimately an exercise in getting the provisioned capacity (blue line) as close to the consumed capacity (orange line) as possible without increasing ThrottledRequests on the table. The space between the two lines is both wasted capacity as well as insurance against a bad user experience due to throttling.

DynamoDB provides auto scaling for provisioned capacity tables which will automatically balance this on your behalf. This lets you track your consumed capacity throughout the day and set the capacity of the table based on a handful of variables.

The screenshot shows the 'Table capacity' configuration section. It includes two options: 'On-demand' (disabled) and 'Provisioned' (selected). The 'Provisioned' option is described as managing and optimizing price by allocating read/write capacity in advance. Below this, the 'Read capacity' section is shown. It includes an 'Auto scaling' setting (set to 'On') with an 'Info' link, a note about dynamically adjusting provisioned throughput, and three input fields: 'Minimum capacity units' (100), 'Maximum capacity units' (500), and 'Target utilization (%)' (70). There is also an 'Initial provisioned units' field with an 'Info' link containing the value 200.

Minimum capacity units

You can set the minimum capacity of a table to limit throttling, but it will not reduce the cost of the table. If your table has periods of low usage followed by a sudden burst of high usage, setting the minimum can prevent auto scaling from setting the table capacity too low.

Maximum capacity units

You can set the maximum capacity of a table to limit a table scaling higher than intended. Consider applying a maximum for Dev or Test tables where large-scale load testing is not desired. You can set a maximum for any table, but be sure to regularly evaluate this setting against the table baseline when using it in Production to prevent accidental throttling.

Target utilization

Setting the target utilization of the table is the primary means of cost optimization for a provisioned capacity table. Setting a lower percent value here will increase how much the table is

overprovisioned, increasing cost, but reducing the risk of throttling. Setting a higher percent value will decrease how much the table is overprovisioned, but increase the risk of throttling.

Additional factors to consider when choosing a table capacity mode

When deciding between the two modes, there are some additional factors worth considering.

Reserved capacity

For provisioned capacity tables, DynamoDB offers the ability to purchase reserved capacity for your read and write capacity (replicated write capacity units (rWCUs) and Standard-IA tables are currently not eligible). If you chose to purchase reservations for this capacity, you can reduce the cost of the table by a significant percent.

When deciding between the two table modes, consider how much this additional discount will affect the cost of the table. In many cases, even a relatively unpredictable workload can be cheaper to run on an overprovisioned provisioned capacity table with reserved capacity.

Improving predictability of your workload

In some situations, a workload may seemingly have both a predictable and unpredictable pattern. While this can be easily supported with an on-demand table, costs will likely be better if the unpredictable patterns in the workload can be improved.

One of the most common causes of these patterns is batch imports. This type of traffic can often exceed the baseline capacity of the table to such a degree that throttling would occur if it were to run. To keep a workload like this running on a provisioned capacity table, consider the following options:

- If the batch occurs at scheduled times, you can schedule an increase to your auto-scaling capacity before it runs
- If the batch occurs randomly, consider trying to extend the time it runs rather than executing as fast as possible
- Add a ramp up period to the import where the velocity of the import starts small but is slowly increased over a few minutes until auto scaling has had the opportunity to start adjusting table capacity

Evaluate your table's auto scaling settings

This section provides an overview of how to evaluate the auto scaling settings on your DynamoDB tables. [Amazon DynamoDB auto scaling](#) is a feature that manages table and global secondary index (GSI) throughput based on your application traffic and your target utilization metric. This ensures your tables or GSIs will have the required capacity required for your application patterns.

The AWS auto scaling service will monitor your current table utilization and compare it to the target utilization value: `TargetValue`. It will notify you if it is time to increase or decrease the capacity allocated.

Topics

- [Understanding your auto scaling settings](#)
- [How to identify tables with low target utilization \(<=50%\)](#)
- [How to address workloads with seasonal variance](#)
- [How to address spiky workloads with unknown patterns](#)
- [How to address workloads with linked applications](#)

Understanding your auto scaling settings

Defining the correct value for the target utilization, initial step, and final values is an activity that requires involvement from your operations team. This allows you to properly define the values based on historical application usage, which will be used to trigger the AWS auto scaling policies. The utilization target is the percentage of your total capacity that needs to be hit during a period of time before the auto scaling rules apply.

When you set a **high utilization target (a target around 90%)** it means your traffic needs to be higher than 90% for a period of time before the auto scaling kicks in. You should not use a high utilization target unless your application is very constant and doesn't receive spikes in traffic.

When you set a very **low utilization (a target less than 50%)** it means your application would need to reach 50% of the provisioned capacity before it triggers an auto scaling policy. Unless your application traffic grows at a very aggressive rate, this usually translates into unused capacity and wasted resources.

How to identify tables with low target utilization (<=50%)

You can use either the AWS CLI or AWS Management Console to monitor and identify the `TargetValues` for your auto scaling policies in your DynamoDB resources:

AWS CLI

1. Return the entire list of resources by running the following command:

```
aws application-autoscaling describe-scaling-policies --service-namespace dynamodb
```

This command will return the entire list of auto scaling policies that are issued to any DynamoDB resource. If you only want to retrieve the resources from a particular table, you can add the `--resource-id` parameter. For example:

```
aws application-autoscaling describe-scaling-policies --service-namespace dynamodb --resource-id "table/<table-name>"
```

2. Return only the auto scaling policies for a particular GSI by running the following command

```
aws application-autoscaling describe-scaling-policies --service-namespace dynamodb --resource-id "table/<table-name>/index/<gsi-name>"
```

The values we're interested in for the auto scaling policies are highlighted below. We want to ensure that the target value is greater than 50% to avoid over-provisioning. You should obtain a result similar to the following:

```
{
    "ScalingPolicies": [
        {
            "PolicyARN": "arn:aws:autoscaling:<region>:<account-id>:scalingPolicy:<uuid>:resource/dynamodb/table/<table-name>/index/<index-name>:policyName/$<full-gsi-name>-scaling-policy",
            "PolicyName": "$<full-gsi-name>",
            "ServiceNamespace": "dynamodb",
            "ResourceId": "table/<table-name>/index/<index-name>",
            "ScalableDimension": "dynamodb:index:WriteCapacityUnits",
            "PolicyType": "TargetTrackingScaling",
            "TargetTrackingScalingPolicyConfiguration": {
                "TargetValue": 70.0,
                "PredefinedMetricSpecification": {
                    "PredefinedMetricType": "DynamoDBWriteCapacityUtilization"
                }
            },
            "Alarms": [

```

```
    ...
],
"CreationTime": "2022-03-04T16:23:48.641000+10:00"
},
{
    "PolicyARN": "arn:aws:autoscaling:<region>:<account-id>:scalingPolicy:<uuid>:resource/dynamodb/table/<table-name>/index/<index-name>:policyName/$<full-gsi-name>-scaling-policy",
    "PolicyName": "$<full-gsi-name>",
    "ServiceNamespace": "dynamodb",
    "ResourceId": "table/<table-name>/index/<index-name>",
    "ScalableDimension": "dynamodb:index:ReadCapacityUnits",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 70.0,
        "PredefinedMetricSpecification": {
            "PredefinedMetricType": "DynamoDBReadCapacityUtilization"
        }
    },
    "Alarms": [
        ...
    ],
    "CreationTime": "2022-03-04T16:23:47.820000+10:00"
}
]
}
```

AWS Management Console

1. Log into the AWS Management Console and navigate to the CloudWatch service page at [Getting Started with the AWS Management Console](#). Select the appropriate AWS region if necessary.
2. On the left navigation bar, select **Tables**. On the **Tables** page, select the table's **Name**.
3. On the **Table Details** page under the **Additional Settings** tab, review your table's auto scaling settings.

Overview	Indexes	Monitor	Global tables	Backups	Exports and streams	Additional settings
Read/write capacity						
The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity.						
Capacity mode	Provisioned					
Table capacity						
Read capacity auto scaling	On	Write capacity auto scaling	On			
Provisioned read capacity units	5	Provisioned write capacity units	5			
Provisioned range for reads	1 - 10	Provisioned range for writes	1 - 10			
Target read capacity utilization	70%	Target write capacity utilization	70%			
▶ Index capacity						

For indexes, expand the **Index Capacity** tab to review the index's auto scaling settings.

Read/write capacity	The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity.	
Capacity mode	Provisioned	
Table capacity		
Read capacity auto scaling	On	Write capacity auto scaling
Provisioned read capacity units	5	On
Provisioned range for reads	1 - 10	Provisioned write capacity units
Target read capacity utilization	70%	5
▼ Index capacity		
Index name	Read capacity	Write capacity
GSI1PK-GSI1SK-index	Range: 1 - 10 Auto scaling at 70% Current provisioned units: 5	Range: 1 - 10 Auto scaling at 70% Current provisioned units: 5

If your target utilization values are less than or equal to 50%, you should explore your table utilization metrics to see if they are [under-provisioned or over-provisioned](#).

How to address workloads with seasonal variance

Consider the following scenario: your application is operating under a minimum average value most of the time, but the utilization target is low so your application can react quickly to events that happen at certain hours in the day and you have enough capacity and avoid getting throttled. This scenario is common when you have an application that is very busy during normal office hours (9 AM to 5 PM) but then it works at a base level during after hours. Since some users will start to connect before 9 am, the application uses this low threshold to ramp up quickly to get to the *required* capacity during peak hours.

This scenario could look like this:

- Between 5 PM and 9 AM the ConsumedWriteCapacity units stay between 90 and 100
- Users start to connect to the application before 9 AM and the capacity units increases considerably (the maximum value you've seen is 1500 WCU)
- On average, your application usage varies between 800 to 1200 during working hours

If the previous scenario applies to you, consider using [scheduled auto scaling](#), where your table could still have an application auto scaling rule configured, but with a less aggressive target utilization that only provisions the extra capacity at the specific intervals you require.

You can use AWS CLI to execute the following steps to create a scheduled auto scaling rule that will execute based on the time of day and the day of the week.

1. Register your DynamoDB table or GSI as scalable target with Application Auto Scaling. A scalable target is a resource that Application Auto Scaling can scale out or in.

```
aws application-autoscaling register-scalable-target \
    --service-namespace dynamodb \
    --scalable-dimension dynamodb:table:WriteCapacityUnits \
    --resource-id table/<table-name> \
    --min-capacity 90 \
    --max-capacity 1500
```

2. Set up scheduled actions according to your requirements.

We'll need two rules to cover the scenario: one to scale up and another to scale down. The first rule to scale up the scheduled action:

```
aws application-autoscaling put-scheduled-action \
--service-namespace dynamodb \
--scalable-dimension dynamodb:table:WriteCapacityUnits \
--resource-id table/<table-name> \
--scheduled-action-name my-8-5-scheduled-action \
--scalable-target-action MinCapacity=800,MaxCapacity=1500 \
--schedule "cron(45 8 ? * MON-FRI *)" \
--timezone "Australia/Brisbane"
```

The second rule to scale down the scheduled action:

```
aws application-autoscaling put-scheduled-action \
--service-namespace dynamodb \
--scalable-dimension dynamodb:table:WriteCapacityUnits \
--resource-id table/<table-name> \
--scheduled-action-name my-5-8-scheduled-down-action \
--scalable-target-action MinCapacity=90,MaxCapacity=1500 \
--schedule "cron(15 17 ? * MON-FRI *)" \
--timezone "Australia/Brisbane"
```

- Run the following command to validate both rules have been activated:

```
aws application-autoscaling describe-scheduled-actions --service-namespace dynamodb
```

You should get a result like this:

```
{  
    "ScheduledActions": [  
        {  
            "ScheduledActionName": "my-5-8-scheduled-down-action",  
            "ScheduledActionARN":  
                "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/  
                table/<table-name>:scheduledActionName/my-5-8-scheduled-down-action",  
            "ServiceNamespace": "dynamodb",  
            "Schedule": "cron(15 17 ? * MON-FRI *)",  
            "Timezone": "Australia/Brisbane",  
            "ResourceId": "table/<table-name>",  
            "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
```

```

        "ScalableTargetAction": {
            "MinCapacity": 90,
            "MaxCapacity": 1500
        },
        "CreationTime": "2022-03-15T17:30:25.100000+10:00"
    },
    {
        "ScheduledActionName": "my-8-5-scheduled-action",
        "ScheduledActionARN":
            "arn:aws:autoscaling:<region>:<account>:scheduledAction:<uuid>:resource/dynamodb/
            table/<table-name>:scheduledActionName/my-8-5-scheduled-action",
        "ServiceNamespace": "dynamodb",
        "Schedule": "cron(45 8 ? * MON-FRI *)",
        "Timezone": "Australia/Brisbane",
        "ResourceId": "table/<table-name>",
        "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
        "ScalableTargetAction": {
            "MinCapacity": 800,
            "MaxCapacity": 1500
        },
        "CreationTime": "2022-03-15T17:28:57.816000+10:00"
    }
]
}

```

The following picture shows a sample workload that always keeps the 70% target utilization. Notice how the auto scaling rules are still applying and the throughput will not be reduced.

Zooming in, we can see there was a spike in the application that triggered the 70% auto scaling threshold, forcing the autoscaling to kick in and provide the extra capacity required for the table. The scheduled auto scaling action will affect maximum and minimum values, and it is your responsibility to set them up.

How to address spiky workloads with unknown patterns

In this scenario, the application uses a very low utilization target because you don't know the application patterns yet, and you want to ensure your workload is not throttled.

Consider using [on-demand capacity mode](#) instead. On-demand tables are perfect for spiky workloads where you don't know the traffic patterns. With on-demand capacity mode, you pay per request for the data reads and writes your application performs on your tables. You do not need to specify how much read and write throughput you expect your application to perform, as DynamoDB instantly accommodates your workloads as they ramp up or down.

How to address workloads with linked applications

In this scenario, the application depends on other systems, like batch processing scenarios where you can have big spikes in traffic according to events in the application logic.

Consider developing custom auto scaling logic that reacts to those events where you can increase table capacity and TargetValues depending on your specific needs. You could benefit from Amazon EventBridge and use a combination of AWS services like Lambda and Step Functions to react to your specific application needs.

Evaluate your table class selection

This section provides an overview of how to select the appropriate table class for your DynamoDB table. With the launch of the Standard Infrequent-Access (Standard-IA) table class, you now have the ability to optimize a table for either lower storage cost or lower throughput cost.

Topics

- [What table classes are available](#)
- [When to select the DynamoDB Standard table class](#)
- [When to select DynamoDB Standard-IA table class](#)
- [Additional factors to consider when choosing a table class](#)

What table classes are available

When you create a DynamoDB Table, you must select either DynamoDB Standard or DynamoDB Standard-IA for the table class. The table class can be changed twice in a 30-day period, so you can always change it in the future. Selecting either table class has no effect on table performance, availability, reliability, or durability.

Update table class

Table class

Select table class to optimize your table's cost based on your workload requirements and data access patterns.

Choose table class

DynamoDB Standard

The default general-purpose table class. Recommended for the vast majority of tables that store frequently accessed data, with throughput (reads and writes) as the dominant table cost.

DynamoDB Standard-IA

Recommended for tables that store data that is infrequently accessed, with storage as the dominant table cost.

 Table class updates is a background process. The time to update your table class depends on your table traffic, storage size, and other related variables. You can still access your table normally while it is converted. Note that no more than two table class updates on your table are allowed in a 30-day trailing period. [Learn more](#) 

[Cancel](#)

[Save changes](#)

Standard table class

The Standard table class is the default option for new tables. This option maintains the original billing balance of DynamoDB which offers a balance of throughput and storage costs for tables with frequently accessed data.

Standard-IA table class

The Standard-IA table class offers a lower storage cost (~60% lower) for workloads that require long-term storage of data with infrequent updates or reads. Since the class is optimized for infrequent access, reads and writes will be billed at a slightly higher cost (~25% higher) than the Standard table class.

When to select the DynamoDB Standard table class

DynamoDB Standard table class is best suited for tables whose storage cost is approximately 50% or less of the overall monthly cost of the table. This cost balance is indicative of a workload that regularly accesses or updates items already stored within DynamoDB.

When to select DynamoDB Standard-IA table class

DynamoDB Standard-IA table class is best suited for tables whose storage cost is approximately 50% or more of the overall monthly cost of the table. This cost balance is indicative of a workload that creates or reads fewer items per month than it keeps in storage.

A common use for the Standard-IA table class is moving less frequently accessed data to individual Standard-IA tables. For further information, see [Optimizing the storage costs of your workloads with Amazon DynamoDB Standard-IA table class](#).

Additional factors to consider when choosing a table class

When deciding between the two table classes, there are some additional factors worth considering as part of your decision.

Reserved capacity

Purchasing reserved capacity for tables using the Standard-IA table class is currently not supported. When transitioning from a Standard table with reserved capacity to a Standard-IA table without reserved capacity, you may not see a cost benefit.

Identifying your unused resources

This section provides an overview of how to evaluate your unused resources regularly. As your application requirements evolve you should ensure no resources are unused and contributing to unnecessary Amazon DynamoDB costs. The procedures described below will use Amazon CloudWatch metrics to identify unused resources and will help you identify and take action on those resources to reduce costs.

You can monitor DynamoDB using CloudWatch, which collects and processes raw data from DynamoDB into readable, near real-time metrics. These statistics are retained for a period of time, so that you can access historical information to better understand your utilization. By default, DynamoDB metric data is sent to CloudWatch automatically. For more information, see [What is Amazon CloudWatch?](#) and [Metrics retention](#) in the *Amazon CloudWatch User Guide*.

Topics

- [How to identify unused resources](#)
- [Identifying unused table resources](#)
- [Cleaning up unused table resources](#)

- [Identifying unused GSI resources](#)
- [Cleaning up unused GSI resources](#)
- [Cleaning up unused global tables](#)
- [Cleaning up unused backups or point-in-time recovery \(PITR\)](#)

How to identify unused resources

To identify unused tables or indexes, we'll look at the following CloudWatch metrics over a period of 30 days to understand if there are any active reads or writes on the table or any reads on the global secondary indexes (GSIs):

[ConsumedReadCapacityUnits](#)

The number of read capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed read capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

[ConsumedWriteCapacityUnits](#)

The number of write capacity units consumed over the specified time period, so you can track how much consumed capacity you have used. You can retrieve the total consumed write capacity for a table and all of its global secondary indexes, or for a particular global secondary index.

Identifying unused table resources

Amazon CloudWatch is a monitoring and observability service which provides the DynamoDB table metrics you'll use to identify unused resources. CloudWatch metrics can be viewed through the AWS Management Console as well as through the AWS Command Line Interface.

AWS Command Line Interface

To view your tables metrics through the AWS Command Line Interface, you can use the following commands.

1. First, evaluate your table's reads:

```
aws cloudwatch get-metric-statistics --metric-name ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
```

```
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving read traffic in the evaluated period:

```
{
    "Timestamp": "2022-08-25T19:40:00Z",
    "Sum": 36023355.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-12T19:40:00Z",
    "Sum": 38025777.5,
    "Unit": "Count"
},
```

The following result shows a table not receiving read traffic in the evaluated period:

```
{
    "Timestamp": "2022-08-01T19:50:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
{
    "Timestamp": "2022-08-20T19:50:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
```

2. Next, evaluate your table's writes:

```
aws cloudwatch get-metric-statistics --metric-name ConsumedWriteCapacityUnits --start-time <start-time> --end-time <end-time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as **30 days**, and an appropriate period, such as **86400**.

In the returned data, any **Sum** above **0** indicates that the table you are evaluating received read traffic during that period.

The following result shows a table receiving write traffic in the evaluated period:

```
{  
    "Timestamp": "2022-08-19T20:15:00Z",  
    "Sum": 41014457.0,  
    "Unit": "Count"  
,  
{  
    "Timestamp": "2022-08-18T20:15:00Z",  
    "Sum": 40048531.0,  
    "Unit": "Count"  
,
```

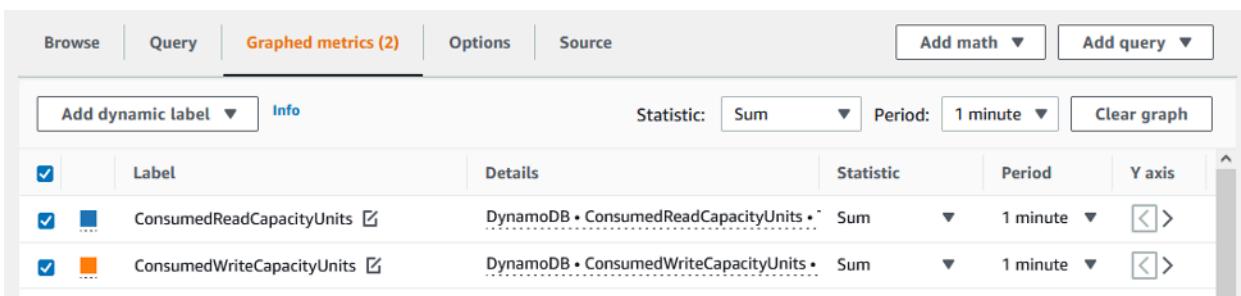

The following result shows a table not receiving write traffic in the evaluated period:

```
{  
    "Timestamp": "2022-07-31T20:15:00Z",  
    "Sum": 0.0,  
    "Unit": "Count"  
,  
{  
    "Timestamp": "2022-08-19T20:15:00Z",  
    "Sum": 0.0,  
    "Unit": "Count"  
,
```

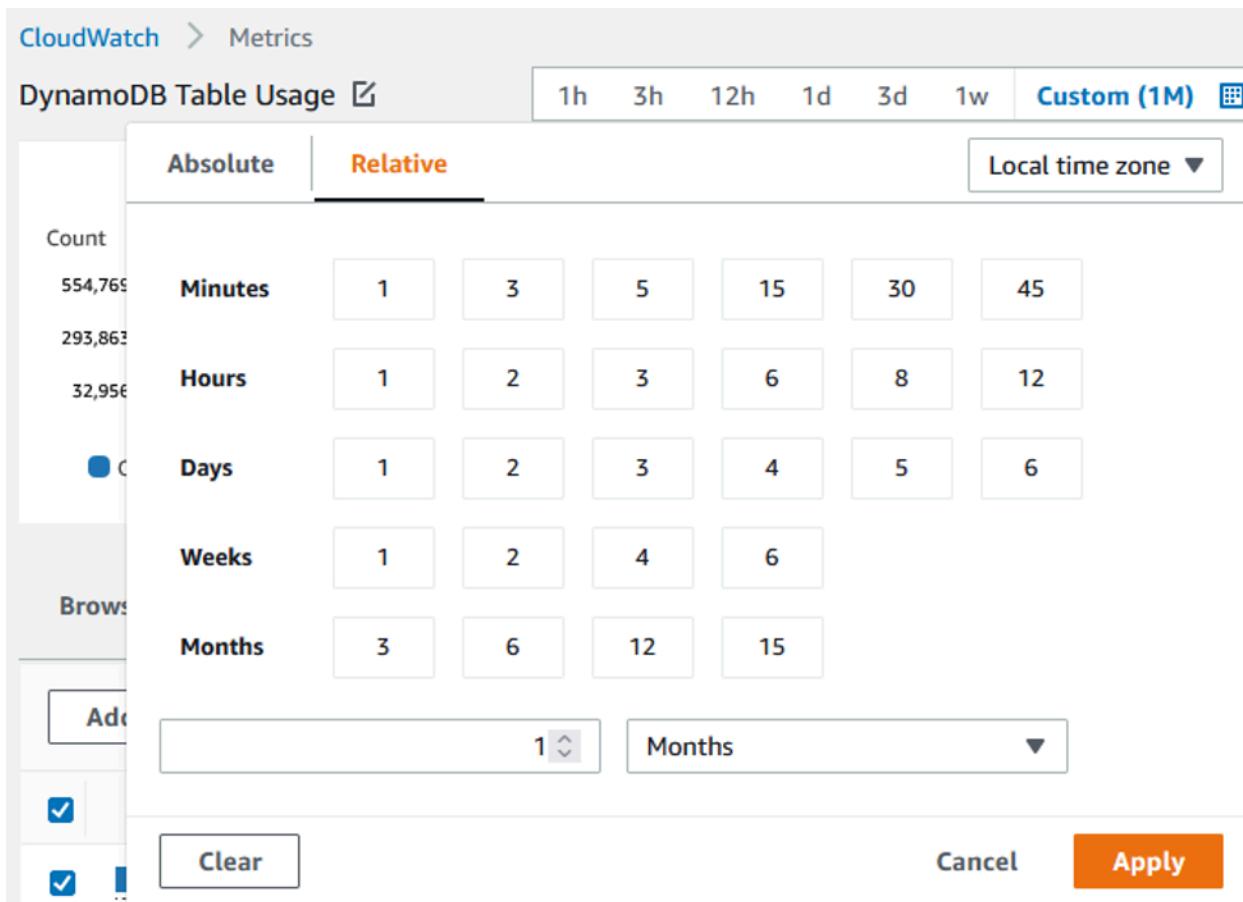

AWS Management Console

The following steps will allow you to evaluate your resources utilization through the AWS Management Console.

1. Log into the AWS console and navigate to the CloudWatch service page at <https://console.aws.amazon.com/cloudwatch/>. Select the appropriate AWS region in the top right of the console, if necessary.
2. On the left navigation bar, locate the Metrics section and select **All metrics**.
3. The action above will open a dashboard with two panels. In the top panel you will see currently graphed metrics. In the bottom you will select the metrics available to graph. Select DynamoDB in the bottom panel.
4. In the DynamoDB metrics selection panel select the **Table Metrics** category to show the metrics for your tables in the current region.
5. Identify your table name by scrolling down the menu, then select the metrics `ConsumedReadCapacityUnits` and `ConsumedWriteCapacityUnits` for your table.
6. Select the **Graphed metrics (2)** tab and adjust the **Statistic** column to **Sum**.

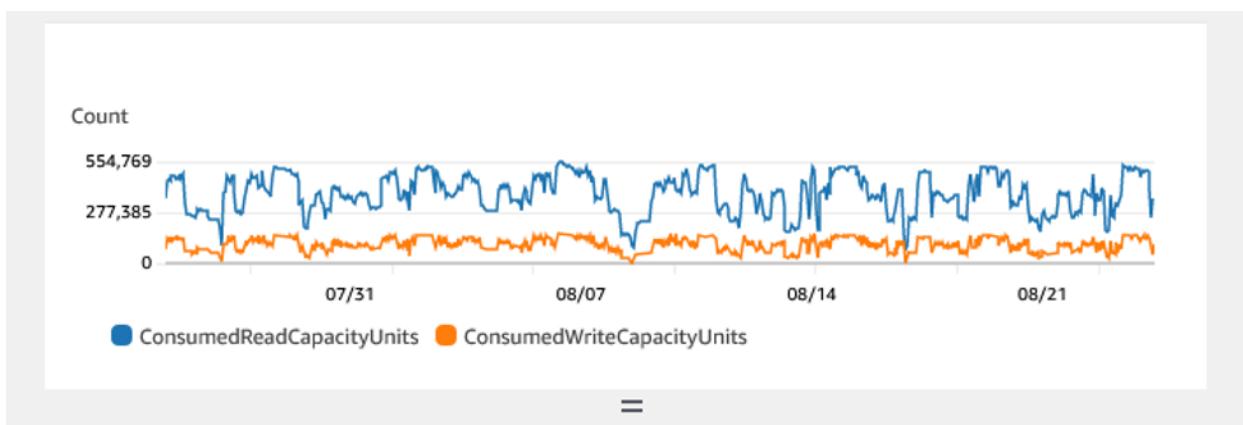

7. To avoid falsely identifying a table as unused, you'll want to evaluate metrics over a longer period. At the top of the graph panel choose an appropriate time frame, such as 1 month, to evaluate your table. Select **Custom**, select **1 Months** in the dropdowns, and choose **Apply**.

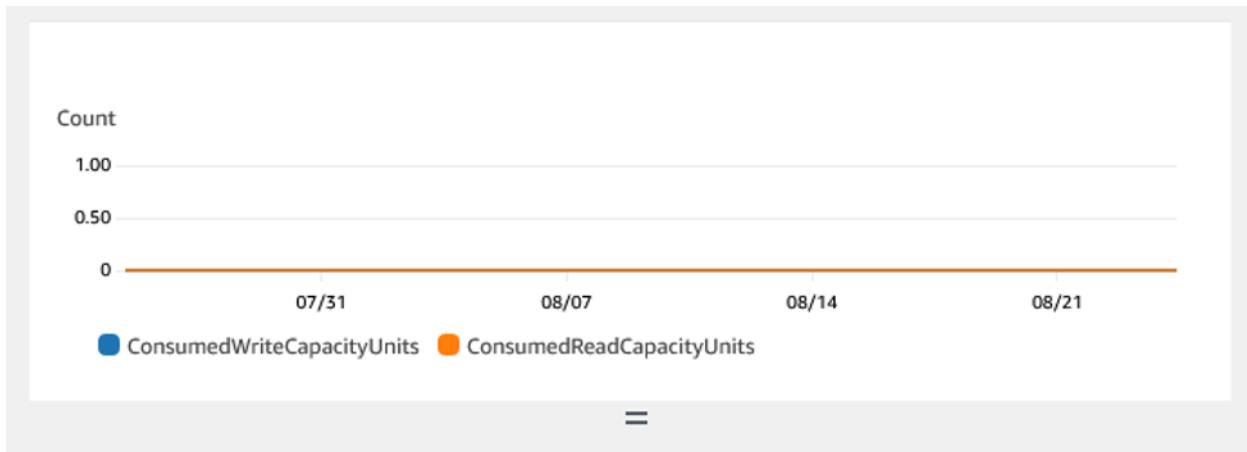

- Evaluate the graphed metrics for your table to determine if it is being used. Metrics that have gone above **0** indicate that a table has been used during the evaluated time period. A flat graph at **0** for both read and write indicates a table that is unused.

The following image shows a table with read traffic:

The following image shows a table without read traffic:

Cleaning up unused table resources

If you have identified unused table resources, you can reduce their ongoing costs in the following ways.

Note

If you have identified an unused table but would still like to keep it available in case it needs to be accessed in the future, consider switching it to on-demand mode. Otherwise, you can consider backing up and deleting the table entirely.

Capacity modes

DynamoDB charges for reading, writing, and storing data in your DynamoDB tables.

DynamoDB has [two capacity modes](#), which come with specific billing options for processing reads and writes on your tables: on-demand and provisioned. The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity.

For on-demand mode tables, you don't need to specify how much read and write throughput you expect your application to perform. DynamoDB charges you for the reads and writes that your application performs on your tables in terms of read request units and write request units. If there is no activity on your table/index you do not pay for throughput but you'll still incur a storage charge.

Table class

DynamoDB also offers [two table classes](#) designed to help you optimize for cost. The DynamoDB Standard table class is the default and is recommended for most workloads. The DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class is optimized for tables where storage is the dominant cost.

If there is no activity on your table or index, storage is likely to be the dominant cost and changing table class will offer a significant savings.

Deleting tables

If you've discovered an unused table and would like to delete it, you may wish to make a backup or export of the data first.

Backups taken through AWS Backup can leverage cold storage tiering, further reducing costs. Refer to the [Using AWS Backup with DynamoDB](#) documentation for information on how enable backups through AWS Backup as well as the [Managing backup plans](#) documentation for information on how to use lifecycle to move your backup to cold storage.

Alternatively, you may choose to export your table's data to S3. To do so, refer to the [Export to Amazon S3](#) documentation. Once your data is exported, if you wish to leverage S3 Glacier Instant Retrieval, S3 Glacier Flexile Retrieval, or S3 Glacier Deep Archive to further reduce costs, see [Managing your storage lifecycle](#).

After your table has been backed up, you may choose to delete it either through the AWS Management Console or through the AWS Command Line Interface.

Identifying unused GSI resources

The steps for identifying an unused global secondary are similar to those for identifying an unused table. Since DynamoDB replicates items written to your base table into your GSI if they contain the attribute used as the GSI's partition key, an unused GSI is still likely to have ConsumedWriteCapacityUnits above 0 if its base table is in use. As a result, you'll be evaluating only the ConsumedReadCapacityUnits metric to determine if your GSI is unused.

To view your GSI metrics through the AWS AWS CLI, you can use the following commands to evaluate your tables reads:

```
aws cloudwatch get-metric-statistics --metric-name  
ConsumedReadCapacityUnits --start-time <start-time> --end-time <end-
```

```
time> --period <period> --namespace AWS/DynamoDB --statistics Sum --
dimensions Name=TableName,Value=<table-name>
Name=GlobalSecondaryIndexName,Value=<index-name>
```

To avoid falsely identifying a table as unused, you will want to evaluate metrics over a longer period. Choose an appropriate start-time and end-time range, such as 30 days, and an appropriate period, such as 86400.

In the returned data, any Sum above 0 indicates that the table you are evaluating received read traffic during that period.

The following result shows a GSI receiving read traffic in the evaluated period:

```
{
  "Timestamp": "2022-08-17T21:20:00Z",
  "Sum": 36319167.0,
  "Unit": "Count"
},
{
  "Timestamp": "2022-08-11T21:20:00Z",
  "Sum": 1869136.0,
  "Unit": "Count"
},
```

The following result shows a GSI receiving minimal read traffic in the evaluated period:

```
{
  "Timestamp": "2022-08-28T21:20:00Z",
  "Sum": 0.0,
  "Unit": "Count"
},
{
  "Timestamp": "2022-08-15T21:20:00Z",
  "Sum": 2.0,
  "Unit": "Count"
},
```

The following result shows a GSI receiving no read traffic in the evaluated period:

```
{
  "Timestamp": "2022-08-17T21:20:00Z",
```

```
        "Sum": 0.0,
        "Unit": "Count"
    },
{
    "Timestamp": "2022-08-11T21:20:00Z",
    "Sum": 0.0,
    "Unit": "Count"
},
```

Cleaning up unused GSI resources

If you've identified an unused GSI, you can choose to delete it. Since all data present in a GSI is also present in the base table, additional backup is not necessary before deleting a GSI. If in the future the GSI is once again needed, it may be added back to the table.

If you have identified an infrequently used GSI, you should consider design changes in your application that would allow you to delete it or reduce its cost. For example, while DynamoDB scans should be used sparingly because they can consume large amounts of system resources, they may be more cost effective than a GSI if the access pattern it supports is used very infrequently.

Additionally, if a GSI is required to support an infrequent access pattern consider projecting a more limited set of attributes. While this may require subsequent queries against the base table to support your infrequent access patterns, it can potentially offer a significant reduction in storage and write costs.

Cleaning up unused global tables

Amazon DynamoDB global tables provide a fully managed solution for deploying a multi-Region, multi-active database, without having to build and maintain your own replication solution.

Global tables are ideal for providing low-latency access to data close to users and as well as a secondary region for disaster recovery.

If the global tables option is enabled for a resource in an effort to provide low-latency access to data but is not part of your disaster recovery strategy, validate that both replicas are actively serving read traffic by evaluating their CloudWatch metrics. If one replica does not serve read traffic, it may be an unused resource.

If global tables are part of your disaster recovery strategy, one replica not receiving read traffic may be expected under an active/standby pattern.

Cleaning up unused backups or point-in-time recovery (PITR)

DynamoDB offers two styles of backup. Point-in-time recovery provides continuous backups for 35 days to help you protect against accidental writes or deletes while on-demand backup allows for snapshot creation which can be saved long term. Both types of backups have costs associated with them.

Refer to the documentation for [Using On-Demand backup and restore for DynamoDB](#) and [Point-in-time recovery for DynamoDB](#) to determine if your tables have backups enabled that may no longer be needed.

Evaluate your table usage patterns

This section provides an overview of how to evaluate if you are efficiently using your DynamoDB tables. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

Topics

- [Perform fewer strongly-consistent read operations](#)
- [Perform fewer transactions for read operations](#)
- [Perform fewer scans](#)
- [Shorten attribute names](#)
- [Enable Time to Live \(TTL\)](#)
- [Replace global tables with cross-Region backups](#)

Perform fewer strongly-consistent read operations

DynamoDB allows you to configure [read consistency](#) on a per-request basis. Read requests are eventually consistent by default. Eventually consistent reads are charged at 0.5 RCU for upto 4 KB of data.

Most parts of distributed workloads are flexible and can tolerate eventual consistency. However, there can be access patterns requiring strongly consistent reads. Strongly consistent reads are charged at 1 RCU for upto 4 KB of data, essentially doubling your read costs. DynamoDB provides you with the flexibility to use both consistency models on the same table.

You can evaluate your workload and application code to confirm if strongly consistent reads are used only where required.

Perform fewer transactions for read operations

DynamoDB allows you to group certain actions in an all-or-nothing manner, which means you have the ability to execute ACID transactions with DynamoDB. However, as is the case with relational databases, it is not necessary to follow this approach for every action.

A [transactional read operation](#) of up to 4 KB consumes 2 RCUs as opposed to the default 0.5 RCUs for reading the same amount of data in an eventually consistent manner. The costs are doubled in write operations which means, a transactional write of up to 1 KB equates to 2 WCUs.

To determine if all operations on your tables are transactions, CloudWatch metrics for the table can be filtered down to the transaction APIs. If transaction APIs are the only graphs available under the `SuccessfulRequestLatency` metrics for the table, this would confirm that every operation is a transaction for this table. Alternatively, if the overall capacity utilization trend matches the transaction API trend, consider revisiting the application design as it seems dominated by transactional APIs.

Perform fewer scans

The extensive use of Scan operations generally stems from the need to run analytical queries on the DynamoDB data. Running frequent Scan operations on large table can be inefficient and expensive.

A better alternative is to use the [Export to S3](#) feature and choosing a point in time to export the table state to S3. AWS offers services like Athena which can then be used to run analytical queries on the data without consuming any capacity from the table.

The frequency for Scan operations can be determined using the `SampleCount` statistic under the `SuccessfulRequestLatency` metric for Scan. If Scan operations are indeed very frequent, the access patterns and data model should be re-evaluated.

Shorten attribute names

The total size of an item in DynamoDB is the sum of its attribute name lengths and values. Having long attribute names not only contributes towards storage costs, but it might also lead to higher RCU/WCU consumption. We recommend that you choose shorter attribute names rather than long ones. Having shorter attribute names can help limit the item size within the next 4KB/1KB boundary after which you would consume additional RCU/WCU to access data.

Enable Time to Live (TTL)

[Time to Live \(TTL\)](#) can identify items older than the expiry time that you have set on an item and remove them from the table. If your data grows over time and older data becomes irrelevant, enabling TTL on the table can help trim your data down and save on storage costs.

Another useful aspect of TTL is that the expired items occur on your DynamoDB streams, so rather than just removing the data from your data, it is possible to consume those items from the stream and archive them to a lower cost storage tier. Additionally, deleting items via TTL comes at no additional cost — it does not consume capacity, and there's no overhead of designing a clean up application.

Replace global tables with cross-Region backups

[Global tables](#) allow you to maintain multiple active replica tables in different Regions — they can all accept write operations and replicate data across each other. It is easy to set up replicas and the synchronization is managed for you. The replicas converge to a consistent state using a last writer wins strategy.

If you are using Global tables purely as a part of failover or disaster recovery (DR) strategy, you can replace them with a cross-Region backup copy for relatively lenient recovery point objectives and recovery time objective requirements. If you do not require fast local access and the high availability of five nines, maintaining a global table replica might not be the best approach for failover.

As an alternative, consider using AWS Backup to manage DynamoDB backups. You can schedule regular backups and copy them across Regions to meet DR requirements in a more cost-effective approach compared to using Global tables.

Evaluate your Streams usage

This section provides an overview of how to evaluate your DynamoDB Streams usage. There are certain usage patterns which are not optimal for DynamoDB, and they allow room for optimization from both a performance and cost perspective.

You have two native streaming integrations for streaming and event-driven use cases:

- [Amazon DynamoDB Streams](#)
- [Amazon Kinesis Data Streams](#)

This page will just focus on cost optimization strategies for these options. If you'd like to instead find out how to choose between the two options, see [Streaming options for change data capture](#).

Topics

- [Optimizing costs for DynamoDB Streams](#)
- [Optimizing costs for Kinesis Data Streams](#)
- [Cost optimization strategies for both types of Streams usage](#)

Optimizing costs for DynamoDB Streams

As mentioned in the [pricing page](#) for DynamoDB Streams, regardless of the table's throughput capacity mode, DynamoDB charges on the number of read requests made towards the table's DynamoDB Stream. Read requests made towards a DynamoDB Stream are different from the read requests made towards a DynamoDB table.

Each read request in terms of the stream is in the form of a GetRecords API call that can return up to 1000 records or 1 MB worth of records in the response, whichever is reached first. None of the [other DynamoDB Stream APIs](#) are charged and DynamoDB Streams are not charged for being idle. In other words, if no read requests are made to a DynamoDB Stream, no charges will be incurred for having a DynamoDB Stream enabled on a table.

Here are a few consumer applications for DynamoDB Streams:

- AWS Lambda function(s)
- Amazon Kinesis Data Streams-based applications
- Customer consumer applications built using an AWS SDK

Read requests made by AWS Lambda-based consumers of DynamoDB Streams are free, whereas calls made by consumers of any other kind are charged. Every month, the first 2,500,000 read requests made by non-Lambda consumers are also free of cost. This applies to all read requests made to any DynamoDB Streams in an AWS Account for each AWS Region.

Monitoring your DynamoDB Streams usage

DynamoDB Streams charges on the billing console are grouped together for all DynamoDB Streams across the AWS Region in an AWS Account. Currently, tagging DynamoDB Streams is not supported, so cost allocation tags cannot be used to identify granular costs for DynamoDB Streams. The volume of GetRecords calls can be obtained at the DynamoDB Stream level

to compute the charges per stream. The volume is represented by the DynamoDB Stream's CloudWatch metric `SuccessfulRequestLatency` and its `SampleCount` statistic. This metric will also include `GetRecords` calls made by global tables to perform on-going replication as well as calls made by AWS Lambda consumers, both of which are not charged. For information on other CloudWatch metrics published by DynamoDB Streams, see [DynamoDB Metrics and dimensions](#).

Using AWS Lambda as the consumer

Evaluate if using AWS Lambda functions as the consumers for DynamoDB Streams is feasible because that can eliminate costs associated with reading from the DynamoDB Stream. On the other hand, DynamoDB Streams Kinesis Adapter or SDK based consumer applications will be charged on the number of `GetRecords` calls they make towards the DynamoDB Stream.

Lambda function invocations will be charged based on standard Lambda pricing, however no charges will be incurred by DynamoDB Streams. Lambda will poll shards in your DynamoDB Stream for records at a base rate of 4 times per second. When records are available, Lambda invokes your function and waits for the result. If processing succeeds, Lambda resumes polling until it receives more records.

Tuning DynamoDB Streams Kinesis Adapter-based consumer applications

Since read requests made by non-Lambda based consumers are charged for DynamoDB Streams, it is important to find a balance between the near real-time requirement and the number of times the consumer application must poll the DynamoDB Stream.

The frequency of polling DynamoDB Streams using a DynamoDB Streams Kinesis Adapter based application is determined by the configured `idleTimeBetweenReadsInMillis` value. This parameter determines the amount of time in milliseconds that the consumer should wait before processing a shard in case the previous `GetRecords` call made to the same shard did not return any records. By default, this value for this parameter is 1000 ms. If near real-time processing is not required, this parameter could be increased to have the consumer application make fewer `GetRecords` calls and optimize on DynamoDB Streams calls.

Optimizing costs for Kinesis Data Streams

When a Kinesis Data Stream is set as the destination to deliver change data capture events for a DynamoDB table, the Kinesis Data Stream may need separate sizing management which will affect the overall costs. DynamoDB charges in terms of Change Data capture Units (CDUs) where each unit is a made of up a 1 KB DynamoDB item size attempted by the DynamoDB service to the destination Kinesis Data Stream.

In addition to charges by the DynamoDB service, standard Kinesis Data Stream charges will be incurred. As mentioned in the [pricing page](#), the service pricing differs based on the capacity mode - provisioned and on-demand, which are distinct from DynamoDB table capacity modes and are user-defined. At a high level, Kinesis Data Streams charges an hourly rate based on the capacity mode, as well as on data ingested into the stream by DynamoDB service. There may be additional charges like data retrieval (for on-demand mode), extended data retention (beyond default 24 hours), and enhanced fan-out consumer retrievals depending on the user configuration for the Kinesis Data Stream.

Monitoring your Kinesis Data Streams usage

Kinesis Data Streams for DynamoDB publishes metrics from DynamoDB in addition to standard Kinesis Data Stream CloudWatch Metrics. It may be possible that a Put attempt by the DynamoDB service is throttled by the Kinesis service because of insufficient Kinesis Data Streams capacity, or by dependent components like a AWS KMS service that may be configured to encrypt the Kinesis Data Stream data at rest.

To learn more about CloudWatch metrics published by DynamoDB service for the Kinesis Data Stream, see [Monitoring change data capture with Kinesis Data Streams](#). In order to avoid additional costs of service retries due to throttles, it is important to right size the Kinesis Data Stream in case of Provisioned Mode.

Choosing the right capacity mode for Kinesis Data Streams

Kinesis Data Streams are supported in two capacity modes – provisioned mode and on-demand mode.

- If the workload involving Kinesis Data Stream has predictable application traffic, traffic that is consistent or ramps gradually, or traffic that can be forecasted accurately, then Kinesis Data Streams' **provisioned mode** is suitable and will be more cost efficient
- If the workload is new, has unpredictable application traffic, or you prefer not to manage capacity, then Kinesis Data Streams' **on-demand mode** is suitable and will be more cost efficient

A best practice to optimize costs would be to evaluate if the DynamoDB table associated with the Kinesis Data Stream has a predictable traffic pattern that can leverage provisioned mode of Kinesis Data Streams. If the workload is new, you could use on-demand mode for the Kinesis Data Streams for a few initial weeks, review the CloudWatch metrics to understand traffic patterns, and then switch the same Stream to provisioned mode based on the nature of the workload. In the case of

provisioned mode, estimation on number shards can be made by following shard management considerations for Kinesis Data Streams.

Evaluate your consumer applications using Kinesis Data Streams for DynamoDB

Since Kinesis Data Streams don't charge on the number of GetRecords calls like DynamoDB Streams, consumer applications could make as many number of calls as possible, provided the frequency is under the throttling limits for GetRecords. In terms of on-demand mode for Kinesis Data Streams, data reads are charged on a per GB basis. For provisioned mode Kinesis Data Streams, reads are not charged if the data is less than 7 days old. In the case of Lambda functions as Kinesis Data Streams consumers, Lambda polls each shard in your Kinesis Stream for records at a base rate of once per second.

Cost optimization strategies for both types of Streams usage

Event filtering for AWS Lambda consumers

Lambda event filtering allows you to discard events based on a filter criteria from being available in the Lambda function invocation batch. This optimizes Lambda costs for processing or discarding unwanted stream records within the consumer function logic. To learn more about configuring event filtering and writing your filtering criteria, see [Lambda event filtering](#).

Tuning AWS Lambda consumers

Costs could be further be optimized by tuning Lambda configuration parameters like increasing the BatchSize to process more per invocation, enabling BisectBatchOnFunctionError to prevent processing duplicates (which incurs additional costs), and setting MaximumRetryAttempts to not run into too many retries. By default, failed consumer Lambda invocations are retried infinitely until the record expires from the stream, which is around 24 hours for DynamoDB Streams and configurable from 24 hours to up to 1 year for Kinesis Data Streams. Additional Lambda configuration options available including the ones mentioned above for DynamoDB Stream consumers are in the [AWS Lambda developer guide](#).

Evaluate your provisioned capacity for right-sized provisioning

This section provides an overview of how to evaluate if you have right-sized provisioning on your DynamoDB tables. As your workload evolves, you should modify your operational procedures appropriately, especially when your DynamoDB table is configured in provisioned mode and you have the risk to over-provision or under-provision your tables.

The procedures described below require statistical information that should be captured from the DynamoDB tables that are supporting your production application. To understand your application behavior, you should define a period of time that is significant enough to capture the data seasonality from your application. For example, if your application shows weekly patterns, using a three week period should give you enough room for analysing application throughput needs.

If you don't know where to start, use at least one month's worth of data usage for the calculations below.

While evaluating capacity, DynamoDB tables can configure **Read Capacity Units (RCUs)** and **Write Capacity Units (WCUs)** independently. If your tables have any Global Secondary Indexes (GSI) configured, you will need to specify the throughput that it will consume, which will be also independent from the RCUs and WCUs from the base table.

 **Note**

Local Secondary Indexes (LSI) consume capacity from the base table.

Topics

- [How to retrieve consumption metrics on your DynamoDB tables](#)
- [How to identify under-provisioned DynamoDB tables](#)
- [How to identify over-provisioned DynamoDB tables](#)

How to retrieve consumption metrics on your DynamoDB tables

To evaluate the table and GSI capacity, monitor the following CloudWatch metrics and select the appropriate dimension to retrieve either table or GSI information:

Read Capacity Units	Write Capacity Units
ConsumedReadCapacityUnits	ConsumedWriteCapacityUnits
ProvisionedReadCapacityUnits	ProvisionedWriteCapacityUnits
ReadThrottleEvents	WriteThrottleEvents

You can do this either through the AWS CLI or the AWS Management Console.

AWS CLI

Before we retrieve the table consumption metrics, we'll need to start by capturing some historical data points using the CloudWatch API.

Start by creating two files: `write-calc.json` and `read-calc.json`. These files will represent the calculations for a table or GSI. You'll need to update some of the fields, as indicated in the table below, to match your environment.

Field Name	Definition	Example
<code><table-name></code>	The name of the table that you will be analysing	SampleTable
<code><period></code>	The period of time that you will be using to evaluate the utilization target, based in seconds	For a 1-hour period you should specify: 3600
<code><start-time></code>	The beginning of your evaluation interval, specified in ISO8601 format	2022-02-21T23:00:00
<code><end-time></code>	The end of your evaluation interval, specified in ISO8601 format	2022-02-22T06:00:00

The write calculations file will retrieve the number of WCU provisioned and consumed in the time period for the date range specified. It will also generate a utilization percentage that will be used for analysis. The full content of the `write-calc.json` file should look like this:

```
{  
  "MetricDataQueries": [  
    {  
      "Id": "provisionedWCU",  
      "MetricStat": {  
        "Metric": {
```

```
"Namespace": "AWS/DynamoDB",
"MetricName": "ProvisionedWriteCapacityUnits",
"Dimensions": [
    {
        "Name": "TableName",
        "Value": "<table-name>"
    }
],
},
"Period": <period>,
"Stat": "Average"
},
"Label": "Provisioned",
"ReturnData": false
},
{
    "Id": "consumedWCU",
    "MetricStat": {
        "Metric": {
            "Namespace": "AWS/DynamoDB",
            "MetricName": "ConsumedWriteCapacityUnits",
            "Dimensions": [
                {
                    "Name": "TableName",
                    "Value": "<table-name>"""
                }
            ],
            "Period": <period>,
            "Stat": "Sum"
        },
        "Label": "",
        "ReturnData": false
    },
    {
        "Id": "m1",
        "Expression": "consumedWCU/PERIOD(consumedWCU)",
        "Label": "Consumed WCUs",
        "ReturnData": false
    },
    {
        "Id": "utilizationPercentage",
        "Expression": "100*(m1/provisionedWCU)",
        "Label": "Utilization Percentage",
    }
]
```

```
        "ReturnData": true
    }
],
"StartTime": "<start-time>",
"EndTime": "<end-time>",
"ScanBy": "TimestampDescending",
"MaxDatapoints": 24
}
```

The read calculations file uses a similar file. This file will retrieve how many RCUs were provisioned and consumed during the time period for the date range specified. The contents of the `read-calc.json` file should look like this:

```
{
    "MetricDataQueries": [
        {
            "Id": "provisionedRCU",
            "MetricStat": {
                "Metric": {
                    "Namespace": "AWS/DynamoDB",
                    "MetricName": "ProvisionedReadCapacityUnits",
                    "Dimensions": [
                        {
                            "Name": "TableName",
                            "Value": "<table-name>"
                        }
                    ]
                },
                "Period": <period>,
                "Stat": "Average"
            },
            "Label": "Provisioned",
            "ReturnData": false
        },
        {
            "Id": "consumedRCU",
            "MetricStat": {
                "Metric": {
                    "Namespace": "AWS/DynamoDB",
                    "MetricName": "ConsumedReadCapacityUnits",
                    "Dimensions": [
                        {
                            "Name": "TableName",
                            "Value": "<table-name>"
                        }
                    ]
                },
                "Period": <period>,
                "Stat": "Average"
            },
            "Label": "Consumed",
            "ReturnData": false
        }
    ]
}
```

```
        "Value": "<table-name>"  
    }  
]  
,  
"Period": <period>,  
"Stat": "Sum"  
,  
"Label": "",  
"ReturnData": false  
,  
{  
    "Id": "m1",  
    "Expression": "consumedRCU/PERIOD(consumedRCU)",  
    "Label": "Consumed RCUs",  
    "ReturnData": false  
,  
{  
    "Id": "utilizationPercentage",  
    "Expression": "100*(m1/provisionedRCU)",  
    "Label": "Utilization Percentage",  
    "ReturnData": true  
}  
,  
"StartTime": "<start-time>",  
"EndTime": "<end-time>",  
"ScanBy": "TimestampDescending",  
"MaxDatapoints": 24  
}
```

Once you've created the files, you can start retrieving utilization data.

1. To retrieve the write utilization data, issue the following command:

```
aws cloudwatch get-metric-data --cli-input-json file://write-calc.json
```

2. To retrieve the read utilization data, issue the following command:

```
aws cloudwatch get-metric-data --cli-input-json file://read-calc.json
```

The result for both queries will be a series of data points in JSON format that will be used for analysis. Your result will depend on the number of data points you specified, the period, and your own specific workload data. It could look something like this:

```
{  
    "MetricDataResults": [  
        {  
            "Id": "utilizationPercentage",  
            "Label": "Utilization Percentage",  
            "Timestamps": [  
                "2022-02-22T05:00:00+00:00",  
                "2022-02-22T04:00:00+00:00",  
                "2022-02-22T03:00:00+00:00",  
                "2022-02-22T02:00:00+00:00",  
                "2022-02-22T01:00:00+00:00",  
                "2022-02-22T00:00:00+00:00",  
                "2022-02-21T23:00:00+00:00"  
            ],  
            "Values": [  
                91.55364583333333,  
                55.066631944444445,  
                2.6114930555555556,  
                24.9496875,  
                40.94725694444445,  
                25.61819444444444,  
                0.0  
            ],  
            "StatusCode": "Complete"  
        }  
    ],  
    "Messages": []  
}
```

Note

If you specify a short period and a long time range, you might need to modify the `MaxDatapoints` which is by default set to 24 in the script. This represents one data point per hour and 24 per day.

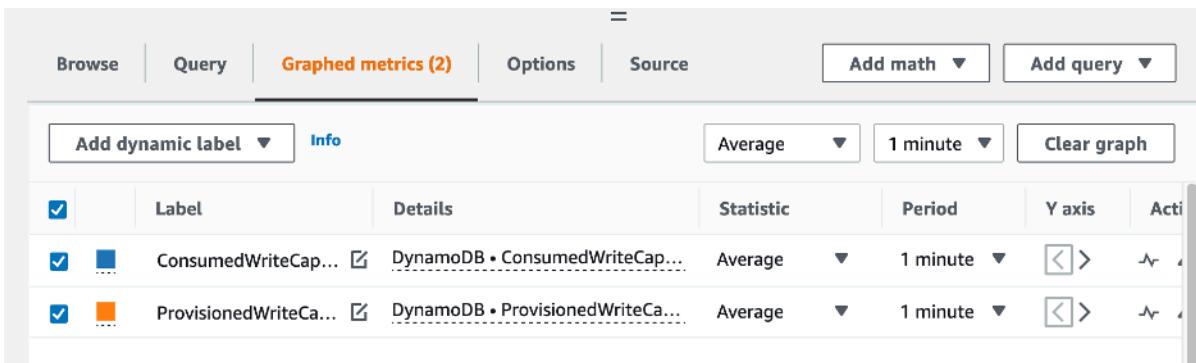

AWS Management Console

1. Log into the AWS Management Console and navigate to the CloudWatch service page at [Getting Started with the AWS Management Console](#). Select the appropriate AWS region if necessary.
2. Locate the Metrics section on the left navigation bar and select **All metrics**.
3. This will open a dashboard with two panels. The top panel will show you the graphic, and the bottom panel will have the metrics you want to graph. Select the DynamoDB panel.
4. Select the **Table Metrics** category from the sub panels. This will show you the tables in your current Region.
5. Identify your table name by scrolling down the menu and selecting the write operation metrics: ConsumedWriteCapacityUnits and ProvisionedWriteCapacityUnits

Note

This example talks about write operation metrics, but you can also use these steps to graph the read operation metrics.

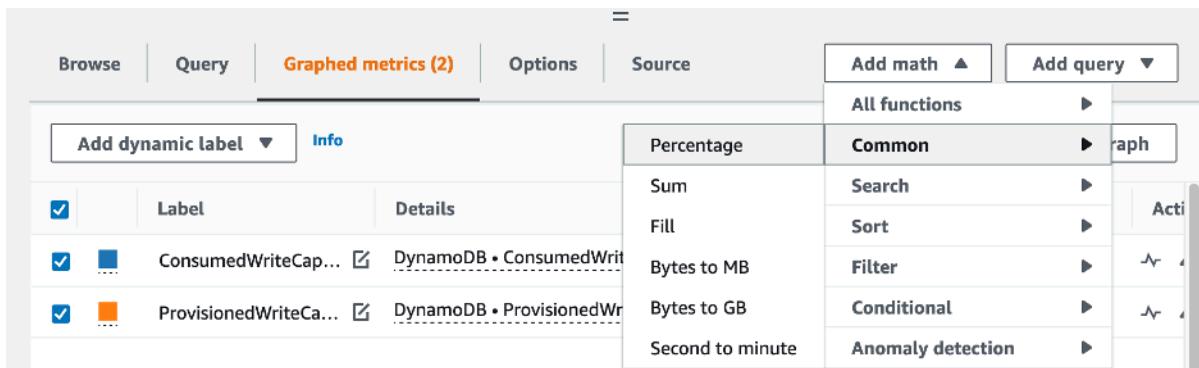

6. Select the **Graphed metrics (2)** tab to modify the formulas. By default CloudWatch will select the statistical function **Average** for the graphs.

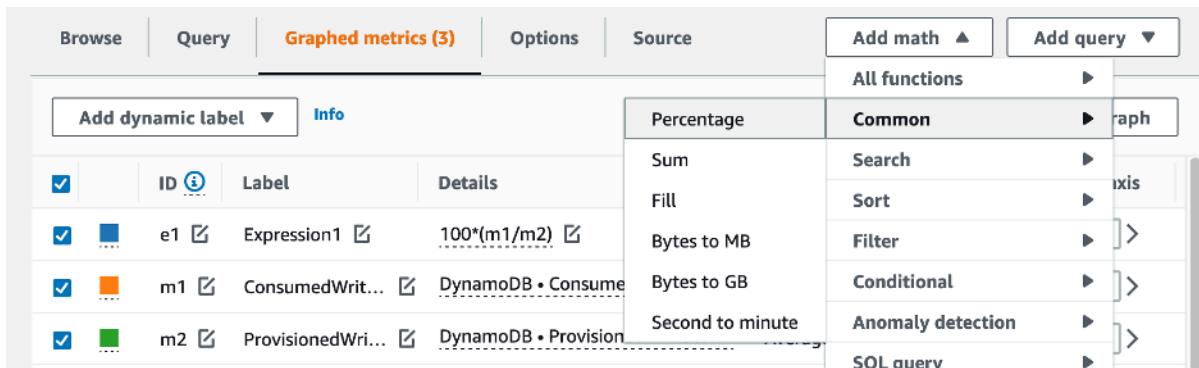

Label	Details	Statistic	Period	Y axis	Action
ConsumedWriteCap...	DynamoDB • ConsumedWriteCap...	Average	1 minute	< >	...
ProvisionedWriteCa...	DynamoDB • ProvisionedWriteCa...	Average	1 minute	< >	...

7. While having both graphed metrics selected (the checkbox on the left) select the menu **Add math**, followed by **Common**, and then select the **Percentage** function. Repeat the procedure twice.

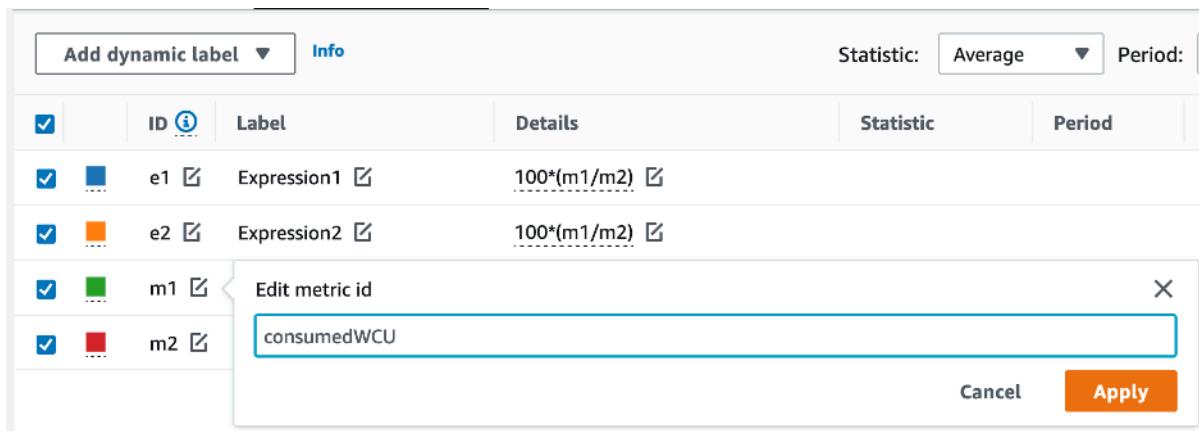

First time selecting the **Percentage** function:

Second time selecting the **Percentage** function:

- At this point you should have four metrics in the bottom menu. Let's work on the `ConsumedWriteCapacityUnits` calculation. To be consistent, we need to match the names for the ones we used in the AWS CLI section. Click on the **m1** ID and change this value to **consumedWCU**.

The screenshot shows the 'Graphed metrics' section of the CloudWatch Metrics console. A modal dialog is open over the list of metrics, titled 'Edit metric label'. Inside the dialog, the current label 'consumedWCU' is displayed in a text input field. Below the input field are two buttons: 'Cancel' and 'Apply'. At the top of the dialog, there are dropdown menus for 'Statistic' set to 'Average' and 'Period' set to '1 minute'. The main list of metrics shows four entries: 'e1' (Expression1), 'e2' (Expression2), 'consumedWCU' (ConsumedWriteCapacity), and 'm2' (ProvisionedWriteCapacity). The 'consumedWCU' entry has its details expanded, showing the metric name 'DynamoDB • ConsumedWriteCapacity' and the statistic 'Average'.

9. Change the statistic from **Average** to **Sum**. This action will automatically create another metric called **ANOMALY_DETECTION_BAND**. For the scope of this procedure, let's can ignore it by removing the checkbox on the newly generated **ad1 metric**.

This screenshot shows the same 'Graphed metrics' section after changing the statistic for 'consumedWCU' to 'Sum'. A dropdown menu for 'Statistic' is open, with 'Sum' selected. The other options in the menu are 'Average', 'Minimum', and 'Maximum'. The rest of the interface remains the same, with the list of metrics and their details visible.

This screenshot shows the 'Graphed metrics' section after completing the steps. The list now includes five metrics: 'e1' (Expression1), 'e2' (Expression2), 'consumedWCU' (ConsumedWriteCapacity, Statistic: Sum), 'ad1' (consumedWCU (e...), ANOMALY_DETECTION_BAND(...)), and 'm2' (ProvisionedWriteCapacity, Statistic: Average). The 'ad1' metric is listed with a note indicating it is a dynamic label. The 'Statistic' dropdown at the top is set to '(multiple)'. The 'Period' dropdown is set to '1 minute'.

10. Repeat step 8 to rename the **m2 ID** to **provisionedWCU**. Leave the statistic set to **Average**.

The screenshot shows the 'Graphed metrics' section of the CloudWatch Metrics console. A modal window titled 'Edit metric label' is open, allowing users to change the label for selected metrics. In the 'Label' field, the value 'provisionedWCU' is entered. The 'Apply' button is visible at the bottom of the modal.

ID	Label	Details	Statistic	Period	Y axis	Actions	
<input checked="" type="checkbox"/>	e1	Expression1	100*(consumedWCU/provision...				
<input checked="" type="checkbox"/>	e2	Expression2	100*(consumedWCU/provision...				
<input checked="" type="checkbox"/>	consumedWCU	DynamoDB + ConsumedWriteCapacity	Sum	1 minute			
<input type="checkbox"/>	ad1	consumedWCU (e...	ANOMALY_DETECTION_BAND(...				
<input checked="" type="checkbox"/>	provisionedWCU	DynamoDB + ProvisionedWriteCapacit...	Average	1 minute			

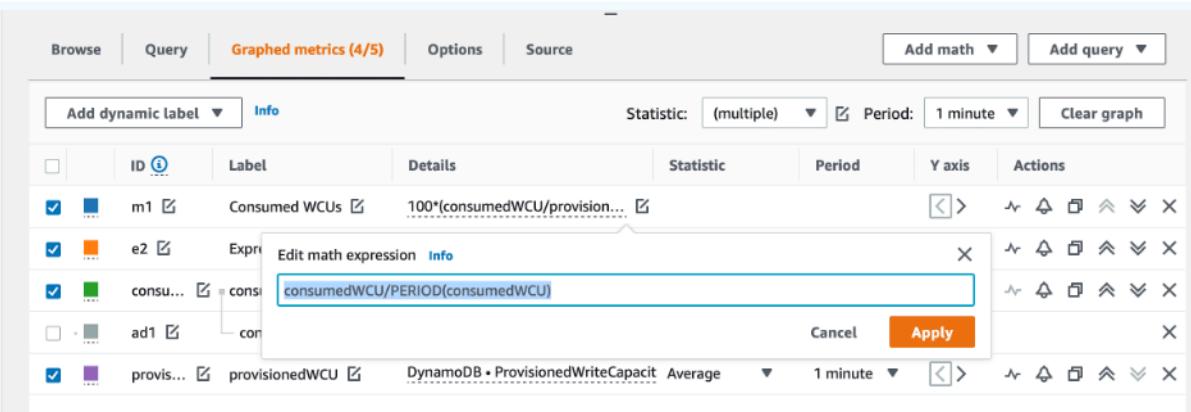

11. Select the **Expression1** label and update the value to **m1** and the label to **Consumed WCUs**.

The screenshot shows the 'Graphed metrics' section of the CloudWatch Metrics console. A modal window titled 'Edit metric label' is open, allowing users to change the label for selected metrics. In the 'Label' field, the value 'Consumed WCUs' is entered. The 'Apply' button is visible at the bottom of the modal. A tooltip 'Expression1' is shown near the 'Expression1' label in the list.

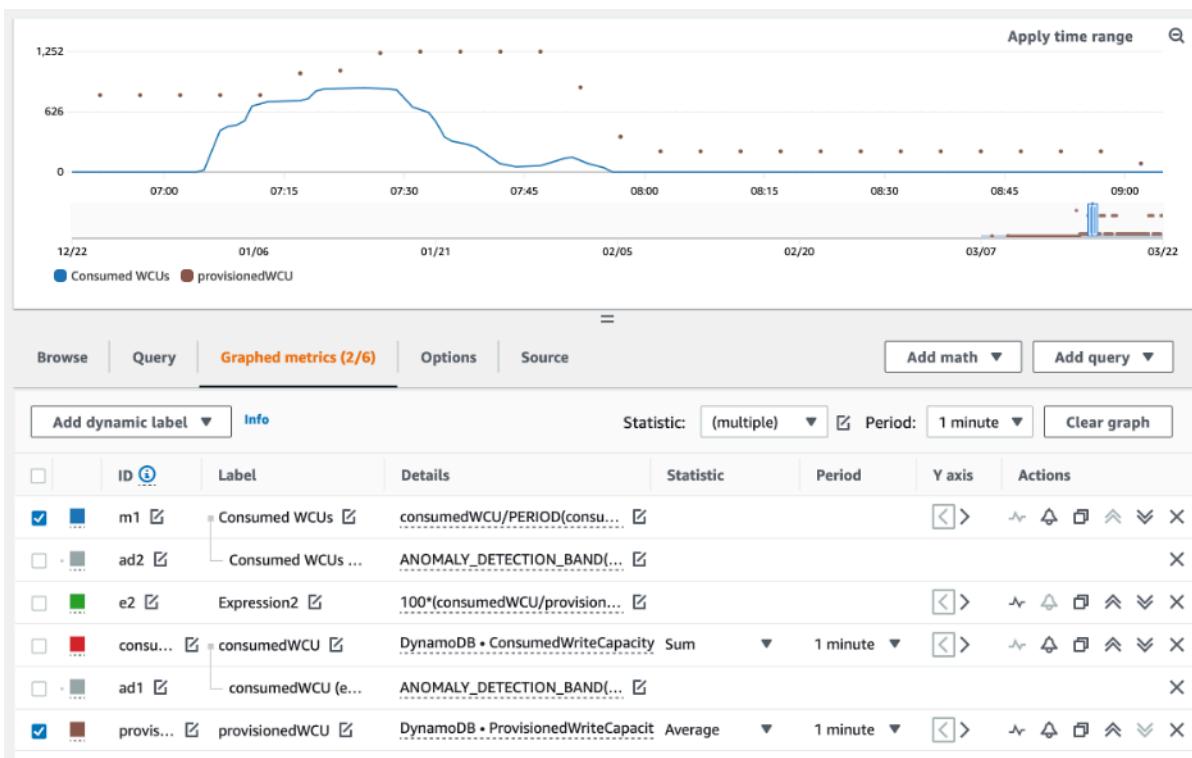

ID	Label	Details	Statistic	Period	Y axis	Actions
<input checked="" type="checkbox"/>	m1	Expression1	Consumed WCUs			
<input checked="" type="checkbox"/>	e2	Expression2				
<input checked="" type="checkbox"/>	consumedWCU	DynamoDB + ConsumedWriteCapacity	Sum	1 minute		
<input type="checkbox"/>	ad1	consumedWCU (e...	ANOMALY_DETECTION_BAND(...			
<input checked="" type="checkbox"/>	provisionedWCU	DynamoDB + ProvisionedWriteCapacit...	Average	1 minute		

Note

Make sure you have only selected **m1** (checkbox on the left) and **provisionedWCU** to properly visualize the data. Update the formula by clicking in **Details** and changing the formula to **consumedWCU/PERIOD(consumedWCU)**. This step might also generate another **ANOMALY_DETECTION_BAND** metric, but for the scope of this procedure we can ignore it.

12. You should have now have two graphics: one that indicates your provisioned WCUs on the table and another that indicates the consumed WCUs. The shape of the graphic might be different from the one below, but you can use it as reference:

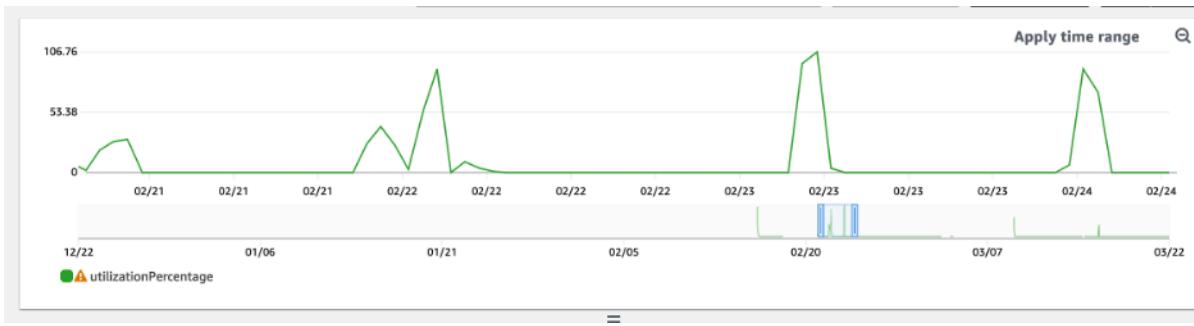

13. Update the percentage formula by selecting the Expression2 graphic (e2). Rename the labels and IDs to **utilizationPercentage**. Rename the formula to match **100*(m1/provisionedWCUs)**.

The screenshot shows the AWS CloudWatch Metrics console interface. At the top, there are tabs for 'Browse', 'Query', and 'Graphed metrics (2/6)', with 'Graphed metrics (2/6)' being the active tab. Below the tabs are buttons for 'Add math' and 'Add query'. The main area displays a table of metrics. One row for 'utilizationPercentage' is selected, and a modal dialog titled 'Edit metric label' is open over it, containing the text 'utilizationPercentage'. The bottom part of the interface shows the 'Edit math expression' dialog with the expression '100*(consumedWCU/provisionedWCU)' entered.

14. Remove the checkbox from all the metrics but **utilizationPercentage** to visualize your utilization patterns. The default interval is set to 1 minute, but feel free to modify it as you need.

Here is view of a longer period of time as well as a bigger period of 1 hour. You can see there are some intervals where the utilization was higher than 100%, but this particular workload has longer intervals with zero utilization.

At this point, you might have different results from the pictures in this example. It all depends on the data from your workload. Intervals with more than 100% utilization are prone to throttling events. DynamoDB offers [burst capacity](#), but as soon as the burst capacity is done anything above 100% will be throttled.

How to identify under-provisioned DynamoDB tables

For most workloads, a table is considered under-provisioned when it constantly consumes more than 80% of their provisioned capacity.

[Burst capacity](#) is a DynamoDB feature that allow customers to temporarily consume more RCUs/WCUs than originally provisioned (more than the per-second provisioned throughput that was defined in the table). The burst capacity was created to absorb sudden increases in traffic due to special events or usage spikes. This burst capacity doesn't last forever. As soon as the unused RCUs and WCUs are depleted, you will get throttled if you try to consume more capacity than provisioned. When your application traffic is getting close to the 80% utilization rate, your risk of throttling is significantly higher.

The 80% utilization rate rule varies from the seasonality of your data and your traffic growth. Consider the following scenarios:

- If your traffic has been **stable** at ~90% utilization rate for the last 12 months, your table has just the right capacity
- If your application traffic is **growing** at a rate of 8% monthly in less than 3 months, you will arrive at 100%
- If your application traffic is **growing** at a rate of 5% in a little more than 4 months, you will still arrive at 100%

The results from the queries above provide a picture of your utilization rate. Use them as a guide to further evaluate other metrics that can help you choose to increase your table capacity as required (for example: a monthly or weekly growth rate). Work with your operations team to define what is a good percentage for your workload and your tables.

There are special scenarios where the data is skewed when we analyse it on a daily or weekly basis. For example, with seasonal applications that have spikes in usage during working hours (but then drops to almost zero outside of working hours), you could benefit by [scheduling auto scaling](#) where you specify the hours of the day (and the days of the week) to increase the provisioned capacity and when to reduce it. Instead of aiming for higher capacity so you can cover the busy hours, you can also benefit from [DynamoDB table auto scaling](#) configurations if your seasonality is less pronounced.

 **Note**

When you create a DynamoDB auto scaling configuration for your base table, remember to include another configuration for any GSI that is associated with the table.

How to identify over-provisioned DynamoDB tables

The query results obtained from the scripts above provide the data points required to perform some initial analysis. If your data set presents values lower than 20% utilization for several intervals, your table might be over-provisioned. To further define if you need to reduce the number of WCUs and RCUS, you should revisit the other readings in the intervals.

When your tables contain several low usage intervals, you can really benefit from using auto scaling policies, either by scheduling auto scaling or just configuring the default auto scaling policies for the table that are based on utilization.

If you have a workload with low utilization to high throttle ratio (**Max(ThrottleEvents)**/**Min(ThrottleEvents)** in the interval), this could happen when you have a very spiky workload where traffic increases a lot during some days (or hours), but in general the traffic is consistently low. In these scenarios it might be beneficial to use [scheduled auto scaling](#).

The AWS [Well-Architected Framework](#) helps cloud architects build secure, high-performing, resilient, and efficient infrastructure for a variety of applications and workloads. Built around six pillars—operational excellence, security, reliability, performance efficiency, cost optimization, and

sustainability—AWS Well-Architected provides a consistent approach for customers and partners to evaluate architectures and implement scalable designs.

The AWS [Well-Architected Lenses](#) extend the guidance offered by AWS Well-Architected to specific industry and technology domains. The Amazon DynamoDB Well-Architected Lens focuses on DynamoDB workloads. It provides best practices, design principles and questions to assess and review a DynamoDB workload. Completing an Amazon DynamoDB Well-Architected Lens review will provide you with education and guidance around recommended design principles as it relates to each of the AWS Well-Architected pillars. This guidance is based on our experience working with customers across various industries, segments, sizes and geographies.

As a direct outcome of the Well-Architected Lens review, you will receive a summary of actionable recommendations to optimize and improve your DynamoDB workload.

Conducting the Amazon DynamoDB Well-Architected Lens review

The DynamoDB Well-Architected Lens review is usually performed by an AWS Solutions Architect together with the customer, but can also be performed by the customer as a self-service. While we recommend reviewing all six of the Well-Architected Pillars as part of the Amazon DynamoDB Well-Architected Lens, you can also decide to prioritize your focus on one or more pillars first.

Additional information and instructions for conducting an Amazon DynamoDB Well-Architected Lens review are available in [this video](#) and the [DynamoDB Well-Architected Lens GitHub page](#).

The pillars of the Amazon DynamoDB Well-Architected Lens

The Amazon DynamoDB Well-Architected Lens is built around six pillars:

Performance efficiency pillar

The performance efficiency pillar includes the ability to use computing resources efficiently to meet system requirements, and to maintain that efficiency as demand changes and technologies evolve.

The primary DynamoDB design principles for this pillar revolve around [modeling the data](#), [choosing partition keys](#) and [sort keys](#), and [defining secondary indexes](#) based on the application access patterns. Additional considerations include choosing the optimal throughput mode for the workload, AWS SDK tuning and, when appropriate, using an optimal caching strategy. To learn more about these design principles, watch this [deep dive video](#) about the performance efficiency pillar of the DynamoDB Well-Architected Lens.

Cost optimization pillar

The cost optimization pillar focuses on avoiding unnecessary costs.

Key topics include understanding and controlling where money is being spent, selecting the most appropriate and right number of resource types, analyzing spend over time, designing your data models to optimize the cost for application-specific access patterns, and scaling to meet business needs without overspending.

The key cost optimization design principles for DynamoDB revolve around choosing the most appropriate capacity mode and table class for your tables and avoiding over-provisioning capacity by either using the on-demand capacity mode, or provisioned capacity mode with autoscaling. Additional considerations include efficient data modeling and querying to reduce the amount of consumed capacity, reserving portions of the consumed capacity at discounted price, minimizing item size, identifying and removing unused resources and using [TTL](#) to automatically delete aged-out data at no cost. To learn more about these design principles, watch this [deep dive video](#) about the cost optimization pillar of the DynamoDB Well-Architected Lens.

See [Cost optimization](#) for additional information on cost optimization best practices for DynamoDB.

Operational excellence pillar

The operational excellence pillar focuses on running and monitoring systems to deliver business value, and continually improving processes and procedures. Key topics include automating changes, responding to events, and defining standards to manage daily operations.

The main operational excellence design principles for DynamoDB include monitoring DynamoDB metrics through Amazon CloudWatch and AWS Config and automatically alert and remediate when predefined thresholds are breached, or non compliant rules are detected. Additional considerations are defining DynamoDB resources via infrastructure as a code and leveraging tags for better organization, identification and cost accounting of your DynamoDB resources. To learn more about these design principles, watch this [deep dive video](#) about the operational excellence pillar of the DynamoDB Well-Architected Lens.

Reliability pillar

The reliability pillar focuses on ensuring a workload performs its intended function correctly and consistently when it's expected to. A resilient workload quickly recovers from failures to meet

business and customer demand. Key topics include distributed system design, recovery planning, and how to handle change.

The essential reliability design principles for DynamoDB revolve around choosing the backup strategy and retention based on your RPO and RTO requirements, using DynamoDB global tables for multi-regional workloads, or cross-region disaster recovery scenarios with low RTO, implementing retry logic with exponential backoff in the application by configuring and using these capabilities in the AWS SDK, and monitoring DynamoDB metrics through Amazon CloudWatch and automatically alerting and remediating when predefined thresholds are breached. To learn more about these design principles, watch this [deep dive video](#) about the reliability pillar of the DynamoDB Well-Architected Lens.

Security pillar

The security pillar focuses on protecting information and systems. Key topics include confidentiality and integrity of data, identifying and managing who can do what with privilege management, protecting systems, and establishing controls to detect security events.

The main security design principles for DynamoDB are encrypting data in transit with HTTPS, choosing the type of keys for data at rest encryption and defining the IAM roles and policies to authenticate, authorize and provide fine grain access to DynamoDB resources. Additional considerations include auditing DynamoDB control plane and data plane operations through AWS CloudTrail. To learn more about these design principles, watch this [deep dive video](#) about the security pillar of the DynamoDB Well-Architected Lens.

See [Security](#) for additional information on security for DynamoDB.

Sustainability pillar

The sustainability pillar focuses on minimizing the environmental impacts of running cloud workloads. Key topics include a shared responsibility model for sustainability, understanding impact, and maximizing utilization to minimize required resources and reduce downstream impacts.

The main sustainability design principles for DynamoDB include identifying and removing unused DynamoDB resources, avoiding over-provisioning though the usage of on-demand capacity mode or provisioned capacity-mode with autoscaling, efficient querying to reduce the amount of capacity being consumed and reduction of the storage footprint by compressing data and by deleting aged-out data through the use of TTL. To learn more about these design principles, watch this [deep dive video](#) about the sustainability pillar of the DynamoDB Well-Architected Lens.

Best practices for designing and using partition keys effectively

The primary key that uniquely identifies each item in an Amazon DynamoDB table can be simple (a partition key only) or composite (a partition key combined with a sort key).

Generally speaking, you should design your application for uniform activity across all logical partition keys in the table and its secondary indexes. You can determine the access patterns that your application requires, and read and write units that each table and secondary index requires.

By default, every partition in the table will strive to deliver the full capacity of 3,000 RCU and 1,000 WCU. The total throughput across all partitions in the table may be constrained by the provisioned throughput in provisioned mode, or by the table level throughput limit in on-demand mode. See [Service Quotas](#) for more information.

Topics

- [Using burst capacity effectively](#)
- [Understanding DynamoDB adaptive capacity](#)
- [Designing partition keys to distribute your workload](#)
- [Using write sharding to distribute workloads evenly](#)
- [Distributing write activity efficiently during data upload](#)

Using burst capacity effectively

DynamoDB provides some flexibility for your throughput provisioning with *burst capacity*.

Whenever you're not fully using your available throughput, DynamoDB reserves a portion of that unused capacity for later *bursts* of throughput to handle usage spikes.

DynamoDB currently retains up to 5 minutes (300 seconds) of unused read and write capacity. During an occasional burst of read or write activity, these extra capacity units can be consumed quickly—even faster than the per-second provisioned throughput capacity that you've defined for your table.

DynamoDB can also consume burst capacity for background maintenance and other tasks without prior notice.

Note that these burst capacity details might change in the future.

Understanding DynamoDB adaptive capacity

Adaptive capacity is a feature that enables DynamoDB to run imbalanced workloads indefinitely. It minimizes throttling due to throughput exceptions. It also helps you reduce costs by enabling you to provision only the throughput capacity that you need.

Adaptive capacity is enabled automatically for every DynamoDB table, at no additional cost. You don't need to explicitly enable or disable it.

Topics

- [Boost throughput capacity to high-traffic partitions](#)
- [Isolate frequently accessed items](#)

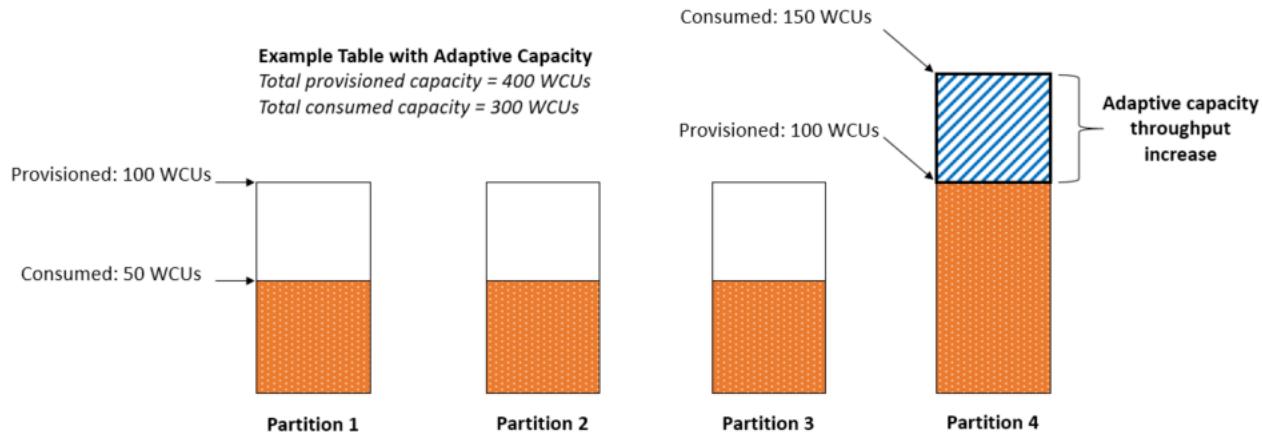

Boost throughput capacity to high-traffic partitions

It's not always possible to distribute read and write activity evenly. When data access is imbalanced, a "hot" partition can receive a higher volume of read and write traffic compared to other partitions. As read and write operations on a partition are managed independently, throttling will occur if a single partition receives more than 3000 read operation or more than 1000 write operations.

To better accommodate uneven access patterns, DynamoDB adaptive capacity enables your application to continue reading and writing to hot partitions without being throttled, provided that traffic does not exceed your table's total provisioned capacity or the partition maximum capacity. Adaptive capacity works by automatically and instantly increasing throughput capacity for partitions that receive more traffic.

The following diagram illustrates how adaptive capacity works. The example table is provisioned with 400 WCUs evenly shared across four partitions, allowing each partition to sustain up to 100 WCUs per second. Partitions 1, 2, and 3 each receives write traffic of 50 WCU/sec. Partition 4 receives 150 WCU/sec. This hot partition can accept write traffic while it still has unused burst capacity, but eventually it throttles traffic that exceeds 100 WCU/sec.

DynamoDB adaptive capacity responds by increasing partition 4's capacity so that it can sustain the higher workload of 150 WCU/sec without being throttled.

Isolate frequently accessed items

If your application drives disproportionately high traffic to one or more items, adaptive capacity rebalances your partitions such that frequently accessed items don't reside on the same partition. This isolation of frequently accessed items reduces the likelihood of request throttling due to your workload exceeding the throughput quota on a single partition. You can also break up an item collection into segments by sort key, as long as the item collection isn't traffic that is tracked by a monotonic increase or decrease of the sort key.

If your application drives consistently high traffic to a single item, adaptive capacity might rebalance your data so that a partition contains only that single, frequently accessed item. In this case, DynamoDB can deliver throughput up to the partition maximum of 3,000 RCU and 1,000 WCUs to that single item's primary key. Adaptive capacity will not split item collections across multiple partitions of the table when there is a [local secondary index](#) on the table.

Designing partition keys to distribute your workload

The partition key portion of a table's primary key determines the logical partitions in which a table's data is stored. This in turn affects the underlying physical partitions. A partition key design that doesn't distribute I/O requests effectively can create "hot" partitions that result in throttling and use your provisioned I/O capacity inefficiently.

The optimal usage of a table's provisioned throughput depends not only on the workload patterns of individual items, but also on the partition key design. This doesn't mean that you must access all partition key values to achieve an efficient throughput level, or even that the percentage of accessed partition key values must be high. It does mean that the more distinct partition key values that your workload accesses, the more those requests will be spread across the partitioned space.

In general, you will use your provisioned throughput more efficiently as the ratio of partition key values accessed to the total number of partition key values increases.

The following is a comparison of the provisioned throughput efficiency of some common partition key schemas.

Partition key value	Uniformity
User ID, where the application has many users.	Good
Status code, where there are only a few possible status codes.	Bad
Item creation date, rounded to the nearest time period (for example, day, hour, or minute).	Bad
Device ID, where each device accesses data at relatively similar intervals.	Good
Device ID, where even if there are many devices being tracked, one is by far more popular than all the others.	Bad

If a single table has only a small number of partition key values, consider distributing your write operations across more distinct partition key values. In other words, structure the primary key elements to avoid one "hot" (heavily requested) partition key value that slows overall performance.

For example, consider a table with a composite primary key. The partition key represents the item's creation date, rounded to the nearest day. The sort key is an item identifier. On a given day, say 2014-07-09, **all** of the new items are written to that single partition key value (and corresponding physical partition).

If the table fits entirely into a single partition (considering growth of your data over time), and if your application's read and write throughput requirements don't exceed the read and write capabilities of a single partition, your application won't encounter any unexpected throttling as a result of partitioning.

To use NoSQL Workbench for DynamoDB to help visualize your partition key design, see [Building data models with NoSQL Workbench](#).

Using write sharding to distribute workloads evenly

One way to better distribute writes across a partition key space in Amazon DynamoDB is to expand the space. You can do this in several different ways. You can add a random number to the partition key values to distribute the items among partitions. Or you can use a number that is calculated based on something that you're querying on.

Sharding using random suffixes

One strategy for distributing loads more evenly across a partition key space is to add a random number to the end of the partition key values. Then you randomize the writes across the larger space.

For example, for a partition key that represents today's date, you might choose a random number between 1 and 200 and concatenate it as a suffix to the date. This yields partition key values like 2014-07-09.1, 2014-07-09.2, and so on, through 2014-07-09.200. Because you are randomizing the partition key, the writes to the table on each day are spread evenly across multiple partitions. This results in better parallelism and higher overall throughput.

However, to read all the items for a given day, you would have to query the items for all the suffixes and then merge the results. For example, you would first issue a Query request for the partition key value 2014-07-09.1. Then issue another Query for 2014-07-09.2, and so on, through 2014-07-09.200. Finally, your application would have to merge the results from all those Query requests.

Sharding using calculated suffixes

A randomizing strategy can greatly improve write throughput. But it's difficult to read a specific item because you don't know which suffix value was used when writing the item. To make it easier to read individual items, you can use a different strategy. Instead of using a random number to distribute the items among partitions, use a number that you can calculate based upon something that you want to query on.

Consider the previous example, in which a table uses today's date in the partition key. Now suppose that each item has an accessible OrderId attribute, and that you most often need to find items by order ID in addition to date. Before your application writes the item to the table, it could calculate a hash suffix based on the order ID and append it to the partition key date. The calculation might

generate a number between 1 and 200 that is fairly evenly distributed, similar to what the random strategy produces.

A simple calculation would likely suffice, such as the product of the UTF-8 code point values for the characters in the order ID, modulo 200, + 1. The partition key value would then be the date concatenated with the calculation result.

With this strategy, the writes are spread evenly across the partition key values, and thus across the physical partitions. You can easily perform a `GetItem` operation for a particular item and date because you can calculate the partition key value for a specific `OrderId` value.

To read all the items for a given day, you still must `Query` each of the `2014-07-09.N` keys (where `N` is 1–200), and your application then has to merge all the results. The benefit is that you avoid having a single "hot" partition key value taking all of the workload.

 **Note**

For a more efficient strategy specifically designed to handle high-volume time series data, see [Time series data](#).

Distributing write activity efficiently during data upload

Typically, when you load data from other data sources, Amazon DynamoDB partitions your table data on multiple servers. You get better performance if you upload data to all the allocated servers simultaneously.

For example, suppose that you want to upload user messages to a DynamoDB table that uses a composite primary key with `UserID` as the partition key and `MessageID` as the sort key.

When you upload the data, one approach you can take is to upload all message items for each user, one user after another:

UserID	MessageID
U1	1
U1	2
U1	...

UserID	MessageID
U1	... up to 100
U2	1
U2	2
U2	...
U2	... up to 200

The problem in this case is that you are not distributing your write requests to DynamoDB across your partition key values. You are taking one partition key value at a time and uploading all of its items before going to the next partition key value and doing the same.

Behind the scenes, DynamoDB is partitioning the data in your table across multiple servers. To fully use all the throughput capacity that is provisioned for the table, you must distribute your workload across your partition key values. By directing an uneven amount of upload work toward items that all have the same partition key value, you are not fully using all the resources that DynamoDB has provisioned for your table.

You can distribute your upload work by using the sort key to load one item from each partition key value, then another item from each partition key value, and so on:

UserID	MessageID
U1	1
U2	1
U3	1
...	...
U1	2
U2	2
U3	2

User ID	Message ID
...	...

Every upload in this sequence uses a different partition key value, keeping more DynamoDB servers busy simultaneously and improving your throughput performance.

Best practices for using sort keys to organize data

In an Amazon DynamoDB table, the primary key that uniquely identifies each item in the table can be composed of a partition key and a sort key.

Well-designed sort keys have two key benefits:

- They gather related information together in one place where it can be queried efficiently. Careful design of the sort key lets you retrieve commonly needed groups of related items using range queries with operators such as `begins_with`, `between`, `>`, `<`, and so on.
- Composite sort keys let you define hierarchical (one-to-many) relationships in your data that you can query at any level of the hierarchy.

For example, in a table listing geographical locations, you might structure the sort key as follows.

```
[country]#[region]#[state]#[county]#[city]#[neighborhood]
```

This would let you make efficient range queries for a list of locations at any one of these levels of aggregation, from country, to a neighborhood, and everything in between.

Using sort keys for version control

Many applications need to maintain a history of item-level revisions for audit or compliance purposes and to be able to retrieve the most recent version easily. There is an effective design pattern that accomplishes this using sort key prefixes:

- For each new item, create two copies of the item: One copy should have a version-number prefix of zero (such as `v0_`) at the beginning of the sort key, and one should have a version-number prefix of one (such as `v1_`).

- Every time the item is updated, use the next higher version-prefix in the sort key of the updated version, and copy the updated contents into the item with version-prefix zero. This means that the latest version of any item can be located easily using the zero prefix.

For example, a parts manufacturer might use a schema like the one illustrated below.

Primary Key		Data-Item Attributes...							
Partition Key	Sort Key (varies)	Attribute 1		Attribute 2		Attribute 3		Attribute 4	...
Equipment_1	Details	Name:	Biphasic Cardiometer <i>(equipment name)</i>	Factory_ID:	S14_Tukwilla <i>(factory where manufactured)</i>	Line_ID	R_7 <i>(assembly-line ID)</i>		
	v0_Audit	Auditor:	Padma <i>(name of the auditor)</i>	Latest:	3 <i>(most recent audit version)</i>	Time:	2018-04-15T11:00 <i>(audit date and time)</i>	Result	Passed <i>(audit result)</i>
	v1_Audit	Auditor:	Rick <i>(name of the auditor)</i>	Time:	2018-03-14T11:00 <i>(audit date and time)</i>	Result	Open <i>(audit result)</i>	Report:	0943922EKG14 <i>(detailed problem report in S3)</i>
	v2_Audit	Auditor:	George <i>(name of the auditor)</i>	Time:	2018-03-18T11:00 <i>(audit date and time)</i>	Result	Open <i>(audit result)</i>	Report:	0943923EKG15 <i>(detailed problem report in S3)</i>
	v3_Audit	Auditor:	Padma <i>(name of the auditor)</i>	Time:	2018-04-15T11:00 <i>(audit date and time)</i>	Result	Passed <i>(audit result)</i>	Report:	x792 <i>(pass confirmation report)</i>

The Equipment_1 item goes through a sequence of audits by various auditors. The results of each new audit are captured in a new item in the table, starting with version number one, and then incrementing the number for each successive revision.

When each new revision is added, the application layer replaces the contents of the zero-version item (having sort key equal to v0_Audit) with the contents of the new revision.

Whenever the application needs to retrieve for the most recent audit status, it can query for the sort key prefix of v0_.

If the application needs to retrieve the entire revision history, it can query all the items under the item's partition key and filter out the v0_ item.

This design also works for audits across multiple parts of a piece of equipment, if you include the individual part-IDs in the sort key after the sort key prefix.

Best practices for using secondary indexes in DynamoDB

Secondary indexes are often essential to support the query patterns that your application requires. At the same time, overusing secondary indexes or using them inefficiently can add cost and reduce performance unnecessarily.

Contents

- [General guidelines for secondary indexes in DynamoDB](#)
 - [Use indexes efficiently](#)
 - [Choose projections carefully](#)
 - [Optimize frequent queries to avoid fetches](#)
 - [Be aware of item-collection size limits when creating local secondary indexes](#)
- [Take advantage of sparse indexes](#)
 - [Examples of sparse indexes in DynamoDB](#)
- [Using Global Secondary Indexes for materialized aggregation queries](#)
- [Overloading Global Secondary Indexes](#)
- [Using Global Secondary Index write sharding for selective table queries](#)
- [Using Global Secondary Indexes to create an eventually consistent replica](#)

General guidelines for secondary indexes in DynamoDB

Amazon DynamoDB supports two types of secondary indexes:

- **Global secondary index (GSI)**—An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary index has no size limitations and has its own provisioned throughput settings for read and write activity that are separate from those of the table.
- **Local secondary index (LSI)**—An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value. As a result, the total size of indexed items for any one partition key value can't exceed 10 GB. Also, a local secondary index shares provisioned throughput settings for read and write activity with the table it is indexing.

Each table in DynamoDB can have up to 20 global secondary indexes (default quota) and 5 local secondary indexes.

Global secondary indexes are often more useful than local secondary indexes. Determining which type of index to use will also depend on your application's requirements. For a comparison of

global secondary indexes and local secondary indexes, and more information on how to choose between them, see [the section called "Working with indexes"](#).

The following are some general principles and design patterns to keep in mind when creating indexes in DynamoDB:

Topics

- [Use indexes efficiently](#)
- [Choose projections carefully](#)
- [Optimize frequent queries to avoid fetches](#)
- [Be aware of item-collection size limits when creating local secondary indexes](#)

Use indexes efficiently

Keep the number of indexes to a minimum. Don't create secondary indexes on attributes that you don't query often. Indexes that are seldom used contribute to increased storage and I/O costs without improving application performance.

Choose projections carefully

Because secondary indexes consume storage and provisioned throughput, you should keep the size of the index as small as possible. Also, the smaller the index, the greater the performance advantage compared to querying the full table. If your queries usually return only a small subset of attributes, and the total size of those attributes is much smaller than the whole item, project only the attributes that you regularly request.

If you expect a lot of write activity on a table compared to reads, follow these best practices:

- Consider projecting fewer attributes to minimize the size of items written to the index. However, this only applies if the size of projected attributes would otherwise be larger than a single write capacity unit (1 KB). For example, if the size of an index entry is only 200 bytes, DynamoDB rounds this up to 1 KB. In other words, as long as the index items are small, you can project more attributes at no extra cost.
- Avoid projecting attributes that you know will rarely be needed in queries. Every time you update an attribute that is projected in an index, you incur the extra cost of updating the index as well. You can still retrieve non-projected attributes in a Query at a higher provisioned throughput cost, but the query cost may be significantly lower than the cost of updating the index frequently.

- Specify ALL only if you want your queries to return the entire table item sorted by a different sort key. Projecting all attributes eliminates the need for table fetches, but in most cases, it doubles your costs for storage and write activity.

Balance the need to keep your indexes as small as possible against the need to keep fetches to a minimum, as explained in the next section.

Optimize frequent queries to avoid fetches

To get the fastest queries with the lowest possible latency, project all the attributes that you expect those queries to return. In particular, if you query a local secondary index for attributes that are not projected, DynamoDB automatically fetches those attributes from the table, which requires reading the entire item from the table. This introduces latency and additional I/O operations that you can avoid.

Keep in mind that "occasional" queries can often turn into "essential" queries. If there are attributes that you don't intend to project because you anticipate querying them only occasionally, consider whether circumstances might change and you might regret not projecting those attributes after all.

For more information about table fetches, see [Provisioned throughput considerations for Local Secondary Indexes](#).

Be aware of item-collection size limits when creating local secondary indexes

An *item collection* is all the items in a table and its local secondary indexes that have the same partition key. No item collection can exceed 10 GB, so it's possible to run out of space for a particular partition key value.

When you add or update a table item, DynamoDB updates all local secondary indexes that are affected. If the indexed attributes are defined in the table, the local secondary indexes grow too.

When you create a local secondary index, think about how much data will be written to it, and how many of those data items will have the same partition key value. If you expect that the sum of table and index items for a particular partition key value might exceed 10 GB, consider whether you should avoid creating the index.

If you can't avoid creating the local secondary index, you must anticipate the item collection size limit and take action before you exceed it. As a best practice, you should utilize the [ReturnItemCollectionMetrics](#) parameter when writing items to monitor and alert on item

collection sizes that approach the 10GB size limit. Exceeding the maximum item collection size will result in failed write attempts. You can mitigate the item collection size issues by monitoring and alerting on item collection sizes before they impact your application.

 **Note**

Once created, you cannot delete a local secondary index.

For strategies on working within the limit and taking corrective action, see [Item collection size limit](#).

Take advantage of sparse indexes

For any item in a table, DynamoDB writes a corresponding index entry **only if the index sort key value is present in the item**. If the sort key doesn't appear in every table item, or if the index partition key is not present in the item, the index is said to be *sparse*.

Sparse indexes are useful for queries over a small subsection of a table. For example, suppose that you have a table where you store all your customer orders, with the following key attributes:

- Partition key: CustomerId
- Sort key: OrderId

To track open orders, you can insert an attribute named `isOpen` in order items that have not already shipped. Then when the order ships, you can delete the attribute. If you then create an index on `CustomerId` (partition key) and `isOpen` (sort key), only those orders with `isOpen` defined appear in it. When you have thousands of orders of which only a small number are open, it's faster and less expensive to query that index for open orders than to scan the entire table.

Instead of using a type of attribute like `isOpen`, you could use an attribute with a value that results in a useful sort order in the index. For example, you could use an `OrderOpenDate` attribute set to the date on which each order was placed, and then delete it after the order is fulfilled. That way, when you query the sparse index, the items are returned sorted by the date on which each order was placed.

Examples of sparse indexes in DynamoDB

Global secondary indexes are sparse by default. When you create a global secondary index, you specify a partition key and optionally a sort key. Only items in the base table that contain those attributes appear in the index.

By designing a global secondary index to be sparse, you can provision it with lower write throughput than that of the base table, while still achieving excellent performance.

For example, a gaming application might track all scores of every user, but generally only needs to query a few high scores. The following design handles this scenario efficiently:

Table	Primary Key		Data Attributes...			
	Partition Key	Sort Key				
	Player_ID	Game_ID	Attribute 1		Attribute 2	
Rick	Rick	Game_1	Score: 36,750 <i>(game score)</i>	Date: 2017-11-14 <i>(date of game)</i>		
		Game_2	Score: 69,450 <i>(game score)</i>	Date: 2017-12-31 <i>(date of game)</i>		
		Game_3	Score: 135,900 <i>(game score)</i>	Date: 2018-01-19 <i>(date of game)</i>	Award: Champ <i>(type of award)</i>	
Padma	Padma	Game_4	Score: 25,350 <i>(game score)</i>	Date: 2018-01-27 <i>(date of game)</i>		
		Game_5	Score: 69,450 <i>(game score)</i>	Date: 2028-01-19 <i>(date of game)</i>		
		Game_6	Score: 147,300 <i>(game score)</i>	Date: 2018-02-02 <i>(date of game)</i>	Award: Champ <i>(type of award)</i>	
		Game_7	Score: 169,100 <i>(game score)</i>	Date: 2018-03-10 <i>(date of game)</i>	Award: Champ <i>(type of award)</i>	

Here, Rick has played three games and achieved Champ status in one of them. Padma has played four games and achieved Champ status in two of them. Notice that the Award attribute is present only in items where the user achieved an award. The associated global secondary index looks like the following:

GSI	Primary Key	Projected Attributes...			
	Partition Key				
	Award	Player_ID	Game_ID	Score	Date
	Champ	Rick	Game_3	135,900	2018-01-19
		Padma	Game_6	147,300	2018-02-02
		Padma	Game_7	169,100	2018-03-10

The global secondary index contains only the high scores that are frequently queried, which are a small subset of the items in the base table.

Using Global Secondary Indexes for materialized aggregation queries

Maintaining near real-time aggregations and key metrics on top of rapidly changing data is becoming increasingly valuable to businesses for making rapid decisions. For example, a music library might want to showcase its most downloaded songs in near-real time.

Consider the following music library table layout:

Music Library Table

Primary Key		Data-Item Attributes...				
Partition Key	Sort Key	Attribute 1		Attribute 2		Attribute 3
Song-129 <i>(song ID)</i>	Details	Title:	Wild Love <i>(song title)</i>	Artist:	Argyboots <i>(artist or band name)</i>	Downloads: 15,314,822 <i>(lifetime total downloads)</i>
		GSI Primary Key		GSI Secondary Key		...etc.
	Month-2018-01	Month:	2018-01 <i>(download month)</i>	MonthTotal:	1,746,992 <i>(month total downloads)</i>	
		Time:	2018-01-01T00:00:07 <i>(download timestamp)</i>			
		Time:	2018-01-01T00:00:07 <i>(download timestamp)</i>			
	Dld-9349823681	Time:	2018-01-01T00:00:07 <i>(download timestamp)</i>			

The table in this example stores songs with the songID as the partition key. You can enable Amazon DynamoDB Streams on this table and attach a Lambda function to the streams so that as each song is downloaded, an entry is added to the table with Partition-Key=SongID and Sort-Key=DownloadID. As these updates are made, they trigger a Lambda function in DynamoDB Streams. The Lambda function can aggregate and group the downloads by songID.

and update the top-level item, `Partition-Key=songID`, and `Sort-Key=Month`. Keep in mind that if a lambda execution fails just after writing the new aggregated value, it may be retried and aggregate the value more than once, leaving you with an approximate value.

To read the updates in near-real time, with single-digit millisecond latency, use the global secondary index with query conditions `Month=2018-01`, `ScanIndexForward=False`, `Limit=1`.

Another key optimization used here is that the global secondary index is a sparse index and is available only on the items that need to be queried to retrieve the data in real time. The global secondary index can serve additional workflows that need information on the top 10 songs that were popular, or any song downloaded in that month.

Overloading Global Secondary Indexes

Although Amazon DynamoDB has a default quota of 20 global secondary indexes per table, in practice, you can index across far more than 20 data fields. As opposed to a table in a relational database management system (RDBMS), in which the schema is uniform, a table in DynamoDB can hold many different kinds of data items at one time. In addition, the same attribute in different items can contain entirely different kinds of information.

Consider the following example of a DynamoDB table layout that saves a variety of different kinds of data.

Primary Key		Data-Item Attributes...				
Partition Key	Sort Key	Attribute 1		Attribute 2		...
HR-974 <i>(employee ID)</i>	Employee_Name	Data:	Murphy, John <i>(employee name)</i>	Start:	2008-11-08 <i>(start date)</i>	...etc.
	YYYY-Q1	Data:	\$5,477 <i>(order totals in USD)</i>	Name:	Murphy, John <i>(employee name)</i>	
	HR_confidential	Data:	2008-11-08 <i>(hire date)</i>	Name:	Murphy, John <i>(employee name)</i>	...etc.
	Warehouse_01	Data:	Murphy, John <i>(employee name)</i>			
	v0_Job_title	Data:	Operator-1 <i>(job title)</i>	Start:	2008-11-08 <i>(start date)</i>	...etc.
	v1_Job_title	Data:	Operator-2 <i>(job title)</i>	Start:	2016-11-04 <i>(start date)</i>	...etc.
	v2_Job_title	Data:	Supervisor-1 <i>(job title)</i>	Start:	2017-11-01 <i>(start date)</i>	...etc.

The Data attribute, which is common to all the items, has different content depending on its parent item. If you create a global secondary index for the table that uses the table's sort key as its partition key and the Data attribute as its sort key, you can make a variety of different queries using that single global secondary index. These queries might include the following:

- Look up an employee by name in the global secondary index, using Employee_Name as the partition key value and the employee's name (for example Murphy, John) as the sort key value.
- Use the global secondary index to find all employees working in a particular warehouse by searching on a warehouse ID (such as Warehouse_01).
- Get a list of recent hires, querying the global secondary index on HR_confidential as a partition key value and using a range of dates in the sort key value.

Using Global Secondary Index write sharding for selective table queries

Applications frequently need to identify a small subset of items in an Amazon DynamoDB table that meet a certain condition. When these items are distributed randomly across the partition keys of the table, you could resort to a table scan to retrieve them. This option can be expensive, but it works well when a large number of items on the table meet the search condition. However, when the key space is large and the search condition is very selective, this strategy can cause a lot of unnecessary processing.

A better solution can be to query the data. To enable selective queries across the entire key space, you can use write sharding by adding an attribute containing a (0-N) value to every item that you will use for the global secondary index partition key.

The following is an example of a schema that uses this in a Critical-Event workflow:

	Primary Key <i>Partition Key</i>	Data Attributes...								
		Attribute 1		Attribute 2		Attribute 3		Attribute 4		
Event_ID		Time: event timestamp	2018-02-07T08:42:40	State:	INFO (event state)	GSI PK:	(random: 0-N) (random GSI-PK value)	GSI SK:	INFO#2018-02-07T08:42:40 (composite state-time)	...etc.
EID_12345		Time: event timestamp	2018-02-07T08:32:40	State:	CRITICAL (event state)	GSI PK:	(random: 0-N) (random GSI-PK value)	GSI SK:	CRITICAL#2018-02-07T08:32:40 (composite state-time)	...etc.
EID_12346		Time: event timestamp	2018-02-07T08:22:40	State:	WARN (event state)	GSI PK:	(random: 0-N) (random GSI-PK value)	GSI SK:	WARN#2018-02-07T08:22:40 (composite state-time)	...etc.
EID_12347		Time: event timestamp	2018-02-07T08:12:40	State:	INFO (event state)	GSI PK:	(random: 0-N) (random GSI-PK value)	GSI SK:	INFO#2018-02-07T08:12:40 (composite state-time)	...etc.
EID_12348		Time: event timestamp	2018-02-07T08:12:40	State:	INFO (event state)	GSI PK:	(random: 0-N) (random GSI-PK value)	GSI SK:	INFO#2018-02-07T08:12:40 (composite state-time)	...etc.

	Primary Key		Data Attributes...		
	Partition Key	Sort Key	Data Attributes...		
	GSI PK	GSI SK	...		
	[0-N]	INFO#2018-02-07T08:42:40 (composite state-time)	...etc.		
	[0-N]	CRITICAL#2018-02-07T08:32:40 (composite state-time)	...etc.		
	[0-N]	WARN#2018-02-07T08:22:40 (composite state-time)	...etc.		
	[0-N]	INFO#2018-02-07T08:12:40 (composite state-time)	...etc.		

Using this schema design, the event items are distributed across 0–N partitions on the GSI, allowing a scatter read using a sort condition on the composite key to retrieve all items with a given state during a specified time period.

This schema pattern delivers a highly selective result set at minimal cost, without requiring a table scan.

Using Global Secondary Indexes to create an eventually consistent replica

You can use a global secondary index to create an eventually consistent replica of a table. Creating a replica can allow you to do the following:

- **Set different provisioned read capacity for different readers.** For example, suppose that you have two applications: One application handles high-priority queries and needs the highest levels of read performance, whereas the other handles low-priority queries that can tolerate throttling of read activity.

If both of these applications read from the same table, a heavy read load from the low-priority application could consume all the available read capacity for the table. This would throttle the high-priority application's read activity.

Instead, you can create a replica through a global secondary index whose read capacity you can set separate from that of the table itself. You can then have your low-priority app query the replica instead of the table.

- **Eliminate reads from a table entirely.** For example, you might have an application that captures a high volume of clickstream activity from a website, and you don't want to risk having reads interfere with that. You can isolate this table and prevent reads by other applications (see [Using IAM policy conditions for fine-grained access control](#)), while letting other applications read a replica created using a global secondary index.

To create a replica, set up a global secondary index that has the same key schema as the parent table, with some or all of the non-key attributes projected into it. In applications, you can direct some or all read activity to this global secondary index rather than to the parent table. You can then adjust the provisioned read capacity of the global secondary index to handle those reads without changing the parent table's provisioned read capacity.

There is always a short propagation delay between a write to the parent table and the time when the written data appears in the index. In other words, your applications should take into account that the global secondary index replica is only *eventually consistent* with the parent table.

You can create multiple global secondary index replicas to support different read patterns. When you create the replicas, project only the attributes that each read pattern actually requires. An application can then consume less provisioned read capacity to obtain only the data it needs rather than having to read the item from the parent table. This optimization can result in significant cost savings over time.

Best practices for storing large items and attributes

Amazon DynamoDB limits the size of each item that you store in a table to 400 KB (see [Service, account, and table quotas in Amazon DynamoDB](#)). If your application needs to store more data in an item than the DynamoDB size limit permits, you can try compressing one or more large attributes or breaking the item into multiple items (efficiently indexed by sort keys). You can also store the item as an object in Amazon Simple Storage Service (Amazon S3) and store the Amazon S3 object identifier in your DynamoDB item.

As a best practice, you should utilize the [ReturnConsumedCapacity](#) parameter when writing items to monitor and alert on items sizes that approach the 400 KB maximum item size. Exceeding the maximum item size will result in failed write attempts. Monitoring and alerting on item sizes will enable you to mitigate the items size issues before they impact your application.

Compressing large attribute values

Compressing large attribute values can let them fit within item limits in DynamoDB and reduce your storage costs. Compression algorithms such as GZIP or LZO produce binary output that you can then store in a Binary attribute type within the item.

As an example, consider a table that stores messages written by forum users. Such messages often contain long strings of text, which are candidates for compression. While compression can reduce item sizes, the downside is that the compressed attribute values are not useful for filtering.

For sample code that demonstrates how to compress such messages in DynamoDB, see the following:

- [Example: Handling binary type attributes using the AWS SDK for Java document API](#)
- [Example: Handling binary type attributes using the AWS SDK for .NET low-level API](#)

Vertical partitioning

An alternative solution to dealing with large items is to break them down into smaller chunks of data and associating all relevant items by the partition key value. You can then use a sort key string to identify the associated information stored alongside it. By doing this, and having multiple items grouped by the same partition key value, you are creating an [*item collection*](#).

For more information on this approach, see:

- [Use vertical partitioning to scale data efficiently in Amazon DynamoDB](#)
- [Implement vertical partitioning in Amazon DynamoDB using AWS Glue](#)

Storing large attribute values in Amazon S3

As mentioned previously, you can also use Amazon S3 to store large attribute values that cannot fit in a DynamoDB item. You can store them as an object in Amazon S3 and then store the object identifier in your DynamoDB item.

You can also use the object metadata support in Amazon S3 to provide a link back to the parent item in DynamoDB. Store the primary key value of the item as Amazon S3 metadata of the object in Amazon S3. Doing this often helps with maintenance of the Amazon S3 objects.

For example, consider the `ProductCatalog` table in the [Creating tables and loading data for code examples in DynamoDB](#) section. Items in this table store information about item price, description, book authors, and dimensions for other products. If you wanted to store an image of each product that was too large to fit in an item, you could store the images in Amazon S3 instead of in DynamoDB.

When implementing this strategy, keep the following in mind:

- DynamoDB doesn't support transactions that cross Amazon S3 and DynamoDB. Therefore, your application must deal with any failures, which could include cleaning up orphaned Amazon S3 objects.
- Amazon S3 limits the length of object identifiers. So you must organize your data in a way that doesn't generate excessively long object identifiers or violate other Amazon S3 constraints.

For more information about how to use Amazon S3, see the [Amazon Simple Storage Service User Guide](#).

Best practices for handling time series data in DynamoDB

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. For most applications, a single table is all you need. However, for time series data, you can often best handle it by using one table per application per period.

Design pattern for time series data

Consider a typical time series scenario, where you want to track a high volume of events. Your write access pattern is that all the events being recorded have today's date. Your read access pattern might be to read today's events most frequently, yesterday's events much less frequently, and then older events very little at all. One way to handle this is by building the current date and time into the primary key.

The following design pattern often handles this kind of scenario effectively:

- Create one table per period, provisioned with the required read and write capacity and the required indexes.
- Before the end of each period, prebuild the table for the next period. Just as the current period ends, direct event traffic to the new table. You can assign names to these tables that specify the periods they have recorded.
- As soon as a table is no longer being written to, reduce its provisioned write capacity to a lower value (for example, 1 WCU), and provision whatever read capacity is appropriate. Reduce the provisioned read capacity of earlier tables as they age. You might choose to archive or delete the tables whose contents are rarely or never needed.

The idea is to allocate the required resources for the current period that will experience the highest volume of traffic and scale down provisioning for older tables that are not used actively, therefore saving costs. Depending on your business needs, you might consider write sharding to distribute traffic evenly to the logical partition key. For more information, see [Using write sharding to distribute workloads evenly](#).

Time series table examples

The following is a time series data example in which the current table is provisioned at a higher read/write capacity and the older tables are scaled down because they are accessed infrequently.

Current table

Provisioned at: WCU=750 and RCU=300

Primary Key		Attributes		
Partition Key	Sort Key	Radiant Intensity	Wavelength	...
2018-03-15	00:00:00.002	17.372 W/Sr	713 nm	...
2018-03-15	00:00:00.004	17.385 W/Sr	712 nm	...
2018-03-15	00:00:00.005	17.478 W/Sr	708 nm	...
2018-03-15	00:00:00.007	19.172 W/Sr	674 nm	...
...

Previous table

Provisioned at: WCU=1 and RCU=100

Primary Key		Attributes		
Partition Key	Sort Key	Radiant Intensity	Wavelength	...
2018-03-14	00:00:00.001	16.473 W/Sr	512	...
2018-03-14	00:00:00.003	16.489 W/Sr	519	...
2018-03-14	00:00:00.004	16.814 W/Sr	522	...

Best practices for managing many-to-many relationships

Adjacency lists are a design pattern that is useful for modeling many-to-many relationships in Amazon DynamoDB. More generally, they provide a way to represent graph data (nodes and edges) in DynamoDB.

Adjacency list design pattern

When different entities of an application have a many-to-many relationship between them, the relationship can be modeled as an adjacency list. In this pattern, all top-level entities (synonymous to nodes in the graph model) are represented using the partition key. Any relationships with other entities (edges in a graph) are represented as an item within the partition by setting the value of the sort key to the target entity ID (target node).

The advantages of this pattern include minimal data duplication and simplified query patterns to find all entities (nodes) related to a target entity (having an edge to a target node).

A real-world example where this pattern has been useful is an invoicing system where invoices contain multiple bills. One bill can belong in multiple invoices. The partition key in this example is either an `InvoiceID` or a `BillID`. `BillID` partitions have all attributes specific to bills. `InvoiceID` partitions have an item storing invoice-specific attributes, and an item for each `BillID` that rolls up to the invoice.

The schema looks like the following.

	Primary Key		Data Attributes...		
	Partition Key	Sort Key (and GSI PK)	Dated:	2018-02-07	
Invoice-92551	Inv_ID:	Invoice-92551 <i>(invoice ID)</i>	Dated:	2018-02-07 <i>(date created)</i>	More attributes of this invoice...
	Bill_ID:	Bill-4224663 <i>(bill ID)</i>	Dated:	2017-12-03 <i>(date created)</i>	Attributes of this bill <i>in this invoice..</i>
	Bill_ID:	Bill-4224687 <i>(bill ID)</i>	Dated:	2018-01-09 <i>(date created)</i>	Attributes of this bill <i>in this invoice..</i>
Invoice-92552	Inv_ID:	Invoice-92552 <i>(invoice ID)</i>	Dated:	2018-03-04 <i>(date created)</i>	More attributes of this invoice...
	Bill_ID:	Bill-4224687 <i>(bill ID)</i>	Dated:	2018-01-09 <i>(date created)</i>	Attributes of this bill <i>in this invoice..</i>
Bill-4224663	Bill_ID:	Bill-4224663 <i>(bill ID)</i>	Dated:	2017-12-03 <i>(date created)</i>	More attributes of this bill...
Bill-4224687	Bill_ID:	Bill-4224687 <i>(bill ID)</i>	Dated:	2018-01-09 <i>(date created)</i>	More attributes of this bill...

Using the preceding schema, you can see that all bills for an invoice can be queried using the primary key on the table. To look up all invoices that contain a part of a bill, create a global secondary index on the table's sort key.

The projections for the global secondary index look like the following.

	Primary Key <i>Partition Key</i>	Projected Attributes...		
		Bill_ID:	Bill-4224663 <i>(table primary key)</i>	Attributes of this bill...
GSI	Bill-4224663	Inv_ID:	Invoice-92551 <i>(table primary key)</i>	Attributes of this bill <i>in this invoice</i> ..
		Bill_ID:	Bill-4224687 <i>(table primary key)</i>	Attributes of this bill...
	Bill-4224687	Inv_ID:	Invoice-92551 <i>(table primary key)</i>	Attributes of this bill <i>in this invoice</i> ..
		Inv_ID:	Invoice-92552 <i>(table primary key)</i>	Attributes of this bill <i>in this invoice</i> ..
		Inv_ID:	Invoice-92551 <i>(table primary key)</i>	Attributes of this invoice...
	Invoice-92551	Inv_ID:	Invoice-92552 <i>(table primary key)</i>	Attributes of this invoice...
	Invoice-92552	Inv_ID:	Invoice-92552 <i>(table primary key)</i>	Attributes of this invoice...

Materialized graph pattern

Many applications are built around understanding rankings across peers, common relationships between entities, neighbor entity state, and other types of graph style workflows. For these types of applications, consider the following schema design pattern.

	Primary Key		Attributes		
	PK (NodeId)	SK (TypeTarget, GSI 2 SK)	Data	GSI PK	Graph Projections
1	PERSON 1	DATE 2 BIRTH	1980-12-19	Hash(Person.Data)	
		PERSON 1	Data (GSI1 SK)	GSI PK	
		PERSON 5 FRIEND	John Doe	Hash(Person.Data)	
		PLACE 4 BIRTH	Data	GSI PK	
		SKILL 6	Jane Smith	Hash(Person.Data)	
	2	DATE 2	Data	GSI PK	
		DATE 2	1980-12-19	0	
	3	PLACE 3	Data	GSI PK	
		PLACE 3	UK England London	0	
	4	PLACE 4	Data	GSI PK	
		PLACE 4	USA Texas Austin	0	...
5	PERSON 5	DATE 2 BIRTH	Data	GSI PK	
		PERSON 5	1980-12-19	Hash(Person.Data)	
		PERSON 1 FRIEND	Data	GSI PK	
		PERSON 1 FRIEND	Jane Smith	Hash(Person.Data)	
		PLACE 3 BIRTH	Data	GSI PK	
	6	SKILL 6	UK England London	Hash(Person.Data)	
		SKILL 7	Data	GSI PK	
		SKILL 7	Guitar Advanced	Hash(Person.Data)	
		SKILL 6	Data	GSI PK	
		SKILL 7	Java Developer	0

The preceding schema shows a graph data structure that is defined by a set of data partitions containing the items that define the edges and nodes of the graph. Edge items contain a Target and a Type attribute. These attributes are used as part of a composite key name "TypeTarget" to identify the item in a partition in the primary table or in a second global secondary index.

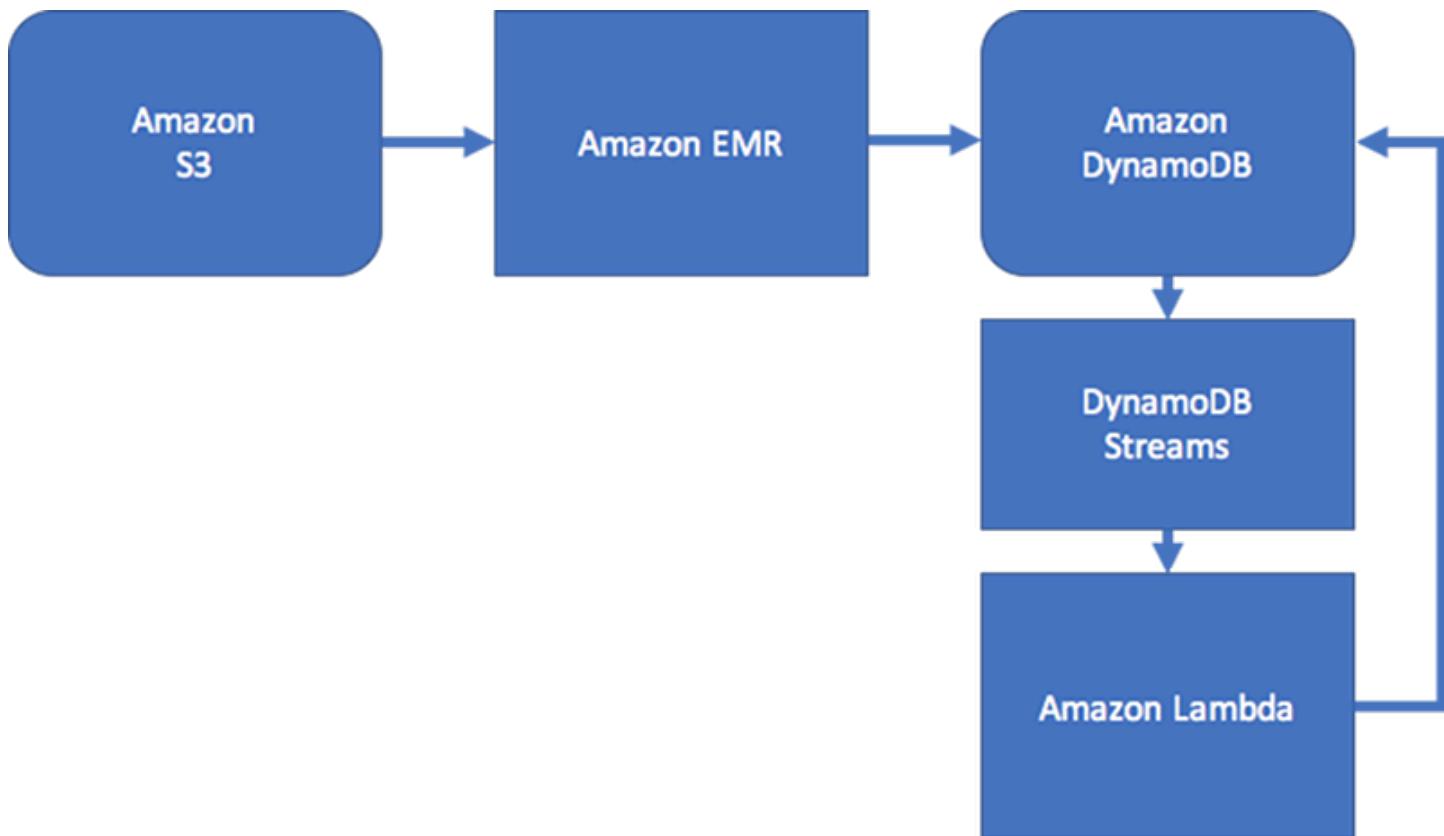

The first global secondary index is built on the Data attribute. This attribute uses global secondary index-overloading as described earlier to index several different attribute types, namely Dates, Names, Places, and Skills. Here, one global secondary index is effectively indexing four different attributes.

As you insert items into the table, you can use an intelligent sharding strategy to distribute item sets with large aggregations (birthdate, skill) across as many logical partitions on the global secondary indexes as are needed to avoid hot read/write problems.

The result of this combination of design patterns is a solid datastore for highly efficient real-time graph workflows. These workflows can provide high-performance neighbor entity state and edge aggregation queries for recommendation engines, social-networking applications, node rankings, subtree aggregations, and other common graph use cases.

If your use case isn't sensitive to real-time data consistency, you can use a scheduled Amazon EMR process to populate edges with relevant graph summary aggregations for your workflows. If your application doesn't need to know immediately when an edge is added to the graph, you can use a scheduled process to aggregate results.

To maintain some level of consistency, the design could include Amazon DynamoDB Streams and AWS Lambda to process edge updates. It could also use an Amazon EMR job to validate results on a regular interval. This approach is illustrated by the following diagram. It is commonly used in social networking applications, where the cost of a real-time query is high and the need to immediately know individual user updates is low.

IT service-management (ITSM) and security applications generally need to respond in real time to entity state changes composed of complex edge aggregations. Such applications need a system that can support real-time multiple node aggregations of second- and third-level relationships, or complex edge traversals. If your use case requires these types of real-time graph query workflows, we recommend that you consider using [Amazon Neptune](#) to manage these workflows.

Note

If you need to query highly connected datasets or execute queries that need to traverse multiple nodes (also known as multi-hop queries) with millisecond latency, you should consider using [Amazon Neptune](#). Amazon Neptune is a purpose-built, high-performance graph database engine optimized for storing billions of relationships and querying the graph with millisecond latency.

Best practices for implementing a hybrid database system

In some circumstances, migrating from one or more relational database management systems (RDBMS) to Amazon DynamoDB might not be advantageous. In these cases, it might be preferable to create a hybrid system.

If you don't want to migrate everything to DynamoDB

For example, some organizations have large investments in the code that produces a multitude of reports needed for accounting and operations. The time it takes to generate a report is not important to them. The flexibility of a relational system is well suited to this kind of task, and re-creating all those reports in a NoSQL context might be prohibitively difficult.

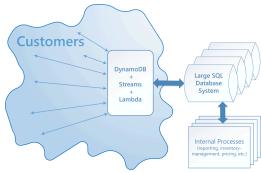

Some organizations also maintain a variety of legacy relational systems that they have acquired or inherited over decades. Migrating data from these systems might be too risky and expensive to justify the effort.

However, the same organizations may now find that their operations depend on high-traffic customer-facing websites, where millisecond response is essential. Relational systems can't scale to meet this requirement except at huge (and often unacceptable) expense.

In these situations, the answer might be to create a hybrid system, in which DynamoDB creates a materialized view of data stored in one or more relational systems and handles high-traffic requests against this view. This type of system can potentially reduce costs by eliminating server hardware, maintenance, and RDBMS licenses that were previously needed to handle customer-facing traffic.

How a hybrid system can be implemented

DynamoDB can take advantage of DynamoDB Streams and AWS Lambda to integrate seamlessly with one or more existing relational database systems:

A system that integrates DynamoDB Streams and AWS Lambda can provide several advantages:

- It can operate as a persisted cache of materialized views.
- It can be set up to fill gradually with data as that data is queried for, and as data is modified in the SQL system. This means that the entire view does not need to be pre-populated. This in turn means that provisioned throughput capacity is more likely to be used efficiently.
- It has low administrative costs and is highly available and reliable.

For this kind of integration to be implemented, essentially three kinds of interoperation must be provided.

1. **Fill the DynamoDB cache incrementally.** When an item is queried, look for it first in DynamoDB. If it is not there, look for it in the SQL system, and load it into DynamoDB.
2. **Write through a DynamoDB cache.** When a customer changes a value in DynamoDB, a Lambda function is triggered to write the new data back to the SQL system.
3. **Update DynamoDB from the SQL system.** When internal processes such as inventory management or pricing change a value in the SQL system, a stored procedure is triggered to propagate the change to the DynamoDB materialized view.

These operations are straightforward, and not all of them are needed for every scenario.

A hybrid solution can also be useful when you want to rely primarily on DynamoDB, but you also want to maintain a small relational system for one-time queries, or for operations that need special security or that are not time-critical.

Best practices for modeling relational data in DynamoDB

This section provides best practices for modeling relational data in Amazon DynamoDB. First, we introduce traditional data modeling concepts. Then, we describe the advantages of using DynamoDB over traditional relational database management systems—how it eliminates the need for JOIN operations and reduces overhead.

We then explain how to design a DynamoDB table that scales efficiently. Finally, we provide an example of how to model relational data in DynamoDB.

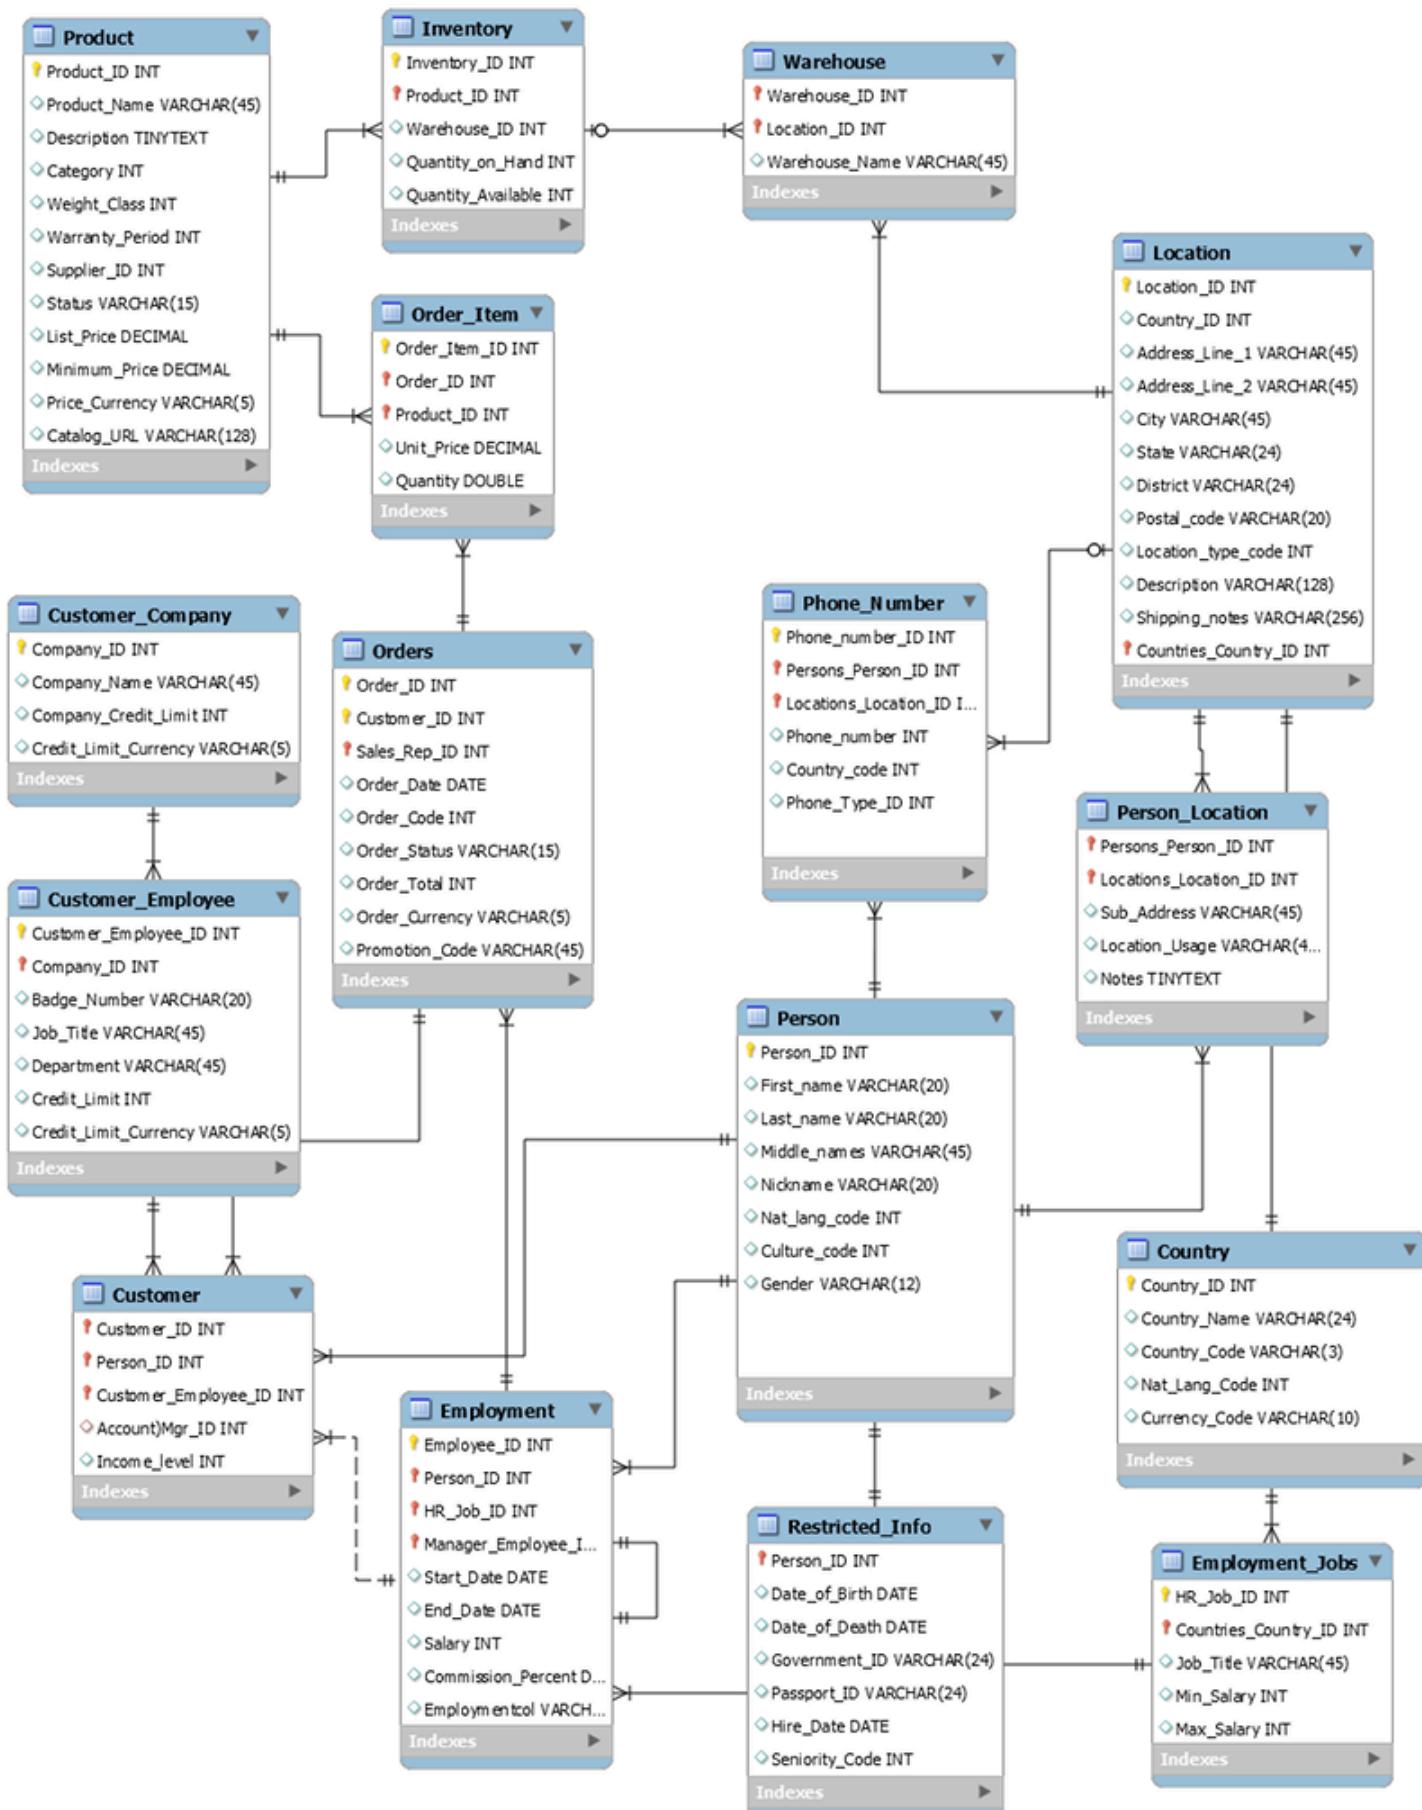

Topics

- [Traditional relational database models](#)
- [How DynamoDB eliminates the need for JOIN operations](#)
- [How DynamoDB transactions eliminate overhead to the write process](#)
- [First steps for modeling relational data in DynamoDB](#)
- [Example of modeling relational data in DynamoDB](#)

Traditional relational database models

A traditional relational database management system (RDBMS) stores data in a normalized relational structure. The objective of the relational data model is to reduce the duplication of data (through normalization) to support referential integrity and reduce data anomalies.

The following schema is an example of a relational data model for a generic order-entry application. The application supports a human resources schema that backs the operational and business support systems of a theoretical manufacturer.

As a non-relational database service, DynamoDB offers many advantages over traditional relational database management systems.

How DynamoDB eliminates the need for JOIN operations

An RDBMS uses a structure query language (SQL) to return data to the application. Because of the normalization of the data model, such queries typically require the use of the JOIN operator to combine data from one or more tables.

For example, to generate a list of purchase order items sorted by the quantity in stock at all warehouses that can ship each item, you could issue the following SQL query against the preceding schema.

```
SELECT * FROM Orders
    INNER JOIN Order_Items ON Orders.Order_ID = Order_Items.Order_ID
    INNER JOIN Products ON Products.Product_ID = Order_Items.Product_ID
    INNER JOIN Inventories ON Products.Product_ID = Inventories.Product_ID
    ORDER BY Quantity_on_Hand DESC
```

SQL queries of this kind can provide a flexible API for accessing data, but they require a significant amount of processing. Each join in the query increases the runtime complexity of the query because the data for each table must stage and then be assembled to return the result set.

Additional factors that can impact how long it takes the queries to run are the size of the tables and whether the columns being joined have indexes. The preceding query initiates complex queries across several tables and then sorts the result set.

Eliminating the need for JOINs is at the heart of NoSQL data modeling. This is why we built DynamoDB to support Amazon.com, and why DynamoDB can deliver consistent performance at any scale. Given the runtime complexity of SQL queries and JOINs, RDBMS performance is not constant at scale. This causes performance issues as customer applications grow.

While normalizing data does reduce the amount of data stored to disk, often the most constrained resources that impact performance are CPU time and network latency.

DynamoDB is built to minimize both constraints by eliminating JOINs (and encouraging denormalization of data) and optimizing the database architecture to fully answer an application query with a single request to an item. These qualities enable DynamoDB to provide single-digit, millisecond performance at any scale. This is because the runtime complexity for DynamoDB operations is constant, regardless of data size, for common access patterns.

How DynamoDB transactions eliminate overhead to the write process

Another factor that can slow down an RDBMS is the use of transactions to write to a normalized schema. As shown in the example, relational data structures used by most online transaction processing (OLTP) applications must be broken down and distributed across multiple logical tables when they are stored in an RDBMS.

Therefore, an ACID-compliant transaction framework is necessary to avoid race conditions and data integrity issues that could occur if an application tries to read an object that is in the process of being written. Such a transaction framework, when coupled with a relational schema, can add significant overhead to the write process.

The implementation of transactions in DynamoDB prohibits common scaling issues that are found with an RDBMS. DynamoDB does this by issuing a transaction as a single API call and bounding the number of items that can be accessed in that single transaction. Long-running transactions can cause operational issues by holding locks on the data either for a long time, or perpetually, because the transaction is never closed.

To prevent such issues in DynamoDB, transactions were implemented with two distinct API operations: `TransactWriteItems` and `TransactGetItems`. These API operations do not have begin and end semantics that are common in an RDBMS. Further, DynamoDB has a 100-item access limit within a transaction to similarly prevent long-running transactions. To learn more about DynamoDB transactions, see [Working with transactions](#).

For these reasons, when your business requires a low-latency response to high-traffic queries, taking advantage of a NoSQL system generally makes technical and economic sense. Amazon DynamoDB helps solve the problems that limit relational system scalability by avoiding them.

The performance of an RDBMS does not typically scale well for the following reasons:

- It uses expensive joins to reassemble required views of query results.
- It normalizes data and stores it on multiple tables that require multiple queries to write to disk.
- It generally incurs the performance costs of an ACID-compliant transaction system.

DynamoDB scales well for these reasons:

- Schema flexibility lets DynamoDB store complex hierarchical data within a single item.
- Composite key design lets it store related items close together on the same table.

- Transactions are performed in a single operation. The limit for the number of items that can be accessed is 100, to avoid long-running operations.

Queries against the data store become much simpler, often in the following form:

```
SELECT * FROM Table_X WHERE Attribute_Y = "somevalue"
```

DynamoDB does far less work to return the requested data compared to the RDBMS in the earlier example.

First steps for modeling relational data in DynamoDB

Important

NoSQL design requires a different mindset than RDBMS design. For an RDBMS, you can create a normalized data model without thinking about access patterns. You can then extend it later when new questions and query requirements arise. By contrast, in Amazon DynamoDB, you shouldn't start designing your schema until you know the questions that it needs to answer. Understanding the business problems and the application use cases up front is absolutely essential.

To start designing a DynamoDB table that will scale efficiently, you must take several steps first to identify the access patterns that are required by the operations and business support systems (OSS/BSS) that it needs to support:

- For new applications, review user stories about activities and objectives. Document the various use cases you identify, and analyze the access patterns that they require.
- For existing applications, analyze query logs to find out how people are currently using the system and what the key access patterns are.

After completing this process, you should end up with a list that might look something like the following.

Most Common/Import Access Patterns in Our Organization	
1	Look up employee details by employee ID
2	Query employee details by employee name
3	Find an employee's phone number(s)
4	Find a customer's phone number(s)
5	Get orders for a given customer within a given date range
6	Show all open orders within a given date range across all customers
7	See all employees hired recently
8	Find all employees working in a given warehouse
9	Get all items on order for a given product
10	Get current inventories for a given product at all warehouses
11	Get customers by account representative
12	Get orders by account representative and date
13	Get all employees with a given job title
14	Get inventory by product and warehouse
15	Get total product inventory
16	Get account representatives ranked by order total and sales period

In a real application, your list might be much longer. But this collection represents the range of query pattern complexity that you might find in a production environment.

A common approach to DynamoDB schema design is to identify application layer entities and use denormalization and composite key aggregation to reduce query complexity.

In DynamoDB, this means using composite sort keys, overloaded global secondary indexes, partitioned tables/indexes, and other design patterns. You can use these elements to structure the data so that an application can retrieve whatever it needs for a given access pattern using a single query on a table or index. The primary pattern that you can use to model the normalized schema shown in [Relational modeling](#) is the adjacency list pattern. Other patterns used in this design can include global secondary index write sharding, global secondary index overloading, composite keys, and materialized aggregations.

Important

In general, you should maintain as few tables as possible in a DynamoDB application.

Exceptions include cases where high-volume time series data are involved, or datasets that have very different access patterns. A single table with inverted indexes can usually enable simple queries to create and retrieve the complex hierarchical data structures required by your application.

To use NoSQL Workbench for DynamoDB to help visualize your partition key design, see [Building data models with NoSQL Workbench](#).

Example of modeling relational data in DynamoDB

This example describes how to model relational data in Amazon DynamoDB. A DynamoDB table design corresponds to the relational order entry schema that is shown in [Relational modeling](#). It follows the [Adjacency list design pattern](#), which is a common way to represent relational data structures in DynamoDB.

The design pattern requires you to define a set of entity types that usually correlate to the various tables in the relational schema. Entity items are then added to the table using a compound (partition and sort) primary key. The partition key of these entity items is the attribute that uniquely identifies the item and is referred to generically on all items as PK. The sort key attribute contains an attribute value that you can use for an inverted index or global secondary index. It is generically referred to as SK.

You define the following entities, which support the relational order entry schema.

1. HR-Employee - PK: EmployeeID, SK: Employee Name
2. HR-Region - PK: RegionID, SK: Region Name
3. HR-Country - PK: CountryId, SK: Country Name
4. HR-Location - PK: LocationID, SK: Country Name
5. HR-Job - PK: JobID, SK: Job Title
6. HR-Department - PK: DepartmentID, SK: DepartmentID
7. OE-Customer - PK: CustomerID, SK: AccountRepID
8. OE-Order - PK OrderID, SK: CustomerID
9. OE-Product - PK: ProductID, SK: Product Name
10. OE-Warehouse - PK: WarehouseID, SK: Region Name

After adding these entity items to the table, you can define the relationships between them by adding edge items to the entity item partitions. The following table demonstrates this step.

In this example, the Employee, Order, and Product Entity partitions on the table have additional edge items that contain pointers to other entity items on the table. Next, define a few global secondary indexes (GSIs) to support all the access patterns defined previously. The entity items don't all use the same type of value for the primary key or the sort key attribute. All that is required is to have the primary key and sort key attributes present to be inserted on the table.

The fact that some of these entities use proper names and others use other entity IDs as sort key values allows the same global secondary index to support multiple types of queries. This technique is called *GSI overloading*. It effectively eliminates the default limit of 20 global secondary indexes for tables that contain multiple item types. This is shown in the following diagram as *GSI 1*.

GSI 2 is designed to support a fairly common application access pattern, which is to get all the items on the table that have a certain state. For a large table with an uneven distribution of items across available states, this access pattern can result in a hot key, unless the items are distributed across more than one logical partition that can be queried in parallel. This design pattern is called *write sharding*.

To accomplish this for *GSI 2*, the application adds the *GSI 2 primary key* attribute to every *Order* item. It populates that with a random number in a range of 0–N, where N can generically be calculated using the following formula, unless there is a specific reason to do otherwise.

```
ItemsPerRCU = 4KB / AvgItemSize
```

```
PartitionMaxReadRate = 3K * ItemsPerRCU
```

```
N = MaxRequiredIO / PartitionMaxReadRate
```

For example, assume that you expect the following:

- Up to 2 million orders will be in the system, growing to 3 million in 5 years.
- Up to 20 percent of these orders will be in an OPEN state at any given time.
- The average order record is around 100 bytes, with three *OrderItem* records in the order partition that are around 50 bytes each, giving you an average order entity size of 250 bytes.

For that table, the N factor calculation would look like the following.

```
ItemsPerRCU = 4KB / 250B = 16
```

```
PartitionMaxReadRate = 3K * 16 = 48K
```

```
N = (0.2 * 3M) / 48K = 13
```

In this case, you need to distribute all the orders across at least 13 logical partitions on *GSI 2* to ensure that a read of all *Order* items with an OPEN status doesn't cause a hot partition on

the physical storage layer. It is a good practice to pad this number to allow for anomalies in the dataset. So a model using $N = 15$ is probably fine. As mentioned earlier, you do this by adding the random $0-N$ value to the GSI 2 PK attribute of each Order and OrderItem record that is inserted on the table.

This breakdown assumes that the access pattern that requires gathering all OPEN invoices occurs relatively infrequently so that you can use burst capacity to fulfill the request. You can query the following global secondary index using a State and Date Range Sort Key condition to produce a subset or all Orders in a given state as needed.

In this example, the items are randomly distributed across the 15 logical partitions. This structure works because the access pattern requires a large number of items to be retrieved. Therefore, it's unlikely that any of the 15 threads will return empty result sets that could potentially represent wasted capacity. A query always uses 1 read capacity unit (RCU) or 1 write capacity unit (WCU), even if nothing is returned or no data is written.

If the access pattern requires a high velocity query on this global secondary index that returns a sparse result set, it's probably better to use a hash algorithm to distribute the items rather than a random pattern. In this case, you might select an attribute that is known when the query is run at runtime and hash that attribute into a 0–14 key space when the items are inserted. Then they can be efficiently read from the global secondary index.

Finally, you can revisit the access patterns that were defined earlier. Following is the list of access patterns and the query conditions that you will use with the new DynamoDB version of the application to accommodate them.

	Access patterns	Query conditions
1	Look up Employee Details by Employee ID	Primary Key on table, ID="HR-EMPLOYEE"
2	Query Employee Details by Employee Name	Use GSI-1, PK="Employee Name"
3	Get an employee's current job details only	Primary Key on table, PK=HR-EMPLOYEE-1, SK starts with "JH"

	Access patterns	Query conditions
4	Get Orders for a customer for a date range	Use GSI-1, PK=CUSTOMER1, SK="STATUS-DATE", for each StatusCode
5	Show all Orders in OPEN status for a date range across all customers	Use GSI-2, PK=query in parallel for the range [0..N], SK between OPEN-Date1 and OPEN-Date2
6	All Employees hired recently	Use GSI-1, PK="HR-CO NFIDENTIAL', SK > date1
7	Find all Employees in specific Warehouse	Use GSI-1, PK=WAREHOUSE1
8	Get all Orderitems for a Product including warehouse location inventories	Use GSI-1, PK=PRODUCT1
9	Get customers by Account Rep	Use GSI-1, PK=ACCOUNT-REP
10	Get orders by Account Rep and date	Use GSI-1, PK=ACCOUNT-REP, SK="STATUS-DATE", for each StatusCode
11	Get all employees with specific Job Title	Use GSI-1, PK=JOBTITLE
12	Get inventory by Product and Warehouse	Primary Key on table, PK=OE-PRODUCT1,SK=PRODUCT1
13	Get total product inventory	Primary Key on table, PK=OE-PRODUCT1,SK=PRODUCT1
14	Get Account Reps ranked by Order Total and Sales Period	Use GSI-1, PK=YYYY-Q1, scanIndexForward=False

Best practices for querying and scanning data

This section covers some best practices for using Query and Scan operations in Amazon DynamoDB.

Performance considerations for scans

In general, Scan operations are less efficient than other operations in DynamoDB. A Scan operation always scans the entire table or secondary index. It then filters out values to provide the result you want, essentially adding the extra step of removing data from the result set.

If possible, you should avoid using a Scan operation on a large table or index with a filter that removes many results. Also, as a table or index grows, the Scan operation slows. The Scan operation examines every item for the requested values and can use up the provisioned throughput for a large table or index in a single operation. For faster response times, design your tables and indexes so that your applications can use Query instead of Scan. (For tables, you can also consider using the GetItem and BatchGetItem APIs.)

Alternatively, you can design your application to use Scan operations in a way that minimizes the impact on your request rate. This can include modeling when it might be more efficient to use a global secondary index instead of a Scan operation. Further information on this process is in the following video.

[Modeling low velocity access patterns](#)

Avoiding sudden spikes in read activity

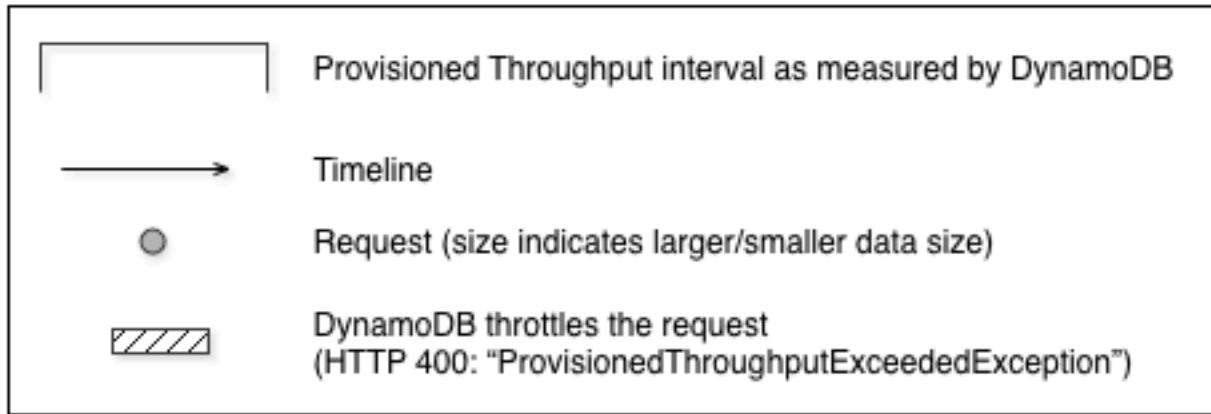

When you create a table, you set its read and write capacity unit requirements. For reads, the capacity units are expressed as the number of strongly consistent 4 KB data read requests per second. For eventually consistent reads, a read capacity unit is two 4 KB read requests per second. A Scan operation performs eventually consistent reads by default, and it can return up to 1 MB (one page) of data. Therefore, a single Scan request can consume $(1 \text{ MB page size} / 4 \text{ KB item size}) / 2$ (eventually consistent reads) = 128 read operations. If you request strongly consistent reads instead, the Scan operation would consume twice as much provisioned throughput—256 read operations.

This represents a sudden spike in usage, compared to the configured read capacity for the table. This usage of capacity units by a scan prevents other potentially more important

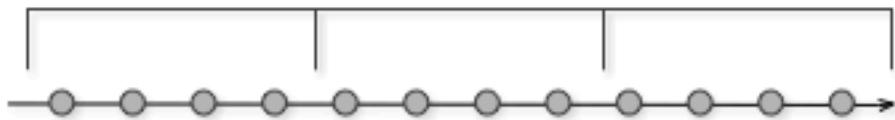

requests for the same table from using the available capacity units. As a result, you likely get a ProvisionedThroughputExceeded exception for those requests.

The problem is not just the sudden increase in capacity units that the Scan uses. The scan is also likely to consume all of its capacity units from the same partition because the scan requests read items that are next to each other on the partition. This means that the request is hitting the same partition, causing all of its capacity units to be consumed, and throttling other requests to that partition. If the request to read data is spread across multiple partitions, the operation would not throttle a specific partition.

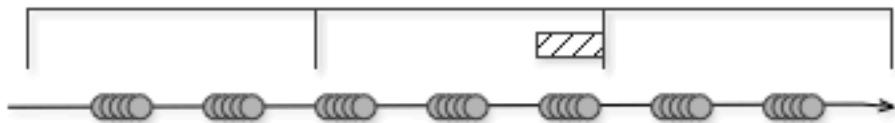

The following diagram illustrates the impact of a sudden spike of capacity unit usage by Query and Scan operations, and its impact on your other requests against the same table.

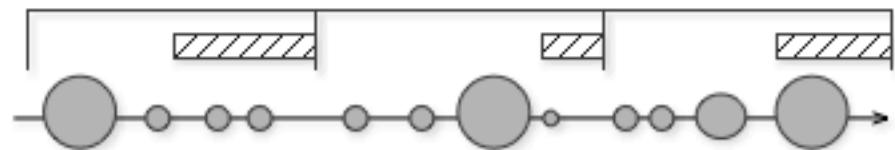

1. Good: Even distribution of requests and size

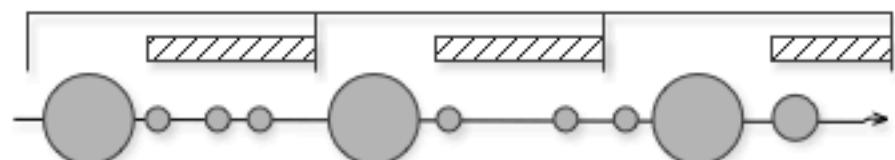

2. Not as Good: Frequent requests in bursts

3. Bad: A few random large requests

4. Bad: Large scan operations

As illustrated here, the usage spike can impact the table's provisioned throughput in several ways:

1. Good: Even distribution of requests and size

2. Not as good: Frequent requests in bursts
3. Bad: A few random large requests
4. Bad: Large scan operations

Instead of using a large Scan operation, you can use the following techniques to minimize the impact of a scan on a table's provisioned throughput.

- **Reduce page size**

Because a Scan operation reads an entire page (by default, 1 MB), you can reduce the impact of the scan operation by setting a smaller page size. The Scan operation provides a *Limit* parameter that you can use to set the page size for your request. Each Query or Scan request that has a smaller page size uses fewer read operations and creates a "pause" between each request. For example, suppose that each item is 4 KB and you set the page size to 40 items. A Query request would then consume only 20 eventually consistent read operations or 40 strongly consistent read operations. A larger number of smaller Query or Scan operations would allow your other critical requests to succeed without throttling.

- **Isolate scan operations**

DynamoDB is designed for easy scalability. As a result, an application can create tables for distinct purposes, possibly even duplicating content across several tables. You want to perform scans on a table that is not taking "mission-critical" traffic. Some applications handle this load by rotating traffic hourly between two tables—one for critical traffic, and one for bookkeeping. Other applications can do this by performing every write on two tables: a "mission-critical" table, and a "shadow" table.

Configure your application to retry any request that receives a response code that indicates you have exceeded your provisioned throughput. Or, increase the provisioned throughput for your table using the `UpdateTable` operation. If you have temporary spikes in your workload that cause your throughput to exceed, occasionally, beyond the provisioned level, retry the request with exponential backoff. For more information about implementing exponential backoff, see [Error retries and exponential backoff](#).

Taking advantage of parallel scans

Many applications can benefit from using parallel Scan operations rather than sequential scans. For example, an application that processes a large table of historical data can perform a parallel

scan much faster than a sequential one. Multiple worker threads in a background "sweeper" process could scan a table at a low priority without affecting production traffic. In each of these examples, a parallel Scan is used in such a way that it does not starve other applications of provisioned throughput resources.

Although parallel scans can be beneficial, they can place a heavy demand on provisioned throughput. With a parallel scan, your application has multiple workers that are all running Scan operations concurrently. This can quickly consume all of your table's provisioned read capacity. In that case, other applications that need to access the table might be throttled.

A parallel scan can be the right choice if the following conditions are met:

- The table size is 20 GB or larger.
- The table's provisioned read throughput is not being fully used.
- Sequential Scan operations are too slow.

Choosing TotalSegments

The best setting for TotalSegments depends on your specific data, the table's provisioned throughput settings, and your performance requirements. You might need to experiment to get it right. We recommend that you begin with a simple ratio, such as one segment per 2 GB of data. For example, for a 30 GB table, you could set TotalSegments to 15 (30 GB / 2 GB). Your application would then use 15 workers, with each worker scanning a different segment.

You can also choose a value for TotalSegments that is based on client resources. You can set TotalSegments to any number from 1 to 1000000, and DynamoDB lets you scan that number of segments. For example, if your client limits the number of threads that can run concurrently, you can gradually increase TotalSegments until you get the best Scan performance with your application.

Monitor your parallel scans to optimize your provisioned throughput use, while also making sure that your other applications aren't starved of resources. Increase the value for TotalSegments if you don't consume all of your provisioned throughput but still experience throttling in your Scan requests. Reduce the value for TotalSegments if the Scan requests consume more provisioned throughput than you want to use.

Best practices for DynamoDB table design

General design principles in Amazon DynamoDB recommend that you keep the number of tables you use to a minimum. In the majority of cases, we recommend that you consider using a single table. However if a single or small number of tables are not viable, these guidelines may be of use.

- The per account limit cannot be increased above 10,000 tables per account. If your application requires more tables, plan for distributing the tables across multiple accounts. For more information see [service, account, and table quotas in Amazon DynamoDB](#).
- Consider control plane limits for concurrent control plane operations that might impact your table management.
- Work with AWS solution architects to validate your design patterns for multi-tenant designs.

Best practices for DynamoDB global table design

Global tables build on Amazon DynamoDB's global footprint to provide you with a fully managed, multi-Region, and multi-active database that delivers fast, local, read and write performance for massively scaled, global applications. With global tables your data replicates automatically across your choice of AWS Regions. Because global tables use existing DynamoDB APIs, no changes to your application will be needed. There are no upfront costs or commitments for using global tables, and you pay only for the resources you use.

Prescriptive guidance for DynamoDB global table design

Efficient use of global tables requires careful considerations of factors like your preferred write mode, routing model, and evacuation processes. You must instrument your application across every Region and be ready to adjust your routing or perform an evacuation to maintain global health. The reward is having a globally distributed data set with low-latency reads and writes and a 99.999% service level agreement.

Key facts about DynamoDB global table design

- There are two versions of global tables: the current version [Global Tables version 2019.11.21 \(Current\)](#) (sometimes called "V2"), and [Global tables version 2017.11.29 \(Legacy\)](#) (sometimes called "V1"). This guide focuses exclusively on the current version, V2.
- Without the use of global tables, DynamoDB is a Regional service. It is highly available and intrinsically resilient to failures of infrastructure with a Region, including the failure of an entire availability zone (AZ). A single-Region DynamoDB table has a 99.99% availability [Service Level Agreement \(SLA\)](https://aws.amazon.com/dynamodb/sla/).
- With the use of global tables, DynamoDB allows a table to replicate its data between two or more Regions. A multi-Region DynamoDB table has a 99.999% availability SLA. With proper planning, global tables can help create an architecture that is resilient and resists Regional failures.
- Global tables employ an active-active replication model. From the perspective of DynamoDB, the table in each Region has equal standing to accept read and write requests. After receiving a write request, the local replica table will replicate the write to other participating Regions in the background.
- Items are replicated individually. Items updated within a single transaction may not be replicated together.
- Each table partition in the source Region replicates its writes in parallel with every other partition. The sequence of writes within the remote Region may not match the sequence of writes that happened within the source Region. For more information about table partitions, see the blog post [Scaling DynamoDB: How partitions, hot keys, and split for heat impact performance](#).
- A newly written item is usually propagated to all replica tables within a second. Nearby Regions tend to propagate faster.
- Amazon CloudWatch provides a `ReplicationLatency` metric for each Region pair. It is calculated based on looking at arriving items and comparing their arrival time with their initial

write time and computing an average. Timings are stored within CloudWatch in the source Region. Viewing the average and maximum timings can help determine the average and worst-case replication lag. There is no SLA on this latency.

- If the same item is updated at about the same time (within this `ReplicationLatency` window) in two different Regions, and the second write happens before the first write was replicated, there's a potential for write conflicts. Global tables resolves such conflicts with a *last writer wins* mechanism, based on the timestamp of the writes. The first write "loses" to the second write. These conflicts are not recorded in CloudWatch or AWS CloudTrail.
- Each item has a last write timestamp held as a private system property. The *last writer wins* approach is implemented by using a conditional write that requires the incoming item's timestamp be greater than the existing item's timestamp.
- A global table will replicate all items to all participating Regions. If you want to have different replication scopes, you can create different tables and give each of the tables different participating Regions.
- Writes will be accepted to the local Region even if the replica Region is offline or the `ReplicationLatency` grows. The local table continues to attempt replicating items to the remote table until each item succeeds.
- In the unlikely event a Region goes fully offline, when it later comes back online all pending outbound and inbound replications will be retried. No special action is required to bring the tables back in sync. The *last writer wins* mechanism ensures the data will eventually become consistent.
- You can add a new Region to a DynamoDB table at any time. DynamoDB will handle the initial sync and ongoing replication. If a Region is removed, even if it's the original Region, that will only delete the table for that Region.
- DynamoDB does not have a global endpoint. All requests are made to a regional endpoint, which then accesses the global table instance that's local to that Region.
- Calls to DynamoDB should not go cross-Region. The best practice is for the compute layer in one Region to directly access only the local DynamoDB endpoint for that Region. If problems are detected within a Region, whether those problems are in the DynamoDB layer or in the surrounding stack, then the end user traffic should be routed to a different compute layer hosted in a different Region. Thanks to global table replication, the different Region will already have a local copy of the same data for it to locally work with. In some circumstances the compute layer in one Region may pass the request onward to another Region's compute layer for processing, but this should not directly access the remote DynamoDB endpoint. For more information on this particular use case see [Compute-layer request routing](#).

Use cases

Global tables provides these common benefits:

- **Lower-latency reads.** You can place a copy of the data closer to the end user to reduce network latency during reads. The cache is kept as fresh as the `ReplicationLatency` value.
- **Lower-latency writes.** You can write to a nearby region to reduce network latency and the time taken to achieve the write. The write traffic must be carefully routed to ensure no conflicts. Techniques for routing are discussed in more detail in [Request routing with global tables](#).
- **Increased resiliency and disaster recovery.** You can evacuate a Region (move away some or all requests going to that Region) should the Region have degraded performance or a full outage, with a Recovery Point Objective (RPO) and Recovery Time Objective (RTO) measured in seconds. Using global tables also increases the [DynamoDB SLA](#) from 99.99% to 99.999%.
- **Seamless Region migration.** You can add a new Region and then delete the old Region to migrate a deployment from one Region to another, all without downtime at the data layer. For example, you can use DynamoDB global tables for an order management system achieve reliably low latency processing at a high scale while also maintaining resilience to AZ and Regional failures.

Write modes with global tables

Global tables are always active-active at the table level. However, you might want to treat them as active-passive by controlling how you route write requests. For example, you might decide to route write requests to a single Region to avoid potential write conflicts.

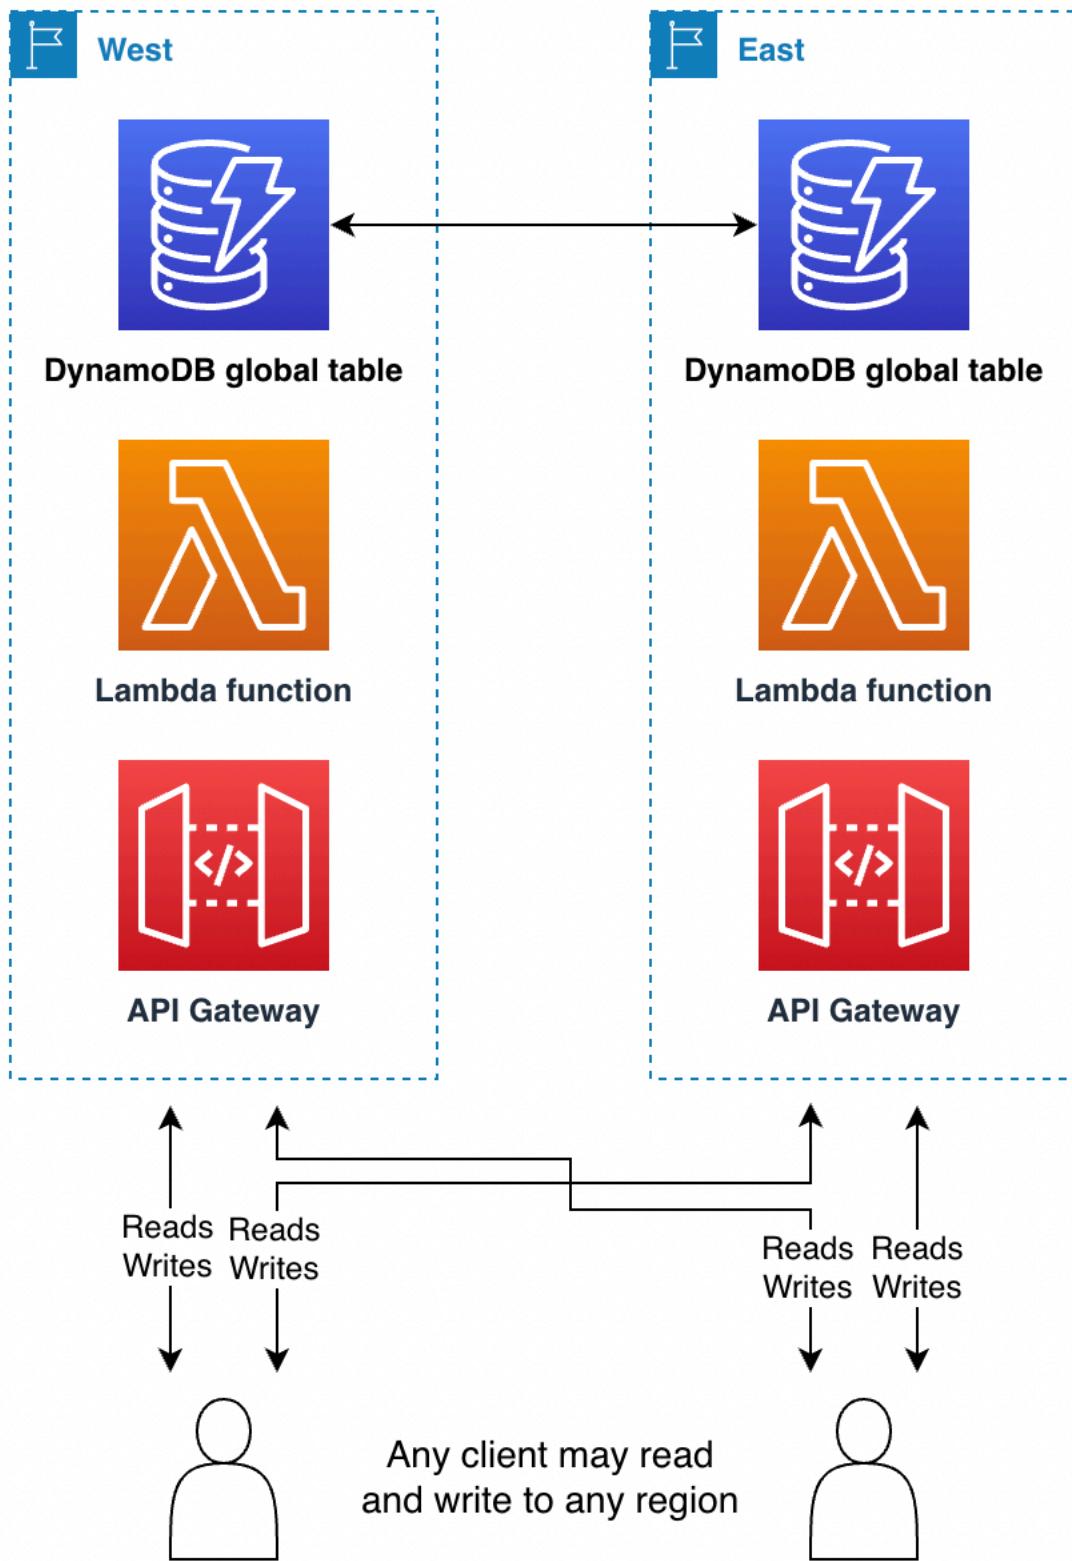

There are three main categorizations of managed write patterns:

- Write to any Region mode (no primary)
- Write to one Region mode (single primary)
- Write to your Region mode (mixed primary)

You should consider which write pattern fits your use case. This choice affects how you route requests, evacuate a Region, and handle disaster recovery. Overall best practices can differ depending on your application's write mode.

Write to any Region mode (no primary)

The *write to any Region* mode is fully active-active and doesn't impose restrictions on where a write may occur. Any Region may accept a write at any time. This is the simplest mode. It can be used only with some type of applications. It's suitable when all writers are idempotent, and therefore safely repeatable so that concurrent or repeated write operations across Regions are not in conflict. For example, when a user updates their contact data. This mode also works well for a special case of being idempotent, an append-only dataset where all writes are unique inserts under a deterministic primary key. Lastly, this mode is suitable where the risk of conflicting writes would be acceptable.

The *write to any Region* mode is the most straightforward architecture to implement. Routing is easier because any Region can be the write target at any time. Failover is easier, because any recent

writes can be replayed any number of times to any secondary Region. Where possible, you should design for this write mode.

For example, video streaming services often use global tables for tracking bookmarks, reviews, watch status flags, and so on. These deployments can use the *write to any Region* mode as long as they ensure that every write is idempotent and the next correct value for an item doesn't depend on its current value. This will be the case for user updates which assign the user's new state directly, such as setting a new latest time code, assigning a new review, or setting a new watch status. If the user's write requests are routed to different Regions, the last write operation will persist and the global state will settle according to the last assignment. Read operations in this mode will eventually become consistent, after being delayed by the latest ReplicationLatency value.

In another example, a financial services firm uses global tables as part of a system to maintain a running tally of debit card purchases for each customer, to calculate that customer's cash-back rewards. New transactions stream in from around the world and go to multiple Regions. For their current design that doesn't take advantage of global tables, they use a single RunningBalance item per customer. Customer actions update the balance with an ADD expression, which is not idempotent because the new correct value depends on the current value. This means the balance got out of sync if there were two write operations to the same balance at around the same time in different Regions.

This same firm could achieve a *write to any Region* mode through a careful redesign with DynamoDB's global tables. The new design could follow an "event streaming" model - essentially a ledger with an append-only workflow. Each customer action appends a new item to the item collection maintained for that customer. The item collection is the set of items that share a primary key, having different sort keys. Each write action that appends the cusomter action is an idempotent insert, using the customer ID as the partition key and transaction ID as the sort key. This design makes the calculation of the balance more involved, because it requires a Query to pull the items followed by some client-side math. But the advantage is that it makes all writes idempotent, which provides significant routing and failover simplifications. For more information see [Request routing with global tables](#).

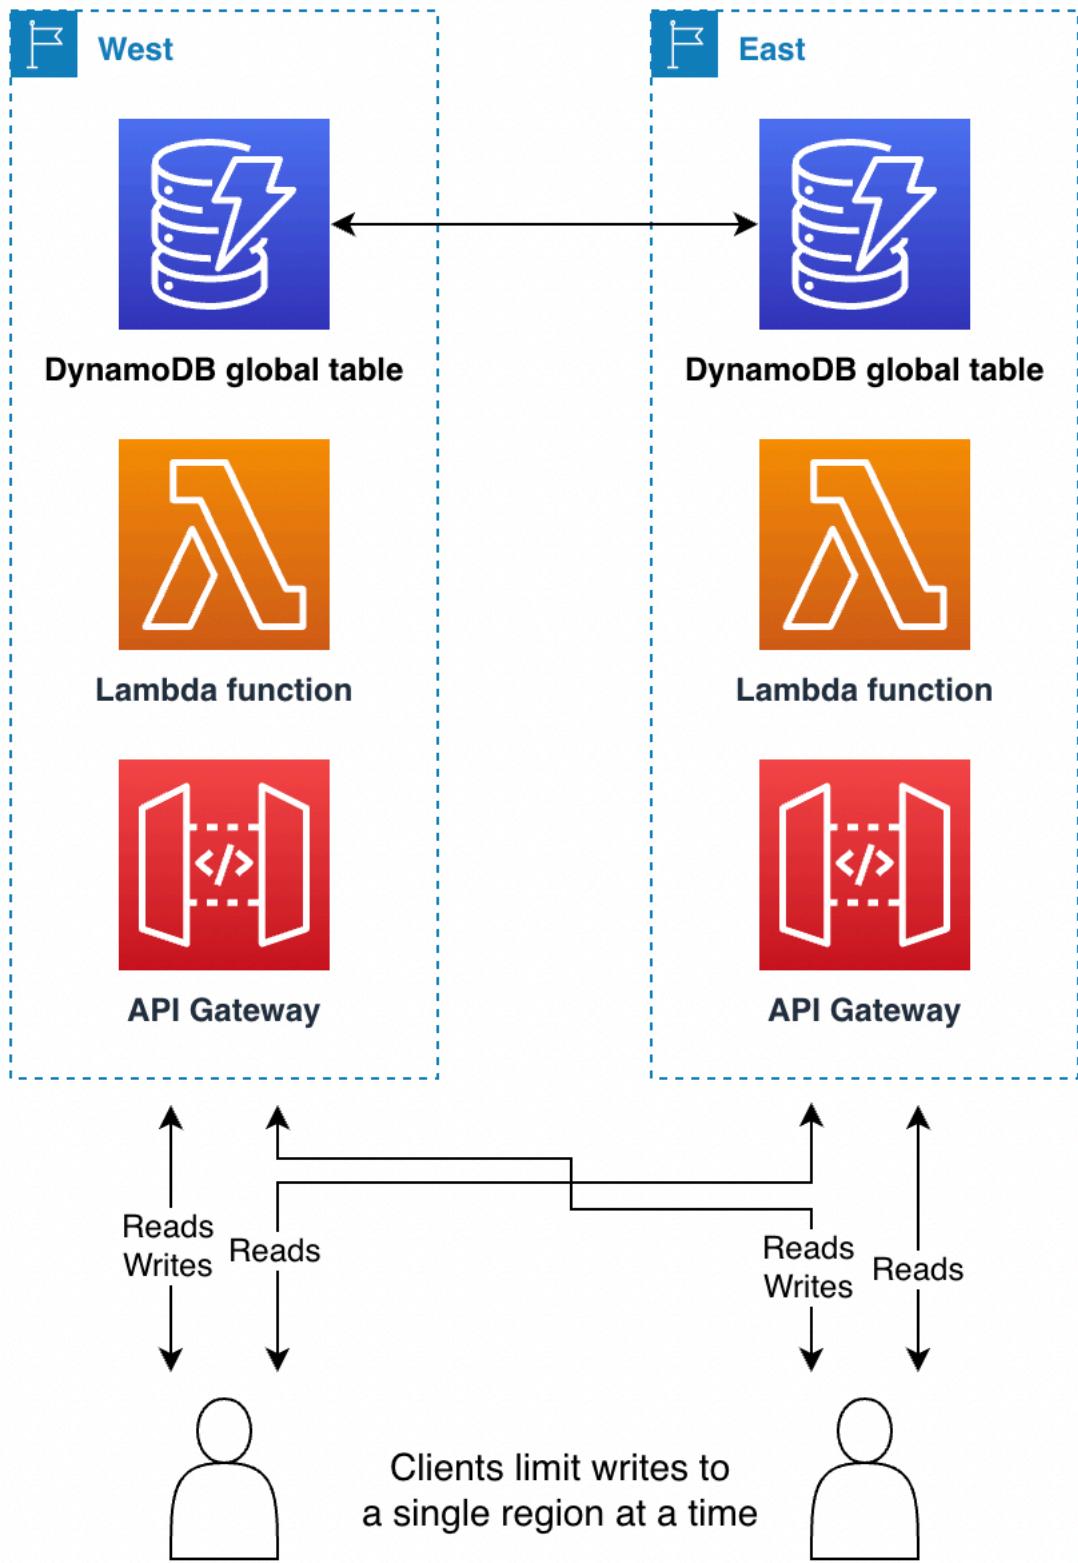

For a third example, let's say there's a customer doing online ad placement. They've decided a low risk of data loss would be acceptable to achieve the design simplifications of the *write to any Region* mode. When they serve ads, they have just a few milliseconds to retrieve enough metadata to determine what ad to show, and then to record the ad impression so the same ad won't repeated to that user. With global tables they can get both low-latency reads for end users across the world

and low-latency writes. They can record all ad impressions for a user within a single item, and represent that as a growing List. They can use one item instead of appending to an item collection, because this way they can remove older ad impressions as part of each write without paying for a delete. This write operation is NOT idempotent, so if the same end user sees ads served out of multiple Regions at approximately the same time there's a chance one ad impression write could overwrite the other. For online ad placement, the risk that a user might occasionally see a repeated ad is worth having this simpler and more efficient design.

Single primary (“Write to one Region”)

The *write to one Region* mode is active-passive and routes all table writes to a single active region. Note that DynamoDB doesn't have a notion of a single active region; the application routing outside DynamoDB manages this. The *write to one Region* mode avoids write conflicts by ensuring writes only flow to one Region at a time. This write mode is helpful when you want to use conditional expressions or transactions, because they won't work unless you know you're acting against the latest data. So using conditional expressions and transactions requires sending all write requests to the one Region with the latest data.

Eventually consistent reads can go to any replica Regions to achieve lower latencies. Strongly consistent reads must go to the single primary region.

It's sometimes necessary to change the active Region in response to a Regional failure, to help with data. [Evacuating a Region with global tables](#) is one example of this use case. Some customers will change the currently active Region on a regular schedule, such as a "follow-the-sun" deployment. This places the active Region near the geography with the most activity, giving it the lowest latency reads and writes. It also has the side benefit of calling the Region-changing code path on a daily basis, making sure it's well tested before any disaster recovery.

The passive Region(s) may keep a downscaled set of infrastructure surrounding DynamoDB that gets built up only should it become the active region. For a more in-depth discussion of pilot light and warm standby designs see [Disaster Recovery \(DR\) Architecture on AWS, Part III: Pilot Light and Warm Standby](#).

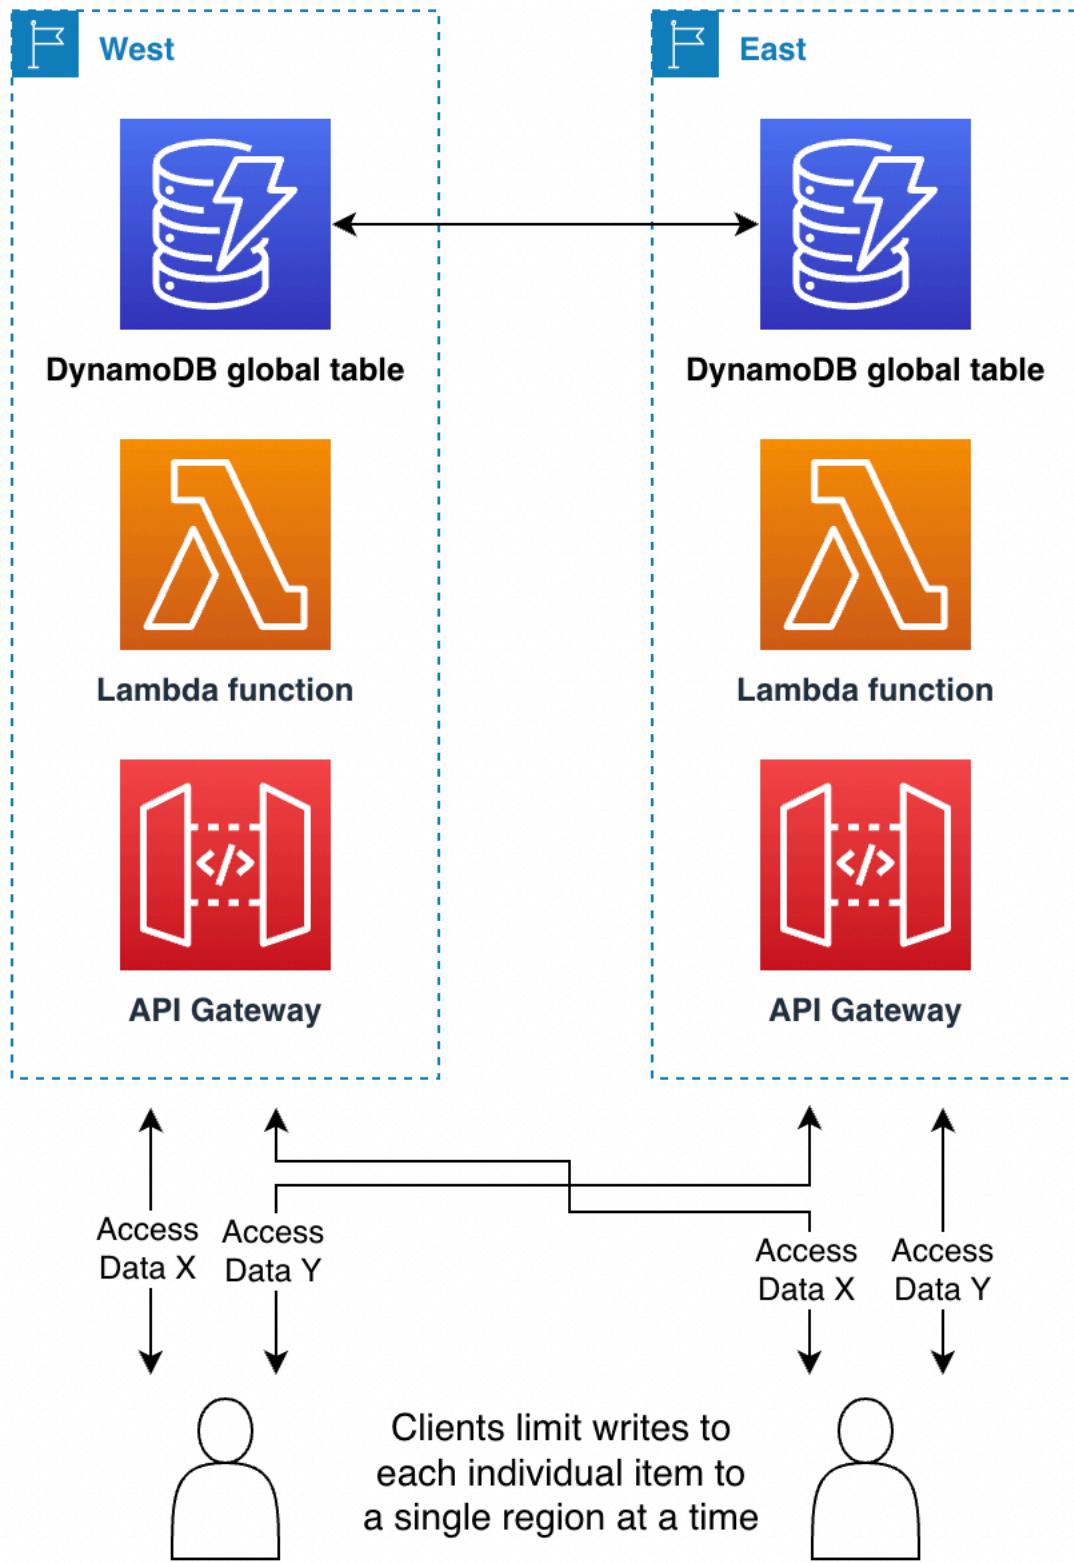

Using the *write to one Region* mode works well when leveraging global tables for low-latency globally distributed reads. For example, a large social media company has millions of users and billions of posts. Each user gets assigned to a Region at time of account creation, placed geographically near to their location. Into that non-global table goes all their data. The company uses a separate global table to hold the mapping of users to their home regions, using a *write to one Region* mode. It keeps read-only copies around the world to help locate each user's data directly with minimum added latency. Updates are rare (only when moving a user's home Region from one to another) and always go through one Region for writing, to avoid any chance of write conflicts.

As another example, consider a financial services customer who implemented a daily cash back calculation. They use *write to any Region* mode for calculating the balance but use *write to one Region* mode for tracking the actual cash back payments. If they want to reward a customer 1 penny for every \$10 spent a day, they will need to Query for all transactions from the previous day, calculate the total spent, write the cash back decision to a new table, delete the queried set of items to mark them as consumed, and replace them with a singular item storing any remainder amount that should go into the next day's calculations. This work requires transactions, and so will work better with the *write to one Region* mode. An application may mix write modes, even on the same table, as long as the workloads have no chance of overlapping.

Mixed primary ("Write to your Region")

The *write to your Region* mode assigns different data subsets to different Regions and allows write operations only to items through its home region. This mode is active-passive but assigns the active Region based on the item. Every Region is primary for its own non-overlapping data set, and writes must be guarded to ensure proper locality.

This mode is similar to *write to one Region* except that it enables lower latency writes, because the data associated with each end user can be placed in closer network proximity to that user. It also spreads the surrounding infrastructure more evenly between Regions and requires less work to build out infrastructure during a failover scenario, because all regions will have a portion of their infrastructure already active.

Determining the home region for items can be done in a variety of ways:

- **Intrinsic:** Some aspect of the data makes clear to what Region it's homed, like its partition key. For example, a customer and all data about that customer would be marked within the customer data as homed to a certain region. This technique is described in [Use Region pinning to set a home Region for items in an Amazon DynamoDB global table](#)
- **Negotiated:** The home region of each data set is negotiated in some external manner, such as with a separate global service that maintains assignments. The assignment may have a finite duration after which it's subject to renegotiation.
- **Table-oriented:** Instead of a single replicating global table, have as many global tables as there are replicating Regions. Each table's name indicates its home Region. In standard operations, all data is written to the home Region while other Regions keep a read-only copy. During a failover, another Region will temporarily adopt write duties for that table.

For example, imagine you're working for a gaming company. You need low latency reads and writes for all gamers around the world. You can home each gamer to the Region closest them. That region takes all their reads and writes, ensuring there's always strong read-after-write consistency. However, if that gamer travels or their home Region suffers an outage, a complete copy of their data will be available in alternative Regions. So the gamer can be assigned to different home Region as is useful.

As another example, imagine you're working at a video conferencing company. Each conference call's metadata gets assigned to a particular Region. Callers can use the Region that's closest to them for lowest latency. If there's a Region outage, using global tables allows quick recovery because the system can move the processing of the call to a different Region where there's already a replicated copy of the data.

Request routing with global tables

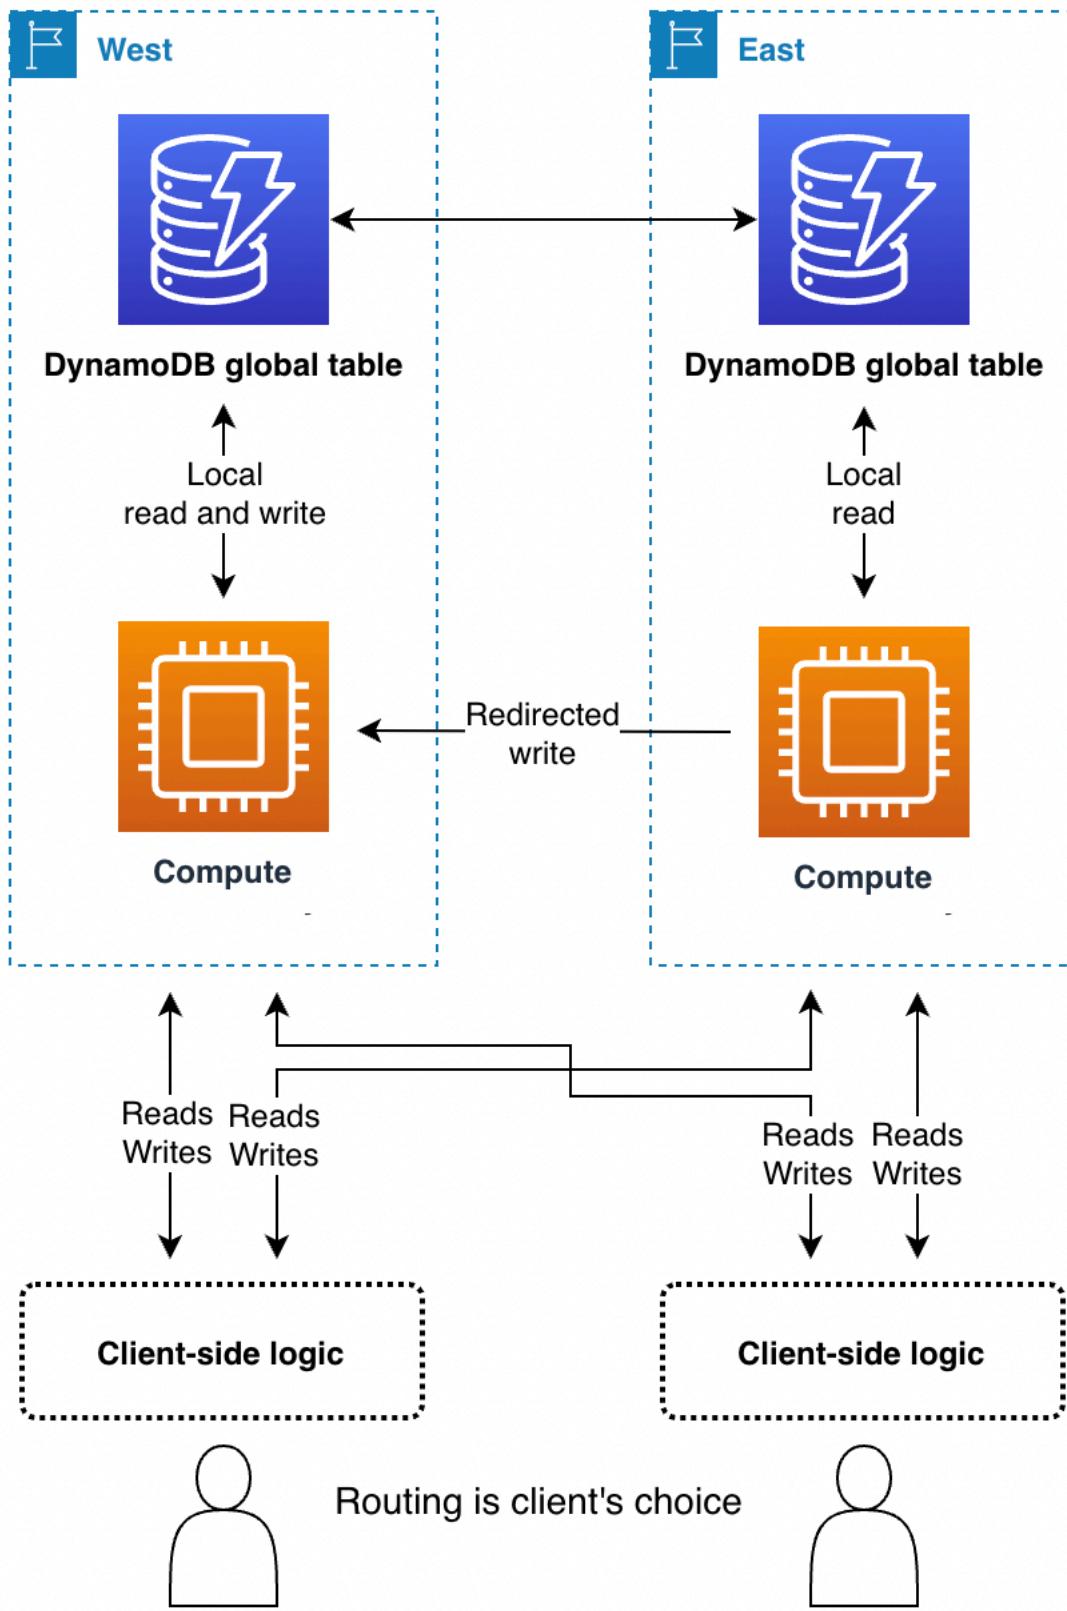

Perhaps the most complex piece of a global table deployment is managing request routing. Requests must first go from an end user to a Region that's chosen and routed in some manner. The request encounters some stack of services in that Region, including a compute layer that perhaps consists of a load balancer backed by an AWS Lambda function, container, or Amazon Elastic Compute Cloud (Amazon EC2) node, and possibly other services including another database. That compute layer communicates with DynamoDB. It should do that by using the local endpoint for that Region. The data in the global table replicates to all other participating Regions, and each Region has a similar stack of services around its DynamoDB table.

The global table provides each stack in the various Regions with a local copy of the same data. You might consider designing for a single stack in a single Region and anticipate making remote calls to a secondary Region's DynamoDB endpoint if there's an issue with the local DynamoDB table. This is not best practice. The latencies associated with going across Regions might be 100 times higher than for local access. A back-and-forth series of 5 requests might take milliseconds when performed locally but seconds when crossing the globe. It's better to route the end user to another Region for processing. To ensure resiliency you need replication across multiple Regions, with replication of the compute layer as well as the data layer.

There are numerous alternative techniques to route an end user request to a Region for processing. The optimum choice depends on your write mode and your failover considerations. This section discusses four options: client-driven, compute-layer, Route 53, and Global Accelerator.

Client-driven request routing

With client-driven request routing, an end user client such as an application, a web page with JavaScript another client will keeps track of the valid application endpoints. In this case that will be application endpoints like an Amazon API Gateway rather than literal DynamoDB endpoints. The end user client uses its own embedded logic to choose which Region to communicate with. It may choose based on random selection, lowest observed latencies, highest observed bandwidth measurements, or locally-performed health checks.

The advantage to client-driven request routing is it can be adaptive to things such as real-world public internet traffic conditions to switch Regions should it notice any degraded performance. The client must be aware of all potential endpoints, but launching a new Regional endpoint is not a frequent occurrence.

With the *write to any Region* mode, a client can unilaterally select its preferred endpoint. If its access to one Region becomes impaired, the client can route to another endpoint.

With the *write to one Region* mode, the client will need a mechanism to route its writes to the currently active region. This could be as basic as empirically testing which region is presently accepting writes (noting any write rejections and falling back to an alternate) or as complex as calling a global coordinator to query for the current application state (perhaps built on the Route 53 Application Recovery Controller (ARC) routing control which provides a 5-region quorum-driven system to maintain global state for needs such as this). The client can decide if reads can go to any Region for eventual consistency or must be routed to the active region for strong consistency. For further information see [How Route 53 works](#).

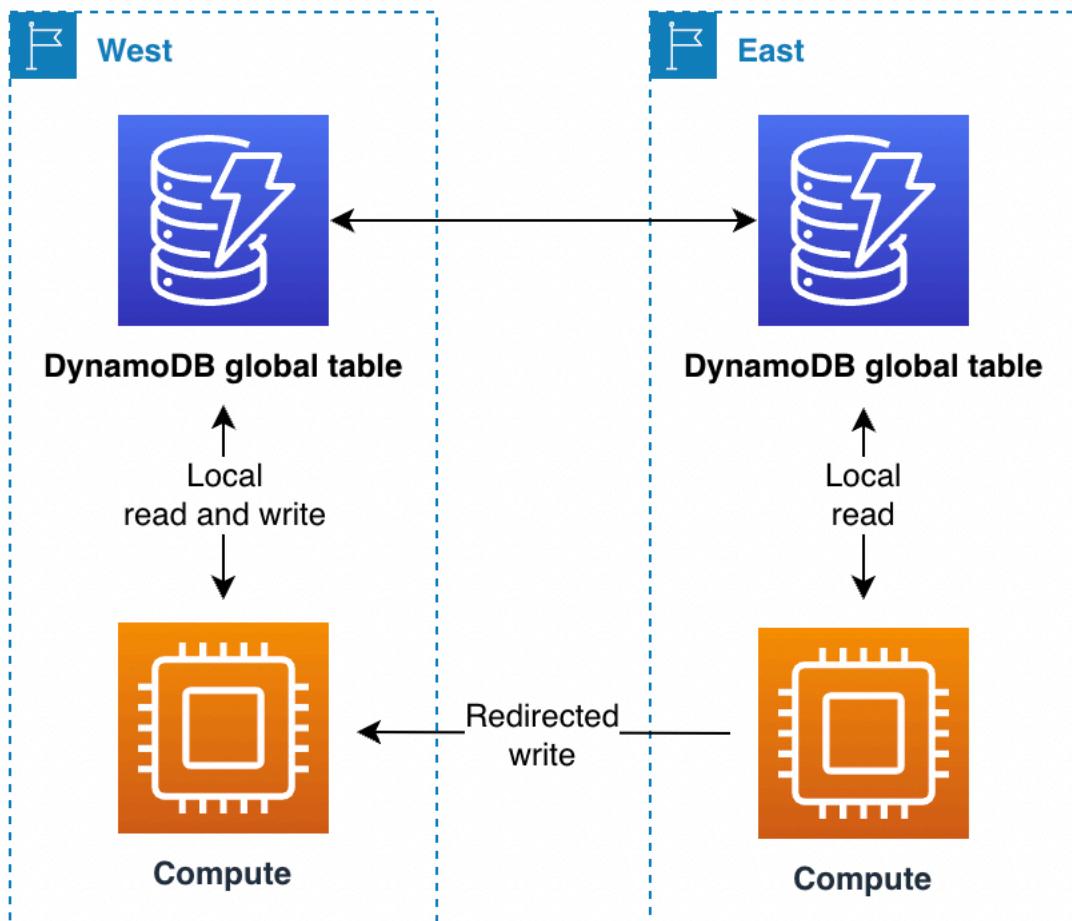

With the *write to your Region* mode, the client needs to determine the home region for the data set it's working against. For example, if the client corresponds to a user account and each user account is homed to a Region, the client can request the appropriate endpoint from a global login system.

For example, a financial services company that helps users manage their business finances via the web could use global tables with a *write to your Region* mode. Each user must login to a central service. That service returns credentials and the endpoint for the Region where those credentials will work. The credentials are valid for a short time. After that the webpage auto-negotiates a new login, which provides an opportunity to potentially redirect the user's activity to a new Region.

Compute-layer request routing

With compute-layer request routing, the code running in the compute layer decides whether it wants to process the request locally, or pass it to a copy of itself that's running in another Region. When you use the *write to one Region* mode, the compute layer may detect that it's not the active region and allow local read operations while forwarding all write operations onto another Region. This compute layer code must be aware of data topology and routing rules, and enforce them reliably based on the latest settings that specify which Regions are active for which data. The outer software stack within the Region doesn't have to be aware of how read and write requests are routed by the microservice. In a robust design, the receiving Region validates whether it is the current primary for the write operation. If it isn't, it generates an error that indicates that the

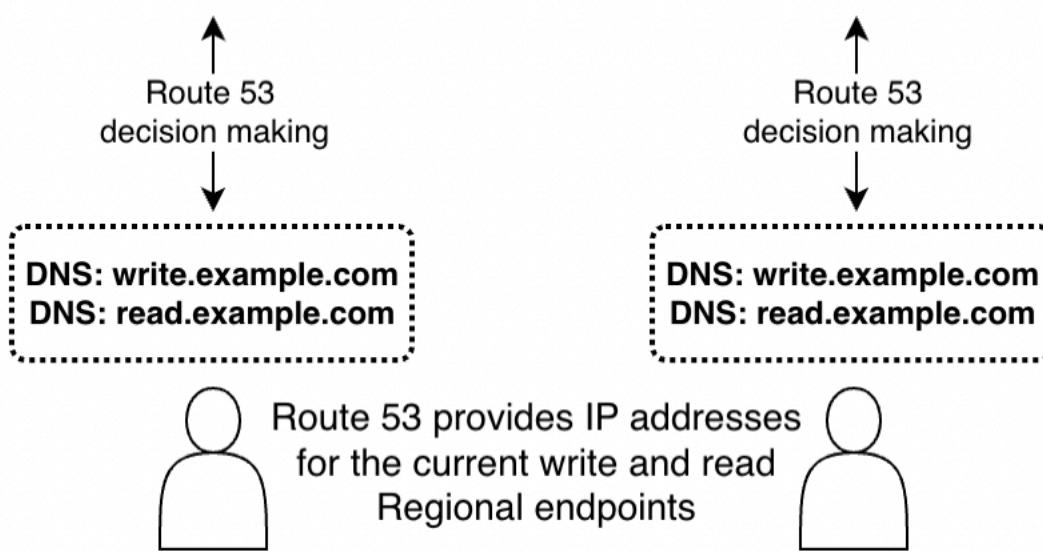

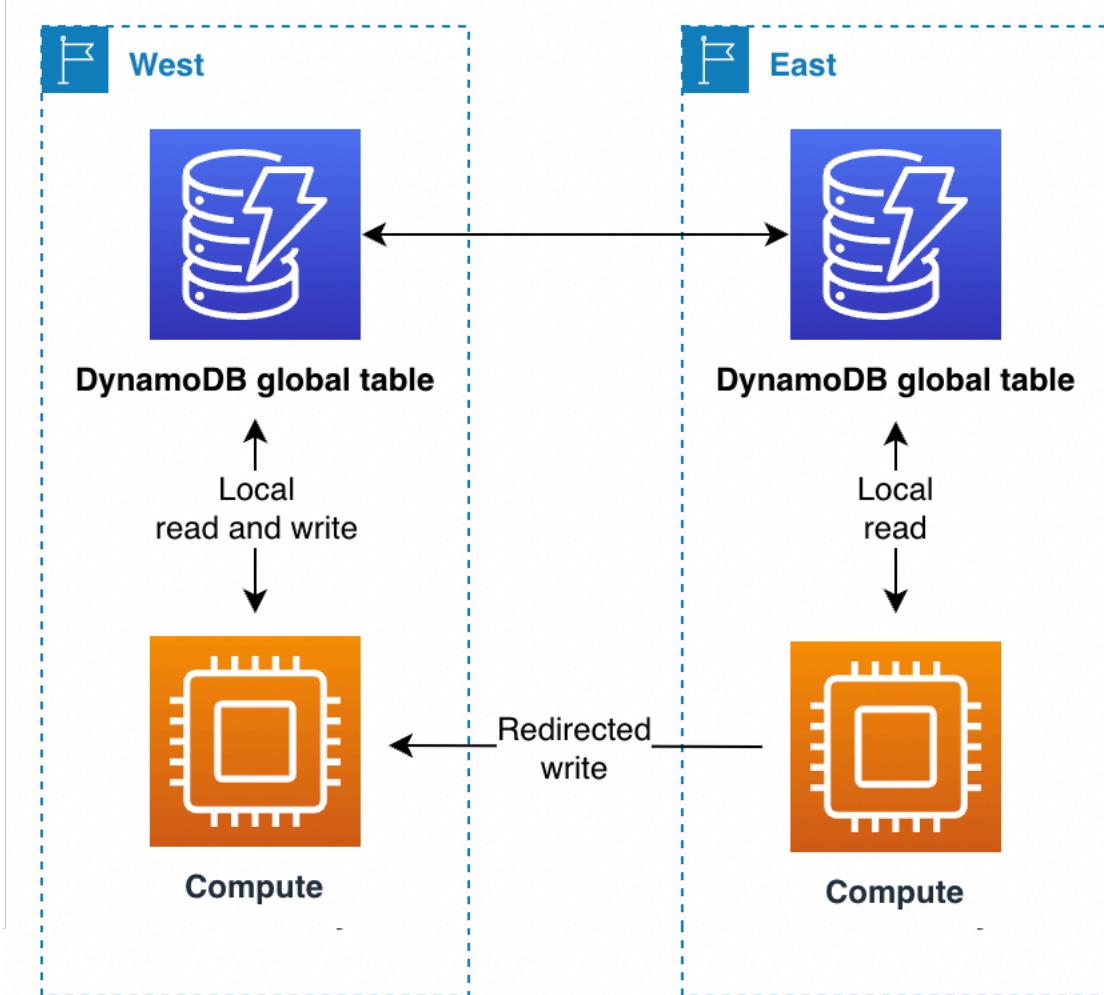

global state needs to be corrected. The receiving Region might also buffer the write operation for a while if the primary Region is in the process of changing. In all cases, the compute stack in a Region writes only to its local DynamoDB endpoint, but the compute stacks might communicate with one another.

In this scenario, let's say a financial services company uses a follow-the-sun Single Primary model. They use a system and a library for this routing process. Their overall system maintains the global state, similar to AWS's Route 53 ARC routing control. They use a global table to track which Region is the primary Region, and when the next primary switch is scheduled. All read and write operations go through the library, which coordinates with their system. The library allows read operations to be performed locally, at low latency. For write operations, the application checks if the local Region is the current primary Region. If so, the write operation completes directly. If not, the library forwards the write task to the library that's in the current primary Region. That receiving library confirms that it also considers itself the primary Region and raises an error if it isn't, which indicates a propagation delay with the global state. This approach provides a validation benefit by not writing directly to a remote DynamoDB endpoint.

Route 53 request routing

Amazon Route 53 Application Recovery Controller is a Domain Name Service (DNS) technology. With Route 53, the client requests its endpoint by looking up a well-known DNS domain name, and Route 53 returns the IP address corresponding to the regional endpoint(s) it thinks most appropriate. Route 53 has a [list of routing policies it uses to determine the appropriate region](#). Route 53 also can do [failover routing to route traffic away from regions that fail health checks](#).

- With *write to any Region* mode, or if combined with the compute-layer request routing on the backend, Route 53 can be given full access to return the Region based on any complex internal rules such as the Region in closest network proximity, or closest geographic proximity, or any other choice.
- With *write to one Region* mode, Route 53 can be configured to return the currently active region (using Route 53 ARC).

 **Note**

Clients cache the IP addresses in the response from Route 53 for a time indicated by the time to live (TTL) setting on the domain name. A longer TTL extends the recovery time objective (RTO) for all clients to recognize the new endpoint. A value of 60 seconds is typical for failover use. Not all software perfectly adheres to DNS TTL expiration.

- With *write to your Region* mode, it's best to avoid Route 53 unless you're also using compute-layer request routing.

Global Accelerator request routing

A client uses [AWS Global Accelerator](#) to looks up the well-known domain name in Route 53. However, instead of getting back an IP address that corresponds to a regional endpoint the client receives an anycast static IP address which routes to the nearest AWS edge location. Starting from that edge location, all traffic gets routed on the private AWS network and to some endpoint (such as a load balancer or API Gateway) in a Region chosen by routing rules that are maintained within Global Accelerator. Compared with routing based on Route 53 rules, Global Accelerator request routing has lower latencies because it reduces the amount of traffic on the public internet. In addition, because Global Accelerator doesn't depend on DNS TTL expiration to change routing rules it can adjust routing more quickly.

- With *write to any Region* mode, or if combined with the compute-layer request routing on the back-end, Global Accelerator works seamlessly. The client connects to the nearest edge location and need not be concerned with which Region receives the request.
- With *write to one Region* Global Accelerator routing rules must send requests to the currently active Region. You can use health checks that artificially report a failure on any Region that's not considered by your global system to be the active Region. As with DNS, it's possible to use an alternative DNS domain name for routing read requests if the requests can be from any Region.
- With *write to your Region* mode, it's best to avoid Global Accelerator unless you're also using compute-layer request routing.

Evacuating a Region with global tables

Evacuating a Region is the process of migrating read and write activity away from that Region. This is most often write activity, and sometimes read activity.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons. The evacuation could be part of usual business activity such as if you're using a follow-the-sun write to one Region mode. The evacuation could also be due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to the alternative Regions through any routing system, and let the write operations that have already occurred in the evacuated Region replicate as usual.

With *write to one Region* and *write to your Region* modes, you must make sure all writes to the active Region have been fully recorded, stream processed, and globally propagated before starting writes in the new active Region. This is necessary to ensure that future writes are against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is

no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: what if Region A went fully offline without notice? This is extremely unlikely, but is still prudent to consider. If this happens, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, reads and writes can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the *last writer wins* conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine you need to maintain an available credit balance without interruption even after Region failure. You could split the balance into two different items, one homed in Region A and one in Region B, each starting with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the balance portion held in Region B. Splitting

the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine you're capturing web form data. You can use [Optimistic Concurrency Control \(OCC\)](#) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data.

Let's imagine that you're using the timestamp as the version. Let's say that the form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).

As a final example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they wanted to make sure that any write activity related to their accounts was either fully available in Region B, or wanted to quarantine their accounts as known partial until Region A came back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, which we will call Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B.

If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher

latency writes (to two Regions: C and then A) and was fortunate to have a data model where the state of an account could be succinctly summarized.

Throughput capacity planning for global tables

Migrating traffic from one Region to another requires careful consideration of DynamoDB table settings regarding capacity.

Some considerations on managing write capacity:

- A global table must be in on-demand mode or provisioned with auto scaling enabled.
- If provisioned with auto scaling, the write settings (minimum, maximum, and target utilization) are replicated across Regions. Although the auto scaling settings are synchronized, the actual provisioned write capacity might float independently between Regions.
- One reason you might see different provisioned write capacity is due to the TTL feature. When you enable TTL in DynamoDB, you can specify an attribute name whose value indicates the time of expiration for the item, in Unix epoch time format in seconds. After that time, DynamoDB can delete the item without incurring write costs. With global tables, you can configure TTL in any Region, and the setting is automatically replicated to other Regions that are associated with the global table. When an item is eligible for deletion through a TTL rule, that work can be done in any Region. The delete operation is performed without consuming write units on the source table, but the replica tables will get a replicated write of that delete operation and will incur replicated write unit costs.
- If you're using auto scaling, make sure that the maximum provisioned write capacity setting is sufficiently high to handle all write operations as well as all potential TTL delete operations. Auto scaling adjusts each Region according to its write consumption. On-demand tables have no maximum provisioned write capacity setting, but the *table-level maximum write throughput limit* specifies the maximum sustained write capacity the on-demand table will allow. The default limit is 40,000, but it is adjustable. We recommend that you set it high enough to handle all write operations (including TTL write operations) that the on-demand table might need. This value must be the same across all participating Regions when you set up global tables.

Some considerations on managing read capacity:

- Read capacity management settings are allowed to differ between Regions because it's assumed that different Regions might have independent read patterns. When you first add a global replica

to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity settings, which aren't transferred to the other side.

- When you use DynamoDB auto scaling, make sure that the maximum provisioned read capacity settings are sufficiently high to handle all read operations across all Regions. During standard operations the read capacity will perhaps be spread across Regions, but during failover the table should be able to automatically adapt to the increased read workload. On-demand tables have no maximum provisioned read capacity setting, but the *table-level maximum read throughput limit* specifies the maximum sustained read capacity the on-demand table will allow. The default limit is 40,000, but it is adjustable. We recommend that you set it high enough to handle all read operations that the table might need if all read operations were to route to this single Region.
- If a table in one Region doesn't usually receive read traffic but might have to absorb a large amount of read traffic after a failover, you can raise the provisioned read capacity of the table, wait for the table to finish updating, and then provision the table down again. You can either leave the table in provisioned mode or switch it to on-demand mode. This pre-warms the table for accepting a higher level of read traffic.

Route 53 ARC has [readiness checks](#) that can be useful for confirming that DynamoDB Regions have similar table settings and account quotas, whether or not you use Route 53 to route requests. These readiness checks can also help in adjusting account-level quotas to make sure they match.

Preparation checklist for global tables and Frequently Asked Questions

Use the following checklist for decisions and tasks when you deploy global tables.

- Determine how many and which Regions should participate in the global table.
- Determine your application's write mode. For more information, see [Write modes with global tables](#).
- Plan your [Request routing with global tables](#) strategy, based on your write mode.
- Define your

Evacuating a Region is the process of migrating read and write activity away from that Region. This is most often write activity, and sometimes read activity.

Evacuating a live Region

You might decide to evacuate a live Region for a number of reasons. The evacuation could be part of usual business activity such as if you're using a follow-the-sun write to one Region mode. The evacuation could also be due to a business decision to change the currently active Region, in response to failures in the software stack outside DynamoDB, or because you're encountering general issues such as higher than usual latencies within the Region.

With *write to any Region* mode, evacuating a live Region is straightforward. You can route traffic to the alternative Regions through any routing system, and let the write operations that have already occurred in the evacuated Region replicate as usual.

With *write to one Region* and *write to your Region* modes, you must make sure all writes to the active Region have been fully recorded, stream processed, and globally propagated before starting writes in the new active Region. This is necessary to ensure that future writes are against the latest version of the data.

Let's say that Region A is active and Region B is passive (either for the full table or for items that are homed in Region A). The typical mechanism to perform an evacuation is to pause write operations to A, wait long enough for those operations to have fully propagated to B, update the architecture stack to recognize B as active, and then resume write operations to B. There is no metric to indicate with absolute certainty that Region A has fully replicated its data to Region B. If Region A is healthy, pausing write operations to Region A and waiting 10 times the recent maximum value of the `ReplicationLatency` metric would typically be sufficient to determine that replication is complete. If Region A is unhealthy and shows other areas of increased latencies, you would choose a larger multiple for the wait time.

Evacuating an offline Region

There's a special case to consider: what if Region A went fully offline without notice? This is extremely unlikely, but is still prudent to consider. If this happens, any write operations in Region A that were not yet propagated are held and propagated after Region A comes back online. The write operations aren't lost, but their propagation is indefinitely delayed.

How to proceed in this event is the application's decision. For business continuity, write operations might need to proceed to the new primary Region B. However, if an item in Region B receives an update while there is a pending propagation of a write operation for that item

from Region A, the propagation is suppressed under the *last writer wins* model. Any update in Region B might suppress an incoming write request.

With the *write to any Region* mode, reads and writes can continue in Region B, trusting that the items in Region A will propagate to Region B eventually and recognizing the potential for missing items until Region A comes back online. When possible, you should consider replaying recent write traffic (for example, by using an upstream event source) to fill in the gap of any potentially missing write operations and let the *last writer wins* conflict resolution suppress the eventual propagation of the incoming write operation.

With the other write modes, you have to consider the degree to which work can continue with a slightly out-of-date view of the world. Some small duration of write operations, as tracked by `ReplicationLatency`, will be missing until Region A comes back online. Can business move forward? In some use cases it can, but in others it might not without additional mitigation mechanisms.

For example, imagine you need to maintain an available credit balance without interruption even after Region failure. You could split the balance into two different items, one homed in Region A and one in Region B, each starting with half the available balance. This would use the *write to your Region* mode. Transactional updates processed in each Region would write against the local copy of the balance. If Region A goes fully offline, work could still proceed with transaction processing in Region B, and write operations would be limited to the balance portion held in Region B. Splitting the balance like this introduces complexities when the balance gets low or the credit has to be rebalanced, but it does provide one example of safe business recovery even with uncertain pending write operations.

As another example, imagine you're capturing web form data. You can use [Optimistic Concurrency Control \(OCC\)](#) to assign versions to data items and embed the latest version into the web form as a hidden field. On each submit, the write operation succeeds only if the version in the database still matches the version that the form was built against. If the versions don't match, the web form can be refreshed (or carefully merged) based on the current version in the database, and the user can proceed again. The OCC model usually protects against another client overwriting and producing a new version of the data, but it can also help during failover where a client might encounter older versions of data.

Let's imagine that you're using the timestamp as the version. Let's say that the form was first built against Region A at 12:00 but (after failover) tries to write to Region B and notices that the latest version in the database is 11:59. In this scenario, the client can either wait for

the 12:00 version to propagate to Region B and then write on top of that version, or build on 11:59 and create a new 12:01 version (which, after writing, would suppress the incoming version after Region A recovers).

As a final example, a financial services company holds data about customer accounts and their financial transactions in a DynamoDB database. In the event of a complete Region A outage, they wanted to make sure that any write activity related to their accounts was either fully available in Region B, or wanted to quarantine their accounts as known partial until Region A came back online. Instead of pausing all business, they decided to pause business only to the tiny fraction of accounts that they determined had unpropagated transactions. To achieve this, they used a third Region, which we will call Region C. Before they processed any write operations in Region A, they placed a succinct summary of those pending operations (for example, a new transaction count for an account) in Region C. This summary was sufficient for Region B to determine if its view was fully up to date. This action effectively locked the account from the time of writing in Region C until Region A accepted the write operations and Region B received them. The data in Region C wasn't used except as part of a failover process, after which Region B could cross-check its data with Region C to check if any of its accounts were out of date. Those accounts would be marked as quarantined until the Region A recovery propagated the partial data to Region B.

If Region C were to fail, a new Region D could be spun up for use instead. The data in Region C was very transient, and after a few minutes Region D would have a sufficiently up-to-date record of the in-flight write operations to be fully useful. If Region B were to fail, Region A could continue accepting write requests in cooperation with Region C. This company was willing to accept higher latency writes (to two Regions: C and then A) and was fortunate to have a data model where the state of an account could be succinctly summarized.

evacuation plan, based on your write mode and routing strategy.

- Capture metrics on the health, latency, and errors across each Region. For a list of DynamoDB metrics, see the AWS blog post [Monitoring Amazon DynamoDB for Operational Awareness](#) for a list of metrics to observe. You should also use [synthetic canaries](#) (artificial requests designed to detect failures, named after the canary in the coal mine), as well as live observation of customer traffic. Not all issues will appear in the DynamoDB metrics.
- Set alarms for any sustained increase in ReplicationLatency. An increase might indicate an accidental misconfiguration in which the global table has different write settings in different Regions, which leads to failed replicated requests and increased latencies. It could also indicate that there is a Regional disruption. A [good example](#) is to generate an alert if the recent average

exceeds 180,000 milliseconds. You might also watch for `ReplicationLatency` dropping to 0, which indicates stalled replication. .

- Assign sufficient maximum read and write settings for each global table.
- Identify the reasons for evacuating a Region in advance. If the decision involves human judgment, document all considerations. This work should be done carefully in advance, not under stress.
- Maintain a runbook for every action that must take place when you evacuate a Region. Usually very little work is involved for the global tables, but moving the rest of the stack might be complex.

 **Note**

It's best practice to rely only on data plane operations and not control plane operations because some control plane operations may be degraded during region failures.

For more information, see the AWS blog post [Build resilient applications with Amazon DynamoDB global tables: Part 4](#).

- Test all aspects of the runbook periodically, including Region evacuations. An untested runbook is an unreliable runbook.
- Consider using Resilience Hub to evaluate the resilience of your entire application (including global tables). It provides a comprehensive view of your overall application portfolio resilience status through its dashboard.
- Consider using Route 53 ARC readiness checks to evaluate the current configuration of your application and track any deviances from best practices.
- When writing a health check for use with Route 53 or Global Accelerator, it's not sufficient to just ping that the DynamoDB endpoint is up. That doesn't cover the many failure modes such as IAM configuration errors, code deployment problems, failure in the stack outside DynamoDB, higher than average read or write latencies, and so on. It's best to perform a set of calls that exercise a full database flow.

Frequently Asked Questions (FAQ) for deploying global tables

What are some useful principles for overall usage of DynamoDB global tables?

DynamoDB global tables has very few control knobs yet still requires a number of considerations. You must determine your write mode, routing model, and evacuation processes. You must instrument your application across every Region and be ready to adjust your routing or perform an evacuation to maintain global health. The reward is having a globally distributed data set with low-latency reads and writes and a 99.999% service level agreement.

What is the pricing for global tables?

A write to a traditional DynamoDB table is priced in Write Capacity Units (WCUs, for provisioned tables) or Write Request Units (WRUs, for on-demand tables). If you write a 5 KB item it incurs a charge of 5 units. A write to a global table is priced in Replicated Write Capacity Units (rWCUs, for provisioned tables) or Replicated Write Request Units (rWRUs, for on-demand tables).

The rWCUs and rWRUs include the cost of the streaming infrastructure needed to manage the replication. As such, they are priced 50% higher than WCUs and WRUs. Cross-Region data transfer fees do apply.

Replicated Write Unit charges are incurred in every Region where the item is directly written or replicate written.

Writing to a Global Secondary Index (GSI) is considered a local write and uses regular Write Units.

There is no Reserved Capacity available for rWCUs at this time. Purchasing Reserved Capacity may still be beneficial for tables with GSIs consuming write units.

The initial bootstrap when adding a new Region to a global table is charged like a restore per GB of data restored, plus cross-Region data transfer fees.

Which Regions does global tables support?

[Global Tables version 2019.11.21 \(Current\)](#) is available in most Regions. You can see the most recent list in the Region dropdown list on the DynamoDB console when you add a replica.

How are GSIs handled with global tables?

In [Global Tables version 2019.11.21 \(Current\)](#), when you create a GSI in one Region it's automatically created in other participating Regions and automatically backfilled.

How do I stop replication of a global table?

You can delete a replica table the same way you would delete any other table. Deleting the global table stops replication to that Region and deletes the table copy kept in that Region. However,

you cannot stop replication while keeping copies of the table as independent entities, nor can you pause replication.

How do DynamoDB Streams interact with global tables?

Each global table produces an independent stream based on all its writes, wherever they started from. You can choose to consume the DynamoDB stream in one Region or in all Regions (independently). If you want to process local but not replicated write operations, you can add your own Region attribute to each item to identify the writing Region. You can then use a Lambda event filter to call the Lambda function only for write operations in the local Region. This helps with insert and update operations, but unfortunately not delete operations.

How do global tables handle transactions?

Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the Region where the write operation originally occurred. Transactions are not supported across Regions in global tables. For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a `TransactWriteItems` operation in the US East (Ohio) Region, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

How do global tables interact with the DynamoDB Accelerator cache (DAX)?

Global tables bypass DAX by updating DynamoDB directly, so DAX isn't aware that it's holding stale data. The DAX cache is refreshed only when the cache's TTL expires.

Do tags on tables propagate?

No, tags do not automatically propagate.

Should I backup tables in all Regions or just one?

The answer depends on the purpose of the backup. If you want to ensure data durability, DynamoDB already provides that safeguard. The service ensures durability. If you want to keep a snapshot for historical records (for example, to meet regulatory requirements), backing up in one Region should suffice. You can copy the backup to additional Regions by using AWS Backup. If you want to recover erroneously deleted or modified data, use [DynamoDB point-in-time recovery \(PITR\)](#) in one Region.

How do I deploy global tables using AWS CloudFormation?

CloudFormation represents a DynamoDB table and a global table as two separate resources: AWS::DynamoDB::Table and AWS::DynamoDB::GlobalTable. One approach is to create all tables that can potentially be global by using the GlobalTable construct. You can then keep them as standalone tables initially, and add Regions later if needed.

In CloudFormation, each global table is controlled by a single stack, in a single Region, regardless of the number of replicas. When you deploy your template, CloudFormation creates and updates all replicas as part of a single stack operation. You should not deploy the same [AWS::DynamoDB::GlobalTable](#) resource in multiple Regions. This will result in errors and is unsupported. If you deploy your application template in multiple Regions, you can use conditions to create the AWS::DynamoDB::GlobalTable resource in a single Region. Alternatively, you can choose to define your AWS::DynamoDB::GlobalTable resources in a stack that's separate from your application stack, and make sure that it's deployed to a single Region.

If you have a regular table and you want to convert it to a global table while keeping it managed by CloudFormation then set the deletion policy to Retain, remove the table from the stack, convert the table to a global table in the console, and then import the global table as a new resource to the stack.

Cross-account replication is not supported at this time.

Best practices for managing the control plane in DynamoDB

Note

DynamoDB is introducing a control plane throttle limit of 2,500 requests per second with the option for a retry. See below for additional details.

DynamoDB control plane operations let you manage DynamoDB tables as well as objects that are dependent on tables such as indexes. For more information about these operations, see [Control plane](#).

In some circumstances, you may need to take actions and use data returned by control plane calls as part of your business logic. For example, you might need to know the value of ProvisionedThroughput returned by `DescribeTable`. In these circumstances, follow these best practices:

- Do not excessively query the DynamoDB control plane.

- Do not mix control plane calls and data plane calls within the same code.
- Handle throttles on control plane requests and retry with a backoff.
- Invoke and track changes to a particular resource from a single client.
- Instead of retrieving data for the same table multiple times at short intervals, cache the data for processing.

Best Practices for Understanding your AWS Billing and Usage Reports

This document explains the `UsageType` billing codes for charges related to DynamoDB.

AWS provides cost and usage reports (CUR) that contain data for the services used. You can use AWS Cost and Usage Report to publish billing reports to Amazon S3 in a CSV format. When setting up the CUR you can choose to break time periods down by hour, day, or month, and you can choose if you want to break out usage by resource ID or not. For more details on generating CUR, please see [Creating Cost and Usage Reports](#)

Within the CSV export, you will find relevant attributes listed for each line. The following are examples of attributes that may be included:

- **lineitem/UsageStartDate:** The start date and time for the line item in UTC, inclusive.
- **lineitem/UsageEndDate:** The end date and time for the corresponding line item in UTC, exclusive.
- **lineitem/ProductCode:** For DynamoDB this will be "AmazonDynamoDB"
- **lineitem/UsageType:** A specific description code for the type of usage, as enumerated in this document
- **lineitem/Operation:** A name that provides context to the charge such as the operation name that incurred the charge (optional).
- **lineitem/ResourceId:** The identifier for the resource that incurred the usage. Available if the CUR includes a breakdown by resource ID.
- **lineitem/UsageAmount:** The amount of usage incurred during the specified time period.
- **lineitem/UnblendedCost:** The cost of this usage.
- **lineitem/LineItemDescription:** Textual description of the line item.

For more information about the CUR data dictionary, see [Cost and Usage Report \(CUR\) 2.0](#). Note that the exact names vary depending on context.

A UsageType is a string with a value such as ReadCapacityUnit-Hrs, USW2-ReadRequestUnits, EU-WriteCapacityUnit-Hrs, or USE1-TimedPITRStorage-ByteHrs. Each usage type begins with an optional Region prefix. If absent, that indicates the us-east-1 Region. If present, the below table maps the short billing Region code to the conventional Region code and name.

For example, the usage named USW2-ReadRequestUnits indicates read request units consumed in us-west-2.

Billing Region Code	Region Code	Region Name
AFS1	af-south-1	Africa (Cape Town)
APE1	ap-east-1	Asia Pacific (Hong Kong)
APN1	ap-northeast-1	Asia Pacific (Tokyo)
APN2	ap-northeast-2	Asia Pacific (Seoul)
APN3	ap-northeast-3	Asia Pacific (Osaka)
APS1	ap-south-1	Asia Pacific (Mumbai)
APS2	ap-south-2	Asia Pacific (Hyderabad)
APS3	ap-southeast-1	Asia Pacific (Singapore)
APS4	ap-southeast-2	Asia Pacific (Sydney)
APS5	ap-southeast-3	Asia Pacific (Jakarta)
APS6	ap-southeast-4	Asia Pacific (Melbourne)
CAN1	ca-central-1	Canada (Central)
EU	eu-central-1	Europe (Frankfurt)
EUC1	eu-central-2	Europe (Zurich)

Billing Region Code	Region Code	Region Name
EUN1	eu-north-1	Europe (Stockholm)
EUS1	eu-south-1	Europe (Milan)
EUS2	eu-south-2	Europe (Spain)
EUW1	eu-west-1	Europe (Ireland)
EUW2	eu-west-2	Europe (London)
EUW3	eu-west-3	Europe (Paris)
ILC1	il-central-1	Israel (Tel Aviv)
MEC1	me-central-1	Middle East (UAE)
MES1	me-south-1	Middle East (Bahrain)
SAE1	sa-east-1	South America (São Paulo)
USE1 (default)	us-east-1	US East (N. Virginia)
USE2	us-east-2	US East (Ohio)
UGE1	us-gov-east-1	US Government East
UGW1	us-gov-west-1	US Government West
USW1	us-west-1	US West (N. California)
USW2	us-west-2	US West (Oregon)

In the following sections, we use REG-UsageType pattern when going through the charges for DynamoDB, where REG specifies the region where usage occurred and usageType is the code for the type of charge. For example if you see a line item for USW1- ReadCapacityUnit-Hrs in your CSV file, that means the usage was incurred in US-West-1 for provisioned read capacity. In that case the listing would say REG-ReadCapacityUnit-Hrs.

Topics

- [DynamoDB Accelerator \(DAX\)](#)

Throughput Capacity

Provisioned Capacity Reads and Writes

When you create a DynamoDB table in provisioned capacity mode, you specify the read and write capacity that you expect your application to require. The usage type depends on your table class (Standard or Standard-Infrequent Access). You provision read and writes based on consumption rate per second, but the charges are priced per hour based on provisioned capacity.

UsageType	Units	Granularity	Description
REG-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard table class.
REG-IA-ReadCapacityUnit-Hrs	RCU-hours	Hour	Charges for reads in provisioned capacity mode using the Standard-IA table class.
REG-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity mode using the Standard table class.
REG-IA-WriteCapacityUnit-Hrs	WCU-hours	Hour	Charges for writes in provisioned capacity

UsageType	Units	Granularity	Description
			mode using the Standard-IA table class.

Reserved Capacity Reads and Writes

With reserved capacity, you pay a one-time upfront fee and commit to a minimum provisioned usage level over a period of time. Reserved capacity is billed at a discounted hourly rate. Any capacity that you provision in excess of your reserved capacity is billed at standard provisioned capacity rates. Reserved capacity is available for single-region, provisioned read and write capacity units (RCU and WCU) on DynamoDB tables that use the standard table class. Both 1-year and 3-year reserved capacity are billed using the same SKUs.

UsageType	Units	Granularity	Description
REG-HeavyUsage:dynamodb.read	RCU-hours	Up-front then monthly	Charges for reserved capacity reads: a one-time up-front charge and a monthly charge at the start of each month covering all the discounted committed RCU-hours during the month. Will have matching zero-cost REG-ReadCapacityUnit-Hrs line items.
REG-HeavyUsage:dynamodb.write	WCUs	Up-front then monthly	Charges for reserved capacity writes: a one-time up-front charge and a monthly charge at the start of each month covering

UsageType	Units	Granularity	Description
			all the discounted committed WCU-hours during the month. Will have matching zero-cost REG-WriteCapacityUnit-Hrs line items.

On-Demand Capacity Reads and Writes

When you create a DynamoDB table in on-demand capacity mode, you pay only for the reads and writes your application performs. The prices for read and write requests depend on your table class.

UsageType	Units	Granularity	Description
REG-ReadRequestUnits	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard table class.
REG-IA-ReadRequest Units	RRUs	Unit	Charges for reads in on-demand capacity mode with Standard-IA table class.
REG-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity mode with Standard table class.
REG-IA-WriteRequestUnits	WRUs	Unit	Charges for writes in on-demand capacity mode with Standard-IA table class.

Global Tables Reads and Writes

DynamoDB charges for global tables usage based on the resources used on each replica table. For provisioned global tables, write requests for global tables are measured in replicated WCUs (rWCUs) instead of standard WCUs and writes to global secondary indexes in global tables are measured in WCUs. For on-demand global tables, write requests are measured in replicated WRUs (rWRUs) instead of standard WRUs. The number of rWCUs or rWRUs consumed for replication depends on the version of global tables you are using. The pricing depends on your table class.

Writes to global secondary indexes (GSIs) are billed using standard write units (WCUs and WRUs). Read requests and data storage are billed identically to single-region tables.

If you add a table replica to create or extend a global table in new Regions, DynamoDB charges for a table restore in the added Regions per gigabyte of data restored. Restored Data is charged as REG-RestoreContentSize-Bytes. Please refer to [Using On-Demand backup and restore for DynamoDB](#) for details. Cross-Region replication and adding replicas to tables that contain data also incur charges for data transfer out.

When you select on-demand capacity mode for your DynamoDB global tables, you pay only for the resources your application uses on each replica table.

UsageType	Units	Granularity	Description
REG-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned, Standard table class.
REG-IA-ReplWriteCapacityUnit-Hrs	rWCU-hours	Hour	Global table, provisioned, Standard-IA table class.
REG-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard table class.
REG-IA-ReplWriteRequestUnits	rWRU	Unit	Global table, on-demand, Standard- IA table class

Streams

DynamoDB has two streaming technologies, DynamoDB Streams and Kinesis. Each have separate pricing.

DynamoDB Streams charges for reading data in read request units. Each GetRecords API call is billed as a streams read request. You are not charged for GetRecords API calls invoked by AWS Lambda as part of DynamoDB triggers or by DynamoDB global tables as part of replication.

UsageType	Units	Granularity	Description
REG-Streams-RequestsCount	Count	Unit	Read request units for DynamoDB Streams.

Amazon Kinesis Data Streams charges in change data capture units. DynamoDB charges one change data capture unit for each write (up to 1 KB). For items larger than 1 KB, additional change data capture units are required. You pay only for the writes your application performs without having to manage throughput capacity on the table.

UsageType	Units	Granularity	Description
REG-ChangeDataCaptureUnits-Kinesis	CDC Units	Unit	Change data capture units for Kinesis Data Streams.

Storage

DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled.

Note

Storage usage values in the CUR will be higher compared with the storage values when using `DescribeTable`, because `DescribeTable` does not include the per-item storage overhead.

Storage is calculated hourly but priced monthly as calculated from an average of the hourly charges.

Although the storage UsageType uses ByteHrs as a suffix, storage usage in the CUR is measured in GB and priced by GB-month.

UsageType	Units	Granularity	Description
REG-TimedStorage-B yteHrs	GB	Month	Amount of storage used by your DynamoDB tables and indexes, for tables with the Standard table class.
REG-IA-TimedStorage- ByteHrs	GB	Month	Amount of storage used by your DynamoDB tables and indexes, for tables with the Standard-IA table class.

Backup and Restore

DynamoDB offers two types of backups: Point In Time Recovery (PITR) backups and on-demand backups. Users can also restore from those backups into DynamoDB tables. The charges below refers to both backups and restores.

Backup storage charges are incurred on the first of the month with adjustments made throughout the month as backups are added or removed. See the [Understanding Amazon DynamoDB On-demand Backups and Billing](#) blog for more information

UsageType	Units	Granularity	Description
REG-TimedBackupStorage-ByteHrs	GB	Month	The storage consumed by on-

UsageType	Units	Granularity	Description
			demand backups of your DynamoDB tables and Local Secondary Indexes.
TimedPITRStorage-ByteHrs	GB	Month	The storage used by point-in-time recovery (PITR) backups. DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges and bills for storage as long as PITR is enabled.
REG-RestoreDataSize-Bytes	GB	Size	The total size of data restored (including table data, local secondary indexes and global secondary indexes) measured in GB from DynamoDB backups.

AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud as well as on premises. AWS Backup is charged for storage (warm or cold storage), restoration activities, and cross-Region data transfer. The following UsageType charges appear under the "AWSBackup" ProductCode rather than "AmazonDynamoDB".

UsageType	Units	Granularity	Description
REG-WarmStorage-ByteHrs-DynamoDB	GB	Month	The storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.
REG-CrossRegion-WarmBytes-DynamoDB	GB	Size	The data transferred to a different AWS Region either within the same account or to a different AWS account. Cross-Region transfers charges occur when copying backups from one Region to another Region. The charge is always billed to the account where the data is transferred from.
REG-Restore-WarmBytes-DynamoDB	GB	Size	The total size of the data restored from warm storage, measured in GB.
REG-ColdStorage-ByteHrs-DynamoDB	GB	Month	The cold storage used by DynamoDB backups managed by AWS Backup throughout the month, measured in GB-Month.

UsageType	Units	Granularity	Description
REG-Restore-ColdBytes-DynamoDB	GB	Month	The total size of the data restored from cold storage, measured in GB.

Export and Import

You can export data from DynamoDB to Amazon S3 or import data from Amazon S3 to a new DynamoDB table.

Although the UsageType uses Bytes as a suffix, export and import usage in the CUR is measured and priced in GB.

UsageType	Units	Granularity	Description
REG-ExportDataSize-Bytes	GB	Size	The charge for exporting data to S3. DynamoDB charges for data you export based on the size of the DynamoDB base table (table data and local secondary indexes) at the specified point in time when the export was created.
REG-ImportDataSize-Bytes	GB	Size	The charge for importing data from S3. The size is calculated based on the uncompressed object size of the data within Amazon

UsageType	Units	Granularity	Description
			S3. There are no extra charges for importing to tables with GSIs.
REG-IncrementalExportDataSize-Bytes	GB	Size	The charge for size of the data processed from the continuous backup to produce incremental exports.

Data Transfer

Data transfer activity may appear associated with the DynamoDB service. DynamoDB does not charge for inbound data transfer, and it does not charge for data transferred between DynamoDB and other AWS services within the same AWS Region (in other words, \$0.00 per GB). Data transferred across AWS Regions (such as between DynamoDB in the US East [N. Virginia] Region and Amazon EC2 in the EU [Ireland] Region) is charged on both sides of the transfer.

UsageType	Units	Granularity	Description
REG-DataTransfer-In-Bytes	GB	Units	Data transferred in to DynamoDB from the internet.
REG-DataTransfer-Out-Bytes	GB	Units	Data transferred out from DynamoDB to the internet.

CloudWatch Contributor Insights

CloudWatch Contributor Insights for DynamoDB is a diagnostic tool for identifying the most frequently accessed and throttled keys in your DynamoDB table. The following UsageType charges appear under the "AmazonCloudWatch" ProductCode rather than "AmazonDynamoDB".

UsageType	Units	Granularity	Description
REG-CW:Contributor EventsManaged	Events processed	Units	The amount of DynamoDB events processed. For example for a table with CloudWatch Contributor Insights enabled, anytime an item is read or written, it's counted as one event. If the table has a sort key, it results in charges for two events.
REG-CW:Contributor RulesManaged	Rule count	Month	DynamoDB creates rules to identify most accessed items and most throttled keys when you enable Cloud Watch Contributor Insights. This charge is incurred for the rules added for each entity (tables and GSIs) configured for logging CloudWatch contributor insights.

DynamoDB Accelerator (DAX)

DynamoDB Accelerator (DAX) is billed by the hour based on the instance type selected for the service. The charges below refers to the DynamoDB Accelerator instances provisioned.

The following UsageType charges appear under the “AmazonDAX” ProductCode rather than “AmazonDynamoDB”.

UsageType	Units	Granularity	Description
REG-NodeUsage:dax-<INSTANCETYPE>	Node-hour	Hour	The hourly usage of a particular instance type. Pricing is per node-hour consumed, from the time a node is launched until it is terminated. Each partial node-hour consumed will be billed as a full hour. DAX charges for each node in a DAX cluster. If you have a cluster with multiple nodes, you would see multiple line items in your billing report.

The instance type will be a value such as one from the following table. For details about node types, refer to [Nodes](#).

<INSTANCETYPE>		
r3.2xlarge	r4.8xlarge	r5.8xlarge
r3.4xlarge	r4.large	r5.large

Using DynamoDB with other AWS services

Amazon DynamoDB is integrated with other AWS services, letting you automate repeating tasks or build applications that span multiple services.

Topics

- [Configuring AWS credentials in your files using Amazon Cognito](#)
- [Loading data from DynamoDB into Amazon Redshift](#)
- [Processing DynamoDB data with Apache Hive on Amazon EMR](#)
- [Integrating with Amazon S3](#)
- [DynamoDB zero-ETL integration with Amazon OpenSearch Service](#)
- [Best practices for integrating with DynamoDB](#)

Configuring AWS credentials in your files using Amazon Cognito

The recommended way to obtain AWS credentials for your web and mobile applications is to use Amazon Cognito. Amazon Cognito helps you avoid hardcoding your AWS credentials on your files. It uses AWS Identity and Access Management (IAM) roles to generate temporary credentials for your application's authenticated and unauthenticated users.

For example, to configure your JavaScript files to use an Amazon Cognito unauthenticated role to access the Amazon DynamoDB web service, do the following.

To configure credentials to integrate with Amazon Cognito

1. Create an Amazon Cognito identity pool that allows unauthenticated identities.

```
aws cognito-identity create-identity-pool \
    --identity-pool-name DynamoPool \
    --allow-unauthenticated-identities \
    --output json
{
    "IdentityPoolId": "us-west-2:12345678-1ab2-123a-1234-a12345ab12",
    "AllowUnauthenticatedIdentities": true,
    "IdentityPoolName": "DynamoPool"
```

{

2. Copy the following policy into a file named `myCognitoPolicy.json`. Replace the identity pool ID (`us-west-2:12345678-1ab2-123a-1234-a12345ab12`) with your own IdentityPoolId obtained in the previous step.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Federated": "cognito-identity.amazonaws.com"  
            },  
            "Action": "sts:AssumeRoleWithWebIdentity",  
            "Condition": {  
                "StringEquals": {  
                    "cognito-identity.amazonaws.com:aud": "us-west-2:12345678-1ab2-123a-1234-a12345ab12"  
                },  
                "ForAnyValue:StringLike": {  
                    "cognito-identity.amazonaws.com:amr": "unauthenticated"  
                }  
            }  
        }  
    ]  
}
```

3. Create an IAM role that assumes the previous policy. In this way, Amazon Cognito becomes a trusted entity that can assume the `Cognito_DynamoPoolUnauth` role.

```
aws iam create-role --role-name Cognito_DynamoPoolUnauth \  
--assume-role-policy-document file://PathToFile/myCognitoPolicy.json --output json
```

4. Grant the `Cognito_DynamoPoolUnauth` role full access to DynamoDB by attaching a managed policy (`AmazonDynamoDBFullAccess`).

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/  
AmazonDynamoDBFullAccess \  
--role-name Cognito_DynamoPoolUnauth
```

Note

Alternatively, you can grant fine-grained access to DynamoDB. For more information, see [Using IAM policy conditions for fine-grained access control](#).

5. Obtain and copy the IAM role Amazon Resource Name (ARN).

```
aws iam get-role --role-name Cognito_DynamoPoolUnauth --output json
```

6. Add the Cognito_DynamoPoolUnauth role to the DynamoPool identity pool. The format to specify is KeyName=string, where KeyName is unauthenticated and the string is the role ARN obtained in the previous step.

```
aws cognito-identity set-identity-pool-roles \  
--identity-pool-id "us-west-2:12345678-1ab2-123a-1234-a12345ab12" \  
--roles unauthenticated=arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth --  
output json
```

7. Specify the Amazon Cognito credentials in your files. Modify the IdentityPoolId and RoleArn accordingly.

```
AWS.config.credentials = new AWS.CognitoIdentityCredentials({  
  IdentityPoolId: "us-west-2:12345678-1ab2-123a-1234-a12345ab12",  
  RoleArn: "arn:aws:iam::123456789012:role/Cognito_DynamoPoolUnauth"  
});
```

You can now run your JavaScript programs against the DynamoDB web service using Amazon Cognito credentials. For more information, see [Setting credentials in a web browser](#) in the *AWS SDK for JavaScript Getting Started Guide*.

Loading data from DynamoDB into Amazon Redshift

Amazon Redshift complements Amazon DynamoDB with advanced business intelligence capabilities and a powerful SQL-based interface. When you copy data from a DynamoDB table into Amazon Redshift, you can perform complex data analysis queries on that data, including joins with other tables in your Amazon Redshift cluster.

In terms of provisioned throughput, a copy operation from a DynamoDB table counts against that table's read capacity. After the data is copied, your SQL queries in Amazon Redshift do not affect DynamoDB in any way. This is because your queries act upon a copy of the data from DynamoDB, rather than upon DynamoDB itself.

Before you can load data from a DynamoDB table, you must first create an Amazon Redshift table to serve as the destination for the data. Keep in mind that you are copying data from a NoSQL environment into a SQL environment, and that there are certain rules in one environment that do not apply in the other. Here are some of the differences to consider:

- DynamoDB table names can contain up to 255 characters, including '.' (dot) and '-' (dash) characters, and are case-sensitive. Amazon Redshift table names are limited to 127 characters, cannot contain dots or dashes and are not case-sensitive. In addition, table names cannot conflict with any Amazon Redshift reserved words.
- DynamoDB does not support the SQL concept of NULL. You need to specify how Amazon Redshift interprets empty or blank attribute values in DynamoDB, treating them either as NULLs or as empty fields.
- DynamoDB data types do not correspond directly with those of Amazon Redshift. You need to ensure that each column in the Amazon Redshift table is of the correct data type and size to accommodate the data from DynamoDB.

Here is an example COPY command from Amazon Redshift SQL:

```
copy favoritemovies from 'dynamodb://my-favorite-movies-table'
credentials 'aws_access_key_id=<Your-Access-Key-ID>;aws_secret_access_key=<Your-Secret-
Access-Key>'
readratio 50;
```

In this example, the source table in DynamoDB is `my-favorite-movies-table`. The target table in Amazon Redshift is `favoritemovies`. The `readratio 50` clause regulates the percentage of provisioned throughput that is consumed; in this case, the COPY command will use no more than 50 percent of the read capacity units provisioned for `my-favorite-movies-table`. We highly recommend setting this ratio to a value less than the average unused provisioned throughput.

For detailed instructions on loading data from DynamoDB into Amazon Redshift, refer to the following sections in the [Amazon Redshift Database Developer Guide](#):

- [Loading data from a DynamoDB table](#)

- [The COPY command](#)
- [COPY examples](#)

Processing DynamoDB data with Apache Hive on Amazon EMR

Amazon DynamoDB is integrated with Apache Hive, a data warehousing application that runs on Amazon EMR. Hive can read and write data in DynamoDB tables, allowing you to:

- Query live DynamoDB data using a SQL-like language (HiveQL).
- Copy data from a DynamoDB table to an Amazon S3 bucket, and vice-versa.
- Copy data from a DynamoDB table into Hadoop Distributed File System (HDFS), and vice-versa.
- Perform join operations on DynamoDB tables.

Topics

- [Overview](#)
- [Tutorial: Working with Amazon DynamoDB and Apache Hive](#)
- [Creating an external table in Hive](#)
- [Processing HiveQL statements](#)
- [Querying data in DynamoDB](#)
- [Copying data to and from Amazon DynamoDB](#)
- [Performance tuning](#)

Overview

Amazon EMR is a service that makes it easy to quickly and cost-effectively process vast amounts of data. To use Amazon EMR, you launch a managed cluster of Amazon EC2 instances running the Hadoop open source framework. *Hadoop* is a distributed application that implements the MapReduce algorithm, where a task is mapped to multiple nodes in the cluster. Each node processes its designated work, in parallel with the other nodes. Finally, the outputs are reduced on a single node, yielding the final result.

You can choose to launch your Amazon EMR cluster so that it is persistent or transient:

- A *persistent* cluster runs until you shut it down. Persistent clusters are ideal for data analysis, data warehousing, or any other interactive use.

- A *transient* cluster runs long enough to process a job flow, and then shuts down automatically. Transient clusters are ideal for periodic processing tasks, such as running scripts.

For information about Amazon EMR architecture and administration, see the [Amazon EMR Management Guide](#).

When you launch an Amazon EMR cluster, you specify the initial number and type of Amazon EC2 instances. You also specify other distributed applications (in addition to Hadoop itself) that you want to run on the cluster. These applications include Hue, Mahout, Pig, Spark, and more.

For information about applications for Amazon EMR, see the [Amazon EMR Release Guide](#).

Depending on the cluster configuration, you might have one or more of the following node types:

- Leader node — Manages the cluster, coordinating the distribution of the MapReduce executable and subsets of the raw data, to the core and task instance groups. It also tracks the status of each task performed and monitors the health of the instance groups. There is only one leader node in a cluster.
- Core nodes — Runs MapReduce tasks and stores data using the Hadoop Distributed File System (HDFS).
- Task nodes (optional) — Runs MapReduce tasks.

Tutorial: Working with Amazon DynamoDB and Apache Hive

In this tutorial, you will launch an Amazon EMR cluster, and then use Apache Hive to process data stored in a DynamoDB table.

Hive is a data warehouse application for Hadoop that allows you to process and analyze data from multiple sources. Hive provides a SQL-like language, *HiveQL*, that lets you work with data stored locally in the Amazon EMR cluster or in an external data source (such as Amazon DynamoDB).

For more information, see to the [Hive Tutorial](#).

Topics

- [Before you begin](#)
- [Step 1: Create an Amazon EC2 key pair](#)
- [Step 2: Launch an Amazon EMR cluster](#)

- [Step 3: Connect to the Leader node](#)
- [Step 4: Load data into HDFS](#)
- [Step 5: Copy data to DynamoDB](#)
- [Step 6: Query the data in the DynamoDB table](#)
- [Step 7: \(Optional\) clean up](#)

Before you begin

For this tutorial, you will need the following:

- An AWS account. If you do not have one, see [Signing up for AWS](#).
- An SSH client (Secure Shell). You use the SSH client to connect to the leader node of the Amazon EMR cluster and run interactive commands. SSH clients are available by default on most Linux, Unix, and Mac OS X installations. Windows users can download and install the [PuTTY](#) client, which has SSH support.

Next step

[Step 1: Create an Amazon EC2 key pair](#)

In this step, you will create the Amazon EC2 key pair you need to connect to an Amazon EMR leader node and run Hive commands.

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose a region (for example, US West (Oregon)). This should be the same region in which your DynamoDB table is located.
3. In the navigation pane, choose **Key Pairs**.
4. Choose **Create Key Pair**.
5. In **Key pair name**, type a name for your key pair (for example, mykeypair), and then choose **Create**.
6. Download the private key file. The file name will end with . pem (such as mykeypair.pem). Keep this private key file in a safe place. You will need it to access any Amazon EMR cluster that you launch with this key pair.

⚠ Important

If you lose the key pair, you cannot connect to the leader node of your Amazon EMR cluster.

For more information about key pairs, see [Amazon EC2 Key Pairs](#) in the *Amazon EC2 User Guide for Linux Instances*.

Next step[Step 2: Launch an Amazon EMR cluster](#)**Step 2: Launch an Amazon EMR cluster**

In this step, you will configure and launch an Amazon EMR cluster. Hive and a storage handler for DynamoDB will already be installed on the cluster.

1. Open the Amazon EMR console at <https://console.aws.amazon.com/emr>.
2. Choose **Create Cluster**.
3. On the **Create Cluster - Quick Options** page, do the following:
 - a. In **Cluster name**, type a name for your cluster (for example: My EMR cluster).
 - b. In **EC2 key pair**, choose the key pair you created earlier.

Leave the other settings at their defaults.

4. Choose **Create cluster**.

It will take several minutes to launch your cluster. You can use the **Cluster Details** page in the Amazon EMR console to monitor its progress.

When the status changes to **Waiting**, the cluster is ready for use.

Cluster log files and Amazon S3

An Amazon EMR cluster generates log files that contain information about the cluster status and debugging information. The default settings for **Create Cluster - Quick Options** include setting up Amazon EMR logging.

If one does not already exist, the AWS Management Console creates an Amazon S3 bucket.

The bucket name is `aws-logs-account-id-region`, where `account-id` is your AWS account number and `region` is the region in which you launched the cluster (for example, `aws-logs-123456789012-us-west-2`).

Note

You can use the Amazon S3 console to view the log files. For more information, see [View Log Files](#) in the *Amazon EMR Management Guide*.

You can use this bucket for purposes in addition to logging. For example, you can use the bucket as a location for storing a Hive script or as a destination when exporting data from Amazon DynamoDB to Amazon S3.

Next step

[Step 3: Connect to the Leader node](#)

Step 3: Connect to the Leader node

When the status of your Amazon EMR cluster changes to **Waiting**, you will be able to connect to the leader node using SSH and perform command line operations.

1. In the Amazon EMR console, choose your cluster's name to view its status.
2. On the **Cluster Details** page, find the **Leader public DNS** field. This is the public DNS name for the leader node of your Amazon EMR cluster.
3. To the right of the DNS name, choose the **SSH** link.
4. Follow the instructions in **Connect to the Leader Node Using SSH**.

Depending on your operating system, choose the **Windows** tab or the **Mac/Linux** tab, and follow the instructions for connecting to the leader node.

After you connect to the leader node using either SSH or PuTTY, you should see a command prompt similar to the following:

```
[hadoop@ip-192-0-2-0 ~]$
```

Next step

[Step 4: Load data into HDFS](#)

Step 4: Load data into HDFS

In this step, you will copy a data file into Hadoop Distributed File System (HDFS), and then create an external Hive table that maps to the data file.

Download the sample data

1. Download the sample data archive (`features.zip`):

```
wget https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/features.zip
```

2. Extract the `features.txt` file from the archive:

```
unzip features.zip
```

3. View the first few lines of the `features.txt` file:

```
head features.txt
```

The result should look similar to this:

```
1535908|Big Run|Stream|WV|38.6370428|-80.8595469|794  
875609|Constable Hook|Cape|NJ|40.657881|-74.0990309|7  
1217998|Gooseberry Island|Island|RI|41.4534361|-71.3253284|10  
26603|Boone Moore Spring|Spring|AZ|34.0895692|-111.410065|3681  
1506738|Missouri Flat|Flat|WA|46.7634987|-117.0346113|2605  
1181348|Minnow Run|Stream|PA|40.0820178|-79.3800349|1558  
1288759|Hunting Creek|Stream|TN|36.343969|-83.8029682|1024  
533060|Big Charles Bayou|Bay|LA|29.6046517|-91.9828654|0  
829689|Greenwood Creek|Stream|NE|41.596086|-103.0499296|3671  
541692|Button Willow Island|Island|LA|31.9579389|-93.0648847|98
```

The features.txt file contains a subset of data from the United States Board on Geographic Names (http://geonames.usgs.gov/domestic/download_data.htm). The fields in each line represent the following:

- Feature ID (unique identifier)
- Name
- Class (lake; forest; stream; and so on)
- State
- Latitude (degrees)
- Longitude (degrees)
- Height (in feet)

4. At the command prompt, enter the following command:

```
hive
```

The command prompt changes to this: hive>

5. Enter the following HiveQL statement to create a native Hive table:

```
CREATE TABLE hive_features
  (feature_id          BIGINT,
   feature_name        STRING ,
   feature_class       STRING ,
   state_alpha         STRING,
   prim_lat_dec       DOUBLE ,
   prim_long_dec      DOUBLE ,
   elev_in_ft          BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '|'
LINES TERMINATED BY '\n';
```

6. Enter the following HiveQL statement to load the table with data:

```
LOAD DATA
LOCAL
INPATH './features.txt'
OVERWRITE
INTO TABLE hive_features;
```

7. You now have a native Hive table populated with data from the `features.txt` file. To verify, enter the following HiveQL statement:

```
SELECT state_alpha, COUNT(*)  
FROM hive_features  
GROUP BY state_alpha;
```

The output should show a list of states and the number of geographic features in each.

Next step

[Step 5: Copy data to DynamoDB](#)

Step 5: Copy data to DynamoDB

In this step, you will copy data from the Hive table (`hive_features`) to a new table in DynamoDB.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. Choose **Create Table**.
3. On the **Create DynamoDB table** page, do the following:
 - a. In **Table**, type **Features**.
 - b. For **Primary key**, in the **Partition key** field, type **Id**. Set the data type to **Number**.

Clear **Use Default Settings**. For **Provisioned Capacity**, type the following:

- **Read Capacity Units**—10
- **Write Capacity Units**—10

Choose **Create**.

4. At the Hive prompt, enter the following HiveQL statement:

```
CREATE EXTERNAL TABLE ddb_features  
(feature_id    BIGINT,  
 feature_name   STRING,  
 feature_class  STRING,  
 state_alpha    STRING,  
 prim_lat_dec  DOUBLE,
```

```
    prim_long_dec DOUBLE,  
    elev_in_ft     BIGINT)  
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'  
TBLPROPERTIES(  
    "dynamodb.table.name" = "Features",  
  
    "dynamodb.column.mapping"="feature_id:Id,feature_name:Name,feature_class:Class,state_alpha:  
);
```

You have now established a mapping between Hive and the Features table in DynamoDB.

- Enter the following HiveQL statement to import data to DynamoDB:

```
INSERT OVERWRITE TABLE ddb_features  
SELECT  
    feature_id,  
    feature_name,  
    feature_class,  
    state_alpha,  
    prim_lat_dec,  
    prim_long_dec,  
    elev_in_ft  
FROM hive_features;
```

Hive will submit a MapReduce job, which will be processed by your Amazon EMR cluster. It will take several minutes to complete the job.

- Verify that the data has been loaded into DynamoDB:

- In the DynamoDB console navigation pane, choose **Tables**.
- Choose the Features table, and then choose the **Items** tab to view the data.

Next step

[Step 6: Query the data in the DynamoDB table](#)

In this step, you will use HiveQL to query the Features table in DynamoDB. Try the following Hive queries:

- All of the feature types (feature_class) in alphabetical order:

```
SELECT DISTINCT feature_class  
FROM ddb_features  
ORDER BY feature_class;
```

2. All of the lakes that begin with the letter "M":

```
SELECT feature_name, state_alpha  
FROM ddb_features  
WHERE feature_class = 'Lake'  
AND feature_name LIKE 'M%'  
ORDER BY feature_name;
```

3. States with at least three features higher than a mile (5,280 feet):

```
SELECT state_alpha, feature_class, COUNT(*)  
FROM ddb_features  
WHERE elev_in_ft > 5280  
GROUP by state_alpha, feature_class  
HAVING COUNT(*) >= 3  
ORDER BY state_alpha, feature_class;
```

Next step

Step 7: (Optional) clean up

Step 7: (Optional) clean up

Now that you have completed the tutorial, you can continue reading this section to learn more about working with DynamoDB data in Amazon EMR. You might decide to keep your Amazon EMR cluster up and running while you do this.

If you don't need the cluster anymore, you should terminate it and remove any associated resources. This will help you avoid being charged for resources you don't need.

1. Terminate the Amazon EMR cluster:
 - a. Open the Amazon EMR console at <https://console.aws.amazon.com/emr>.
 - b. Choose the Amazon EMR cluster, choose **Terminate**, and then confirm.
2. Delete the Features table in DynamoDB:

- a. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
 - b. In the navigation pane, choose **Tables**.
 - c. Choose the Features table. From the **Actions** menu, choose **Delete Table**.
3. Delete the Amazon S3 bucket containing the Amazon EMR log files:
- a. Open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
 - b. From the list of buckets, choose aws-logs- *accountID-region*, where *accountID* is your AWS account number and *region* is the region in which you launched the cluster.
 - c. From the **Action** menu, choose **Delete**.

Creating an external table in Hive

In [Tutorial: Working with Amazon DynamoDB and Apache Hive](#), you created an external Hive table that mapped to a DynamoDB table. When you issued HiveQL statements against the external table, the read and write operations were passed through to the DynamoDB table.

You can think of an external table as a pointer to a data source that is managed and stored elsewhere. In this case, the underlying data source is a DynamoDB table. (The table must already exist. You cannot create, update, or delete a DynamoDB table from within Hive.) You use the `CREATE EXTERNAL TABLE` statement to create the external table. After that, you can use HiveQL to work with data in DynamoDB, as if that data were stored locally within Hive.

Note

You can use `INSERT` statements to insert data into an external table and `SELECT` statements to select data from it. However, you cannot use `UPDATE` or `DELETE` statements to manipulate data in the table.

If you no longer need the external table, you can remove it using the `DROP TABLE` statement. In this case, `DROP TABLE` only removes the external table in Hive. It does not affect the underlying DynamoDB table or any of its data.

Topics

- [CREATE EXTERNAL TABLE syntax](#)
- [Data type mappings](#)

CREATE EXTERNAL TABLE syntax

The following shows the HiveQL syntax for creating an external Hive table that maps to a DynamoDB table:

```
CREATE EXTERNAL TABLE hive_table
  (hive_column1_name hive_column1_datatype, hive_column2_name hive_column2_datatype...)
  STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
  TBLPROPERTIES (
    "dynamodb.table.name" = "dynamodb_table",
    "dynamodb.column.mapping" =
    "hive_column1_name:dynamodb_attribute1_name,hive_column2_name:dynamodb_attribute2_name..."
  );
```

Line 1 is the start of the CREATE EXTERNAL TABLE statement, where you provide the name of the Hive table (*hive_table*) you want to create.

Line 2 specifies the columns and data types for *hive_table*. You need to define columns and data types that correspond to the attributes in the DynamoDB table.

Line 3 is the STORED BY clause, where you specify a class that handles data management between the Hive and the DynamoDB table. For DynamoDB, STORED BY should be set to 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'.

Line 4 is the start of the TBLPROPERTIES clause, where you define the following parameters for DynamoDBStorageHandler:

- dynamodb.table.name—the name of the DynamoDB table.
- dynamodb.column.mapping—pairs of column names in the Hive table and their corresponding attributes in the DynamoDB table. Each pair is of the form *hive_column_name*:*dynamodb_attribute_name*, and the pairs are separated by commas.

Note the following:

- The name of the Hive table name does not have to be the same as the DynamoDB table name.
- The Hive table column names do not have to be the same as those in the DynamoDB table.
- The table specified by dynamodb.table.name must exist in DynamoDB.

- For dynamodb.column.mapping:

- You must map the key schema attributes for the DynamoDB table. This includes the partition key and the sort key (if present).
- You do not have to map the non-key attributes of the DynamoDB table. However, you will not see any data from those attributes when you query the Hive table.
- If the data types of a Hive table column and a DynamoDB attribute are incompatible, you will see NULL in these columns when you query the Hive table.

 **Note**

The CREATE EXTERNAL TABLE statement does not perform any validation on the TBLPROPERTIES clause. The values you provide for dynamodb.table.name and dynamodb.column.mapping are only evaluated by the DynamoDBStorageHandler class when you attempt to access the table.

Data type mappings

The following table shows DynamoDB data types and compatible Hive data types:

DynamoDB Data Type	Hive Data Type
String	STRING
Number	BIGINT or DOUBLE
Binary	BINARY
String Set	ARRAY<STRING>
Number Set	ARRAY<BIGINT> or ARRAY<DOUBLE>
Binary Set	ARRAY<BINARY>

Note

The following DynamoDB data types are not supported by the `DynamoDBStorageHandler` class, so they cannot be used with `dynamodb.column.mapping`:

- Map
- List
- Boolean
- Null

However, if you need to work with these data types, you can create a single entity called `item` that represents the entire DynamoDB item as a map of strings for both keys and values in the map. For more information, see [Copying data without a column mapping](#)

If you want to map a DynamoDB attribute of type Number, you must choose an appropriate Hive type:

- The Hive BIGINT type is for 8-byte signed integers. It is the same as the `long` data type in Java.
- The Hive DOUBLE type is for 8-bit double precision floating point numbers. It is the same as the `double` type in Java.

If you have numeric data stored in DynamoDB that has a higher precision than the Hive data type you choose, then accessing the DynamoDB data could cause a loss of precision.

If you export data of type Binary from DynamoDB to (Amazon S3) or HDFS, the data is stored as a Base64-encoded string. If you import data from Amazon S3 or HDFS into the DynamoDB Binary type, you must ensure the data is encoded as a Base64 string.

Processing HiveQL statements

Hive is an application that runs on Hadoop, which is a batch-oriented framework for running MapReduce jobs. When you issue a HiveQL statement, Hive determines whether it can return the results immediately or whether it must submit a MapReduce job.

For example, consider the *ddb_features* table (from [Tutorial: Working with Amazon DynamoDB and Apache Hive](#)). The following Hive query prints state abbreviations and the number of summits in each:

```
SELECT state_alpha, count(*)  
FROM ddb_features  
WHERE feature_class = 'Summit'  
GROUP BY state_alpha;
```

Hive does not return the results immediately. Instead, it submits a MapReduce job, which is processed by the Hadoop framework. Hive will wait until the job is complete before it shows the results from the query:

```
AK 2  
AL 2  
AR 2  
AZ 3  
CA 7  
CO 2  
CT 2  
ID 1  
KS 1  
ME 2  
MI 1  
MT 3  
NC 1  
NE 1  
NM 1  
NY 2  
OR 5  
PA 1  
TN 1  
TX 1  
UT 4  
VA 1  
VT 2  
WA 2  
WY 3  
  
Time taken: 8.753 seconds, Fetched: 25 row(s)
```

Monitoring and canceling jobs

When Hive launches a Hadoop job, it prints output from that job. The job completion status is updated as the job progresses. In some cases, the status might not be updated for a long time. (This can happen when you are querying a large DynamoDB table that has a low provisioned read capacity setting.)

If you need to cancel the job before it is complete, you can type **Ctrl+C** at any time.

Querying data in DynamoDB

The following examples show some ways that you can use HiveQL to query data stored in DynamoDB.

These examples refer to the *ddb_features* table in the tutorial ([Step 5: Copy data to DynamoDB](#)).

Topics

- [Using aggregate functions](#)
- [Using the GROUP BY and HAVING clauses](#)
- [Joining two DynamoDB tables](#)
- [Joining tables from different sources](#)

Using aggregate functions

HiveQL provides built-in functions for summarizing data values. For example, you can use the MAX function to find the largest value for a selected column. The following example returns the elevation of the highest feature in the state of Colorado.

```
SELECT MAX(elev_in_ft)
FROM ddb_features
WHERE state_alpha = 'CO';
```

Using the GROUP BY and HAVING clauses

You can use the GROUP BY clause to collect data across multiple records. This is often used with an aggregate function such as SUM, COUNT, MIN, or MAX. You can also use the HAVING clause to discard any results that do not meet certain criteria.

The following example returns a list of the highest elevations from states that have more than five features in the *ddb_features* table.

```
SELECT state_alpha, max(elev_in_ft)
FROM ddb_features
GROUP BY state_alpha
HAVING count(*) >= 5;
```

Joining two DynamoDB tables

The following example maps another Hive table (*east_coast_states*) to a table in DynamoDB. The SELECT statement is a join across these two tables. The join is computed on the cluster and returned. The join does not take place in DynamoDB.

Consider a DynamoDB table named *EastCoastStates* that contains the following data:

StateName	StateAbbrev
Maine	ME
New Hampshire	NH
Massachusetts	MA
Rhode Island	RI
Connecticut	CT
New York	NY
New Jersey	NJ
Delaware	DE
Maryland	MD
Virginia	VA
North Carolina	NC
South Carolina	SC
Georgia	GA
Florida	FL

Let's assume the table is available as a Hive external table named *east_coast_states*:

```
CREATE EXTERNAL TABLE ddb_east_coast_states (state_name STRING, state_alpha STRING)
STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'
TBLPROPERTIES ("dynamodb.table.name" = "EastCoastStates",
"dynamodb.column.mapping" = "state_name:StateName,state_alpha:StateAbbrev");
```

The following join returns the states on the East Coast of the United States that have at least three features:

```
SELECT ecs.state_name, f.feature_class, COUNT(*)  
FROM ddb_east_coast_states ecs  
JOIN ddb_features f on ecs.state_alpha = f.state_alpha  
GROUP BY ecs.state_name, f.feature_class  
HAVING COUNT(*) >= 3;
```

Joining tables from different sources

In the following example, `s3_east_coast_states` is a Hive table associated with a CSV file stored in Amazon S3. The `ddb_features` table is associated with data in DynamoDB. The following example joins these two tables, returning the geographic features from states whose names begin with "New."

```
create external table s3_east_coast_states (state_name STRING, state_alpha STRING)  
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','  
LOCATION 's3://<bucketname>/path/subpath/';
```

```
SELECT ecs.state_name, f.feature_name, f.feature_class  
FROM s3_east_coast_states ecs  
JOIN ddb_features f  
ON ecs.state_alpha = f.state_alpha  
WHERE ecs.state_name LIKE 'New%';
```

Copying data to and from Amazon DynamoDB

In the [Tutorial: Working with Amazon DynamoDB and Apache Hive](#), you copied data from a native Hive table into an external DynamoDB table, and then queried the external DynamoDB table. The table is external because it exists outside of Hive. Even if you drop the Hive table that maps to it, the table in DynamoDB is not affected.

Hive is an excellent solution for copying data among DynamoDB tables, Amazon S3 buckets, native Hive tables, and Hadoop Distributed File System (HDFS). This section provides examples of these operations.

Topics

- [Copying data between DynamoDB and a native Hive table](#)
- [Copying data between DynamoDB and Amazon S3](#)
- [Copying data between DynamoDB and HDFS](#)

- [Using data compression](#)
- [Reading non-printable UTF-8 character data](#)

Copying data between DynamoDB and a native Hive table

If you have data in a DynamoDB table, you can copy the data to a native Hive table. This will give you a snapshot of the data, as of the time you copied it.

You might decide to do this if you need to perform many HiveQL queries, but do not want to consume provisioned throughput capacity from DynamoDB. Because the data in the native Hive table is a copy of the data from DynamoDB, and not "live" data, your queries should not expect that the data is up-to-date.

 **Note**

The examples in this section are written with the assumption you followed the steps in [Tutorial: Working with Amazon DynamoDB and Apache Hive](#) and have an external table in DynamoDB named *ddb_features*.

Example From DynamoDB to native Hive table

You can create a native Hive table and populate it with data from *ddb_features*, like this:

```
CREATE TABLE features_snapshot AS  
SELECT * FROM ddb_features;
```

You can then refresh the data at any time:

```
INSERT OVERWRITE TABLE features_snapshot  
SELECT * FROM ddb_features;
```

In these examples, the subquery `SELECT * FROM ddb_features` will retrieve all of the data from *ddb_features*. If you only want to copy a subset of the data, you can use a `WHERE` clause in the subquery.

The following example creates a native Hive table, containing only some of the attributes for lakes and summits:

```
CREATE TABLE lakes_and_summits AS
SELECT feature_name, feature_class, state_alpha
FROM ddb_features
WHERE feature_class IN ('Lake', 'Summit');
```

Example From native Hive table to DynamoDB

Use the following HiveQL statement to copy the data from the native Hive table to *ddb_features*:

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM features_snapshot;
```

Copying data between DynamoDB and Amazon S3

If you have data in a DynamoDB table, you can use Hive to copy the data to an Amazon S3 bucket.

You might do this if you want to create an archive of data in your DynamoDB table. For example, suppose you have a test environment where you need to work with a baseline set of test data in DynamoDB. You can copy the baseline data to an Amazon S3 bucket, and then run your tests. Afterward, you can reset the test environment by restoring the baseline data from the Amazon S3 bucket to DynamoDB.

If you worked through [Tutorial: Working with Amazon DynamoDB and Apache Hive](#), then you already have an Amazon S3 bucket that contains your Amazon EMR logs. You can use this bucket for the examples in this section, if you know the root path for the bucket:

1. Open the Amazon EMR console at <https://console.aws.amazon.com/emr>.
2. For **Name**, choose your cluster.
3. The URI is listed in **Log URI** under **Configuration Details**.
4. Make a note of the root path of the bucket. The naming convention is:

`s3://aws-logs-accountID-region`

where *accountID* is your AWS account ID and *region* is the AWS region for the bucket.

Note

For these examples, we will use a subpath within the bucket, as in this example:

```
s3://aws-logs-123456789012-us-west-2/hive-test
```

The following procedures are written with the assumption you followed the steps in the tutorial and have an external table in DynamoDB named *ddb_features*.

Topics

- [Copying data using the Hive default format](#)
- [Copying data with a user-specified format](#)
- [Copying data without a column mapping](#)
- [Viewing the data in Amazon S3](#)

Copying data using the Hive default format

Example From DynamoDB to Amazon S3

Use an `INSERT OVERWRITE` statement to write directly to Amazon S3.

```
INSERT OVERWRITE DIRECTORY 's3://aws-logs-123456789012-us-west-2/hive-test'  
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135  
1178153^AJones Run^ASTream^APA^A41.2120086^A-79.25920781260  
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133  
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900  
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as `^A`.

Example From Amazon S3 to DynamoDB

1. Create an external table pointing to the unformatted data in Amazon S3.

```
CREATE EXTERNAL TABLE s3_features_unformatted  
(feature_id      BIGINT,  
 feature_name    STRING ,  
 feature_class   STRING ,
```

```
    state_alpha      STRING,  
    prim_lat_dec   DOUBLE ,  
    prim_long_dec  DOUBLE ,  
    elev_in_ft     BIGINT)  
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features  
SELECT * FROM s3_features_unformatted;
```

Copying data with a user-specified format

If you want to specify your own field separator character, you can create an external table that maps to the Amazon S3 bucket. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to Amazon S3

1. Create a Hive external table that maps to Amazon S3. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE s3_features_csv  
(feature_id      BIGINT,  
 feature_name    STRING,  
 feature_class   STRING,  
 state_alpha     STRING,  
 prim_lat_dec   DOUBLE,  
 prim_long_dec  DOUBLE,  
 elev_in_ft     BIGINT)  
ROW FORMAT DELIMITED  
FIELDS TERMINATED BY ','  
LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE s3_features_csv  
SELECT * FROM ddb_features;
```

The data file in Amazon S3 looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135  
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260  
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133  
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900  
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features  
SELECT * FROM s3_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to Amazon S3 without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in Amazon S3.

Example From DynamoDB to Amazon S3

1. Create an external table associated with your DynamoDB table. (There is no dynamodb.column.mapping in this HiveQL statement.)

```
CREATE EXTERNAL TABLE ddb_features_no_mapping  
  (item MAP<STRING, STRING>)  
 STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'  
 TBLPROPERTIES ("dynamodb.table.name" = "Features");
```

2. Create another external table associated with your Amazon S3 bucket.

```
CREATE EXTERNAL TABLE s3_features_no_mapping  
  (item MAP<STRING, STRING>)  
 ROW FORMAT DELIMITED  
 FIELDS TERMINATED BY '\t'  
 LINES TERMINATED BY '\n'  
 LOCATION 's3://aws-logs-123456789012-us-west-2/hive-test';
```

3. Copy the data from DynamoDB to Amazon S3.

```
INSERT OVERWRITE TABLE s3_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in Amazon S3 looks like this:

```
Name^C{"s":"Soldiers Farewell
Hill"}^BState^C{"s":"NM"}^BCClass^C{"s":"Summit"}^BElevation^C{"n":6135"}^BLatitude^C{"n":32.25
Name^C{"s":"Jones
Run"}^BState^C{"s":"PA"}^BCClass^C{"s":"Stream"}^BElevation^C{"n":1260"}^BLatitude^C{"n":41.25
Name^C{"s":"Sentinel
Dome"}^BState^C{"s":"CA"}^BCClass^C{"s":"Summit"}^BElevation^C{"n":8133"}^BLatitude^C{"n":37.25
Name^C{"s":"NeverSweet
Gulch"}^BState^C{"s":"CA"}^BCClass^C{"s":"Valley"}^BElevation^C{"n":2900"}^BLatitude^C{"n":41.25
Name^C{"s":"Chacaloochee
Bay"}^BState^C{"s":"AL"}^BCClass^C{"s":"Bay"}^BElevation^C{"n":0"}^BLatitude^C{"n":30.6979676}
```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as ^B and ETX appears as ^C.

Example From Amazon S3 to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from Amazon S3:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM s3_features_no_mapping;
```

Viewing the data in Amazon S3

If you use SSH to connect to the leader node, you can use the AWS Command Line Interface (AWS CLI) to access the data that Hive wrote to Amazon S3.

The following steps are written with the assumption you have copied data from DynamoDB to Amazon S3 using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

```
hive> exit;
```

2. List the contents of the hive-test directory in your Amazon S3 bucket. (This is where Hive copied the data from DynamoDB.)

```
aws s3 ls s3://aws-logs-123456789012-us-west-2/hive-test/
```

The response should look similar to this:

```
2016-11-01 23:19:54 81983 000000_0
```

The file name (`000000_0`) is system-generated.

3. (Optional) You can copy the data file from Amazon S3 to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

```
aws s3 cp s3://aws-logs-123456789012-us-west-2/hive-test/000000_0 .
```

The response should look similar to this:

```
download: s3://aws-logs-123456789012-us-west-2/hive-test/000000_0  
to ./000000_0
```

 **Note**

The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Copying data between DynamoDB and HDFS

If you have data in a DynamoDB table, you can use Hive to copy the data to the Hadoop Distributed File System (HDFS).

You might do this if you are running a MapReduce job that requires data from DynamoDB. If you copy the data from DynamoDB into HDFS, Hadoop can process it, using all of the available nodes in the Amazon EMR cluster in parallel. When the MapReduce job is complete, you can then write the results from HDFS to DDB.

In the following examples, Hive will read from and write to the following HDFS directory: `/user/hadoop/hive-test`

Note

The examples in this section are written with the assumption you followed the steps in [Tutorial: Working with Amazon DynamoDB and Apache Hive](#) and you have an external table in DynamoDB named *ddb_features*.

Topics

- [Copying data using the Hive default format](#)
- [Copying data with a user-specified format](#)
- [Copying data without a column mapping](#)
- [Accessing the data in HDFS](#)

Copying data using the Hive default format**Example From DynamoDB to HDFS**

Use an `INSERT OVERWRITE` statement to write directly to HDFS.

```
INSERT OVERWRITE DIRECTORY 'hdfs://user/hadoop/hive-test'  
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709^ASoldiers Farewell Hill^ASummit^ANM^A32.3564729^A-108.33004616135  
1178153^AJones Run^ASTream^APA^A41.2120086^A-79.25920781260  
253838^ASentinel Dome^ASummit^ACA^A37.7229821^A-119.584338133  
264054^ANeversweet Gulch^AValley^ACA^A41.6565269^A-122.83614322900  
115905^AChacaloochee Bay^ABay^AAL^A30.6979676^A-87.97388530
```

Each field is separated by an SOH character (start of heading, 0x01). In the file, SOH appears as `^A`.

Example From HDFS to DynamoDB

1. Create an external table that maps to the unformatted data in HDFS.

```
CREATE EXTERNAL TABLE hdfs_features_unformatted
```

```
(feature_id      BIGINT,
 feature_name    STRING ,
 feature_class   STRING ,
 state_alpha     STRING,
 prim_lat_dec   DOUBLE ,
 prim_long_dec  DOUBLE ,
 elev_in_ft      BIGINT)
LOCATION 'hdfs://user/hadoop/hive-test';
```

2. Copy the data to DynamoDB.

```
INSERT OVERWRITE TABLE ddb_features
SELECT * FROM hdfs_features_unformatted;
```

Copying data with a user-specified format

If you want to use a different field separator character, you can create an external table that maps to the HDFS directory. You might use this technique for creating data files with comma-separated values (CSV).

Example From DynamoDB to HDFS

1. Create a Hive external table that maps to HDFS. When you do this, ensure that the data types are consistent with those of the DynamoDB external table.

```
CREATE EXTERNAL TABLE hdfs_features_csv
(feature_id      BIGINT,
 feature_name    STRING ,
 feature_class   STRING ,
 state_alpha     STRING,
 prim_lat_dec   DOUBLE ,
 prim_long_dec  DOUBLE ,
 elev_in_ft      BIGINT)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY ','
LOCATION 'hdfs://user/hadoop/hive-test';
```

2. Copy the data from DynamoDB.

```
INSERT OVERWRITE TABLE hdfs_features_csv
SELECT * FROM ddb_features;
```

The data file in HDFS looks like this:

```
920709,Soldiers Farewell Hill,Summit,NM,32.3564729,-108.3300461,6135  
1178153,Jones Run,Stream,PA,41.2120086,-79.2592078,1260  
253838,Sentinel Dome,Summit,CA,37.7229821,-119.58433,8133  
264054,Neversweet Gulch,Valley,CA,41.6565269,-122.8361432,2900  
115905,Chacaloochee Bay,Bay,AL,30.6979676,-87.9738853,0
```

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features  
SELECT * FROM hdfs_features_csv;
```

Copying data without a column mapping

You can copy data from DynamoDB in a raw format and write it to HDFS without specifying any data types or column mapping. You can use this method to create an archive of DynamoDB data and store it in HDFS.

Note

If your DynamoDB table contains attributes of type Map, List, Boolean or Null, then this is the only way you can use Hive to copy data from DynamoDB to HDFS.

Example From DynamoDB to HDFS

1. Create an external table associated with your DynamoDB table. (There is no dynamodb.column.mapping in this HiveQL statement.)

```
CREATE EXTERNAL TABLE ddb_features_no_mapping  
  (item MAP<STRING, STRING>)  
 STORED BY 'org.apache.hadoop.hive.dynamodb.DynamoDBStorageHandler'  
 TBLPROPERTIES ("dynamodb.table.name" = "Features");
```

2. Create another external table associated with your HDFS directory.

```
CREATE EXTERNAL TABLE hdfs_features_no_mapping
  (item MAP<STRING, STRING>)
ROW FORMAT DELIMITED
FIELDS TERMINATED BY '\t'
LINES TERMINATED BY '\n'
LOCATION 'hdfs://user/hadoop/hive-test';
```

3. Copy the data from DynamoDB to HDFS.

```
INSERT OVERWRITE TABLE hdfs_features_no_mapping
SELECT * FROM ddb_features_no_mapping;
```

The data file in HDFS looks like this:

```
Name^C{"s":"Soldiers Farewell
Hill"}^BState^C{"s":"NM"}^BClass^C{"s":"Summit"}^BElevation^C{"n":6135"}^BLatitude^C{"n":32.25}^BLongitude^C{"n":-106.35}
Name^C{"s":"Jones
Run"}^BState^C{"s":"PA"}^BClass^C{"s":"Stream"}^BElevation^C{"n":1260"}^BLatitude^C{"n":41.25}^BLongitude^C{"n":-75.75}
Name^C{"s":"Sentinel
Dome"}^BState^C{"s":"CA"}^BClass^C{"s":"Summit"}^BElevation^C{"n":8133"}^BLatitude^C{"n":37.83}^BLongitude^C{"n":-122.45}
Name^C{"s":"Neversweet
Gulch"}^BState^C{"s":"CA"}^BClass^C{"s":"Valley"}^BElevation^C{"n":2900"}^BLatitude^C{"n":41.25}^BLongitude^C{"n":-121.75}
Name^C{"s":"Chacaloochee
Bay"}^BState^C{"s":"AL"}^BClass^C{"s":"Bay"}^BElevation^C{"n":0"}^BLatitude^C{"n":30.69796767}^BLongitude^C{"n":-86.75}
```

Each field begins with an STX character (start of text, 0x02) and ends with an ETX character (end of text, 0x03). In the file, STX appears as ^B and ETX appears as ^C.

Example From HDFS to DynamoDB

With a single HiveQL statement, you can populate the DynamoDB table using the data from HDFS:

```
INSERT OVERWRITE TABLE ddb_features_no_mapping
SELECT * FROM hdfs_features_no_mapping;
```

Accessing the data in HDFS

HDFS is a distributed file system, accessible to all of the nodes in the Amazon EMR cluster. If you use SSH to connect to the leader node, you can use command line tools to access the data that Hive wrote to HDFS.

HDFS is not the same thing as the local file system on the leader node. You cannot work with files and directories in HDFS using standard Linux commands (such as `cat`, `cp`, `mv`, or `rm`). Instead, you perform these tasks using the `hadoop fs` command.

The following steps are written with the assumption you have copied data from DynamoDB to HDFS using one of the procedures in this section.

1. If you are currently at the Hive command prompt, exit to the Linux command prompt.

```
hive> exit;
```

2. List the contents of the `/user/hadoop/hive-test` directory in HDFS. (This is where Hive copied the data from DynamoDB.)

```
hadoop fs -ls /user/hadoop/hive-test
```

The response should look similar to this:

```
Found 1 items  
-rw-r--r-- 1 hadoop hadoop 29504 2016-06-08 23:40 /user/hadoop/hive-test/000000_0
```

The file name (`000000_0`) is system-generated.

3. View the contents of the file:

```
hadoop fs -cat /user/hadoop/hive-test/000000_0
```

Note

In this example, the file is relatively small (approximately 29 KB). Be careful when you use this command with files that are very large or contain non-printable characters.

4. (Optional) You can copy the data file from HDFS to the local file system on the leader node. After you do this, you can use standard Linux command line utilities to work with the data in the file.

```
hadoop fs -get /user/hadoop/hive-test/000000_0
```

This command will not overwrite the file.

Note

The local file system on the leader node has limited capacity. Do not use this command with files that are larger than the available space in the local file system.

Using data compression

When you use Hive to copy data among different data sources, you can request on-the-fly data compression. Hive provides several compression codecs. You can choose one during your Hive session. When you do this, the data is compressed in the specified format.

The following example compresses data using the Lempel-Ziv-Oberhumer (LZO) algorithm.

```
SET hive.exec.compress.output=true;
SET io.seqfile.compression.type=BLOCK;
SET mapred.output.compression.codec = com.hadoop.compression.lzo.LzopCodec;

CREATE EXTERNAL TABLE lzo_compression_table (line STRING)
ROW FORMAT DELIMITED FIELDS TERMINATED BY '\t' LINES TERMINATED BY '\n'
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE lzo_compression_table SELECT *
FROM hiveTableName;
```

The resulting file in Amazon S3 will have a system-generated name with .lzo at the end (for example, 8d436957-57ba-4af7-840c-96c2fc7bb6f5-000000.lzo).

The available compression codecs are:

- org.apache.hadoop.io.compress.GzipCodec
- org.apache.hadoop.io.compress.DefaultCodec
- com.hadoop.compression.lzo.LzoCodec
- com.hadoop.compression.lzo.LzopCodec
- org.apache.hadoop.io.compress.BZip2Codec
- org.apache.hadoop.io.compress.SnappyCodec

Reading non-printable UTF-8 character data

To read and write non-printable UTF-8 character data, you can use the STORED AS SEQUENCEFILE clause when you create a Hive table. A SequenceFile is a Hadoop binary file format. You need to use Hadoop to read this file. The following example shows how to export data from DynamoDB into Amazon S3. You can use this functionality to handle non-printable UTF-8 encoded characters.

```
CREATE EXTERNAL TABLE s3_export(a_col string, b_col bigint, c_col array<string>)
STORED AS SEQUENCEFILE
LOCATION 's3://bucketname/path/subpath/';

INSERT OVERWRITE TABLE s3_export SELECT *
FROM hiveTableName;
```

Performance tuning

When you create a Hive external table that maps to a DynamoDB table, you do not consume any read or write capacity from DynamoDB. However, read and write activity on the Hive table (such as INSERT or SELECT) translates directly into read and write operations on the underlying DynamoDB table.

Apache Hive on Amazon EMR implements its own logic for balancing the I/O load on the DynamoDB table and seeks to minimize the possibility of exceeding the table's provisioned throughput. At the end of each Hive query, Amazon EMR returns runtime metrics, including the number of times your provisioned throughput was exceeded. You can use this information, together with CloudWatch metrics on your DynamoDB table, to improve performance in subsequent requests.

The Amazon EMR console provides basic monitoring tools for your cluster. For more information, see [View and Monitor a Cluster](#) in the *Amazon EMR Management Guide*.

You can also monitor your cluster and Hadoop jobs using web-based tools, such as Hue, Ganglia, and the Hadoop web interface. For more information, see [View Web Interfaces Hosted on Amazon EMR Clusters](#) in the *Amazon EMR Management Guide*.

This section describes steps you can take to performance-tune Hive operations on external DynamoDB tables.

Topics

- [DynamoDB provisioned throughput](#)
- [Adjusting the mappers](#)
- [Additional topics](#)

DynamoDB provisioned throughput

When you issue HiveQL statements against the external DynamoDB table, the `DynamoDBStorageHandler` class makes the appropriate low-level DynamoDB API requests, which consume provisioned throughput. If there is not enough read or write capacity on the DynamoDB table, the request will be throttled, resulting in slow HiveQL performance. For this reason, you should ensure that the table has enough throughput capacity.

For example, suppose that you have provisioned 100 read capacity units for your DynamoDB table. This will let you read 409,600 bytes per second (100×4 KB read capacity unit size). Now suppose that the table contains 20 GB of data (21,474,836,480 bytes) and you want to use the SELECT statement to select all of the data using HiveQL. You can estimate how long the query will take to run like this:

$$21,474,836,480 / 409,600 = 52,429 \text{ seconds} = 14.56 \text{ hours}$$

In this scenario, the DynamoDB table is a bottleneck. It won't help to add more Amazon EMR nodes, because the Hive throughput is constrained to only 409,600 bytes per second. The only way to decrease the time required for the SELECT statement is to increase the provisioned read capacity of the DynamoDB table.

You can perform a similar calculation to estimate how long it would take to bulk-load data into a Hive external table mapped to a DynamoDB table. Determine the total number of write capacity units needed per item (less than 1KB = 1, 1-2KB = 2, etc), and multiply that by the number of items to load. This will give you the number of write capacity units required. Divide that number by the number of write capacity units that are allocated per second. This will yield the number of seconds it will take to load the table.

You should regularly monitor the CloudWatch metrics for your table. For a quick overview in the DynamoDB console, choose your table and then choose the **Metrics** tab. From here, you can view read and write capacity units consumed and read and write requests that have been throttled.

Read capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of ProvisionedThroughputExceeded messages in the job output, you can adjust the default read rate. To do this, you can modify the dynamodb.throughput.read.percent configuration variable. You can use the SET command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.read.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, dynamodb.throughput.read.percent will return to its default value.

The value of dynamodb.throughput.read.percent can be between 0.1 and 1.5, inclusively. 0.5 represents the default read rate, meaning that Hive will attempt to consume half of the read capacity of the table. If you increase the value above 0.5, Hive will increase the request rate; decreasing the value below 0.5 decreases the read request rate. (The actual read rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned read capacity of the table, or if your read requests are being throttled too much, try reducing dynamodb.throughput.read.percent below 0.5. If you have sufficient read capacity in the table and want more responsive HiveQL operations, you can set the value above 0.5.

Write capacity

Amazon EMR manages the request load against your DynamoDB table, according to the table's provisioned throughput settings. However, if you notice a large number of ProvisionedThroughputExceeded messages in the job output, you can adjust the default write rate. To do this, you can modify the dynamodb.throughput.write.percent configuration variable. You can use the SET command to set this variable at the Hive command prompt:

```
SET dynamodb.throughput.write.percent=1.0;
```

This variable persists for the current Hive session only. If you exit Hive and return to it later, dynamodb.throughput.write.percent will return to its default value.

The value of dynamodb.throughput.write.percent can be between 0.1 and 1.5, inclusively. 0.5 represents the default write rate, meaning that Hive will attempt to consume half of the write capacity of the table. If you increase the value above 0.5, Hive will increase the request rate;

decreasing the value below `0.5` decreases the write request rate. (The actual write rate will vary, depending on factors such as whether there is a uniform key distribution in the DynamoDB table.)

If you notice that Hive is frequently depleting the provisioned write capacity of the table, or if your write requests are being throttled too much, try reducing `dynamodb.throughput.write.percent` below `0.5`. If you have sufficient capacity in the table and want more responsive HiveQL operations, you can set the value above `0.5`.

When you write data to DynamoDB using Hive, ensure that the number of write capacity units is greater than the number of mappers in the cluster. For example, consider an Amazon EMR cluster consisting of 10 `m1.xlarge` nodes. The `m1.xlarge` node type provides 8 mapper tasks, so the cluster would have a total of 80 mappers (10×8). If your DynamoDB table has fewer than 80 write capacity units, then a Hive write operation could consume all of the write throughput for that table.

To determine the number of mappers for Amazon EMR node types, see [Task Configuration](#) in the *Amazon EMR Developer Guide*.

For more information on mappers, see [Adjusting the mappers](#).

Adjusting the mappers

When Hive launches a Hadoop job, the job is processed by one or more mapper tasks. Assuming that your DynamoDB table has sufficient throughput capacity, you can modify the number of mappers in the cluster, potentially improving performance.

Note

The number of mapper tasks used in a Hadoop job are influenced by *input splits*, where Hadoop subdivides the data into logical blocks. If Hadoop does not perform enough input splits, then your write operations might not be able to consume all the write throughput available in the DynamoDB table.

Increasing the number of mappers

Each mapper in an Amazon EMR has a maximum read rate of 1 MiB per second. The number of mappers in a cluster depends on the size of the nodes in your cluster. (For information about node sizes and the number of mappers per node, see [Task Configuration](#) in the *Amazon EMR Developer Guide*.)

If your DynamoDB table has ample throughput capacity for reads, you can try increasing the number of mappers by doing one of the following:

- Increase the size of the nodes in your cluster. For example, if your cluster is using *m1.large* nodes (three mappers per node), you can try upgrading to *m1.xlarge* nodes (eight mappers per node).
- Increase the number of nodes in your cluster. For example, if you have three-node cluster of *m1.xlarge* nodes, you have a total of 24 mappers available. If you were to double the size of the cluster, with the same type of node, you would have 48 mappers.

You can use the AWS Management Console to manage the size or the number of nodes in your cluster. (You might need to restart the cluster for these changes to take effect.)

Another way to increase the number of mappers is to modify the `mapred.tasktracker.map.tasks.maximum` Hadoop configuration parameter. (This is a Hadoop parameter, not a Hive parameter. You cannot modify it interactively from the command prompt.). If you increase the value of `mapred.tasktracker.map.tasks.maximum`, you can increase the number of mappers without increasing the size or number of nodes. However, it is possible for the cluster nodes to run out of memory if you set the value too high.

You set the value for `mapred.tasktracker.map.tasks.maximum` as a bootstrap action when you first launch your Amazon EMR cluster. For more information, see [\(Optional\) Create Bootstrap Actions to Install Additional Software](#) in the *Amazon EMR Management Guide*.

Decreasing the number of mappers

If you use the `SELECT` statement to select data from an external Hive table that maps to DynamoDB, the Hadoop job can use as many tasks as necessary, up to the maximum number of mappers in the cluster. In this scenario, it is possible that a long-running Hive query can consume all of the provisioned read capacity of the DynamoDB table, negatively impacting other users.

You can use the `dynamodb.max.map.tasks` parameter to set an upper limit for map tasks:

```
SET dynamodb.max.map.tasks=1
```

This value must be equal to or greater than 1. When Hive processes your query, the resulting Hadoop job will use no more than `dynamodb.max.map.tasks` when reading from the DynamoDB table.

Additional topics

The following are some more ways to tune applications that use Hive to access DynamoDB.

Retry duration

By default, Hive will rerun a Hadoop job if it has not returned any results from DynamoDB within two minutes. You can adjust this interval by modifying the `dynamodb.retry.duration` parameter:

```
SET dynamodb.retry.duration=2;
```

The value must be a nonzero integer, representing the number of minutes in the retry interval. The default for `dynamodb.retry.duration` is 2 (minutes).

Parallel data requests

Multiple data requests, either from more than one user or more than one application to a single table can drain read provisioned throughput and slow performance.

Process duration

Data consistency in DynamoDB depends on the order of read and write operations on each node. While a Hive query is in progress, another application might load new data into the DynamoDB table or modify or delete existing data. In this case, the results of the Hive query might not reflect changes made to the data while the query was running.

Request time

Scheduling Hive queries that access a DynamoDB table when there is lower demand on the DynamoDB table improves performance. For example, if most of your application's users live in San Francisco, you might choose to export daily data at 4:00 A.M. PST when the majority of users are asleep and not updating records in your DynamoDB database.

Integrating with Amazon S3

Amazon DynamoDB import and export capabilities provide a simple and efficient way to move data between Amazon S3 and DynamoDB tables without writing any code.

DynamoDB import and export features help you move, transform, and copy DynamoDB table accounts. You can import from your S3 sources, and you can export your DynamoDB table data to

Amazon S3 and use AWS services such as Athena, Amazon SageMaker, and AWS Lake Formation to analyze your data and extract actionable insights. You can also import data directly into new DynamoDB tables to build new applications with single-digit millisecond performance at scale, facilitate data sharing between tables and accounts, and simplify your disaster recovery and business continuity plans.

DynamoDB data import from Amazon S3: how it works

To import data into DynamoDB, your data must be in an Amazon S3 bucket in CSV, DynamoDB JSON, or Amazon Ion format. Data can be compressed in ZSTD or GZIP format, or can be directly imported in uncompressed form. Source data can either be a single Amazon S3 object or multiple Amazon S3 objects that use the same prefix.

Your data will be imported into a new DynamoDB table, which will be created when you initiate the import request. You can create this table with secondary indexes, then query and update your data across all primary and secondary indexes as soon as the import is complete. You can also add a global table replica after the import is complete.

Note

During the Amazon S3 import process, DynamoDB creates a new target table that will be imported into. Import into existing tables is not currently supported by this feature.

Import from Amazon S3 does not consume write capacity on the new table, so you do not need to provision any extra capacity for importing data into DynamoDB. Data import pricing is based on the uncompressed size of the source data in Amazon S3, that is processed as a result of the import. Items that are processed but fail to load into the table due to formatting or other inconsistencies in the source data are also billed as part of the import process. See [Amazon DynamoDB pricing](#) for details.

You can import data from an Amazon S3 bucket owned by a different account if you have the correct permissions to read from that specific bucket. The new table may also be in a different

Region from the source Amazon S3 bucket. For more information, see [Amazon Simple Storage Service setup and permissions](#).

Import times are directly related to your data's characteristics in Amazon S3. This includes data size, data format, compression scheme, uniformity of data distribution, number of Amazon S3 objects, and other related variables. In particular, data sets with uniformly distributed keys will be faster to import than skewed data sets. For example, if your secondary index's key is using the month of the year for partitioning, and all your data is from the month of December, then importing this data may take significantly longer.

The attributes associated with keys are expected to be unique on the base table. If any keys are not unique, the import will overwrite the associated items until only the last overwrite remains. For example, if the primary key is the month and multiple items are set to the month of September, each new item will overwrite the previously written items and only one item with the primary key of "month" set to September will remain. In such cases, the number of items processed in the import table description will not match the number of items in the target table.

AWS CloudTrail logs all console and API actions for table import. For more information, see [Logging DynamoDB operations by using AWS CloudTrail](#).

The following video is an introduction to importing directly from Amazon S3 into DynamoDB.

[Import from Amazon S3](#)

Requesting a table import in DynamoDB

DynamoDB import allows you to import data from an Amazon S3 bucket to a new DynamoDB table. You can request a table import using the [DynamoDB console](#), the [CLI](#), [CloudFormation](#) or the [DynamoDB API](#).

If you want to use the AWS CLI, you must configure it first. For more information, see [Accessing DynamoDB](#).

 **Note**

- The Import Table feature interacts with multiple different AWS Services such as Amazon S3 and CloudWatch. Before you begin an import, make sure that the user or role that invokes the import APIs has permissions to all services and resources the feature depends on.
 - Do not modify the Amazon S3 objects while the import is in progress, as this can cause the operation to fail or be cancelled.

For more information on errors and troubleshooting, see [Import format quotas and validation](#)

Topics

- [Setting up IAM permissions](#)
 - [Requesting an import using the AWS Management Console](#)
 - [Getting details about past imports in the AWS Management Console](#)
 - [Requesting an import using the AWS CLI](#)
 - [Getting details about past imports in the AWS CLI](#)

Setting up IAM permissions

You can import data from any Amazon S3 bucket you have permission to read from. The source bucket does not need to be in the same Region or have the same owner as the source table. Your AWS Identity and Access Management (IAM) must include the relevant actions on the source Amazon S3 bucket, and required CloudWatch permissions for providing debugging information. An example policy is shown below.

```
        "dynamodb:DescribeImport",
        "dynamodb>ListImports"
    ],
    "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table*"
},
{
    "Sid": "AllowS3Access",
    "Effect": "Allow",
    "Action": [
        "s3:GetObject",
        "s3>ListBucket"
    ],
    "Resource": [
        "arn:aws:s3:::your-bucket/*",
        "arn:aws:s3:::your-bucket"
    ]
},
{
    "Sid": "AllowCloudwatchAccess",
    "Effect": "Allow",
    "Action": [
        "logs>CreateLogGroup",
        "logs>CreateLogStream",
        "logs>DescribeLogGroups",
        "logs>DescribeLogStreams",
        "logs>PutLogEvents",
        "logs>PutRetentionPolicy"
    ],
    "Resource": "arn:aws:logs:us-east-1:111122223333:log-group:/aws-dynamodb/*"
}
]
}
```

Amazon S3 permissions

When starting an import on an Amazon S3 bucket source that is owned by another account, ensure that the role or user has access to the Amazon S3 objects. You can check that by executing an Amazon S3 GetObject command and using the credentials. When using the API, the Amazon S3 bucket owner parameter defaults to the current user's account ID. For cross account imports, ensure that this parameter is correctly populated with the bucket owner's account ID. The following code is an example Amazon S3 bucket policy in the source account.

{

```
"Version": "2012-10-17",
"Statement": [
    {"Sid": "ExampleStatement",
        "Effect": "Allow",
        "Principal": {"AWS": "arn:aws:iam::123456789012:user/Dave"},
        "Action": [
            "s3:GetObject",
            "s3>ListBucket"
        ],
        "Resource": "arn:aws:s3:::awsexamplebucket1/*"
    }
]
```

AWS Key Management Service

When creating the new table for import, if you select an encryption at rest key that is not owned by DynamoDB then you must provide the AWS KMS permissions required to operate a DynamoDB table encrypted with customer managed keys. For more information see [Authorizing use of your AWS KMS key](#). If the Amazon S3 objects are encrypted with server side encryption KMS (SSE-KMS), ensure that the role or user initiating the import has access to decrypt using the AWS KMS key. This feature does not support customer-provided encryption keys (SSE-C) encrypted Amazon S3 objects.

CloudWatch permissions

The role or user that is initiating the import will need create and manage permissions for the log group and log streams associated with the import.

Requesting an import using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to import existing data to a new table named MusicCollection.

To request a table import

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Import from S3**.
3. On the page that appears, select **Import from S3**.

4. Choose **Import from S3**.
5. Enter the Amazon S3 source URL.

If the source bucket is owned by your account, you can find it by using the **Browse S3** button. Alternately, you can enter the URL of the bucket in the `s3://bucket/prefix` format. The prefix is an Amazon S3 key prefix that is either the Amazon S3 object name that you want to import, or the key prefix shared by all the Amazon S3 objects that you want to import.

6. Specify if you are the **S3 bucket owner**. If the source bucket is owned by a different account, select **A different AWS account**. Then enter the account ID of the bucket owner.
7. Under **Import file compression**, select either **No compression**, **GZIP** or **ZSTD** as appropriate.
8. Select the appropriate Import file format. The options are **DynamoDB JSON**, **Amazon Ion** or **CSV**. If you select **CSV**, you will have two additional options: **CSV header** and **CSV delimiter character**.

For **CSV header**, choose if the header will either be taken from the first line of the file or be customized. If you select **Customize your headers**, you can specify the header values you want to import with. CSV Headers specified by this method are case-sensitive and are expected to contain the keys of the target table.

For **CSV delimiter character**, you set the character which will separate items. Comma is selected by default. If you select **Custom delimiter character**, the delimiter must match the regex pattern: `[, ; : | \t]`.

9. Select the **Next** button and select the options for the new table that will be created to store your data.

 **Note**

Primary Key and Sort Key must match the attributes in the file, or the import will fail. The attributes are case sensitive.

10. Select **Next** again to review your import options, then click **Import** to begin the import task. You will first see your new table listed in the "Tables" with the status "Creating". At this time the table is not accessible.
11. Once the import completes, the status will show as "Active" and you can start using the table.

Getting details about past imports in the AWS Management Console

You can find information about import tasks you've run in the past by clicking **Import from S3** in the navigation sidebar, then selecting the **Imports** tab. The import panel contains a list of all imports you've created in the past 90 days. Selecting the ARN of a task listed in the Imports tab will retrieve information about that import, including any advanced configuration settings you chose.

Requesting an import using the AWS CLI

The following example imports CSV formatted data from an S3 bucket called `bucket` with a prefix of `prefix` to a new table called `target-table`.

```
aws dynamodb import-table --s3-bucket-source S3Bucket=bucket,S3KeyPrefix=prefix \
    --input-format CSV --table-creation-parameters '{"TableName":"target-
table","KeySchema": \
    [{"AttributeName":"hk","KeyType":"HASH"}],"AttributeDefinitions": \
    [{"AttributeName":"hk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}' \
    --input-format-options '{"Csv": {"HeaderList": ["hk", "title", "artist", \
    "year_of_release"], "Delimiter": ";"}}'
```

Note

If you choose to encrypt your import using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination Amazon S3 bucket.

Getting details about past imports in the AWS CLI

You can find information about import tasks you've run in the past by using the `list-imports` command. This command returns a list of all imports you've created in the past 90 days. Note that although import task metadata expires after 90 days and jobs older than that are no longer found on this list, DynamoDB does not delete any of the objects in your Amazon S3 bucket or the table created during import.

```
aws dynamodb list-imports
```

To retrieve detailed information about a specific import task, including any advanced configuration settings, use the `describe-import` command.

```
aws dynamodb describe-import \
--import-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/exp
```

Amazon S3 import formats for DynamoDB

DynamoDB can import data in three formats: CSV, DynamoDB JSON, and Amazon Ion.

Topics

- [CSV](#)
- [DynamoDB Json](#)
- [Amazon Ion](#)

CSV

A file in CSV format consists of multiple items delimited by newlines. By default, DynamoDB interprets the first line of an import file as the header and expects columns to be delimited by commas. You can also define headers that will be applied, as long as they match the number of columns in the file. If you define headers explicitly, the first line of the file will be imported as values.

Note

When importing from CSV files, all columns other than the hash range and keys of your base table and secondary indexes are imported as DynamoDB strings.

Escaping double quotes

Any double quotes characters that exist in the CSV file must be escaped. If they are not escaped, such as in this following example, the import will fail:

```
id,value
"123",Women's Full Lenth Dress
```

This same import will succeed if the quotes are escaped with two sets of double quotes:

```
id,value
""""123""""",Women's Full Lenth Dress
```

Once the text has been properly escaped and imported, it will appear as it did in the original CSV file:

```
id,value
"123",Women's Full Lenth Dress
```

DynamoDB Json

A file in DynamoDB JSON format can consist of multiple Item objects. Each individual object is in DynamoDB's standard marshalled JSON format, and newlines are used as item delimiters. As an added feature, exports from point in time are supported as an import source by default.

Note

New lines are used as item delimiters for a file in DynamoDB JSON format and shouldn't be used within an item object.

```
{
  "Item": {
    "Authors": {
      "SS": ["Author1", "Author2"]
    },
    "Dimensions": {
      "S": "8.5 x 11.0 x 1.5"
    },
    "ISBN": {
      "S": "333-3333333333"
    },
    "Id": {
      "N": "103"
    },
    "InPublication": {
      "BOOL": false
    },
    "PageCount": {
      "N": "600"
    },
    "Price": {
      "N": "2000"
    },
    "ProductCategory": {
```

```
        "S": "Book"
    },
    "Title": {
        "S": "Book 103 Title"
    }
}
```

Note

New lines are used as item delimiters for a file in DynamoDB JSON format and shouldn't be used within an item object.

```
{
    "Item": {
        "Authors": {
            "SS": ["Author1", "Author2"]
        },
        "Dimensions": {
            "S": "8.5 x 11.0 x 1.5"
        },
        "ISBN": {
            "S": "333-333333333"
        },
        "Id": {
            "N": "103"
        },
        "InPublication": {
            "BOOL": false
        },
        "PageCount": {
            "N": "600"
        },
        "Price": {
            "N": "2000"
        },

```

Amazon Ion

[Amazon Ion](#) is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures.

When you import data in Ion format, the Ion datatypes are mapped to DynamoDB datatypes in the new DynamoDB table.

	Ion to DynamoDB datatype conversion	B
1	Ion Data Type	DynamoDB Representation
2	string	String (s)
3	bool	Boolean (BOOL)
4	decimal	Number (N)
5	blob	Binary (B)

	Ion to DynamoDB datatype conversion	B
6	list (with type annotation \$dynamodb_SS, \$dynamodb_NS, or \$dynamodb_BS)	Set (SS, NS, BS)
7	list	List
8	struct	Map

Items in an Ion file are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format.

 **Note**

In the following example, an item from an Ion-formatted file has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Item: {
        Authors:$dynamodb_SS::["Author1", "Author2"],
        Dimensions:"8.5 x 11.0 x 1.5",
        ISBN:"333-333333333",
        Id:103.,
        InPublication:false,
        PageCount:6d2,
        Price:2d3,
        ProductCategory:"Book",
        Title:"Book 103 Title"
    }
}
```

Import format quotas and validation

Import quotas

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. These default quotas are applied to every account. If you feel you need to revise these quotas, please contact your account team, and this will be considered on a case-by-case basis. For more details on DynamoDB limits, see [Service Quotas](#).

Validation errors

During the import process, DynamoDB may encounter errors while parsing your data. For each error, DynamoDB emits a CloudWatch log and keeps a count of the total number of errors encountered. If the Amazon S3 object itself is malformed or if its contents cannot form a DynamoDB item, then we may skip processing the remaining portion of the object.

Note

If the Amazon S3 data source has multiple items that share the same key, the items will overwrite until one remains. This can appear as if 1 item was imported and the others were ignored. The duplicate items will be overwritten in random order, are not counted as errors, and are not emitted to CloudWatch logs.

Once the import is complete you can see the total count of items imported, total count of errors, and total count of items processed. For further troubleshooting you can also check the total size of items imported and total size of data processed.

There are three categories of import errors: API validation errors, data validation errors, and configuration errors.

API validation errors

API validation errors are item-level errors from the sync API. Common causes are permissions issues, missing required parameters and parameter validation failures. Details on why the API call failed are contained in the exceptions thrown by the `ImportTable` request.

Data validation errors

Data validation errors can occur at either the item level or file level. During import, items are validated based on DynamoDB rules before importing into the target table. When an item fails validation and is not imported, the import job skips over that item and continues on with the next item. At the end of job, the import status is set to FAILED with a FailureCode, ItemValidationError and the FailureMessage "Some of the items failed validation checks and were not imported. Please check CloudWatch error logs for more details."

Common causes for data validation errors include objects being unparsable, objects being in the incorrect format (input specifies DYNAMODB_JSON but the object is not in DYNAMODB_JSON), and schema mismatch with specified source table keys.

Configuration errors

Configuration errors are typically workflow errors due to permission validation. The Import workflow checks some permissions after accepting the request. If there are issues calling any of the required dependencies like Amazon S3 or CloudWatch the process marks the import status as FAILED. The failureCode and failureMessage point to the reason for failure. Where applicable, the failure message also contains the request id that you can use to investigate the reason for failure in CloudTrail.

Common configuration errors include having the wrong URL for the Amazon S3 bucket, and not having permission to access the Amazon S3 bucket, CloudWatch Logs, and AWS KMS keys used to decrypt the Amazon S3 object. For more information see [Using and data keys](#).

Validating source Amazon S3 objects

In order to validate source S3 objects, take the following steps.

1. Validate the data format and compression type

- Make sure that all matching Amazon S3 objects under the specified prefix have the same format (DYNAMODB_JSON, DYNAMODB_ION, CSV)
- Make sure that all matching Amazon S3 objects under the specified prefix are compressed the same way (GZIP, ZSTD, NONE)

Note

The Amazon S3 objects do not need to have the corresponding extension (.csv / .json / .ion / .gz / .zstd etc) as the input format specified in ImportTable call takes precedence.

2. Validate that the import data conforms to the desired table schema

- Make sure that each item in the source data has the primary key. A sort key is optional for imports.
- Make sure that the attribute type associated with the primary key and any sort key matches the attribute type in the Table and the GSI schema, as specified in table creation parameters

Troubleshooting

CloudWatch logs

For Import jobs that fail, detailed error messages are posted to CloudWatch logs. To access these logs, first retrieve the ImportArn from the output and describe-import using this command:

```
aws dynamodb describe-import --import-arn arn:aws:dynamodb:us-east-1:ACCOUNT:table/  
target-table/import/01658528578619-c4d4e311  
}
```

Example output:

```
aws dynamodb describe-import --import-arn "arn:aws:dynamodb:us-  
east-1:531234567890:table/target-table/import/01658528578619-c4d4e311"  
{  
    "ImportTableDescription": {  
        "ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/  
import/01658528578619-c4d4e311",  
        "ImportStatus": "FAILED",  
        "TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",  
        "TableId": "7b7ecc22-302f-4039-8ea9-8e7c3eb2bcb8",  
        "ClientToken": "30f8891c-e478-47f4-af4a-67a5c3b595e3",  
        "S3BucketSource": {  
            "S3BucketOwner": "ACCOUNT",  
            "S3Bucket": "my-import-source",
```

```
        "S3KeyPrefix": "import-test"
    },
    "ErrorCount": 1,
    "CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-dynamodb/imports:*",
    "InputFormat": "CSV",
    "InputCompressionType": "NONE",
    "TableCreationParameters": {
        "TableName": "target-table",
        "AttributeDefinitions": [
            {
                "AttributeName": "pk",
                "AttributeType": "S"
            }
        ],
        "KeySchema": [
            {
                "AttributeName": "pk",
                "KeyType": "HASH"
            }
        ],
        "BillingMode": "PAY_PER_REQUEST"
    },
    "StartTime": 1658528578.619,
    "EndTime": 1658528750.628,
    "ProcessedSizeBytes": 70,
    "ProcessedItemCount": 1,
    "ImportedItemCount": 0,
    "FailureCode": "ItemValidationException",
    "FailureMessage": "Some of the items failed validation checks and were not imported. Please check CloudWatch error logs for more details."
}
}
```

Retrieve the log group and the import id from the above response and use it to retrieve the error logs. The import ID is the last path element of the ImportArn field. The log group name is /aws-dynamodb/imports. The error log stream name is import-id/error. For this example, it would be 01658528578619-c4d4e311/error.

Missing the key pk in the item

If the source S3 object does not contain the primary key that was provided as a parameter, the import will fail. For example, when you define the primary key for the import as column name "pk".

```
aws dynamodb import-table --s3-bucket-source S3Bucket=my-import-source,S3KeyPrefix=import-test.csv \
    --input-format CSV --table-creation-parameters '{"TableName":"target-table","KeySchema": \
        [{"AttributeName":"pk","KeyType":"HASH"}],"AttributeDefinitions": \
        [{"AttributeName":"pk","AttributeType":"S"}],"BillingMode":"PAY_PER_REQUEST"}'
```

The column "pk" is missing from the the source object `import-test.csv` which has the following contents:

```
title,artist,year_of_release
The Dark Side of the Moon,Pink Floyd,1973
```

This import will fail due to item validation error because of the missing primary key in the data source.

Example CloudWatch error log:

```
aws logs get-log-events --log-group-name /aws-dynamodb/imports --log-stream-name
01658528578619-c4d4e311/error
{
  "events": [
    {
      "timestamp": 1658528745319,
      "message": "{\"itemS3Pointer\":{\"bucket\":\"my-import-source\",\"key\":\\\"import-test.csv\\\",\\\"itemIndex\\\":0},\\\"importArn\\\":\\\"arn:aws:dynamodb:us-east-1:531234567890:table/target-table/import/01658528578619-c4d4e311\\\",\\\"errorMessages\\\":\\\"One or more parameter values were invalid: Missing the key pk in the item\\\"]}",
      "ingestionTime": 1658528745414
    }
  ],
  "nextForwardToken": "f/36986426953797707963335499204463414460239026137054642176/s",
  "nextBackwardToken": "b/36986426953797707963335499204463414460239026137054642176/s"
}
```

This error log indicates that "One or more parameter values were invalid: Missing the key pk in the item". Since this import job failed, the table "target-table" now exists and is empty because no items were imported. The first item was processed and the object failed Item Validation.

To fix the issue, first delete "target-table" if it is no longer needed. Then either use a primary key column name that exists in the source object, or update the source data to:

```
pk,title,artist,year_of_release
Albums::Rock::Classic::1973::AlbumId::ALB25,The Dark Side of the Moon,Pink Floyd,1973
```

Target table exists

When you start an import job and receive a response as follows:

```
An error occurred (ResourceInUseException) when calling the ImportTable operation:
Table already exists: target-table
```

To fix this error, you will need to choose a table name that doesn't already exist and retry the import.

The specified bucket does not exist

If the source bucket does not exist, the import will fail and log the error message details in CloudWatch.

Example describe import:

```
aws dynamodb --endpoint-url $ENDPOINT describe-import --import-arn "arn:aws:dynamodb:us-east-1:531234567890:table/target-table/import/01658530687105-e6035287"
{
  "ImportTableDescription": {
    "ImportArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table/import/01658530687105-e6035287",
    "ImportStatus": "FAILED",
    "TableArn": "arn:aws:dynamodb:us-east-1:ACCOUNT:table/target-table",
    "TableId": "e1215a82-b8d1-45a8-b2e2-14b9dd8eb99c",
    "ClientToken": "3048e16a-069b-47a6-9dfb-9c259fd2fb6f",
    "S3BucketSource": {
      "S3BucketOwner": "531234567890",
      "S3Bucket": "BUCKET_DOES_NOT_EXIST",
      "S3KeyPrefix": "import-test"
    },
    "ErrorCount": 0,
    "CloudWatchLogGroupArn": "arn:aws:logs:us-east-1:ACCOUNT:log-group:/aws-dynamodb/imports:*",
    "InputFormat": "CSV",
    "InputCompressionType": "NONE",
    "TableCreationParameters": {
      "TableName": "target-table",
    }
  }
}
```

```
"AttributeDefinitions": [
    {
        "AttributeName": "pk",
        "AttributeType": "S"
    }
],
"KeySchema": [
    {
        "AttributeName": "pk",
        "KeyType": "HASH"
    }
],
"BillingMode": "PAY_PER_REQUEST"
},
"StartTime": 1658530687.105,
"EndTime": 1658530701.873,
"ProcessedSizeBytes": 0,
"ProcessedItemCount": 0,
"ImportedItemCount": 0,
"FailureCode": "S3NoSuchBucket",
"FailureMessage": "The specified bucket does not exist (Service: Amazon S3; Status Code: 404; Error Code: NoSuchBucket; Request ID: Q4W6QYYFDWY6WAKH; S3 Extended Request ID: ObqSlLeIMJpQqHLRX2C5Sy7n+8g6iGPwy7ixg7eEeTuEkg/+chU/JF+RbliWytMlkUlUcuCLTrI=; Proxy: null)"
}
}
```

The `FailureCode` is `S3NoSuchBucket`, with `FailureMessage` containing details such as request id and the service that threw the error. Since the error was caught before the data was imported into the table, a new DynamoDB table is not created. In some cases, when these errors are encountered after the data import has started, the table with partially imported data is retained.

To fix this error, make sure that the source Amazon S3 bucket exists and then restart the import process.

Best practices for importing from Amazon S3 into DynamoDB

The following are the best practices for importing data from Amazon S3 into DynamoDB.

Stay under the limit of 50,000 S3 objects

Each import job supports a maximum of 50,000 S3 objects. If your dataset contains more than 50,000 objects, consider consolidating them into larger objects.

Avoid excessively large S3 objects

S3 objects are imported in parallel. Having numerous mid-sized S3 objects allows for parallel execution without excessive overhead. For items under 1 KB, consider placing 4,000,000 items into each S3 object. If you have a larger average item size, place proportionally fewer items into each S3 object.

Randomize sorted data

If an S3 object holds data in sorted order, it can create a *rolling hot partition*. This is a situation where one partition receives all the activity, and then the next partition after that, and so on. Data in sorted order is defined as items in sequence in the S3 object that will be written to the same target partition during the import. One common situation where data is in sorted order is a CSV file where items are sorted by partition key so that repeated items share the same partition key.

To avoid a rolling hot partition, we recommend that you randomize the order in these cases. This can improve performance by spreading the write operations. For more information, see [Distributing write activity efficiently during data upload](#).

Compress data to keep the total S3 object size below the Regional limit

In the [import from S3 process](#), there is a limit on the sum total size of the S3 object data to be imported. The limit is 15 TB in the us-east-1, us-west-2, and eu-west-1 Regions, and 1 TB in all other Regions. The limit is based on the raw S3 object sizes.

Compression allows more raw data to fit within the limit. If compression alone isn't sufficient to fit the import within the limit, you can also contact [AWS Premium Support](#) for a quota increase.

Be aware of how item size impacts performance

If your average item size is very small (below 200 bytes), the import process might take a little longer than for larger item sizes.

Consider importing without any Global Secondary Indexes

The duration of an import task may depend on the presence of one or multiple global secondary indexes (GSIs). If you plan to establish indexes with partition keys that have low cardinality, you may see a faster import if you defer index creation until after the import task is finished (rather than including them in the import job).

Note

Creating a GSI during the import does not incur write charges (creating a GSI after the import would).

DynamoDB data export to Amazon S3: how it works

DynamoDB export to S3 is a fully managed solution for exporting your DynamoDB data to an Amazon S3 bucket at scale. Using DynamoDB export to S3, you can export data from an Amazon DynamoDB table from any time within your [point-in-time recovery \(PITR\)](#) window to an Amazon S3 bucket. You need to enable PITR on your table to use the export functionality. This feature enables you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS Glue, Amazon SageMaker, Amazon EMR, and AWS Lake Formation.

DynamoDB export to S3 allows you to export both full and incremental data from your DynamoDB table. Exports do not consume any [read capacity units \(RCUs\)](#) and have no impact on table performance and availability. The export file formats supported are DynamoDB JSON and Amazon Ion formats. You can also export data to an S3 bucket owned by another AWS account and to a different AWS region. Your data is always encrypted end-to-end.

DynamoDB full exports are charged based on the size of the DynamoDB table (table data and local secondary indexes) at the point in time for which the export is done. DynamoDB incremental exports are charged based on the size of data processed from your continuous backups for the time period being exported. Additional charges apply for storing exported data in Amazon S3 and for PUT requests made against your Amazon S3 bucket. For more information about these charges, see [Amazon DynamoDB pricing](#) and [Amazon S3 pricing](#).

For specifics on service quotas, see [Table export to Amazon S3](#).

Topics

- [DynamoDB table export output format](#)

Requesting a table export in DynamoDB

DynamoDB table exports allow you to export table data to an Amazon S3 bucket, enabling you to perform analytics and complex queries on your data using other AWS services such as Athena, AWS

Glue, Amazon SageMaker, Amazon EMR, and AWS Lake Formation. You can request a table export using the AWS Management Console, the AWS CLI, or the DynamoDB API.

DynamoDB supports both full export and incremental export:

- With **full exports**, you can export a full snapshot of your table from any point in time within the point-in-time recovery (PITR) window to your Amazon S3 bucket.
- With **incremental exports**, you can export data from your DynamoDB table that was changed, updated, or deleted between a specified time period, within your PITR window, to your Amazon S3 bucket.

Topics

- [Prerequisites](#)
- [Requesting an export using the AWS Management Console](#)
- [Getting details about past exports in the AWS Management Console](#)
- [Requesting an export using the AWS CLI](#)
- [Getting details about past exports in the AWS CLI](#)
- [Requesting an export using the AWS SDK](#)
- [Getting details about past exports using the AWS SDK](#)

Prerequisites

Enable PITR

To use the export to S3 feature, you will need to enable PITR on your table. For details on how to enable PITR, see [Point-in-time recovery](#). If you request an export for a table that does not have PITR enabled, your request will fail with an exception message: "An error occurred (PointInTimeRecoveryUnavailableException) when calling the ExportTableToPointInTime operation: Point in time recovery is not enabled for table 'my-dynamodb-table'".

Set up S3 permissions

You can export your table data to any Amazon S3 bucket you have permission to write to. The destination bucket does not need to be in the same AWS Region or have the same owner as the source table owner. Your AWS Identity and Access Management (IAM) policy needs to allow you to be able to perform S3 actions (`s3:AbortMultipartUpload`,

`s3:PutObject`, and `s3:PutObjectAcl`) and the DynamoDB export action (`dynamodb:ExportTableToPointInTime`). Here is an example of a sample policy that will grant your user permissions to perform exports to an S3 bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowDynamoDBExportAction",  
            "Effect": "Allow",  
            "Action": "dynamodb:ExportTableToPointInTime",  
            "Resource": "arn:aws:dynamodb:us-east-1:111122223333:table/my-table"  
        },  
        {  
            "Sid": "AllowWriteToDestinationBucket",  
            "Effect": "Allow",  
            "Action": [  
                "s3:AbortMultipartUpload",  
                "s3:PutObject",  
                "s3:PutObjectAcl"  
            ],  
            "Resource": "arn:aws:s3:::your-bucket/*"  
        }  
    ]  
}
```

If you need to write to an S3 bucket that is in another account or you don't have permissions to write to, the S3 bucket owner will need to add a bucket policy to allow you to export from DynamoDB to that bucket. Here is an example policy on the target S3 bucket.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "ExampleStatement",  
            "Effect": "Allow",  
            "Principal": {  
                "AWS": "arn:aws:iam::123456789012:user/Dave"  
            },  
            "Action": [  
                "s3:AbortMultipartUpload",  
                "s3:PutObject",  
                "s3:PutObjectAcl"  
            ]  
        }  
    ]  
}
```

```
        "s3:PutObjectAcl"
    ],
    "Resource": "arn:aws:s3:::awsexamplebucket1/*"
}
]
```

Revoking these permissions while an export is in progress will result in partial files.

 **Note**

If the table or bucket you're exporting to is encrypted with customer managed keys, that KMS key's policies must give DynamoDB permission to use it. This permission is given through the IAM User/Role that triggers the export job. For more information on encryption including best practices, see [How DynamoDB uses AWS KMS](#) and [Using a custom KMS key](#).

Requesting an export using the AWS Management Console

The following example demonstrates how to use the DynamoDB console to export an existing table named `MusicCollection`.

 **Note**

This procedure assumes that you have enabled point-in-time recovery. To enable it for the `MusicCollection` table, on the table's **Overview** tab, in the **Table details** section, choose **Enable for Point-in-time recovery**.

To request a table export

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Exports to S3**.
3. Select the **Export to S3** button.
4. Choose a source table and destination S3 bucket. If the destination bucket is owned by your account, you can use the **Browse S3** button to find it. Otherwise, enter the URL of the bucket

using the `s3://bucketname/prefix` format. The **prefix** is an optional folder to help keep your destination bucket organized.

5. Choose **Full export** or **Incremental export**. A **full export** outputs the full table snapshot of your table as it was at the point in time you specify. An **incremental export** outputs the changes made to your table during the specified export period. Your output is compacted such that it will only contain the final state of the item from the export period. The item will only appear once in the export even if it has multiple updates within the same export period.

Full export

1. Select the point in time you want to export the full table snapshot from. This can be any point in time within the PITR window. Alternatively, you can select **Current time** to export the latest snapshot.

Export settings

Full export
Export the table data in its current state, or from any specific point up to 35 days ago.

Incremental export
Export any table data that's changed within a specific time period.

Export from a specific point in time | [Info](#)

Current time

Export from an earlier point in time
Your earliest export point is the same as the earliest restore point for your table.

2023/09/01 [Calendar icon](#) 12:00:00 (UTC+01:00)

For date, use YYYY/MM/DD format. For time, use 24-hour format.

2. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

 **Note**

If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

Exported file format | [Info](#)

DynamoDB JSON

Amazon Ion

Open-source text format, which is a superset of JSON.

Incremental export

1. Select the **Export period** you want to export the incremental data for. Pick a start time within the PITR window. The export period duration must be at least 15 minutes and be no longer than 24 hours. The export period's start time is inclusive and the end time is exclusive.

Export settings

Full export

Export the table data in its current state, or from any specific point up to 35 days ago.

Incremental export

Export any table data that's changed within a specific time period.

Export period

Specify when the incremental export starts and ends. Your earliest export point is the same as the earliest restore point for your table.

 2023-09-01T12:00:00+01:00 — 2023-09-02T12:00:00+01:00

2. Choose between **Absolute mode** or **Relative mode**.

- a. **Absolute mode** will export incremental data for the time period you specify.

Relative modeAbsolute mode

<August 2023September 2023>

Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue	Wed	Thu	Fri	Sat	Sun

- Last 6 hours
- Last 12 hours
- Last 24 hours
- Custom range

Set a custom range in the past

[Clear](#)[Cancel](#)[Apply](#)

3. For **Exported file format**, choose between **DynamoDB JSON** and **Amazon Ion**. By default, your table will be exported in DynamoDB JSON format from the latest restorable time in the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3). You can change these export settings if necessary.

Note

If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

Exported file format | [Info](#) **DynamoDB JSON** **Amazon Ion**

Open-source text format, which is a superset of JSON.

4. For **Export view type**, select either **New and old images** or **New images only**. New image provides the latest state of the item. Old image provides the state of the item right before the specified “start date and time”. The default setting is **New and old images**. For more information on new images and old images, see [Incremental export output](#).

Export view type

- New and old images**
- New images only**

6. Click the **Export** button to begin the export.

Exported data is not transactionally consistent. This means that your transaction operations can be torn between two export outputs. You may see a subset of items modified by a transaction operation reflected in the export, while another subset of modifications in the same transaction is not reflected in the same export request. However, exports are eventually consistent. If a transaction is torn during an export, you are guaranteed to have the remaining transaction in your next contiguous export, with no duplicates. The time periods used for exports are based on an internal system clock and can vary by one minute of your application's local clock.

Getting details about past exports in the AWS Management Console

You can find information about export tasks you've run in the past by clicking the **Exports to S3** section in the navigation sidebar. This section contains a list of all exports you've created in the past 90 days. Selecting the ARN of a task listed in the Exports tab will retrieve information about that export, including any advanced configuration settings you chose. Note that although export task metadata expires after 90 days and jobs older than that are no longer found in this list, the objects in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Requesting an export using the AWS CLI

The following example shows how to use the AWS CLI to export an existing table named `MusicCollection` to an S3 bucket called `ddb-export-musiccollection`.

Note

This procedure assumes that you have enabled point-in-time recovery. To enable it for the MusicCollection table, run the following command.

```
aws dynamodb update-continuous-backups \
--table-name MusicCollection \
--point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
```

Full export

The following command exports the MusicCollection to an S3 bucket called ddb-export-musiccollection-9012345678 with a prefix of 2020-Nov. Table data will be exported in DynamoDB JSON format from a specific time within the point in time recovery window and encrypted using an Amazon S3 key (SSE-S3).

Note

If requesting a cross-account table export, make sure to include the `--s3-owner` option.

```
aws dynamodb export-table-to-point-in-time \
--table-arn arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection \
--s3-bucket ddb-export-musiccollection-9012345678 \
--s3-prefix 2020-Nov \
--export-format DYNAMODB_JSON \
--export-time 1604632434 \
--s3-owner 9012345678 \
--s3-sse-algorithm AES256
```

Incremental export

The following command performs an incremental export by providing a new `--export-type` and `--incremental-export-specification`. Substitute your own values for anything in *italics*. Times are specified as seconds since epoch.

```
aws dynamodb export-table-to-point-in-time \
```

```
--table-arn arn:aws:dynamodb:REGION:ACCOUNT:table/TABLENAME \
--s3-bucket BUCKET --s3-prefix PREFIX \
--incremental-export-specification
ExportFromTime=1693569600,ExportToTime=1693656000,ExportViewType=NEW_AND_OLD_IMAGES
\
--export-type INCREMENTAL_EXPORT
```

Note

If you choose to encrypt your export using a key protected by AWS Key Management Service (AWS KMS), the key must be in the same Region as the destination S3 bucket.

Getting details about past exports in the AWS CLI

You can find information about export requests you've run in the past by using the `list-exports` command. This command returns a list of all exports you've created in the past 90 days. Note that although export task metadata expires after 90 days and jobs older than that are no longer returned by the `list-exports` command, the objects in your S3 bucket remain as long as their bucket policies allow. DynamoDB never deletes any of the objects it creates in your S3 bucket during an export.

Exports have a status of PENDING until they either succeed or fail. If they succeed, the status will change to COMPLETED. If they fail, the status will change to FAILED with a `failure_message` and `failure_reason`.

In the following example, we use the optional `table-arn` parameter to list only exports of a specific table.

```
aws dynamodb list-exports \
--table-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog
```

To retrieve detailed information about a specific export task, including any advanced configuration settings, use the `describe-export` command.

```
aws dynamodb describe-export \
--export-arn arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/
export/01234567890123-a1b2c3d4
```

Requesting an export using the AWS SDK

Use these code snippets to request a table export using the AWS SDK of your choice.

Python

Full export

```
import boto3
from datetime import datetime

# remove endpoint_url for real use
client = boto3.client('dynamodb')

# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/
# dynamodb/client/export_table_to_point_in_time.html
client.export_table_to_point_in_time(
    TableName='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',
    ExportTime=datetime(2023, 9, 20, 12, 0, 0),
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
    ExportFormat='DYNAMODB_JSON'
)
```

Incremental export

```
import boto3
from datetime import datetime

client = boto3.client('dynamodb')

client.export_table_to_point_in_time(
    TableName='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',
    IncrementalExportSpecification={
        'ExportFromTime': datetime(2023, 9, 20, 12, 0, 0),
        'ExportToTime': datetime(2023, 9, 20, 13, 0, 0),
        'ExportViewType': 'NEW_AND_OLD_IMAGES'
    },
    ExportType='INCREMENTAL_EXPORT',
    S3Bucket='bucket',
    S3Prefix='prefix',
    S3SseAlgorithm='AES256',
```

```
    ExportFormat='DYNAMODB_JSON'  
)
```

Getting details about past exports using the AWS SDK

Use these code snippets to get details about past table exports using the AWS SDK of your choice.

Python

Full export

```
import boto3  
  
client = boto3.client('dynamodb')  
  
# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/dynamodb/client/list\_exports.html  
  
print(  
    client.list_exports(  
        TableArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE',  
    )  
)
```

Incremental export

```
import boto3  
  
client = boto3.client('dynamodb')  
  
# https://boto3.amazonaws.com/v1/documentation/api/latest/reference/services/dynamodb/client/describe\_export.html  
  
print(  
    client.describe_export(  
        ExportArn='arn:aws:dynamodb:us-east-1:0123456789:table/TABLE/  
export/01695353076000-06e2188f',  
        )['ExportDescription'])
```

DynamoDB table export output format

A DynamoDB table export includes manifest files in addition to the files containing your table data. These files are all saved in the Amazon S3 bucket that you specify in your [export request](#). The following sections describe the format and contents of each output object.

Full export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynoDB/ExportId/manifest-summary.json  
export-prefix/AWSDynoDB/ExportId/manifest-summary.checksum  
export-prefix/AWSDynoDB/ExportId/manifest-files.json  
export-prefix/AWSDynoDB/ExportId/manifest-files.checksum
```

You choose an **export-prefix** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **ExportId** is a unique token generated by the service to ensure that multiple exports to the same S3 bucket and **export-prefix** don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

Note

DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{  
    "version": "2020-06-30",  
    "exportArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog/  
export/01234567890123-a1b2c3d4",  
    "startTime": "2020-11-04T07:28:34.028Z",  
    "endTime": "2020-11-04T07:33:43.897Z",  
    "tableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/ProductCatalog",  
    "tableId": "12345a12-abcd-123a-ab12-1234abc12345",  
    "exportTime": "2020-11-04T07:28:34.028Z",  
    "s3Bucket": "ddb-productcatalog-export",  
    "s3Prefix": "2020-Nov",  
    "s3SseAlgorithm": "AES256",  
    "s3SseKmsKeyId": null,  
    "manifestFilesS3Key": "AWSDynoDB/01693685827463-2d8752fd/manifest-files.json",  
    "billedSizeBytes": 0,  
    "itemCount": 8,  
    "outputFormat": "DYNAMODB_JSON",  
    "exportType": "FULL_EXPORT"  
}
```

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in [JSON lines](#) format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{  
    "itemCount": 8,  
    "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",  
    "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",  
    "dataFileS3Key": "AWSDynoDB/01693685827463-2d8752fd/data/asdl123dasas.json.gz"  
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The directory structure of your S3 bucket after a full export will contain all of your manifest files and data files under the export Id folder.

DestinationBucket/DestinationPrefix

```
.  
### AWSDynamoDB  
### 01693685827463-2d8752fd      // the single full export  
# ### manifest-files.json        // manifest points to files under 'data' subfolder  
# ### manifest-files.checksum  
# ### manifest-summary.json     // stores metadata about request  
# ### manifest-summary.md5  
# ### data                      // The data exported by full export  
# # ### asdl123dasas.json.gz  
# # ...  
# ### _started                  // empty file for permission check
```

DynamoDB JSON

A table export in DynamoDB JSON format consists of multiple Item objects. Each individual object is in DynamoDB's standard marshalled JSON format.

When creating custom parsers for DynamoDB JSON export data, the format is [JSON lines](#). This means that newlines are used as item delimiters. Many AWS services, such as Athena and AWS Glue, will parse this format automatically.

In the following example, a single item from a DynamoDB JSON export has been formatted on multiple lines for the sake of readability.

```
{  
    "Item":{  
        "Authors":{  
            "SS":[  
                "Author1",  
                "Author2"  
            ]  
        },  
        "Dimensions":{  
            "S":"8.5 x 11.0 x 1.5"  
        },  
        "ISBN":{  
            "S":"333-333333333"  
        },  
        "Id":{  
            "N":"103"  
        },  
        "InPublication":{  
            "B":true  
        }  
    }  
}
```

```
        "BOOL":false
    },
    "PageCount":{
        "N":"600"
    },
    "Price":{
        "N":"2000"
    },
    "ProductCategory":{
        "S":"Book"
    },
    "Title":{
        "S":"Book 103 Title"
    }
}
}
```

Amazon Ion

[Amazon Ion](#) is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's [text format](#), which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to [Ion datatypes](#). DynamoDB sets use [Ion type annotations](#) to disambiguate the datatype used in the source table.

DynamoDB to ion datatype conversion

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation \$dynamodb_SS, \$dynamodb_NS, or \$dynamodb_BS)

DynamoDB data type	Ion representation
List	list
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Item: {
        Authors:$dynamodb_SS::["Author1", "Author2"],
        Dimensions:"8.5 x 11.0 x 1.5",
        ISBN:"333-333333333",
        Id:103.,
        InPublication:false,
        PageCount:6d2,
        Price:2d3,
        ProductCategory:"Book",
        Title:"Book 103 Title"
    }
}
```

Incremental export output

Manifest files

DynamoDB creates manifest files, along with their checksum files, in the specified S3 bucket for each export request.

```
export-prefix/AWSDynoDB/ExportId/manifest-summary.json
export-prefix/AWSDynoDB/ExportId/manifest-summary.checksum
export-prefix/AWSDynoDB/ExportId/manifest-files.json
export-prefix/AWSDynoDB/ExportId/manifest-files.checksum
```

You choose an **export-prefix** when you request a table export. This helps you keep files in the destination S3 bucket organized. The **ExportId** is a unique token generated by the service to ensure that multiple exports to the same S3 bucket and export-prefix don't overwrite each other.

The export creates at least 1 file per partition. For partitions that are empty, your export request will create an empty file. All of the items in each file are from that particular partition's hashed keyspace.

Note

DynamoDB also creates an empty file named `_started` in the same directory as the manifest files. This file verifies that the destination bucket is writable and that the export has begun. It can safely be deleted.

The summary manifest

The `manifest-summary.json` file contains summary information about the export job. This allows you to know which data files in the shared data folder are associated with this export. Its format is as follows:

```
{  
  "version": "2023-08-01",  
  "exportArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test/  
  export/01695097218000-d6299cbd",  
  "startTime": "2023-09-19T04:20:18.000Z",  
  "endTime": "2023-09-19T04:40:24.780Z",  
  "tableArn": "arn:aws:dynamodb:us-east-1:599882009758:table/export-test",  
  "tableId": "b116b490-6460-4d4a-9a6b-5d360abf4fb3",  
  "exportFromTime": "2023-09-18T17:00:00.000Z",  
  "exportToTime": "2023-09-19T04:00:00.000Z",  
  "s3Bucket": "jason-exports",  
  "s3Prefix": "20230919-prefix",  
  "s3SseAlgorithm": "AES256",  
  "s3SseKmsKeyId": null,  
  "manifestFilesS3Key": "20230919-prefix/AWSDynoDB/01693685934212-ac809da5/manifest-  
  files.json",  
  "billedSizeBytes": 20901239349,  
  "itemCount": 169928274,  
  "outputFormat": "DYNAMODB_JSON",  
  "outputView": "NEW_AND_OLD_IMAGES",  
  "exportType": "INCREMENTAL_EXPORT"  
}
```

The files manifest

The `manifest-files.json` file contains information about the files that contain your exported table data. The file is in [JSON lines](#) format, so newlines are used as item delimiters. In the following example, the details of one data file from a files manifest are formatted on multiple lines for the sake of readability.

```
{  
  "itemCount": 8,  
  "md5Checksum": "sQMSpEILNgoQmarvDFonGQ==",  
  "etag": "af83d6f217c19b8b0fff8023d8ca4716-1",  
  "dataFileS3Key": "AWSDynoDB/data/sgad6417s6vss4p7owp0471bcq.json.gz"  
}
```

Data files

DynamoDB can export your table data in two formats: DynamoDB JSON and Amazon Ion. Regardless of the format you choose, your data will be written to multiple compressed files named by the keys. These files are also listed in the `manifest-files.json` file.

The data files for incremental exports are all contained in a common data folder in your S3 bucket. Your manifest files are under your export ID folder.

```
DestinationBucket/DestinationPrefix  
. . .  
### AWSDynoDB  
### 01693685934212-ac809da5      // an incremental export ID  
#   ### manifest-files.json      // manifest points to files under 'data' folder  
#   ### manifest-files.checksum  
#   ### manifest-summary.json    // stores metadata about request  
#   ### manifest-summary.md5  
#   ### _started                // empty file for permission check  
### 01693686034521-ac809da5  
#   ### manifest-files.json  
#   ### manifest-files.checksum  
#   ### manifest-summary.json  
#   ### manifest-summary.md5  
#   ### _started  
### data                      // stores all the data files for incremental  
exports  
#   ### sgad6417s6vss4p7owp0471bcq.json.gz  
#   ...
```

If you export files, each item's output includes a timestamp that represents when that item was updated in your table and a data structure that indicates if it was an `insert`, `update`, or `delete` operation. The timestamp is based on an internal system clock and can vary from your application clock. For incremental exports, you can choose between two export view types for your output structure: **new and old images** or **new images only**.

- **New image** provides the latest state of the item
- **Old image** provides the state of the item right before the specified **start date and time**

View types can be helpful if you want to see how the item was changed within the export period. It can also be useful for efficiently updating your downstream systems, especially if those downstream systems have a partition key that is not the same as your DynamoDB partition key.

You can infer whether an item in your incremental export output was an `insert`, `update`, or `delete` by looking at the structure of the output. The incremental export structure and its corresponding operations are summarized in the table below for both export view types.

Operation	New images only	New and old images
Insert	Keys + new image	Keys + new image
Update	Keys + new image	Key + new image + old image
Delete	Keys	Keys + old image
Insert + delete	No output	No output

DynamoDB JSON

A table export in DynamoDB JSON format consists of a metadata timestamp that indicates the write time of the item, followed by the keys of the item and the values. The following shows an example DynamoDB JSON output using export view type as **New and Old images**.

```
// Ex 1: Insert
// An insert means the item did not exist before the incremental export window
// and was added during the incremental export window

{
  "Metadata": {
```

```
"WriteTimestampMicros": "1680109764000000"
},
"Key": {
    "PK": {
        "S": "CUST#100"
    }
},
"NewImage": {
    "PK": {
        "S": "CUST#100"
    },
    "FirstName": {
        "S": "John"
    },
    "LastName": {
        "S": "Don"
    }
}
}

// Ex 2: Update
// An update means the item existed before the incremental export window
// and was updated during the incremental export window.
// The OldImage would not be present if choosing "New images only".

{
    "Metadata": {
        "WriteTimestampMicros": "1680109764000000"
    },
    "Key": {
        "PK": {
            "S": "CUST#200"
        }
    },
    "OldImage": {
        "PK": {
            "S": "CUST#200"
        },
        "FirstName": {
            "S": "Mary"
        },
        "LastName": {
            "S": "Grace"
        }
    }
}
```

```
},
  "NewImage": {
    "PK": {
      "S": "CUST#200"
    },
    "FirstName": {
      "S": "Mary"
    },
    "LastName": {
      "S": "Smith"
    }
  }
}

// Ex 3: Delete
// A delete means the item existed before the incremental export window
// and was deleted during the incremental export window
// The OldImage would not be present if choosing "New images only".

{
  "Metadata": {
    "WriteTimestampMicros": "1680109764000000"
  },
  "Key": {
    "PK": {
      "S": "CUST#300"
    }
  },
  "OldImage": {
    "PK": {
      "S": "CUST#300"
    },
    "FirstName": {
      "S": "Jose"
    },
    "LastName": {
      "S": "Hernandez"
    }
  }
}

Amazon Ion

[Amazon Ion](#) is a richly-typed, self-describing, hierarchical data serialization format built to address rapid development, decoupling, and efficiency challenges faced every day while engineering large-scale, service-oriented architectures. DynamoDB supports exporting table data in Ion's [text format](#), which is a superset of JSON.

When you export a table to Ion format, the DynamoDB datatypes used in the table are mapped to [Ion datatypes](#). DynamoDB sets use [Ion type annotations](#) to disambiguate the datatype used in the source table.

DynamoDB to ion datatype conversion

DynamoDB data type	Ion representation
String (S)	string
Boolean (BOOL)	bool
Number (N)	decimal
Binary (B)	blob
Set (SS, NS, BS)	list (with type annotation \$dynamodb_SS, \$dynamodb_NS, or \$dynamodb_BS)
List	list
Map	struct

Items in an Ion export are delimited by newlines. Each line begins with an Ion version marker, followed by an item in Ion format. In the following example, an item from an Ion export has been formatted on multiple lines for the sake of readability.

```
$ion_1_0 {
    Record: {
        Keys: {
            ISBN: "333-3333333333"
```

```
        },
        Metadata:{
            WriteTimestampMicros:1684374845117899.
        },
        OldImage:{
            Authors:$dynamodb_SS::["Author1","Author2"],
            ISBN:"333-333333333",

        }
    }
}
```

DynamoDB zero-ETL integration with Amazon OpenSearch Service

Amazon DynamoDB offers a zero-ETL integration with Amazon OpenSearch Service through the **DynamoDB plugin for OpenSearch Ingestion**. Amazon OpenSearch Ingestion offers a fully managed, no-code experience for ingesting data into Amazon OpenSearch Service.

With the DynamoDB plugin for OpenSearch Ingestion, you can use one or more DynamoDB tables as a source for ingestion to one or more OpenSearch Service indexes. You can browse and configure your OpenSearch Ingestion pipelines with DynamoDB as a source from either OpenSearch Ingestion or DynamoDB Integrations in the AWS Management Console.

- Get started with OpenSearch Ingestion by following along in the [OpenSearch Ingestion getting started guide](#).

- Learn about the prerequisites and all the configuration options for the DynamoDB plugin at [DynamoDB plugin for OpenSearch Ingestion documentation](#).

How it works

The plugin uses [DynamoDB export to Amazon S3](#) to create an initial snapshot to load into OpenSearch. After the snapshot has been loaded, the plugin uses DynamoDB Streams to replicate any further changes in near real time. Every item is processed as an event in OpenSearch Ingestion and can be modified with processor plugins. You can drop attributes or create composite attributes and send them to different indexes through routes.

You must have [point-in-time recovery \(PITR\)](#) enabled to use export to Amazon S3. You must also have [DynamoDB Streams](#) enabled (with the **new & old images** option selected) to be able to use it. It's possible to create a pipeline without taking a snapshot by excluding export settings.

You can also create a pipeline with only a snapshot and no updates by excluding streams settings. The plugin does not use read or write throughput on your table, so it is safe to use without impacting your production traffic. There are limits to the number of parallel consumers on a stream that you should consider before creating this or other integrations. For other considerations, see [the section called "Integration best practices"](#).

For simple pipelines, a single OpenSearch Compute Unit (OCU) can process about 1 MB per second of writes. This is the equivalent of about 1000 write request units (WCU). Depending on your pipeline's complexity and other factors, you might achieve more or less than this.

OpenSearch Ingestion supports a dead-letter queue (DLQ) for events that cause unrecoverable errors. Additionally, the pipeline can resume from where it left off without user intervention even if there's an interruption of service with either DynamoDB, the pipeline, or Amazon OpenSearch Service.

If interruption goes on for longer than 24 hours, this can cause a loss of updates. However, the pipeline would continue to process the updates that were still available when availability is restored. You would need to do a fresh index build to fix any irregularities due to the dropped events unless they were in the dead-letter queue.

For all the settings and details for the plugin, see [OpenSearch Ingestion DynamoDB plugin documentation](#).

Integrated create experience through the console

DynamoDB and OpenSearch Service have an integrated experience in the AWS Management Console, which streamlines the getting started process. When you go through these steps, the service will automatically select the DynamoDB blueprint and add the appropriate DynamoDB information for you.

To create an integration, follow along in the [OpenSearch Ingestion getting started guide](#). When you get to [Step 3: Create a pipeline](#), replace Steps 1 and 2 with the following steps:

1. Navigate to the DynamoDB console.
2. In the left-hand navigation pane, choose **Integration**.
3. Select the DynamoDB table that you'd like to replicate to OpenSearch.
4. Choose **Create**.

From here, you can continue on with the rest of the tutorial.

Next steps

For a better understanding of how DynamoDB integrates with OpenSearch Service, see the following:

- [Getting started with Amazon OpenSearch Ingestion](#)
- [DynamoDB plugin configuration and requirements](#)

Handling breaking changes to your index

OpenSearch can dynamically add new attributes to your index. However, after your mapping template has been set for a given key, you'll need to take additional action to change it. Additionally, if your change requires you to reprocess all the data in your DynamoDB table, you'll need to take steps to initiate a fresh export.

Note

In all these options, you might still run into issues if your DynamoDB table has type conflicts with the mapping template you've specified. Ensure that you have a dead-letter queue (DLQ) enabled (even in development). This makes it easier to understand what might

be wrong with the record that causes a conflict when it's being indexed into your index on OpenSearch.

Topics

- [How it works](#)
- [Delete your index and reset the pipeline \(pipeline-centric option\)](#)
- [Recreate your index and reset the pipeline \(index-centric option\)](#)
- [Create a new index and sink \(online option\)](#)
- [Best practices for avoiding and debugging type conflicts](#)

How it works

Here's a quick overview of the actions taken when handling breaking changes to your index. See the step-by-step procedures in the sections that follow.

- **Stop and start the pipeline:** This option resets the pipeline's state, and the pipeline will restart with a new full export. It is non-destructive, so it does **not** delete your index or any data in DynamoDB. If you don't create a fresh index before you do this, you might see a high number of errors from version conflicts because the export tries to insert older documents than the current `_version` in the index. You can safely ignore these errors. You will not be billed for the pipeline while it is stopped.
- **Update the pipeline:** This option updates the configuration in the pipeline with a [blue/green](#) approach, without losing any state. If you make significant changes to your pipeline (such as adding new routes, indexes, or keys to existing indexes), you might need to do a full reset of the pipeline and recreate your index. This option does **not** perform a full export.
- **Delete and recreate the index:** This option removes your data and mapping settings on your index. You should do this before making any breaking changes to your mappings. It will break any applications that rely on the index until the index is recreated and synchronized. Deleting the index does **not** initiate a fresh export. You should delete your index only after you've updated your pipeline. Otherwise, your index might be recreated before you update your settings.

Delete your index and reset the pipeline (pipeline-centric option)

This method is often the fastest option if you're still in development. You'll delete your index in OpenSearch Service, and then [stop and start](#) your pipeline to initiate a fresh export of all your data. This ensures that there are no mapping template conflicts with existing indexes, and no loss of data from an incomplete processed table.

1. Stop the pipeline either through the AWS Management Console, or by using the `StopPipeline` API operation with the AWS CLI or an SDK.
2. [Update your pipeline configuration](#) with your new changes.
3. Delete your index in OpenSearch Service, either through a REST API call or your OpenSearch Dashboard.
4. Start the pipeline either through the console, or by using the `StartPipeline` API operation with the AWS CLI or an SDK.

 **Note**

This initiates a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.
6. Confirm that the index matches your expectations in OpenSearch Service.

After the export has completed and it resumes reading from the stream, your DynamoDB table data will now be available in the index.

Recreate your index and reset the pipeline (index-centric option)

This method works well if you need to do a lot of iterations on the index design in OpenSearch Service before resuming the pipeline from DynamoDB. This can be useful for development when you want to iterate very quickly on your search patterns, and want to avoid waiting on fresh exports to complete between each iteration.

1. Stop the pipeline either through the AWS Management Console, or by calling the `StopPipeline` API operation with the AWS CLI or an SDK.
2. Delete and recreate your index in OpenSearch with the mapping template you want to use. You can manually insert some sample data to confirm that your searches are working as

- intended. If your sample data might conflict with any data from DynamoDB, be sure to delete it before moving onto the next step.
3. If you have an indexing template in your pipeline, remove it or replace it with the one you've created already in OpenSearch Service. Ensure that the name of your index matches the name in the pipeline.
 4. Start the pipeline either through console, or by calling the `StartPipeline` API operation with the AWS CLI or an SDK.

 **Note**

This will initiate a fresh full export, which will incur additional costs.

5. Monitor for any unexpected issues because a fresh export is generated to create the new index.

After the export has completed and it resumes reading from the stream, you should be your DynamoDB table data will now be available in the index.

Create a new index and sink (online option)

This method works well if you need to update your mapping template but are currently using your index in production. This creates a brand new index, which you'll need to move your application over to after it's synchronized and validated.

 **Note**

This will create another consumer on the stream. This can be an issue if you also have other consumers like AWS Lambda or global tables. You might need to pause updates to your existing pipeline to create capacity to load the new index.

1. [Create a new pipeline](#) with new settings and a different index name.
2. Monitor the new index for any unexpected issues.
3. Swap the application over to the new index.
4. Stop and delete the old pipeline after validating that everything is working correctly.

Best practices for avoiding and debugging type conflicts

- Always use a dead-letter queue (DLQ) to make it easier to debug when there are type conflicts.
- Always use an index template with mappings and set `include_keys`. While OpenSearch Service dynamically maps new keys, this can cause issues with unexpected behaviors (such as expecting something to be a `GeoPoint`, but it's created as a `string` or `object`) or errors (such as having a number that is a mix of `long` and `float` values).
- If you need to keep your existing index working in production, you can also replace any of the previous [delete index steps](#) with just renaming your index in your pipeline config file. This creates a brand new index. Your application will then need to be updated to point to the new index after it's complete.
- If you have a type conversion issue that you fix with a processor, you can test this with `UpdatePipeline`. To do this, you'll need to do a stop and start or [process your dead-letter queues](#) to fix any previously skipped documents that had errors.

Best practices for integrating with DynamoDB

When integrating DynamoDB with other services, you should always follow the best practices for using each individual service. However, there are some best practices specific to integration that you should consider.

Topics

- [Creating a snapshot in DynamoDB](#)
- [Capturing data change in DynamoDB](#)
- [DynamoDB zero-ETL integration with OpenSearch Service](#)

Creating a snapshot in DynamoDB

- Generally, we recommend using [export to Amazon S3](#) to create snapshots for initial replication. It is both cost effective, and won't compete with your application's traffic for throughput. You can also consider a backup and restore to a new table followed by a scan operation. This will avoid competing for throughput with your application, but will generally be substantially less cost effective than an export.
- Always set a `StartTime` when doing an export. This makes it easy to determine where you'll start your change data capture (CDC) from.

- When using export to S3, set a lifecycle action on the S3 bucket. Typically, an expiration action set at 7 days is safe, but you should follow any guidelines that your company might have. Even if you explicitly delete your items after ingestion, this action can help catch issues, which helps reduce unnecessary costs and prevents policy violations.

Capturing data change in DynamoDB

- If you need near real-time CDC, use [DynamoDB Streams](#) or [Amazon Kinesis Data Streams \(KDS\)](#). When you're deciding which one to use, generally consider which is easiest to use with the downstream service. If you need to provide in-order event processing at a partition-key level, or if you have items that are exceptionally large, use DynamoDB Streams.
- If you don't need near real-time CDC, you can use [export to Amazon S3 with incremental exports](#) to export only the changes that have happened between two points in time.

If you used export to S3 for generating a snapshot, this can be especially helpful because you can use similar code to process incremental exports. Typically, export to S3 is slightly cheaper than the previous streaming options, but cost is typically not the main factor for which option to use.

- You can generally only have two simultaneous consumers of a DynamoDB stream. Consider this when planning your integration strategy.
- Don't use scans to detect changes. This might work on a small scale, but becomes impractical fairly quickly.

DynamoDB zero-ETL integration with OpenSearch Service

DynamoDB has a [DynamoDB zero-ETL integration with Amazon OpenSearch Service](#). For more information, see the [DynamoDB plugin for OpenSearch Ingestion](#) and [specific best practices for Amazon OpenSearch Service](#).

Configuration

- Only index data that you need to perform searches on. Always use a mapping template (`template_type: index_template` and `template_content`) and `include_keys` to implement this.
- Monitor your logs for errors that are related to type conflicts. OpenSearch Service expects all values for a given key to have the same type. It generates exceptions if there's a mismatch. If you

encounter one of these errors, you can add a processor to catch that a given key is always be the same value.

- Generally use the `primary_key` metadata value for the `document_id` value. In OpenSearch Service, the document ID is the equivalent of the primary key in DynamoDB. Using the primary key will make it easy to find your document and ensure that updates are consistently replicated to it without conflicts.

You can use the helper function `getMetadata` to get your primary key (for example, `document_id: "${getMetadata('primary_key')}"`). If you're using a composite primary key, the helper function will concatenate them together for you.

- In general, use the `opensearch_action` metadata value for the `action` setting. This will ensure that updates are replicated in such a way that the data in OpenSearch Service matches the latest state in DynamoDB.

You can use the helper function `getMetadata` to get your primary key (for example, `action: "${getMetadata('opensearch_action')}"`). You can also get the stream event type through `dynamodb_event_name` for use cases like filtering. However, you should typically not use it for the `action` setting.

Observability

- Always use a dead-letter queue (DLQ) on your OpenSearch sinks to handle dropped events. DynamoDB is generally less structured than OpenSearch Service, and it's always possible for something unexpected to happen. With a dead-letter queue, you can recover individual events, and even automate the recovery process. This will help you to avoid needing to rebuild your entire index.
- Always set alerts that your replication delay doesn't go over an expected amount. It is typically safe to assume one minute without the alert being too noisy. This can vary depending on how spiky your write traffic is and your OpenSearch Compute Unit (OCU) settings on the pipeline.

If your replication delay goes over 24 hours, your stream will start to drop events, and you'll have accuracy issues unless you do a full rebuild of your index from scratch.

Scaling

- Use auto scaling for pipelines to help scale up or down the OCUs to best fit the workload.

- For provisioned throughput tables without auto scaling, we recommend setting OCUs based on your write capacity units (WCUs) divided by 1000. Set the minimum to 1 OCU below that amount (but at least 1), and set the maximum to at least 1 OCU above that amount.

- Formula:**

```
OCU_minimum = GREATEST((table_WCU / 1000) - 1, 1)  
OCU_maximum = (table_WCU / 1000) + 1
```

- Example:** Your table has 25000 WCUs provisioned. Your pipeline's OCUs should be set with a minimum of 24 ($25000/1000 - 1$) and maximum of at least 26 ($25000/1000 + 1$).
- For provisioned throughput tables with auto scaling, we recommend setting OCUs based on your minimum and maximum WCUs, divided by 1000. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.

- Formula:**

```
OCU_minimum = GREATEST((table_minimum_WCU / 1000) - 1, 1)  
OCU_maximum = (table_maximum_WCU / 1000) + 1
```

- Example:** Your table has an auto scaling policy with a minimum of 8000 and maximum of 14000. Your pipeline's OCUs should be set with a minimum of 7 ($8000/1000 - 1$) and a maximum of 15 ($14000/1000 + 1$).
- For on-demand throughput tables, we recommend setting OCUs based on your typical peak and valley for write request units per second. You might need to average over a longer time period, depending on the aggregation that's available to you. Set the minimum to 1 OCU below the minimum from DynamoDB, and set the maximum to at least 1 OCU above the maximum from DynamoDB.

- Formula:**

```
# Assuming we have writes aggregated at the minute level  
OCU_minimum = GREATEST((min(table_writes_1min) / (60 * 1000)) - 1, 1)  
OCU_maximum = (max(table_writes_1min) / (60 * 1000)) + 1
```

- Example:** Your table has an average valley of 300 write request units per second and an average peak of 4300. Your pipeline's OCUs should be set with a minimum of 1 ($300/1000 - 1$, but at least 1) and a maximum of 5 ($4300/1000 + 1$).
- Follow best practices on scaling your destination OpenSearch Service indexes. If your indexes are under-scaled, it will slow down ingestion from DynamoDB, and might cause delays.

Note

GREATEST is a SQL function that, given a set of arguments, returns the argument with the greatest value.

Service, account, and table quotas in Amazon DynamoDB

This section describes current quotas, formerly referred to as limits, within Amazon DynamoDB. Each quota applies on a per-Region basis unless otherwise specified.

Topics

- [Read/write capacity mode and throughput](#)
- [Reserved Capacity](#)
- [Import quotas](#)
- [Contributor Insights](#)
- [Tables](#)
- [Global tables](#)
- [Secondary indexes](#)
- [Partition keys and sort keys](#)
- [Naming rules](#)
- [Data types](#)
- [Items](#)
- [Attributes](#)
- [Expression parameters](#)
- [DynamoDB transactions](#)
- [DynamoDB Streams](#)
- [DynamoDB Accelerator \(DAX\)](#)
- [API-specific limits](#)
- [DynamoDB encryption at rest](#)
- [Table export to Amazon S3](#)
- [Backup and restore](#)

Read/write capacity mode and throughput

You can switch between read/write capacity modes once every 24 hours. The only exception to this is if you switch a provisioned mode table to on-demand mode: you can switch back to provisioned mode in the same 24-hour period.

Capacity unit sizes (for provisioned tables)

One read capacity unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write capacity unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB.

Transactional write requests require two write capacity units to perform one write per second for items up to 1 KB.

Request unit sizes (for on-demand tables)

One read request unit = one strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.

One write request unit = one write per second, for items up to 1 KB in size.

Transactional read requests require two read request units to perform one read per second for items up to 4 KB.

Transactional write requests require two write request units to perform one write per second for items up to 1 KB.

Throughput default quotas

AWS places some default quotas on the throughput that your account can provision and consume within a Region.

The account-level read throughput and account-level write throughput quotas apply at the account level. These account-level quotas apply to the sum of the provisioned throughput capacity for all your account's tables and global secondary indexes in a given Region. All the account's available throughput can be provisioned for a single table or across multiple tables. These quotas only apply to tables using the provisioned capacity mode.

The table-level read throughput and table-level write throughput quotas apply differently to tables that use the provisioned capacity mode, and tables that use the on-demand capacity mode.

For provisioned capacity mode tables and GSIs, the quota is the maximum amount of read and write capacity units that can be provisioned for any table or any of its GSIs in the Region. The total

of any individual table and all its GSIs must also remain below the account-level read and write throughput quota. This is in addition to the requirement that the total of all provisioned tables and their GSIs must remain below the account-level read and write throughput quota.

For on-demand capacity mode tables and GSIs, the table-level quota is the maximum read and write capacity units that are available for any table, or any individual GSI within that table. No account-level read and write throughput quotas are applied to tables in on-demand mode.

Below are the throughput quotas that apply on your account, by default.

	On-Demand	Provisioned	Adjustable
Per table	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units	Yes
Per account	Not applicable	80,000 read capacity units and 80,000 write capacity units	Yes
Minimum throughput for any table or global secondary index	Not applicable	1 read capacity unit and 1 write capacity unit	Yes

You can use the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) to request quota increases for the adjustable quotas when needed.

For your account-level throughput quotas, you can use the [Service Quotas console](#), the [AWS CloudWatch console](#), the [AWS API](#) and the [AWS CLI](#) to create CloudWatch alarms and be notified automatically when your current usage reaches a specified percentage of your applied quota values. Using CloudWatch you can also monitor your usage by looking at the AccountProvisionedReadCapacityUnits and AccountProvisionedWriteCapacityUnits AWS usage metrics. To learn more about usage metrics, see [AWS usage metrics](#).

Increasing or decreasing throughput (for provisioned tables)

Increasing provisioned throughput

You can increase ReadCapacityUnits or WriteCapacityUnits as often as necessary, using the AWS Management Console or the UpdateTable operation. In a single call, you can increase the provisioned throughput for a table, for any global secondary indexes on that table, or for any combination of these. The new settings do not take effect until the UpdateTable operation is complete.

You can't exceed your per-account quotas when you add provisioned capacity, and DynamoDB doesn't allow you to increase provisioned capacity very rapidly. Aside from these restrictions, you can increase the provisioned capacity for your tables as high as you need. For more information about per-account quotas, see the preceding section, [Throughput default quotas](#).

Decreasing provisioned throughput

For every table and global secondary index in an UpdateTable operation, you can decrease ReadCapacityUnits or WriteCapacityUnits (or both). The new settings don't take effect until the UpdateTable operation is complete.

There is a default quota on the number of provisioned capacity decreases you can perform on your DynamoDB table per day. A day is defined according to Universal Time Coordinated (UTC). On a given day, you can start by performing up to four decreases within one hour as long as you have not performed any other decreases yet during that day. Subsequently, you can perform one additional decrease per hour (once every 60 minutes). This effectively brings the maximum number of decreases in a day to 27 times.

You can use the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) to request quota increases, when needed.

Important

Table and global secondary index decrease limits are decoupled, so any global secondary indexes for a particular table have their own decrease limits. However, if a single request decreases the throughput for a table and a global secondary index, it is rejected if either exceeds the current limits. Requests are not partially processed.

Example

In the first 4 hours of a day, a table with a global secondary index can be modified as follows:

- Decrease the table's WriteCapacityUnits or ReadCapacityUnits (or both) four times.
- Decrease the WriteCapacityUnits or ReadCapacityUnits (or both) of the global secondary index four times.

At the end of that same day, the table and the global secondary index throughput can potentially be decreased a total of 27 times each.

Reserved Capacity

AWS places a default quota on the amount of active reserved capacity that your account can purchase. The quota limit is a combination of reserved capacity for write capacity units (WCUs) and read capacity units (RCUs).

	Active reserved capacity	Adjustable
Per account	1,000,000 provisioned capacity units (WCUs _ RCUs)	Yes

If you attempt to purchase more than 1,000,000 provisioned capacity units in a single purchase, you will receive an error for this service quota limit. If you have active reserved capacity and attempt to purchase additional reserved capacity that would result in more than 1,000,000 active provisioned capacity units, you will receive an error for this service quota limit.

If you need reserved capacity for more than 1,000,000 provisioned capacity units, you can request a quota increase by submitting a request to the [support](#) team.

Import quotas

DynamoDB Import from Amazon S3 can support up to 50 concurrent import jobs with a total import source object size of 15TB at a time in us-east-1, us-west-2, and eu-west-1 regions. In all other regions, up to 50 concurrent import tasks with a total size of 1TB is supported. Each import job can take up to 50,000 Amazon S3 objects in all regions. For more information on import and validation, see [import format quotas and validation](#).

Contributor Insights

When you enable Customer Insights on your DynamoDB table, you're still subject to Contributor Insights rules limits. For more information, see [CloudWatch service quotas](#).

Tables

Table size

There is no practical limit on a table's size. Tables are unconstrained in terms of the number of items or the number of bytes.

Maximum number of tables per account per region

For any AWS account, there is an initial quota of 2,500 tables per AWS Region.

If you need more than 2,500 tables for a single account, please reach out to your AWS account team to explore an increase up to a maximum of 10,000 tables. For more than 10,000, the recommended best practice is to setup multiple accounts, each of which can serve up to 10,000 tables.

You can use the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) to view the default and applied quota values for the maximum number of tables for in your account, and to request quota increases, when needed. You can also request quota increases by cutting a ticket to [AWS support](#)

Using the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) you can create CloudWatch alarms to get notified automatically when your current usage reaches a specified percentage of your current quota. Using CloudWatch you can also monitor your usage by looking at the TableCount AWS usage metrics. To learn more about usage metrics, see [AWS usage metrics](#).

Global tables

AWS places some default quotas on the throughput you can provision or utilize when using global tables.

	On-Demand	Provisioned
Per table	40,000 read request units and 40,000 write request units	40,000 read capacity units and 40,000 write capacity units
Per table, per destination Region, per day	10 TB for all source tables to which a replica was added for this destination Region	10 TB for all source tables to which a replica was added for this destination Region

Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and you perform a `TransactWriteItems` operation in the US East (N. Virginia) Region. In this case, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

Note

There may be instances where you will need to request a quota limit increase through AWS Support. If any of the following apply to you, please see <https://aws.amazon.com/support>:

- If you are adding a replica for a table that is configured to use more than 40,000 write capacity units (WCU), you must request a service quota increase for your add replica WCU quota.
- If you are adding a replica or replicas to one destination Region within a 24-hour period with a combined total greater than 10TB, you must request a service quota increase for your add replica data backfill quota.
- If you encounter an error similar to the following:
 - Cannot create a replica of table 'example_table' in region 'example_region_A' because its exceeds your current account limit in region 'example_region_B'.

Secondary indexes

Secondary indexes per table

You can define a maximum of 5 local secondary indexes.

There is a default quota of 20 global secondary indexes per table. You can use the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) to check the global secondary indexes per table default and current quotas that apply for your account, and to request quota increases, when needed. You can also request quota increases by cutting a ticket to <https://aws.amazon.com/support>.

You can create or delete only one global secondary index per `UpdateTable` operation.

Projected Secondary Index attributes per table

You can project a total of up to 100 attributes into all of a table's local and global secondary indexes. This only applies to user-specified projected attributes.

In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the total count of attributes specified in `NonKeyAttributes`, summed across all of the secondary indexes, must not exceed 100. If you project the same attribute name into two different indexes, this counts as two distinct attributes when determining the total.

This limit does not apply for secondary indexes with a `ProjectionType` of `KEYS_ONLY` or `ALL`.

Partition keys and sort keys

Partition key length

The minimum length of a partition key value is 1 byte. The maximum length is 2048 bytes.

Partition key values

There is no practical limit on the number of distinct partition key values, for tables or for secondary indexes.

Sort key length

The minimum length of a sort key value is 1 byte. The maximum length is 1024 bytes.

Sort key values

In general, there is no practical limit on the number of distinct sort key values per partition key value.

The exception is for tables with secondary indexes. An item collection is the set of items which have the same value of partition key attribute. In a global secondary index the item collection is independent of the base table (and can have a different partition key attribute), but in a local secondary index the indexed view is colocated in the same partition as the item in the table and shares the same partition key attribute. As a result of this locality, when a table has one or more LSIs, the item collection cannot be distributed to multiple partitions.

For a table with one or more LSIs, item collections cannot exceed 10GB in size. This includes all base table items and all projected LSI views which have the same value of the partition key attribute. 10GB is the maximum size of a partition. For more detailed information, see [Item collection size limit](#).

Naming rules

Table names and Secondary Index names

Names for tables and secondary indexes must be at least 3 characters long, but no greater than 255 characters long. The following are the allowed characters:

- A-Z
- a-z
- 0-9
- _ (underscore)
- - (hyphen)
- . (dot)

Attribute names

In general, an attribute name must be at least one character long, but no greater than 64 KB long.

The following are the exceptions. These attribute names must be no greater than 255 characters long:

- Secondary index partition key names.
 - Secondary index sort key names.
 - The names of any user-specified projected attributes (applicable only to local secondary indexes). In a `CreateTable` operation, if you specify a `ProjectionType` of `INCLUDE`, the names of the attributes in the `NonKeyAttributes` parameter are length-restricted. The `KEYS_ONLY` and `ALL` projection types are not affected.

These attribute names must be encoded using UTF-8, and the total size of each name (after encoding) cannot exceed 255 bytes.

Data types

String

The length of a String is constrained by the maximum item size of 400 KB.

Strings are Unicode with UTF-8 binary encoding. Because UTF-8 is a variable width encoding, DynamoDB determines the length of a String using its UTF-8 bytes.

Number

A Number can have up to 38 digits of precision, and can be positive, negative, or zero.

DynamoDB uses JSON strings to represent Number data in requests and replies. For more information, see [DynamoDB low-level API](#).

If number precision is important, you should pass numbers to DynamoDB using strings that you convert from a number type.

Binary

The length of a Binary is constrained by the maximum item size of 400 KB.

Applications that work with Binary attributes must encode the data in base64 format before sending it to DynamoDB. Upon receipt of the data, DynamoDB decodes it into an unsigned byte array and uses that as the length of the attribute.

Items

Item size

The maximum item size in DynamoDB is 400 KB, which includes both attribute name binary length (UTF-8 length) and attribute value lengths (again binary length). The attribute name counts towards the size limit.

For example, consider an item with two attributes: one attribute named "shirt-color" with value "R" and another attribute named "shirt-size" with value "M". The total size of that item is 23 bytes.

Item size for tables with Local Secondary Indexes

For each local secondary index on a table, there is a 400 KB limit on the total of the following:

- The size of an item's data in the table.
- The size of corresponding entries (including key values and projected attributes) in all local secondary indexes.

Attributes

Attribute name-value pairs per item

The cumulative size of attributes per item must fit within the maximum DynamoDB item size (400 KB).

Number of values in list, map, or set

There is no limit on the number of values in a List, a Map, or a Set, as long as the item containing the values fits within the 400 KB item size limit.

Attribute values

Empty String and Binary attribute values are allowed, if the attribute is not used as a key attribute for a table or index. Empty String and Binary values are allowed inside Set, List, and Map types. An

attribute value cannot be an empty Set (String Set, Number Set, or Binary Set). However, empty Lists and Maps are allowed.

Nested attribute depth

DynamoDB supports nested attributes up to 32 levels deep.

Expression parameters

Expression parameters include `ProjectionExpression`, `ConditionExpression`, `UpdateExpression`, and `FilterExpression`.

Lengths

The maximum length of any expression string is 4 KB. For example, the size of the `ConditionExpression` `a=b` is 3 bytes.

The maximum length of any single expression attribute name or expression attribute value is 255 bytes. For example, `#name` is 5 bytes; `:val` is 4 bytes.

The maximum length of all substitution variables in an expression is 2 MB. This is the sum of the lengths of all `ExpressionAttributeNames` and `ExpressionAttributeValues`.

Operators and operands

The maximum number of operators or functions allowed in an `UpdateExpression` is 300. For example, the `UpdateExpression` `SET a = :val1 + :val2 + :val3` contains two "+" operators.

The maximum number of operands for the IN comparator is 100.

Reserved words

DynamoDB does not prevent you from using names that conflict with reserved words. (For a complete list, see [Reserved words in DynamoDB](#).)

However, if you use a reserved word in an expression parameter, you must also specify `ExpressionAttributeNames`. For more information, see [Expression attribute names in DynamoDB](#).

DynamoDB transactions

DynamoDB transactional API operations have the following constraints:

- A transaction cannot contain more than 100 unique items.
- A transaction cannot contain more than 4 MB of data.
- No two actions in a transaction can work against the same item in the same table. For example, you cannot both ConditionCheck and Update the same item in one transaction.
- A transaction cannot operate on tables in more than one AWS account or Region.
- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the AWS Region where the write is made originally. Transactions are not supported across Regions in global tables. For example, suppose that you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and you perform a TransactWriteItems operation in the US East (N. Virginia) Region. In this case, you might observe partially completed transactions in the US West (Oregon) Region as changes are replicated. Changes are replicated to other Regions only after they have been committed in the source Region.

DynamoDB Streams

Simultaneous readers of a shard in DynamoDB Streams

For single-Region tables that are not global tables, you can design for up to two processes to read from the same DynamoDB Streams shard at the same time. Exceeding this limit can result in request throttling. For global tables, we recommend you limit the number of simultaneous readers to one to avoid request throttling.

Maximum write capacity for a table with DynamoDB Streams enabled

AWS places some default quotas on the write capacity for DynamoDB tables with DynamoDB Streams enabled. These default quotas are applicable only for tables in provisioned read/write capacity mode. The following are throughput quotas that apply to your account by default.

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), South America (São Paulo), Europe (Frankfurt), Europe (Ireland), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), China (Beijing) Regions:

- Per table – 40,000 write capacity units
- All other Regions:
 - Per table – 10,000 write capacity units

You can use the [Service Quotas console](#), the [AWS API](#) and the [AWS CLI](#) to check the maximum write capacity for a table with DynamoDB Streams enabled default and current quotas that apply on your account, and to request quota increases, when needed. You can also request quota increases by cutting a ticket to [AWS support](#).

Note

The provisioned throughput quotas also apply for DynamoDB tables with DynamoDB Streams enabled. When you request a quota increase on the write capacity for a table with Streams enabled, make sure you also request an increase of the provisioned throughput capacity for this table. For more information, see [Throughput Default Quotas](#). Other quotas also apply when processing higher throughput DynamoDB Streams. For more information, see [Amazon DynamoDB Streams API reference guide](#).

DynamoDB Accelerator (DAX)

AWS region availability

For a list of AWS Regions in which DAX is available, see [DynamoDB Accelerator \(DAX\)](#) in the [AWS General Reference](#).

Nodes

A DAX cluster consists of exactly one primary node, and between zero and ten read replica nodes.

The total number of nodes (per AWS account) cannot exceed 50 in a single AWS Region.

Parameter groups

You can create up to 20 DAX parameter groups per Region.

Subnet groups

You can create up to 50 DAX subnet groups per Region.

Within a subnet group, you can define up to 20 subnets.

API-specific limits

CreateTable/UpdateTable/DeleteTable/PutResourcePolicy/DeleteResourcePolicy

In general, you can have up to 500 [CreateTable](#), [UpdateTable](#), [DeleteTable](#), [PutResourcePolicy](#), and [DeleteResourcePolicy](#) requests running simultaneously in any combination. As a result, the total number of tables in the CREATING, UPDATING, or DELETING state cannot exceed 500.

You can submit up to 2,500 requests per second of mutable (CreateTable, DeleteTable, UpdateTable, PutResourcePolicy, and DeleteResourcePolicy) control plane API requests across a group of tables. However, the PutResourcePolicy and DeleteResourcePolicy requests have lower individual limits. For more information, see the following quotas details for PutResourcePolicy and DeleteResourcePolicy.

CreateTable and PutResourcePolicy requests which include a resource-based policy will count as two additional requests for each KB of the policy. For example, a CreateTable or PutResourcePolicy request with a policy of size 5 KB will count as 11 requests. 1 for the CreateTable request and 10 for the resource-based policy (2×5 KB). Similarly, a policy of size 20 KB will count as 41 requests. 1 for the CreateTable request and 40 for the resource-based policy (2×20 KB).

PutResourcePolicy

You can submit up to 25 PutResourcePolicy API requests per second across a group of tables. After a successful request for an individual table, no new PutResourcePolicy requests are supported for the following 15 seconds.

The maximum size supported for a resource-based policy document is 20 KB. DynamoDB counts whitespaces when calculating the size of a policy against this limit.

DeleteResourcePolicy

You can submit up to 50 DeleteResourcePolicy API requests per second across a group of tables. After a successful PutResourcePolicy request for an individual table, no DeleteResourcePolicy requests are supported for the following 15 seconds.

BatchGetItem

A single BatchGetItem operation can retrieve a maximum of 100 items. The total size of all the items retrieved cannot exceed 16 MB.

BatchWriteItem

A single BatchWriteItem operation can contain up to 25 PutItem or DeleteItem requests. The total size of all the items written cannot exceed 16 MB.

DescribeStream

You can call DescribeStream at a maximum rate of 10 times per second.

DescribeTableReplicaAutoScaling

DescribeTableReplicaAutoScaling method supports only 10 requests per second.

DescribeLimits

DescribeLimits should be called only periodically. You can expect throttling errors if you call it more than once in a minute.

DescribeContributorInsights/ListContributorInsights/UpdateContributorInsights

DescribeContributorInsights, ListContributorInsights and UpdateContributorInsights should be called only periodically. DynamoDB supports up to five requests per second for each of these APIs.

DescribeTable>ListTables/GetResourcePolicy

You can submit up to 2,500 requests per second of a combination of read-only (DescribeTable, ListTables, and GetResourcePolicy) control plane API requests. The GetResourcePolicy API has a lower individual limit of 100 requests per second.

Query

The result set from a Query is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the query response to retrieve more results.

Scan

The result set from a Scan is limited to 1 MB per call. You can use the `LastEvaluatedKey` from the scan response to retrieve more results.

UpdateKinesisStreamingDestination

When performing `UpdateKinesisStreamingDestination` operations, you can set `ApproximateCreationDateTimePrecision` to a new value a maximum of 3 times in a 24 hour period.

UpdateTableReplicaAutoScaling

`UpdateTableReplicaAutoScaling` method supports only ten requests per second.

UpdateTableTimeToLive

The `UpdateTableTimeToLive` method supports only one request to enable or disable Time to Live (TTL) per specified table per hour. This change can take up to one hour to fully process. Any additional `UpdateTimeToLive` calls for the same table during this one hour duration result in a `ValidationException`.

DynamoDB encryption at rest

You can switch between an AWS owned key, an AWS managed key, and a customer managed key up to four times, anytime per 24-hour window, on a per table basis, starting from when the table was created. If there was no change in the past six hours, an additional change is allowed. This effectively brings the maximum number of changes in a day to eight (four changes in the first six hours, and one change for each of the subsequent six hour windows in a day).

You can switch encryption keys to use an AWS owned key as often as necessary, even if the above quota has been exhausted.

These are the quotas unless you request a higher amount. To request a service quota increase, see <https://aws.amazon.com/support>.

Table export to Amazon S3

Full export: up to 300 concurrent export tasks, or up to a total of 100TB from all in-flight table exports, can be exported. Both of these limits are checked before an export is queued.

Incremental export: up to 300 concurrent jobs, or 100TB of table size, in an export period window between 15 minutes minimum and 24 hours maximum, can be exported concurrently.

Backup and restore

When restoring through DynamoDB on-demand backup, you can execute up to 50 concurrent restores that total 50TB. When restoring through AWS Backup, you can execute up to 50 concurrent restores that total 25TB. For more information about backups, see [Using On-Demand backup and restore for DynamoDB](#).

Low-level API reference

The [Amazon DynamoDB API reference](#) contains a complete list of operations supported by:

- [DynamoDB](#).
- [DynamoDB Streams](#).
- [DynamoDB Accelerator \(DAX\)](#).

Troubleshooting Amazon DynamoDB

The following topics provide troubleshooting advice for errors and issues that you might encounter when using Amazon DynamoDB. If you find an issue that is not listed here, you can use the Feedback button on this page to report it.

For more troubleshooting advice and answers to common support questions, visit the [AWS Knowledge Center](#).

Topics

- [Troubleshooting latency issues in Amazon DynamoDB](#)
- [Troubleshooting throttling issues in Amazon DynamoDB](#)

Troubleshooting latency issues in Amazon DynamoDB

If your workload appears to experience high latency, you can analyze the CloudWatch SuccessfulRequestLatency metric, and check the average latency to see if it's related to DynamoDB. Some variability in the reported SuccessfulRequestLatency is normal, and occasional spikes (particularly in the Maximum statistic) should not be cause for concern. However, if the Average statistic shows a sharp increase and persists, you should check the AWS Service Health Dashboard and your Personal Health Dashboard for more information. Some possible causes include the size of the item in your table (a 1kb item and a 400kb item will vary in latency) or the size of the query (10 items versus 100 items).

If necessary, consider opening a support case with AWS Support, and continue to assess any available fall-back options for your application (such as evacuation of a Region if you have a multi-Region architecture) according to your runbooks. You should log request IDs for slow requests for providing these IDs to AWS Support when you open a support case.

The SuccessfulRequestLatency metric only measures latency which is internal to the DynamoDB service - client side activity and network trip times are not included. To learn more about overall latency for calls from your client to the DynamoDB service, you can enable latency metric logging in your AWS SDK.

Note

For most singleton operations (operations which apply to a single item by fully specifying the primary key's value), DynamoDB delivers single-digit millisecond Average SuccessfulRequestLatency. This value does not include the transport overhead for the caller code accessing the DynamoDB endpoint. For multi-item data operations, the latency will vary based on factors such as size of the result set, the complexity of the data structures returned, and any condition expressions and filter expressions applied. For repeated multi-item operations to the same data set with the same parameters, DynamoDB will provide highly consistent Average SuccessfulRequestLatency.

Consider one or more of the following strategies to reduce latency:

- **Adjust request timeout and retry behavior:** The path from your client to DynamoDB traverses many components, each of which is designed with redundancy in mind. Think about the scope of network resiliency, TCP packet timeouts, and the distributed architecture of DynamoDB itself. The default SDK behaviors are designed to find the right balance for most applications. If the best possible latency is your highest priority, you should consider adjusting the default request timeout and retry settings for your SDK to closely track to the typical latency for a successful request measured by your client. A request which is taking significantly longer than normal is less likely to ultimately succeed - if you fail fast and make a new request, this is likely to take a different path and may quickly succeed. Keep in mind that there can be downsides to being too aggressive in these settings. A helpful discussion on this topic can be found in [Tuning AWS Java SDK HTTP request settings for latency-aware Amazon DynamoDB applications](#).
- **Reduce the distance between the client and DynamoDB endpoint:** If you have globally dispersed users, consider using [Global tables - multi-Region replication for DynamoDB](#). With global tables, you can specify the AWS Regions where you want the table to be available. Reading data from a local global tables replica can significantly reduce latency for your users. Also, consider using a DynamoDB [gateway endpoint](#) to keep your client traffic within your VPC.
- **Use caching:** If your traffic is read heavy, consider using a caching service, such as [In-memory acceleration with DynamoDB Accelerator \(DAX\)](#). DAX is a fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement, from milliseconds to microseconds, even at millions of requests per second.
- **Reuse connections:** DynamoDB requests are made via an authenticated session which defaults to HTTPS. Initiating the connection takes time so the latency of the first request is higher than

typical. Requests over an already initialized connection deliver DynamoDB's consistent low latency. For this reason, you may wish to make a "keep-alive" GetItem request every 30 seconds if no other requests are made, to avoid the latency of establishing a new connection.

- **Use eventually consistent reads:** If your application doesn't require strongly consistent reads, consider using the default eventually consistent reads. Eventually consistent reads are lower cost and are also less likely to experience transient increases in latency. For more information, see [Read consistency](#).

Troubleshooting throttling issues in Amazon DynamoDB

In service-oriented architectures and distributed systems, limiting the rate at which API calls are processed by various service components is called throttling. This helps to smooth spikes, control for mismatches in component throughput, and allows for more predictable recoveries when there's an unexpected operational event. DynamoDB is designed for these types of architectures, and DynamoDB clients have retries built in for throttled requests. Some degree of throttling is not necessarily a problem for your application, but persistent throttling of a latency-sensitive part of your data workflow can negatively impact user experience and reduce the overall efficiency of the system.

If your read or write operations on your DynamoDB table are being throttled (or if you are getting ProvisionedThroughputExceededException when you perform an operation), consider using the following strategies to help resolve the issue.

Topics

- [Make sure provisioned mode tables have adequate capacity](#)
- [Consider switching to on-demand mode](#)
- [Distribute read and write operations evenly between partition keys](#)
- [Increase your table-level read or write throughput quota](#)

Make sure provisioned mode tables have adequate capacity

DynamoDB reports minute-level metrics to CloudWatch. The metrics are calculated as the sum for a minute and then averaged. However, the DynamoDB rate limits are applied per second. For example, if you provisioned 60 write capacity units for your table, you can perform 3600 write units in one minute, but trying to perform more than 60 write units in any one second might result in some requests being throttled.

To resolve this issue, make sure that your table has enough capacity to serve your traffic and retry throttled requests using [exponential backoff](#). If you are using an AWS SDK, then this logic is implemented by default. For this reason, throttles might occur, and be retried successfully on the second or third retry, while never causing errors in your code. In order to understand throttles as they happen, each AWS-SDK flavor has a way to detect throttles. For example, in Python check the number in the returned `ResponseMetadata.RetryAttempts` field. If this is greater than zero, it indicates there were throttles. A great strategy upon detecting this is to log the Partition Key involved, as it may be a hot key pattern that would be hard to diagnose with CloudWatch alone.

Also, consider using [auto scaling](#) on your provisioned tables to automatically adjust provisioned capacity based on workload. You should also consider updating the scaling policy to have a higher minimum or a lower target utilization, and make sure the maximum setting isn't set too low.

Consider switching to on-demand mode

Amazon DynamoDB auto scaling uses the [Application Auto Scaling](#) service to dynamically adjust provisioned throughput capacity in response to actual traffic patterns. Application Auto Scaling initiates a scale up only when two consecutive data points for consumed capacity units exceed the configured target utilization value within a one-minute span. Application Auto Scaling automatically scales the provisioned capacity only when the consumed capacity is higher than target utilization for two consecutive minutes. Also, a scale-down event is initiated when 15 consecutive data points for consumed capacity in CloudWatch are lower than the target utilization.

After Application Auto Scaling is initiated, an `UpdateTable` API call is invoked to update the provisioned capacity for your DynamoDB table or index. Application Auto Scaling requires consecutive data points with higher target utilization values to scale up the provisioned capacity of the DynamoDB table. During this period, any requests that exceed the provisioned capacity of the table are throttled. Therefore, consider using [On-demand mode](#) for extremely unpredictable (bursty) traffic patterns. For more information, see [Managing throughput capacity automatically with DynamoDB auto scaling](#).

Distribute read and write operations evenly between partition keys

In DynamoDB, a partition key with low cardinality can result in many requests targeting only a few partitions and resulting in a hot partition. A hot partition can cause throttling if the partition limits of 3000 RCU and 1000 WCU per second are exceeded.

To find the most accessed and throttled items in your table, use [Amazon CloudWatch Contributor Insights](#). Amazon CloudWatch Contributor Insights is a diagnostic tool that provides a summarized

view of your DynamoDB tables traffic trends and helps you identify the most frequently accessed partition keys. With this tool, you can continuously monitor the graphs for your table's item access patterns. A hot partition can degrade the overall performance of your table. To avoid this poor performance, distribute the read and write operations as evenly as possible by choosing a high cardinality key. For more information, see [Designing partition keys to distribute your workload](#) and [Choosing the right DynamoDB partition key](#).

 **Note**

Using the Amazon CloudWatch Contributor Insights tool for DynamoDB incurs additional charges. For more information, see [CloudWatch contributor insights for DynamoDB billing](#).

Increase your table-level read or write throughput quota

The table-level [read throughput and table-level write throughput quotas](#) apply at the account level in any Region. These quotas apply for tables with both provisioned capacity mode and on-demand capacity mode. By default, the throughput quota placed on your table is 40,000 read requests units and 40,000 write requests units. If the traffic to your table exceeds this quota, then the table might be throttled. For more information on how to prevent this from happening, see [Monitoring Amazon DynamoDB for operational awareness](#).

To resolve this issue, use the [Service Quotas console](#) to increase the table-level read or write throughput quota for your account.

Troubleshooting SSL/TLS connection establishment issues

Amazon DynamoDB is in the process of moving our endpoints to secure certificates signed by the Amazon Trust Services (ATS) Certificate Authority instead of third-party Certificate Authority. In December 2017, we launched the EU-WEST-3 (Paris) Region with the secure certificates issued by the Amazon Trust Services. All new regions launched after December 2017 have endpoints with the certificates issued by the Amazon Trust Services. This guide shows you how to validate and troubleshoot SSL/TLS connection issues.

Testing your application or service

Most AWS SDKs and Command Line Interfaces (CLIs) support the Amazon Trust Services Certificate Authority. If you are using a version of the AWS SDK for Python or CLI released before October 29, 2013, you must upgrade. The .NET, Java, PHP, Go, JavaScript, and C++ SDKs and CLIs do not bundle any certificates, their certificates come from the underlying operating system. The Ruby SDK has included at least one of the required CAs since June 10, 2015. Before that date, the Ruby V2 SDK did not bundle certificates. If you use an unsupported, custom, or modified version of the AWS SDK, or if you use custom trust store, you might not have the support needed for Amazon Trust Services Certificate Authority.

To validate access to DynamoDB endpoints, you will need to develop a test that accesses DynamoDB API or DynamoDB Streams API in the EU-WEST-3 region and validate that the TLS handshake succeeds. The specific endpoints you will need to access in such test are:

- DynamoDB: <https://dynamodb.eu-west-3.amazonaws.com>
- DynamoDB Streams: <https://streams.dynamodb.eu-west-3.amazonaws.com>

If your application does not support Amazon Trust Services Certificate Authority you will see one of the following failures:

- SSL/TLS Negotiation errors
- A long delay before your software receives an error indicating SSL/TLS negotiation failure. The delay time depends on the retry strategy and timeout configuration of your client.

Testing your client browser

To verify that your browser can connect to Amazon DynamoDB, open the following URL: <https://dynamodb.eu-west-3.amazonaws.com>. If the test is successful, you will see a message like this:

healthy: dynamodb.eu-west-3.amazonaws.com

If the test is unsuccessful, it will display an error similar to this: <https://untrusted-root.badssl.com/>.

Updating your software application client

Applications accessing DynamoDB or DynamoDB Streams API endpoints (whether through browsers or programmatically) will need to update the trusted CA list on the client machines if they do not already support any of the following CAs:

- Amazon Root CA 1
- Starfield Services Root Certificate Authority - G2
- Starfield Class 2 Certification Authority

If the clients already trust ANY of the above three CAs then these will trust certificates used by DynamoDB and no action is required. However, if your clients do not already trust any of the above CAs, the HTTPS connections to the DynamoDB or DynamoDB Streams APIs will fail. For more

information, please visit this blog post: <https://aws.amazon.com/blogs/security/how-to-prepare-for-aws-move-to-its-own-certificate-authority/>.

Updating your client browser

You can update the certificate bundle in your browser simply by updating your browser. Instructions for the most common browsers can be found on the browsers' websites:

- Chrome: <https://support.google.com/chrome/answer/95414?hl=en>
- Firefox: <https://support.mozilla.org/en-US/kb/update-firefox-latest-version>
- Safari: <https://support.apple.com/en-us/HT204416>
- Internet Explorer: <https://support.microsoft.com/en-us/help/17295/windows-internet-explorer-which-version#ie=other>

Manually updating your certificate bundle

If you cannot access the DynamoDB API or DynamoDB Streams API then you need to update your certificate bundle. To do this, you need to import at least one of the required CAs. You can find these at <https://www.amazontrust.com/repository/>.

The following operating systems and programming languages support Amazon Trust Services certificates:

- Microsoft Windows versions that have January 2005 or later updates installed, Windows Vista, Windows 7, Windows Server 2008, and newer versions.
- MacOS X 10.4 with Java for MacOS X 10.4 Release 5, MacOS X 10.5 and newer versions.
- Red Hat Enterprise Linux 5 (March 2007), Linux 6, and Linux 7 and CentOS 5, CentOS 6, and CentOS 7
- Ubuntu 8.10
- Debian 5.0
- Amazon Linux (all versions)
- Java 1.4.2_12, Java 5 update 2, and all newer versions, including Java 6, Java 7, and Java 8

If you are still unable to connect please consult your software documentation, OS Vendor or contact AWS Support <https://aws.amazon.com/support> for further assistance.

Example tables and data

The *Amazon DynamoDB Developer Guide* uses sample tables to illustrate various aspects of DynamoDB.

Table name	Primary key
<i>ProductCatalog</i>	Simple primary key: <ul style="list-style-type: none">• Id (Number)
<i>Forum</i>	Simple primary key: <ul style="list-style-type: none">• Name (String)
<i>Thread</i>	Composite primary key: <ul style="list-style-type: none">• ForumName (String)• Subject (String)
<i>Reply</i>	Composite primary key: <ul style="list-style-type: none">• Id (String)• ReplyDateTime (String)

The *Reply* table has a global secondary index named *PostedBy-Message-Index*. This index will facilitate queries on two non-key attributes of the *Reply* table.

Index name	Primary key
<i>PostedBy-Message-Index</i>	Composite primary key: <ul style="list-style-type: none">• PostedBy (String)• Message (String)

For more information about these tables, see [Step 1: Create a table](#) and [Step 2: Write data to a table using the console or AWS CLI](#).

Sample data files

Topics

- [ProductCatalog sample data](#)
- [Forum sample data](#)
- [Thread sample data](#)
- [Reply sample data](#)

The following sections show the sample data files that are used for loading the *ProductCatalog*, *Forum*, *Thread* and *Reply* tables.

Each data file contains multiple PutRequest elements, each of which contain a single item. These PutRequest elements are used as input to the BatchWriteItem operation, using the AWS Command Line Interface (AWS CLI).

For more information, see [Step 2: Write data to a table using the console or AWS CLI](#) in [Creating tables and loading data for code examples in DynamoDB](#).

ProductCatalog sample data

```
{  
    "ProductCatalog": [  
        {  
            "PutRequest": {  
                "Item": {

Creating example tables and uploading data

Topics

- [Creating example tables and uploading data using the AWS SDK for Java](#)
- [Creating example tables and uploading data using the AWS SDK for .NET](#)

In [Creating tables and loading data for code examples in DynamoDB](#), you first create tables using the DynamoDB console and then use the AWS CLI to add data to the tables. This appendix provides code to both create the tables and add data programmatically.

Creating example tables and uploading data using the AWS SDK for Java

The following Java code example creates tables and uploads data to the tables. The resulting table structure and data is shown in [Creating tables and loading data for code examples in DynamoDB](#). For step-by-step instructions to run this code using Eclipse, see [Java code examples](#).

```
package com.amazonaws.codesamples;

import java.text.SimpleDateFormat;
import java.util.ArrayList;
import java.util.Arrays;
import java.util.Date;
import java.util.HashSet;
import java.util.TimeZone;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.CreateTableRequest;
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.LocalSecondaryIndex;
import com.amazonaws.services.dynamodbv2.model.Projection;
import com.amazonaws.services.dynamodbv2.model.ProjectionType;
import com.amazonaws.services.dynamodbv2.model.ProvisionedThroughput;
```

```

DynamoDB example application using the AWS SDK for Python (Boto): Tic-tac-toe

Topics

- [Step 1: Deploy and test locally](#)
- [Step 2: Examine the data model and implementation details](#)
- [Step 3: Deploy in production using the DynamoDB service](#)
- [Step 4: Clean up resources](#)

The Tic-Tac-Toe game is an example web application built on Amazon DynamoDB. The application uses the AWS SDK for Python (Boto) to make the necessary DynamoDB calls to store game data

in a DynamoDB table, and the Python web framework Flask to illustrate end-to-end application development in DynamoDB, including how to model data. It also demonstrates best practices when it comes to modeling data in DynamoDB, including the table you create for the game application, the primary key you define, additional indexes you need based on your query requirements, and the use of concatenated value attributes.

You play the Tic-Tac-Toe application on the web as follows:

1. You log in to the application home page.
2. You then invite another user to play the game as your opponent.

Until another user accepts your invitation, the game status remains as PENDING. After an opponent accepts the invite, the game status changes to IN_PROGRESS.

3. The game begins after the opponent logs in and accepts the invite.
4. The application stores all game moves and status information in a DynamoDB table.
5. The game ends with a win or a draw, which sets the game status to FINISHED.

The end-to-end application building exercise is described in steps:

- **Step 1: Deploy and test locally** – In this section, you download, deploy, and test the application on your local computer. You will create the required tables in the downloadable version of DynamoDB.
- **Step 2: Examine the data model and implementation details** – This section first describes in detail the data model, including the indexes and the use of the concatenated value attribute. Then the section explains how the application works.
- **Step 3: Deploy in production using the DynamoDB service** – This section focuses on deployment considerations in production. In this step, you create a table using the Amazon DynamoDB service and deploy the application using AWS Elastic Beanstalk. When you have the application in production, you also grant appropriate permissions so the application can access the DynamoDB table. The instructions in this section walk you through the end-to-end production deployment.
- **Step 4: Clean up resources** – This section highlights areas that are not covered by this example. The section also provides steps for you to remove the AWS resources you created in the preceding steps so that you avoid incurring any charges.

Step 1: Deploy and test locally

Topics

- [1.1: Download and install the required packages](#)
- [1.2: Test the game application](#)

In this step you download, deploy, and test the Tic-Tac-Toe game application on your local computer. Instead of using the Amazon DynamoDB web service, you will download DynamoDB to your computer, and create the required table there.

1.1: Download and install the required packages

You will need the following to test this application locally:

- Python
- Flask (a microframework for Python)
- AWS SDK for Python (Boto)
- DynamoDB running on your computer
- Git

To get these tools, do the following:

1. Install Python. For step-by-step instructions, see [Download Python](#).

The Tic-Tac-Toe application has been tested using Python version 2.7.

2. Install Flask and AWS SDK for Python (Boto) using the Python Package Installer (PIP):

- Install PIP.

For instructions, see [Install PIP](#). On the installation page, choose the **get-pip.py** link, and then save the file. Then open a command terminal as an administrator, and enter the following at the command prompt.

```
python.exe get-pip.py
```

On Linux, you don't specify the .exe extension. You only specify `python get-pip.py`.

- Using PIP, install the Flask and Boto packages using the following code.

```
pip install Flask  
pip install boto  
pip install configparser
```

3. Download DynamoDB to your computer. For instructions on how to run it, see [Setting up DynamoDB local \(downloadable version\)](#).
4. Download the Tic-Tac-Toe application:
 - a. Install Git. For instructions, see [git downloads](#).
 - b. Run the following code to download the application.

```
git clone https://github.com/awslabs/dynamodb-tictactoe-example-app.git
```

1.2: Test the game application

To test the Tic-Tac-Toe application, you need to run DynamoDB locally on your computer.

To run the tic-tac-toe application

1. Start DynamoDB.
2. Start the web server for the Tic-Tac-Toe application.

To do so, open a command terminal, navigate to the folder where you downloaded the Tic-Tac-Toe application, and run the application locally using the following code.

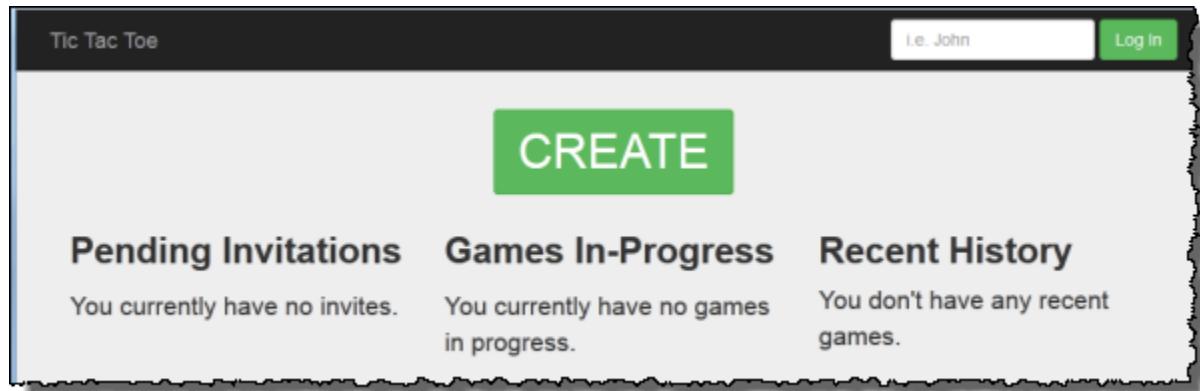

```
python.exe application.py --mode local --serverPort 5000 --port 8000
```

On Linux, you don't specify the .exe extension.

3. Open your web browser, and enter the following.

```
http://localhost:5000/
```

The browser shows the home page.

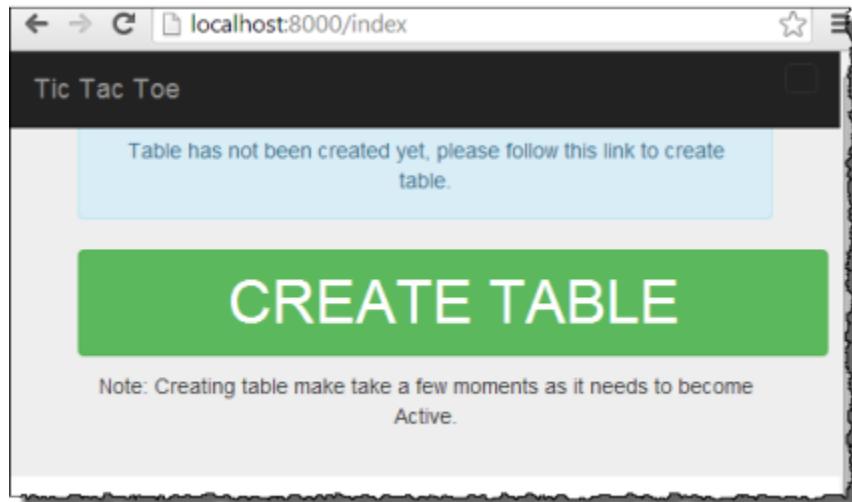

4. Enter **user1** in the **Log in** box to log in as user1.

Note

This example application does not perform any user authentication. The user ID is only used to identify players. If two players log in with the same alias, the application works as if you are playing in two different browsers.

5. If this is your first time playing the game, a page appears requesting you to create the required table (Games) in DynamoDB. Choose **CREATE TABLE**.

6. Choose **CREATE** to create the first tic-tac-toe game.
7. Enter **user2** in the **Choose an Opponent** box, and choose **Create Game!**

Doing this creates the game by adding an item in the Games table. It sets the game status to PENDING.

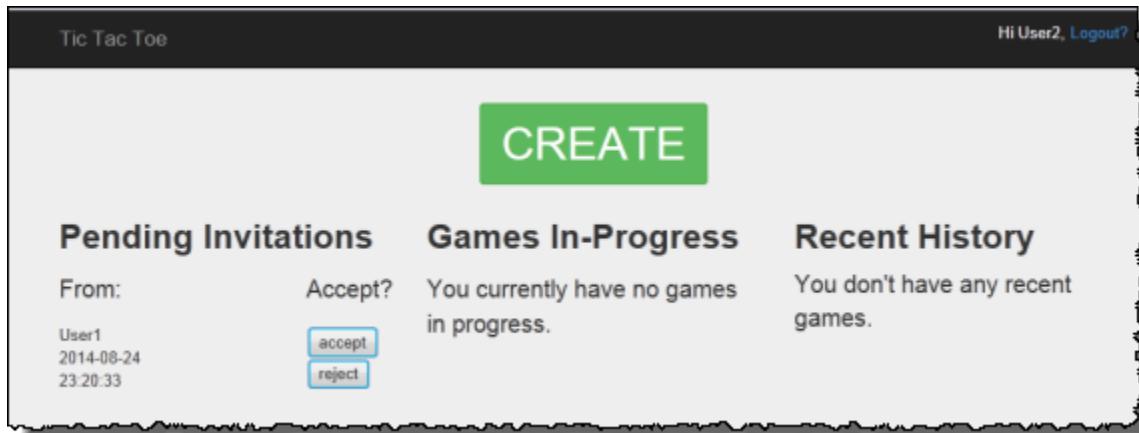

8. Open another browser window, and enter the following.

```
http://localhost:5000/
```

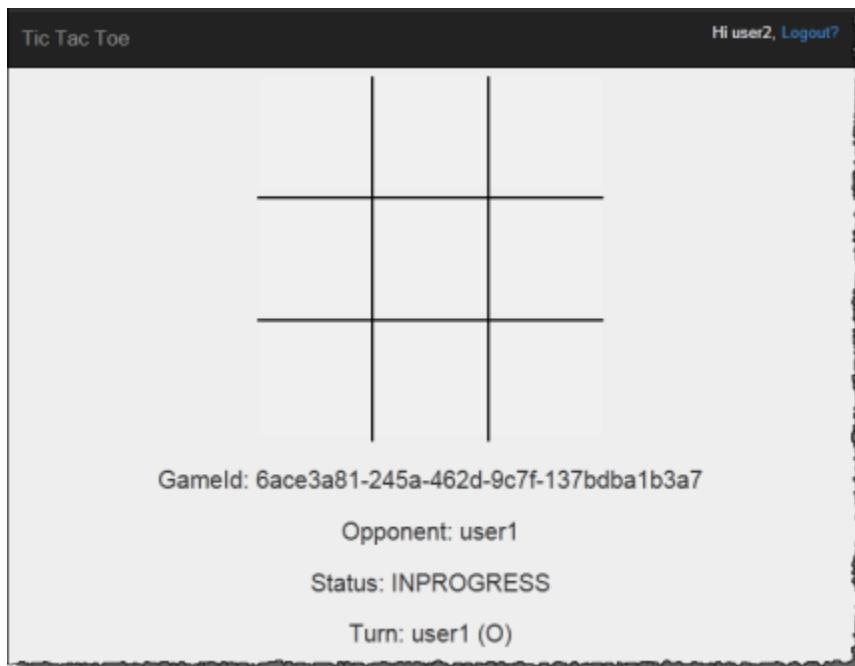

The browser passes information through cookies, so you should use incognito mode or private browsing so that your cookies don't carry over.

9. Log in as user2.

A page appears that shows a pending invitation from user1.

10. Choose **accept** to accept the invitation.

The game page appears with an empty tic-tac-toe grid. The page also shows relevant game information such as the game ID, whose turn it is, and game status.

11. Play the game.

For each user move, the web service sends a request to DynamoDB to conditionally update the game item in the Games table. For example, the conditions ensure that the move is valid, the square that the user chose is available, and that it was the turn of the user who made the move. For a valid move, the update operation adds a new attribute corresponding to the selection on the board. The update operation also sets the value of the existing attribute to the user who can make the next move.

On the game page, the application makes asynchronous JavaScript calls every second, for up to 5 minutes, to check if the game state in DynamoDB has changed. If it has, the application updates the page with new information. After 5 minutes, the application stops making the requests, and you need to refresh the page to get updated information.

Step 2: Examine the data model and implementation details

Topics

- [2.1: Basic data model](#)
- [2.2: Application in action \(code walkthrough\)](#)

2.1: Basic data model

This example application highlights the following DynamoDB data model concepts:

- **Table** – In DynamoDB, a table is a collection of items (that is, records), and each item is a collection of name-value pairs called attributes.

In this Tic-Tac-Toe example, the application stores all game data in a table, Games. The application creates one item in the table per game and stores all game data as attributes. A tic-tac-toe game can have up to nine moves. Because DynamoDB tables do not have a schema in cases where only the primary key is the required attribute, the application can store varying number of attributes per game item.

The Games table has a simple primary key made of one attribute, GameId, of string type. The application assigns a unique ID to each game. For more information on DynamoDB primary keys, see [Primary key](#).

When a user initiates a tic-tac-toe game by inviting another user to play, the application creates a new item in the Games table with attributes storing game metadata, such as the following:

- HostId, the user who initiated the game.
- Opponent, the user who was invited to play.
- The user whose turn it is to play. The user who initiated the game plays first.
- The user who uses the O symbol on the board. The user who initiates the games uses the O symbol.

In addition, the application creates a StatusDate concatenated attribute, marking the initial game state as PENDING. The following screenshot shows an example item as it appears in the DynamoDB console:

Amazon DynamoDB Explore Table Games		
List Tables	Browse Items	Item Details
Edit Item	Copy to New	Delete Item
Attribute	Type	Value
Gameld (Hash Key)	String	"6ffd7f5-e293-4b4a-bacf-6ddde49ef0ae"
HostId	String	"user1"
O	String	"user1"
Opponent	String	"user2"
StatusDate	String	"PENDING_2014-07-06 21:28:02.354807"
Turn	String	"user1"

As the game progresses, the application adds one attribute to the table for each game move. The attribute name is the board position, for example TopLeft or BottomRight. For example, a move might have a TopLeft attribute with the value 0, a TopRight attribute with the value 0, and a BottomRight attribute with the value X. The attribute value is either 0 or X, depending on which user made the move. For example, consider the following board.

- Concatenated value attributes** – The StatusDate attribute illustrates a concatenated value attribute. In this approach, instead of creating separate attributes to store game status (PENDING, IN_PROGRESS, and FINISHED) and date (when the last move was made), you combine them as single attribute, for example IN_PROGRESS_2014-04-30 10:20:32.

The application then uses the StatusDate attribute in creating secondary indexes by specifying StatusDate as a sort key for the index. The benefit of using the StatusDate concatenated value attribute is further illustrated in the indexes discussed next.

- **Global secondary indexes** – You can use the table's primary key, GameId, to efficiently query the table to find a game item. To query the table on attributes other than the primary key attributes, DynamoDB supports the creation of secondary indexes. In this example application, you build the following two secondary indexes:

Global Secondary Indexes										
Index Name	Hash Key	Range Key	Projected Attributes	Status	Read Capacity Units	Write Capacity Units	Last Decrease Time	Last Increase Time	Index Size (Bytes)*	Item Count*
This table has no local secondary indexes.										
hostStatusDate	HostId (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125
oppStatusDate	OpponentId (String)	StatusDate (String)	All	Active	20	20		Sat May 31 10:35:42 GMT-700 2014	20305	125

- **HostId-StatusDate-index**. This index has HostId as a partition key and StatusDate as a sort key. You can use this index to query on HostId, for example to find games hosted by a particular user.
- **OpponentId-StatusDate-index**. This index has OpponentId as a partition key and StatusDate as a sort key. You can use this index to query on Opponent, for example to find games where a particular user is the opponent.

These indexes are called global secondary indexes because the partition key in these indexes is not the same the partition key (GameId), used in the primary key of the table.

Note that both the indexes specify StatusDate as a sort key. Doing this enables the following:

- You can query using the BEGINS_WITH comparison operator. For example, you can find all games with the IN_PROGRESS attribute hosted by a particular user. In this case, the BEGINS_WITH operator checks for the StatusDate value that begins with IN_PROGRESS.
- DynamoDB stores the items in the index in sorted order, by sort key value. So if all status prefixes are the same (for example, IN_PROGRESS), the ISO format used for the date part will have items sorted from oldest to the newest. This approach enables certain queries to be performed efficiently, for example the following:
 - Retrieve up to 10 of the most recent IN_PROGRESS games hosted by the user who is logged in. For this query, you specify the HostId-StatusDate-index index.
 - Retrieve up to 10 of the most recent IN_PROGRESS games where the user logged in is the opponent. For this query, you specify the OpponentId-StatusDate-index index.

For more information about secondary indexes, see [Improving data access with secondary indexes](#).

2.2: Application in action (code walkthrough)

This application has two main pages:

- **Home page** – This page provides the user a simple login, a **CREATE** button to create a new tic-tac-toe game, a list of games in progress, game history, and any active pending game invitations.

The home page is not refreshed automatically; you must refresh the page to refresh the lists.

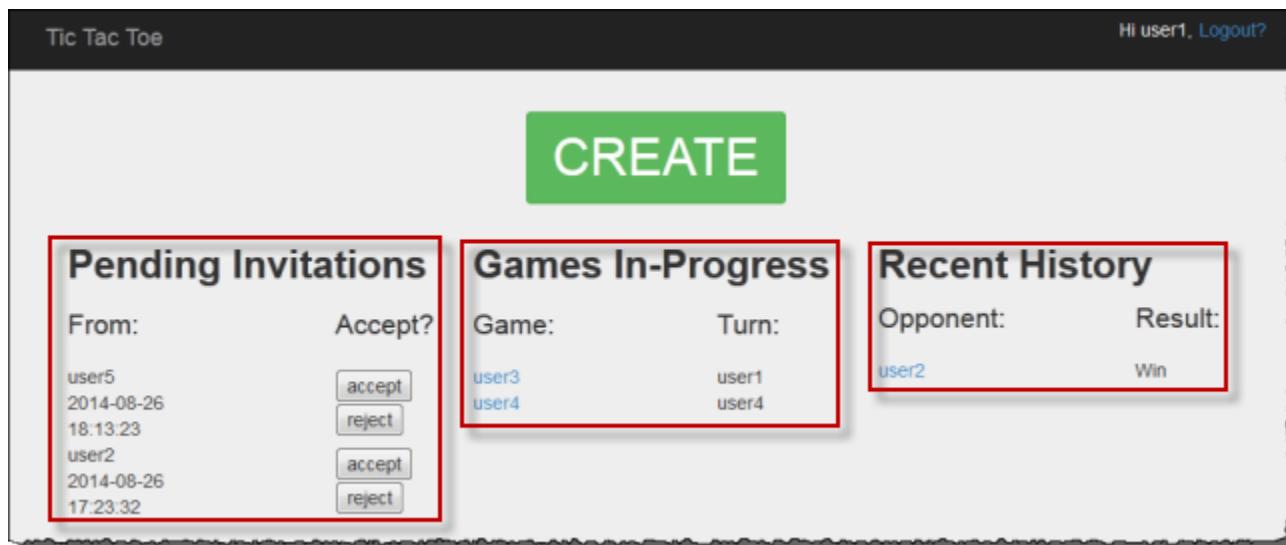

- **Game page** – This page shows the tic-tac-toe grid where users play.

The application updates the game page automatically every second. The JavaScript in your browser calls the Python web server every second to query the Games table whether the game items in the table have changed. If they have, JavaScript triggers a page refresh so that the user sees the updated board.

Let us see in detail how the application works.

Home page

After the user logs in, the application displays the following three lists of information.

- **Invitations** – This list shows up to the 10 most recent invitations from others that are pending acceptance by the user who is logged in. In the preceding screenshot, user1 has invitations from user5 and user2 pending.

- **Games in-progress** – This list shows up to the 10 most recent games that are in progress. These are games that the user is actively playing, which have the status IN_PROGRESS. In the screenshot, user1 is actively playing a tic-tac-toe game with user3 and user4.
- **Recent history** – This list shows up to the 10 most recent games that the user finished, which have the status FINISHED. In game shown in the screenshot, user1 has previously played with user2. For each completed game, the list shows the game result.

In the code, the `index` function (in `application.py`) makes the following three calls to retrieve game status information:

```
inviteGames      = controller.getGameInvites(session["username"])
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
finishedGames    = controller.getGamesWithStatus(session["username"], "FINISHED")
```

Each of these calls returns a list of items from DynamoDB that are wrapped by the Game objects. It is easy to extract data from these objects in the view. The `index` function passes these object lists to the view to render the HTML.

```
return render_template("index.html",
                      user=session["username"],
                      invites=inviteGames,
                      inprogress=inProgressGames,
                      finished=finishedGames)
```

The Tic-Tac-Toe application defines the Game class primarily to store game data retrieved from DynamoDB. These functions return lists of Game objects that enable you to isolate the rest of the application from code related to Amazon DynamoDB items. Thus, these functions help you decouple your application code from the details of the data store layer.

The architectural pattern described here is also referred as the model-view-controller (MVC) UI pattern. In this case, the Game object instances (representing data) are the model, and the HTML page is the view. The controller is divided into two files. The `application.py` file has the controller logic for the Flask framework, and the business logic is isolated in the `gameController.py` file. That is, the application stores everything that has to do with DynamoDB SDK in its own separate file in the dynamodb folder.

Let us review the three functions and how they query the Games table using global secondary indexes to retrieve relevant data.

Using getGameInvites to get the list of pending game invitations

The `getGameInvites` function retrieves the list of the 10 most recent pending invitations. These games have been created by users, but the opponents have not accepted the game invitations. For these games, the status remains PENDING until the opponent accepts the invite. If the opponent declines the invite, the application removes the corresponding item from the table.

The function specifies the query as follows:

- It specifies the OpponentId-StatusDate-index index to use with the following index key values and comparison operators:
 - The partition key is `OpponentId` and takes the index key `user ID`.
 - The sort key is `StatusDate` and takes the comparison operator and index key value `beginswith="PENDING_"`.

You use the `OpponentId-StatusDate-index` index to retrieve games to which the logged-in user is invited—that is, where the logged-in user is the opponent.

- The query limits the result to 10 items.

```
gameInvitesIndex = self.cm.getGamesTable().query(  
    Opponent__eq=user,  
    StatusDate__beginswith="PENDING_",  
    index="OpponentId-StatusDate-index",  
    limit=10)
```

In the index, for each `OpponentId` (the partition key) DynamoDB keeps items sorted by `StatusDate` (the sort key). Therefore, the games that the query returns will be the 10 most recent games.

Using getGamesWithStatus to get the list of games with a specific status

After an opponent accepts a game invitation, the game status changes to IN_PROGRESS. After the game completes, the status changes to FINISHED.

Queries to find games that are either in progress or finished are the same except for the different status value. Therefore, the application defines the `getGamesWithStatus` function, which takes the status value as a parameter.

```
inProgressGames = controller.getGamesWithStatus(session["username"], "IN_PROGRESS")
```

```
finishedGames = controller.getGamesWithStatus(session["username"], "FINISHED")
```

The following section discusses in-progress games, but the same description also applies to finished games.

A list of in-progress games for a given user includes both the following:

- In-progress games hosted by the user
- In-progress games where the user is the opponent

The `getGamesWithStatus` function runs the following two queries, each time using the appropriate secondary index.

- The function queries the `Games` table using the `HostId-StatusDate-index` index. For the index, the query specifies primary key values—both the partition key (`HostId`) and sort key (`StatusDate`) values, along with comparison operators.

```
hostGamesInProgress = self.cm.getGamesTable().query(HostId__eq=user,  
                                                StatusDate__beginswith=status,  
                                                index="HostId-StatusDate-index",  
                                                limit=10)
```

Note the Python syntax for comparison operators:

- `HostId__eq=user` specifies the equality comparison operator.
- `StatusDate__beginswith=status` specifies the `BEGINS_WITH` comparison operator.
- The function queries the `Games` table using the `OpponentId-StatusDate-index` index.

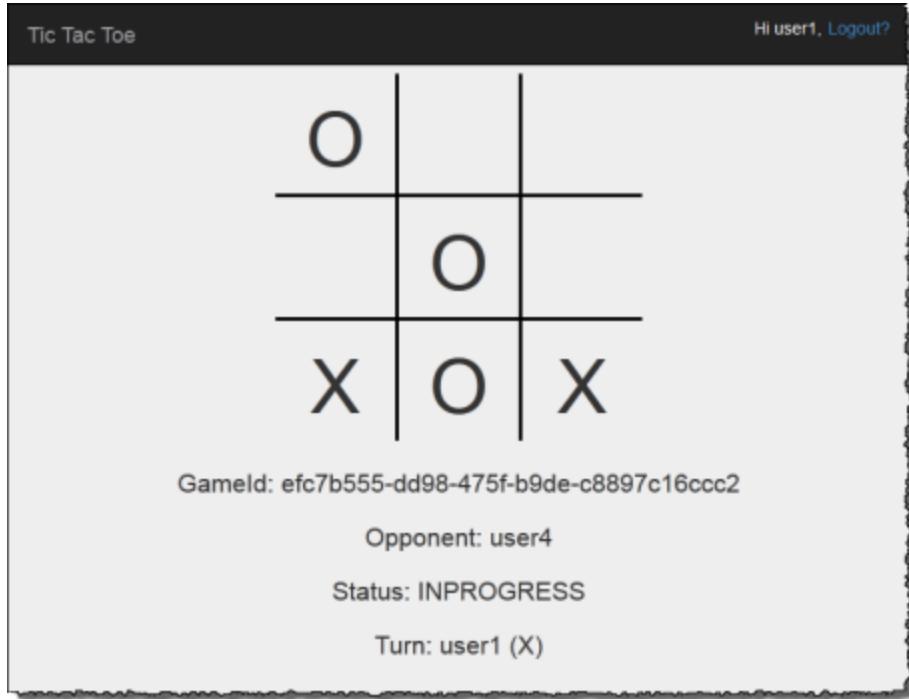

```
oppGamesInProgress = self.cm.getGamesTable().query(Opponent__eq=user,  
                                                StatusDate__beginswith=status,  
                                                index="OpponentId-StatusDate-index",  
                                                limit=10)
```

- The function then combines the two lists, sorts, and for the first 0 to 10 items creates a list of the `Game` objects and returns the list to the calling function (that is, the index).

```
games = self.mergeQueries(hostGamesInProgress,  
                           oppGamesInProgress)  
return games
```

Game page

The game page is where the user plays tic-tac-toe games. It shows the game grid along with game-relevant information. The following screenshot shows an example game in progress:

The application displays the game page in the following situations:

- The user creates a game inviting another user to play.

In this case, the page shows the user as host and the game status as PENDING, waiting for the opponent to accept.

- The user accepts one of the pending invitations on the home page.

In this case, the page shows the user as the opponent and game status as IN_PROGRESS.

A user selection on the board generates a form POST request to the application. That is, Flask calls the `selectSquare` function (in `application.py`) with the HTML form data. This function, in turn, calls the `updateBoardAndTurn` function (in `gameController.py`) to update the game item as follows:

- It adds a new attribute specific to the move.
- It updates the `Turn` attribute value to the user whose turn is next.

```
controller.updateBoardAndTurn(item, value, session["username"])
```

The function returns true if the item update was successful; otherwise, it returns false. Note the following about the `updateBoardAndTurn` function:

- The function calls the `update_item` function of the SDK for Python to make a finite set of updates to an existing item. The function maps to the `UpdateItem` operation in DynamoDB. For more information, see [UpdateItem](#).

 **Note**

The difference between the `UpdateItem` and `PutItem` operations is that `PutItem` replaces the entire item. For more information, see [PutItem](#).

For the `update_item` call, the code identifies the following:

- The primary key of the Games table (that is, `ItemId`).

```
key = { "GameId" : { "S" : gameId } }
```

- The new attribute to add, specific to the current user move, and its value (for example, `TopLeft="X"`).

```
attributeUpdates = {
    position : {
        "Action" : "PUT",
        "Value" : { "S" : representation }
    }
}
```

- Conditions that must be true for the update to take place:
 - The game must be in progress. That is, the `StatusDate` attribute value must begin with `IN_PROGRESS`.
 - The current turn must be a valid user turn as specified by the `Turn` attribute.
 - The square that the user chose must be available. That is, the attribute corresponding to the square must not exist.

```
expectations = {"StatusDate" : {"AttributeValueList": [{"S" : "IN_PROGRESS_"}]},  
    "ComparisonOperator": "BEGINS_WITH"},  
    "Turn" : {"Value" : {"S" : current_player}},  
    position : {"Exists" : False}}
```

Now the function calls `update_item` to update the item.

```
self.cm.db.update_item("Games", key=key,  
    attribute_updates=attributeUpdates,  
    expected=expectations)
```

After the function returns, the `selectSquare` function calls `redirect`, as shown in the following example.

```
redirect("/game="+gameId)
```

This call causes the browser to refresh. As part of this refresh, the application checks to see if the game has ended in a win or draw. If it has, the application updates the game item accordingly.

Step 3: Deploy in production using the DynamoDB service

Topics

- [3.1: Create an IAM role for Amazon EC2](#)
- [3.2: Create the games table in Amazon DynamoDB](#)
- [3.3: Bundle and deploy the tic-tac-toe application code](#)
- [3.4: Set up the AWS Elastic Beanstalk environment](#)

In the preceding sections, you deployed and tested the Tic-Tac-Toe application locally on your computer using DynamoDB local. Now, you deploy the application in production as follows:

- Deploy the application using AWS Elastic Beanstalk, an easy-to-use service for deploying and scaling web applications and services. For more information, see [Deploying a flask application to AWS Elastic Beanstalk](#).

Elastic Beanstalk launches one or more Amazon Elastic Compute Cloud (Amazon EC2) instances, which you configure through Elastic Beanstalk, on which your Tic-Tac-Toe application will run.

- Using the Amazon DynamoDB service, create a Games table that exists on AWS rather than locally on your computer.

In addition, you also have to configure permissions. Any AWS resources you create, such as the Games table in DynamoDB, are private by default. Only the resource owner, that is the AWS account that created the Games table, can access this table. Thus, by default your Tic-Tac-Toe application cannot update the Games table.

To grant necessary permissions, you create an AWS Identity and Access Management (IAM) role and grant this role permissions to access the Games table. Your Amazon EC2 instance first assumes this role. In response, AWS returns temporary security credentials that the Amazon EC2 instance can use to update the Games table on behalf of the Tic-Tac-Toe application. When you configure your Elastic Beanstalk application, you specify the IAM role that the Amazon EC2 instance or instances can assume. For more information about IAM roles, see [IAM roles for amazon EC2](#) in the *Amazon EC2 User Guide for Linux Instances*.

 **Note**

Before you create Amazon EC2 instances for the Tic-Tac-Toe application, you must first decide the AWS Region where you want Elastic Beanstalk to create the instances. After you create the Elastic Beanstalk application, you provide the same Region name and endpoint in a configuration file. The Tic-Tac-Toe application uses information in this file to create the Games table and send subsequent requests in a specific AWS Region. Both the DynamoDB Games table and the Amazon EC2 instances that Elastic Beanstalk launches must be in the same Region. For a list of available Regions, see [Amazon DynamoDB](#) in the *Amazon Web Services General Reference*.

In summary, you do the following to deploy the Tic-Tac-Toe application in production:

1. Create an IAM role using the IAM service. You attach a policy to this role granting permissions for DynamoDB actions to access the Games table.
2. Bundle the Tic-Tac-Toe application code and a configuration file, and create a .zip file. You use this .zip file to give the Tic-Tac-Toe application code to Elastic Beanstalk to put on your servers. For more information about creating a bundle, see [Creating an application source bundle](#) in the *AWS Elastic Beanstalk Developer Guide*.

In the configuration file (`beanstalk.config`), you provide AWS Region and endpoint information. The Tic-Tac-Toe application uses this information to determine which DynamoDB Region to talk to.

3. Set up the Elastic Beanstalk environment. Elastic Beanstalk launches an Amazon EC2 instance or instances and deploys your Tic-Tac-Toe application bundle on them. After the Elastic Beanstalk environment is ready, you provide the configuration file name by adding the `CONFIG_FILE` environment variable.
4. Create the DynamoDB table. Using the Amazon DynamoDB service, you create the Games table on AWS, rather than locally on your computer. Remember, this table has a simple primary key made of the GameId partition key of string type.
5. Test the game in production.

3.1: Create an IAM role for Amazon EC2

Creating an IAM role of the **Amazon EC2** type allows the Amazon EC2 instance that is running your Tic-Tac-Toe application to assume the correct role and make application requests to access the Games table. When creating the role, choose the **Custom Policy** option and copy and paste the following policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "dynamodb>ListTables"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        },  
        {  
            "Action": [  
                "dynamodb:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:922852403271:table/Games",  
                "arn:aws:dynamodb:us-west-2:922852403271:table/Games/index/*"  
            ]  
        }  
    ]  
}
```

```
    }  
]  
}
```

For further instructions, see [Creating a role for an AWS service \(AWS Management Console\)](#) in the [IAM User Guide](#).

3.2: Create the games table in Amazon DynamoDB

The Games table in DynamoDB stores game data. If the table does not exist, the application creates the table for you. In this case, let the application create the Games table.

3.3: Bundle and deploy the tic-tac-toe application code

If you followed this example's steps, then you already have the downloaded the Tic-Tac-Toe application. If not, download the application and extract all the files to a folder on your local computer. For instructions, see [Step 1: Deploy and test locally](#).

After you extract all files, you will have a code folder. To hand off this folder to Elastic Beanstalk, you bundle the contents of this folder as a .zip file. First, you add a configuration file to that folder. Your application uses the Region and endpoint information to create a DynamoDB table in the specified Region and make subsequent table operation requests using the specified endpoint.

1. Switch to the folder where you downloaded the Tic-Tac-Toe application.
2. In the root folder of the application, create a text file named beanstalk.config with the following content.

```
[dynamodb]  
region=<AWS region>  
endpoint=<Amazon DynamoDB endpoint>
```

For example, you might use the following content.

```
[dynamodb]  
region=us-west-2  
endpoint=dynamodb.us-west-2.amazonaws.com
```

For a list of available Regions, see [Amazon DynamoDB](#) in the [Amazon Web Services General Reference](#).

Important

The Region specified in the configuration file is the location where the Tic-Tac-Toe application creates the Games table in DynamoDB. You must create the Elastic Beanstalk application discussed in the next section in the same Region.

Note

When you create your Elastic Beanstalk application, you request to launch an environment where you can choose the environment type. To test the Tic-Tac-Toe example application, you can choose the **Single Instance** environment type, skip the following, and go to the next step.

However, the **Load balancing, autoscaling** environment type provides a highly available and scalable environment, something you should consider when you create and deploy other applications. If you choose this environment type, you also need to generate a UUID and add it to the configuration file, as shown following.

```
[dynamodb]
region=us-west-2
endpoint=dynamodb.us-west-2.amazonaws.com
[flask]
secret_key= 284e784d-1a25-4a19-92bf-8eeb7a9example
```

In client-server communication, when the server sends a response, for security's sake the server sends a signed cookie that the client sends back to the server in the next request. When there is only one server, the server can locally generate an encryption key when it starts. When there are many servers, they all need to know the same encryption key; otherwise, they won't be able to read cookies set by the peer servers. By adding `secret_key` to the configuration file, you tell all servers to use this encryption key.

3. Zip the content of the root folder of the application (which includes the `beanstalk.config` file)—for example, `TicTacToe.zip`.
4. Upload the `.zip` file to an Amazon Simple Storage Service (Amazon S3) bucket. In the next section, you provide this `.zip` file to Elastic Beanstalk to upload on the server or servers.

For instructions on how to upload to an Amazon S3 bucket, see [Create a bucket](#) and [Add an object to a bucket](#) in the *Amazon Simple Storage Service User Guide*.

3.4: Set up the AWS Elastic Beanstalk environment

In this step, you create an Elastic Beanstalk application, which is a collection of components including environments. For this example, you launch one Amazon EC2 instance to deploy and run your Tic-Tac-Toe application.

1. Enter the following custom URL to set up an Elastic Beanstalk console to set up the environment.

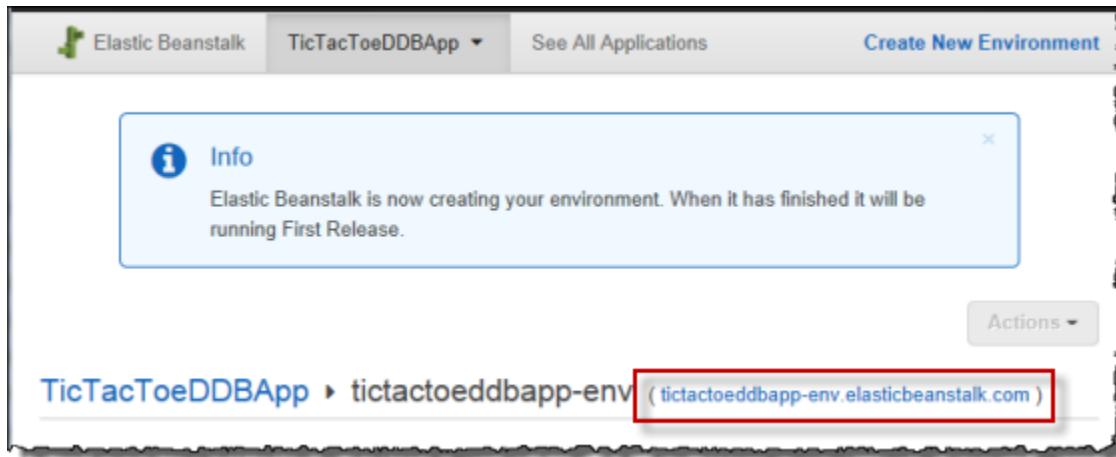

```
https://console.aws.amazon.com/elasticbeanstalk/?region=<AWS-Region>#/newApplication  
?applicationName=TicTacToe<your-name>  
&solutionStackName=Python  
&sourceBundleUrl=https://s3.amazonaws.com/<bucket-name>/TicTacToe.zip  
&environmentType=SingleInstance  
&instanceType=t1.micro
```

For more information about custom URLs, see [Constructing a Launch Now URL](#) in the *AWS Elastic Beanstalk Developer Guide*. For the URL, note the following:

- You must provide an AWS Region name (the same as the one you provided in the configuration file), an Amazon S3 bucket name, and the object name.
- For testing, the URL requests the **SingleInstance** environment type, and **t1.micro** as the instance type.
- The application name must be unique. Thus, in the preceding URL, we suggest you prepend your name to the `applicationName`.

Doing this opens the Elastic Beanstalk console. In some cases, you might need to sign in.

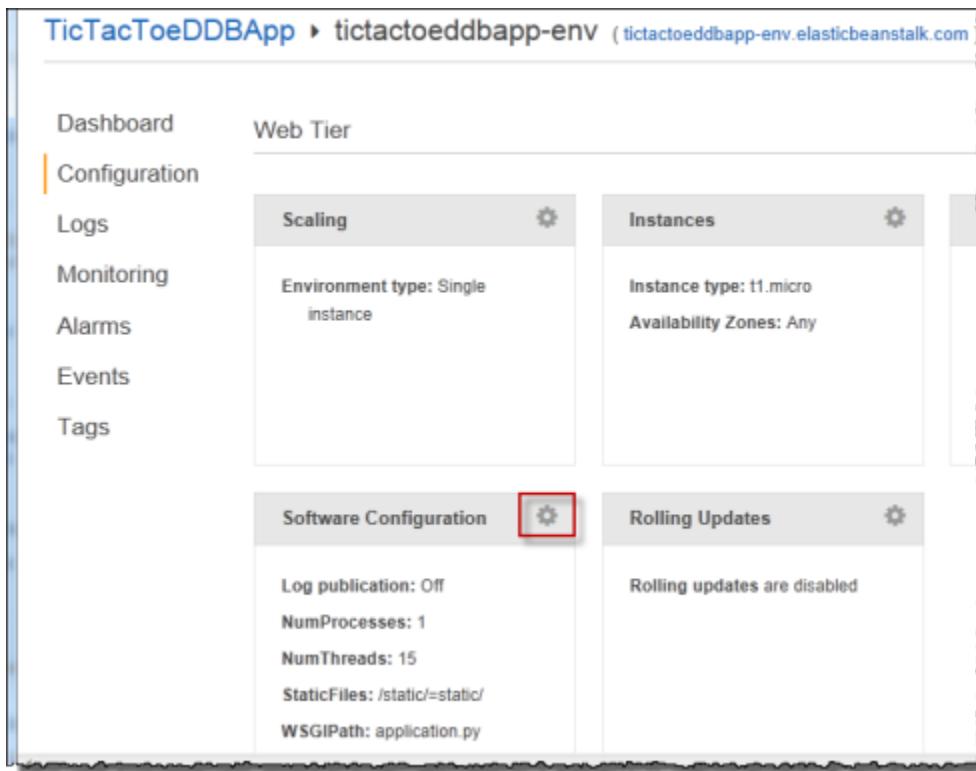

2. In the Elastic Beanstalk console, choose **Review and Launch**, and then choose **Launch**.
3. Note the URL for future reference. This URL opens your Tic-Tac-Toe application home page.

4. Configure the Tic-Tac-Toe application so it knows the location of the configuration file.

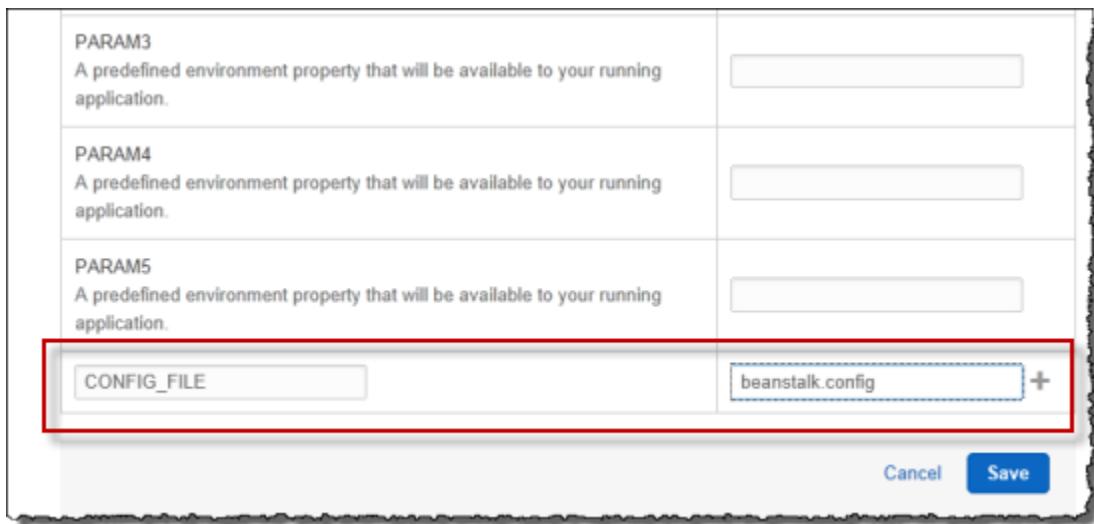

After Elastic Beanstalk creates the application, choose **Configuration**.

- Choose the gear icon next to **Software Configuration**, as shown in the following screenshot.

- At the end of the **Environment Properties** section, enter **CONFIG_FILE** and its value **beanstalk.config**, and then choose **Save**.

It might take a few minutes for this environment update to complete.

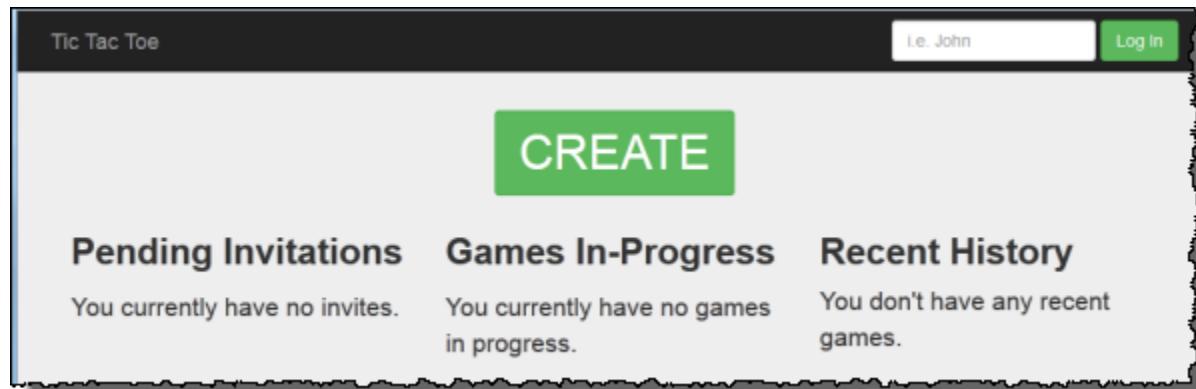

After the update completes, you can play the game.

5. In the browser, enter the URL you copied in the previous step, as shown in the following example.

`http://<app-name>.elasticbeanstalk.com`

Doing this opens the application home page.

6. Log in as testuser1, and choose **CREATE** to start a new tic-tac-toe game.
7. Enter **testuser2** in the **Choose an Opponent** box.

8. Open another browser window.

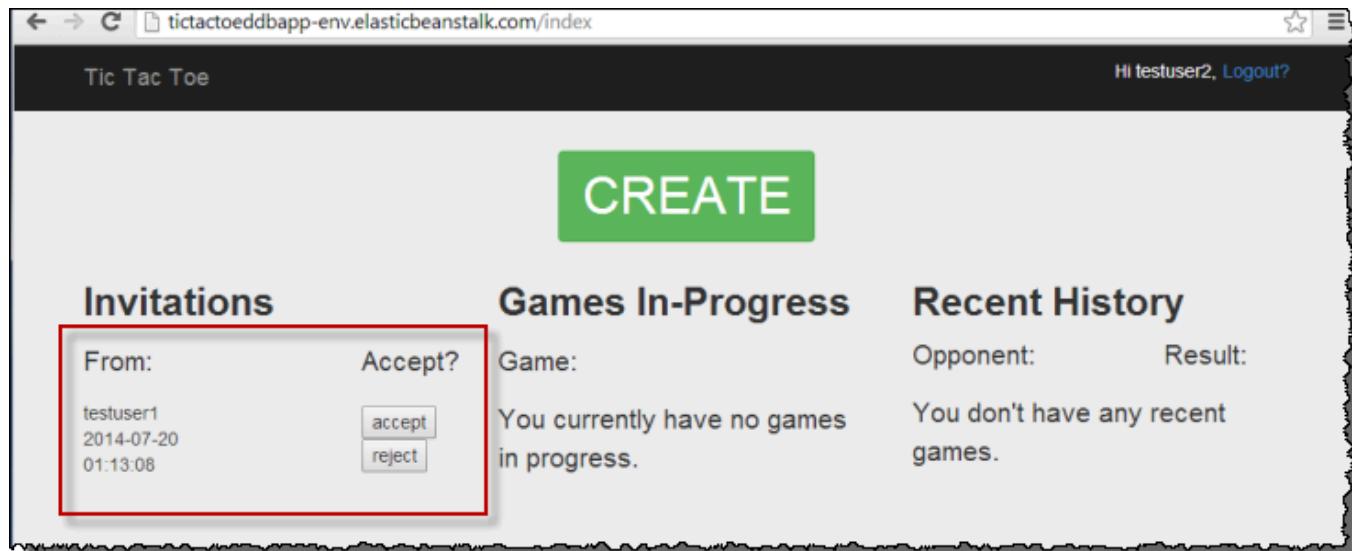

Make sure that you clear all cookies in your browser window so you won't be logged in as same user.

9. Enter the same URL to open the application home page, as shown in the following example.

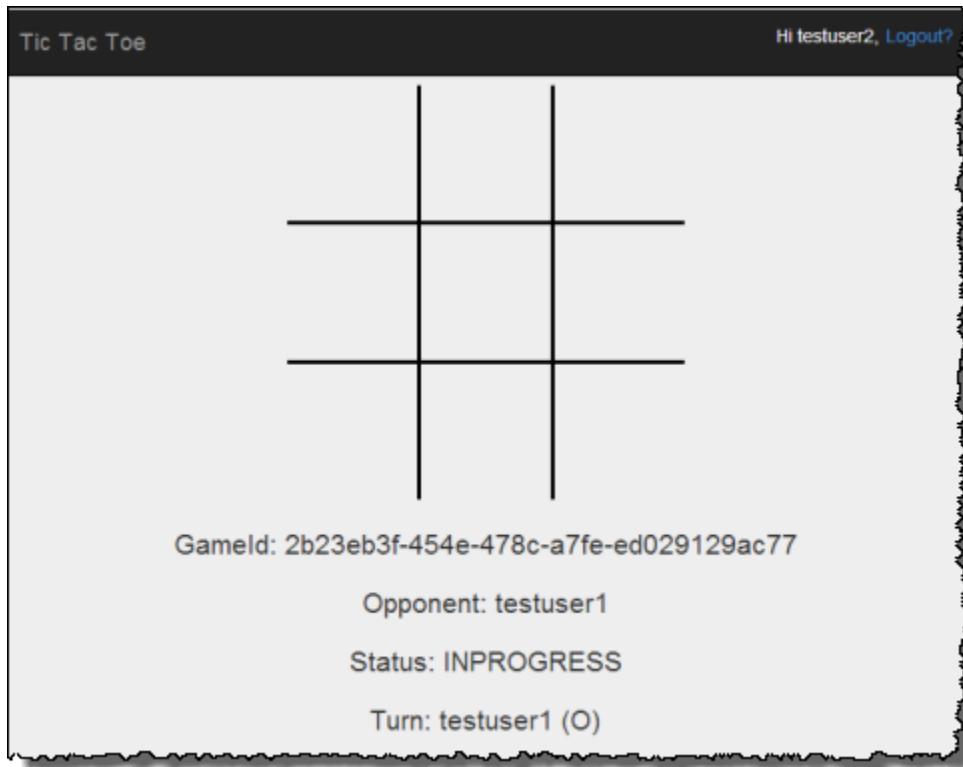

`http://<env-name>.elasticbeanstalk.com`

10. Log in as testuser2.

11. For the invitation from testuser1 in the list of pending invitations, choose **accept**.

12. Now the game page appears.

Both testuser1 and testuser2 can play the game. For each move, the application saves the move in the corresponding item in the Games table.

Step 4: Clean up resources

Now you have completed the Tic-Tac-Toe application deployment and testing. The application covers end-to-end web application development on Amazon DynamoDB, except for user authentication. The application uses the login information on the home page only to add a player name when creating a game. In a production application, you would add the necessary code to perform user login and authentication.

If you are done testing, you can remove the resources you created to test the Tic-Tac-Toe application to avoid incurring any charges.

To remove the resources you created

1. Remove the Games table that you created in DynamoDB.
2. Terminate the Elastic Beanstalk environment to free up the Amazon EC2 instances.
3. Delete the IAM role that you created.

4. Remove the object that you created in Amazon S3.

Exporting and importing DynamoDB data using AWS Data Pipeline

You can use AWS Data Pipeline to export data from a DynamoDB table to a file in an Amazon S3 bucket. You can also use the console to import data from Amazon S3 into a DynamoDB table, in the same AWS region or in a different region.

 **Note**

DynamoDB Console now natively supports importing from Amazon S3 and exporting to Amazon S3. These flows are not compatible with AWS Data Pipeline import flow. For more information see [Import from Amazon S3](#), [Export from Amazon S3](#), and the blog post [Export Amazon DynamoDB table data to your data lake in Amazon S3](#).

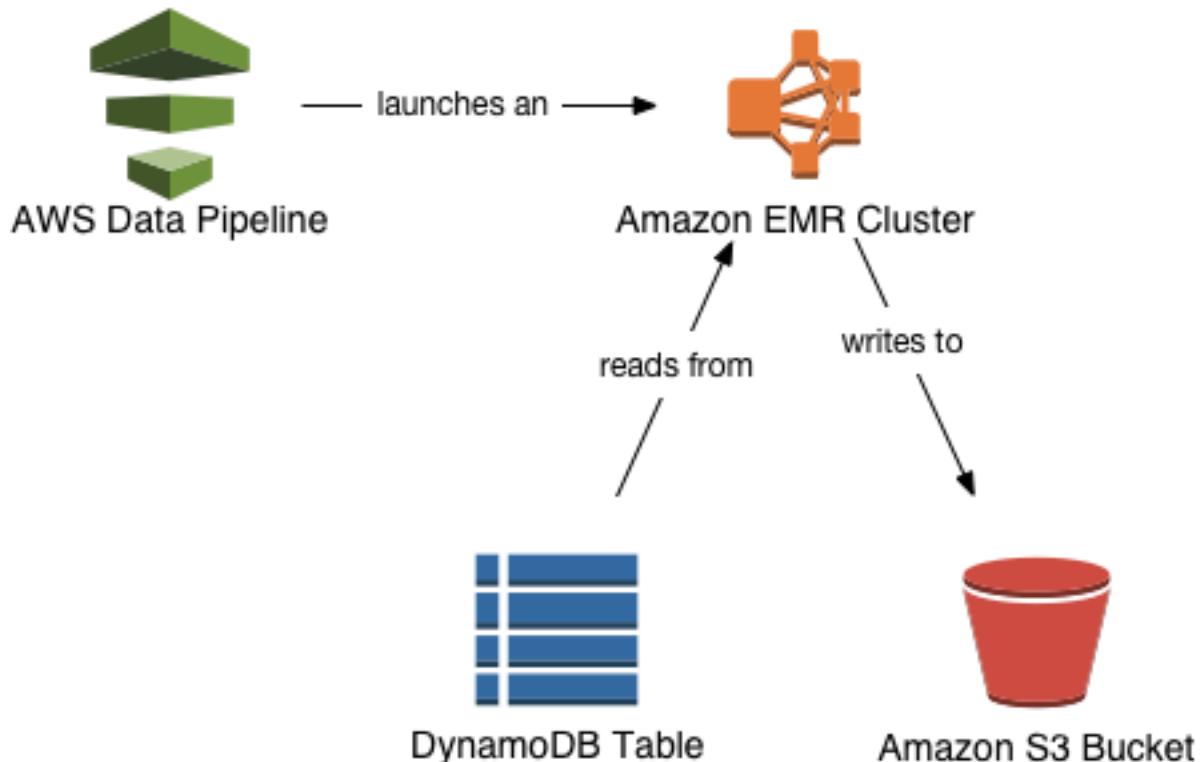

The ability to export and import data is useful in many scenarios. For example, suppose you want to maintain a baseline set of data, for testing purposes. You could put the baseline data into a DynamoDB table and export it to Amazon S3. Then, after you run an application that modifies the test data, you could "reset" the data set by importing the baseline from Amazon S3 back into the DynamoDB table. Another example involves accidental deletion of data, or even an accidental DeleteTable operation. In these cases, you could restore the data from a previous export file in Amazon S3. You can even copy data from a DynamoDB table in one AWS region, store the data in Amazon S3, and then import the data from Amazon S3 to an identical DynamoDB table in a second region. Applications in the second region could then access their nearest DynamoDB endpoint and work with their own copy of the data, with reduced network latency.

 **Important**

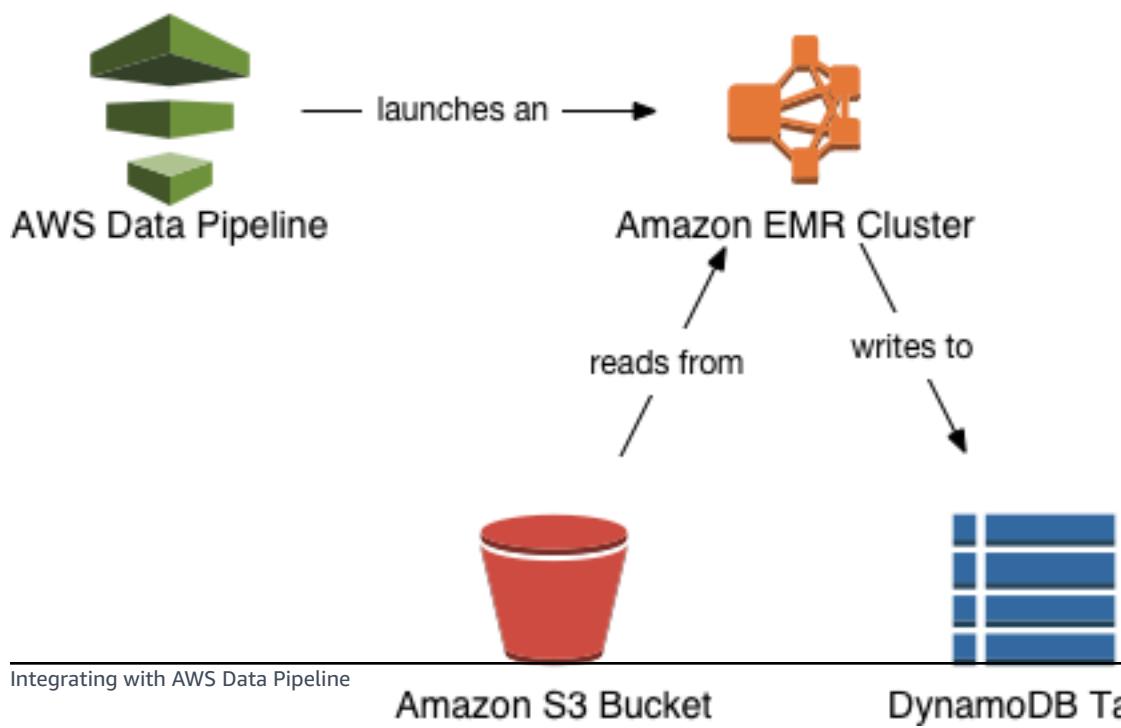

DynamoDB Backup and Restore is a fully managed feature. You can back up tables from a few megabytes to hundreds of terabytes of data, with no impact on the performance and availability of your production applications. You can restore your table with a single click in the AWS Management Console or a single API call. We highly recommend that you use DynamoDB's native backup and restore feature instead of using AWS Data Pipeline. For more information, see [Using On-Demand backup and restore for DynamoDB](#).

The following diagram shows an overview of exporting and importing DynamoDB data using AWS Data Pipeline.

Exporting Data from DynamoDB to Amazon S3

Importing Data from Amazon S3 to DynamoDB

To export a DynamoDB table, you use the AWS Data Pipeline console to create a new pipeline. The pipeline launches an Amazon EMR cluster to perform the actual export. Amazon EMR reads the data from DynamoDB, and writes the data to an export file in an Amazon S3 bucket.

The process is similar for an import, except that the data is read from the Amazon S3 bucket and written to the DynamoDB table.

Important

When you export or import DynamoDB data, you will incur additional costs for the underlying AWS services that are used:

- **AWS Data Pipeline**— manages the import/export workflow for you.
- **Amazon S3**— contains the data that you export from DynamoDB, or import into DynamoDB.
- **Amazon EMR**— runs a managed Hadoop cluster to perform reads and writes between DynamoDB to Amazon S3. The cluster configuration is one `m3.xlarge` instance leader node and one `m3.xlarge` instance core node.

For more information see [AWS Data Pipeline pricing](#), [Amazon EMR pricing](#), and [Amazon S3 pricing](#).

Prerequisites to export and import data

When you use AWS Data Pipeline for exporting and importing data, you must specify the actions that the pipeline is allowed to perform, and which resources the pipeline can consume. The permitted actions and resources are defined using AWS Identity and Access Management (IAM) roles.

You can also control access by creating IAM policies and attaching them to users, roles or groups. These policies let you specify which users are allowed to import and export your DynamoDB data.

Important

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions for the interface that you want to use.</p> <ul style="list-style-type: none">For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center in the <i>AWS Command Line Interface User Guide</i>.For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the <i>AWS SDKs and Tools Reference Guide</i>.
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions in Using temporary credentials with AWS resources in the <i>IAM User Guide</i> .

Which user needs programmatic access?	To	By
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. <ul style="list-style-type: none">For the AWS CLI, see Authenticating using IAM user credentials in the <i>AWS Command Line Interface User Guide</i>.For AWS SDKs and tools, see Authenticate using long-term credentials in the <i>AWS SDKs and Tools Reference Guide</i>.For AWS APIs, see Managing access keys for IAM users in the <i>IAM User Guide</i>.

Creating IAM roles for AWS Data Pipeline

In order to use AWS Data Pipeline, the following IAM roles must be present in your AWS account:

- ***DataPipelineDefaultRole*** — the actions that your pipeline can take on your behalf.
- ***DataPipelineDefaultResourceRole*** — the AWS resources that the pipeline will provision on your behalf. For exporting and importing DynamoDB data, these resources include an Amazon EMR cluster and the Amazon EC2 instances associated with that cluster.

If you've never used AWS Data Pipeline before, you'll need to create *DataPipelineDefaultRole* and *DataPipelineDefaultResourceRole* yourself. Once you've created these roles, you can use them any time to export or import DynamoDB data.

Note

If you have previously used the AWS Data Pipeline console to create a pipeline, then *DataPipelineDefaultRole* and *DataPipelineDefaultResourceRole* were created for you at that time. No further action is required; you can skip this section and begin creating pipelines using the DynamoDB console. For more information, see [Exporting data from DynamoDB to Amazon S3](#) and [Importing data from Amazon S3 to DynamoDB](#).

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. From the IAM Console Dashboard, click **Roles**.
3. Click **Create Role** and do the following:
 - a. In the **AWS Service** trusted entity, choose **Data Pipeline**.
 - b. In the **Select your use case** panel, choose **Data Pipeline** and then choose **Next:Permissions**.
 - c. Notice that the **AWSDataPipelineRole** policy is automatically attached. Choose **Next:Review**.
 - d. In the **Role name** field, type **DataPipelineDefaultRole** as the role name and choose **Create role**.
4. Click **Create Role** and do the following:
 - a. In the **AWS Service** trusted entity, choose **Data Pipeline**.
 - b. In the **Select your use case** panel, choose **EC2 Role for Data Pipeline** and then choose **Next:Permissions**.
 - c. Notice that the **AmazonEC2RoleForDataPipelineRole** policy is automatically attached. Choose **Next:Review**.
 - d. In the **Role name** field, type **DataPipelineDefaultResourceRole** as the role name and choose **Create role**.

Now that you have created these roles, you can begin creating pipelines using the DynamoDB console. For more information, see [Exporting data from DynamoDB to Amazon S3](#) and [Importing data from Amazon S3 to DynamoDB](#).

Granting users and groups permission to perform export and import tasks using AWS Identity and Access Management

If you want to allow other users, roles or groups to export and import your DynamoDB table data, you can create an IAM policy and attach it to the users or groups that you designate. The policy contains only the necessary permissions for performing these tasks.

Granting full access

The following procedure describes how to attach the AWS managed policies `AmazonDynamoDBFullAccess`, `AWSDataPipeline_FullAccess` and an Amazon EMR inline policy to a user. These managed policies provides full access to AWS Data Pipeline and to DynamoDB resources, and used with the Amazon EMR inline policy, allow the user to perform the actions described in this documentation.

Note

To limit the scope of the suggested permissions, the inline policy above is enforcing the usage of the tag `dynamodbdatapipeline`. If you want to utilize this documentation without this limitation, you can remove the `Condition` section of the suggested policy.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. From the IAM Console Dashboard, click **Users** and select the user you want to modify.
3. In the **Permissions** tab, click **Add Policy**.
4. In the **Attach permissions** panel, click **Attach existing policies directly**.
5. Select both `AmazonDynamoDBFullAccess` and `AWSDataPipeline_FullAccess` and click **Next:Review**.
6. Click **Add permissions**.
7. Back on **Permissions** tab, click **Add inline policy**.
8. In the **Create a policy** page, click **JSON** tab.
9. Paste the content below.

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [  
    {  
        "Sid": "EMR",  
        "Effect": "Allow",  
        "Action": [  
            "elasticmapreduce:DescribeStep",  
            "elasticmapreduce:DescribeCluster",  
            "elasticmapreduce:RunJobFlow",  
            "elasticmapreduce:TerminateJobFlows"  
        ],  
        "Resource": "*",  
        "Condition": {  
            "Null": {  
                "elasticmapreduce:RequestTag/dynamodbdatipeline": "false"  
            }  
        }  
    }  
]
```

10. Click **Review policy**.

11. Type EMRforDynamoDBDataPipeline on the name field.

12. Click **Create policy**.

 **Note**

You can use a similar procedure to attach this managed policy to a role or group, rather than to a user.

Restricting access to particular DynamoDB tables

If you want to restrict access so that a user can only export or import a subset of your tables, you'll need to create a customized IAM policy document. You can use the process described on [Granting full access](#) as a starting point for your custom policy, and then modify the policy so that a user can only work with the tables that you specify.

For example, suppose that you want to allow a user to export and import only the *Forum*, *Thread*, and *Reply* tables. This procedure describes how to create a custom policy so that a user can work with those tables, but no others.

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. From the IAM Console Dashboard, click **Policies** and then click **Create Policy**.
3. In the **Create Policy** panel, go to **Copy an AWS Managed Policy** and click **Select**.
4. In the **Copy an AWS Managed Policy** panel, go to **AmazonDynamoDBFullAccess** and click **Select**.
5. In the **Review Policy** panel, do the following:
 - a. Review the autogenerated **Policy Name** and **Description**. If you want, you can modify these values.
 - b. In the **Policy Document** text box, edit the policy to restrict access to specific tables. By default, the policy permits all DynamoDB actions on all of your tables:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "cloudwatch:DeleteAlarms",  
                "cloudwatch:DescribeAlarmHistory",  
                "cloudwatch:DescribeAlarms",  
                "cloudwatch:DescribeAlarmsForMetric",  
                "cloudwatch:GetMetricStatistics",  
                "cloudwatch>ListMetrics",  
                "cloudwatch:PutMetricAlarm",  
                "dynamodb:*",  
                "sns>CreateTopic",  
                "sns>DeleteTopic",  
                "sns>ListSubscriptions",  
                "sns>ListSubscriptionsByTopic",  
                "sns>ListTopics",  
                "sns:Subscribe",  
                "sns:Unsubscribe"  
            ],  
            "Effect": "Allow",  
            "Resource": "*",  
            "Sid": "DDBConsole"  
        },  
        ...remainder of document omitted...
```

To restrict the policy, first remove the following line:

```
"dynamodb:*",
```

Next, construct a new Action that allows access to only the *Forum*, *Thread* and *Reply* tables:

```
{  
    "Action": [  
        "dynamodb:*"  
    ],  
    "Effect": "Allow",  
    "Resource": [  
        "arn:aws:dynamodb:us-west-2:123456789012:table/Forum",  
        "arn:aws:dynamodb:us-west-2:123456789012:table/Thread",  
        "arn:aws:dynamodb:us-west-2:123456789012:table/Reply"  
    ]  
},
```

 **Note**

Replace `us-west-2` with the region in which your DynamoDB tables reside.
Replace `123456789012` with your AWS account number.

Finally, add the new Action to the policy document:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "dynamodb:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Forum",  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Thread",  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Reply"  
            ]  
        }  
    ]  
}
```

```
},
{
    "Action": [
        "cloudwatch:DeleteAlarms",
        "cloudwatch:DescribeAlarmHistory",
        "cloudwatch:DescribeAlarms",
        "cloudwatch:DescribeAlarmsForMetric",
        "cloudwatch:GetMetricStatistics",
        "cloudwatch>ListMetrics",
        "cloudwatch:PutMetricAlarm",
        "sns>CreateTopic",
        "sns>DeleteTopic",
        "sns>ListSubscriptions",
        "sns>ListSubscriptionsByTopic",
        "sns>ListTopics",
        "sns>Subscribe",
        "sns>Unsubscribe"
    ],
    "Effect": "Allow",
    "Resource": "*",
    "Sid": "DDBConsole"
},
...remainder of document omitted...
```

6. When the policy settings are as you want them, click **Create Policy**.

After you have created the policy, you can attach it to a user.

1. From the IAM Console Dashboard, click **Users** and select the user you want to modify.
2. In the **Permissions** tab, click **Attach Policy**.
3. In the **Attach Policy** panel, select the name of your policy and click **Attach Policy**.

Note

You can use a similar procedure to attach your policy to a role or group, rather than to a user.

Exporting data from DynamoDB to Amazon S3

This section describes how to export data from one or more DynamoDB tables to an Amazon S3 bucket. You need to create the Amazon S3 bucket before you can perform the export.

Important

If you have never used AWS Data Pipeline before, you will need to set up two IAM roles before following this procedure. For more information, see [Creating IAM roles for AWS Data Pipeline](#).

1. Sign in to the AWS Management Console and open the AWS Data Pipeline console at <https://console.aws.amazon.com/datapipeline/>.
2. If you do not already have any pipelines in the current AWS region, choose **Get started now**. Otherwise, if you already have at least one pipeline, choose **Create new pipeline**.
3. On the **Create Pipeline** page, do the following:
 - a. In the **Name** field, type a name for your pipeline. For example: MyDynamoDBExportPipeline.
 - b. For the **Source** parameter, select **Build using a template**. From the drop-down template list, choose **Export DynamoDB table to S3**.
 - c. In the **Source DynamoDB table name** field, type the name of the DynamoDB table that you want to export.
 - d. In the **Output S3 Folder** text box, enter an Amazon S3 URI where the export file will be written. For example: s3://mybucket/exports

The format of this URI is `s3://bucketname/folder` where:

- `bucketname` is the name of your Amazon S3 bucket.
 - `folder` is the name of a folder within that bucket. If the folder does not exist, it will be created automatically. If you do not specify a name for the folder, a name will be assigned for it in the form `s3://bucketname/region/tablename`.
- e. In the **S3 location for logs** text box, enter an Amazon S3 URI where the log file for the export will be written. For example: s3://mybucket/logs/

The URI format for **S3 Log Folder** is the same as for **Output S3 Folder**. The URI must resolve to a folder; log files cannot be written to the top level of the S3 bucket.

4. Add a tag with the Key dynamodbdatapipeline and the Value true.
5. When the settings are as you want them, click **Activate**.

Your pipeline will now be created; this process can take several minutes to complete. You can monitor the progress in the AWS Data Pipeline console.

When the export has finished, you can go to the [Amazon S3 console](#) to view your export file. The output file name is an identifier value with no extension, such as this example: ae10f955-fb2f-4790-9b11-fbfea01a871e_000000. The internal format of this file is described at [File Structure](#) in the *AWS Data Pipeline Developer Guide*.

Importing data from Amazon S3 to DynamoDB

This section assumes that you have already exported data from a DynamoDB table, and that the export file has been written to your Amazon S3 bucket. The internal format of this file is described at [File Structure](#) in the *AWS Data Pipeline Developer Guide*. Note that this is the *only* file format that DynamoDB can import using AWS Data Pipeline.

We will use the term *source table* for the original table from which the data was exported, and *destination table* for the table that will receive the imported data. You can import data from an export file in Amazon S3, provided that all of the following are true:

- The destination table already exists. (The import process will not create the table for you.)
- The destination table has the same key schema as the source table.

The destination table does not have to be empty. However, the import process will replace any data items in the table that have the same keys as the items in the export file. For example, suppose you have a *Customer* table with a key of *CustomerId*, and that there are only three items in the table (*CustomerId* 1, 2, and 3). If your export file also contains data items for *CustomerId* 1, 2, and 3, the items in the destination table will be replaced with those from the export file. If the export file also contains a data item for *CustomerId* 4, then that item will be added to the table.

The destination table can be in a different AWS region. For example, suppose you have a *Customer* table in the US West (Oregon) region and export its data to Amazon S3. You could then import that data into an identical *Customer* table in the Europe (Ireland) region. This is referred to as a

cross-region export and import. For a list of AWS regions, go to [Regions and endpoints in the AWS General Reference](#).

Note that the AWS Management Console lets you export multiple source tables at once. However, you can only import one table at a time.

1. Sign in to the AWS Management Console and open the AWS Data Pipeline console at <https://console.aws.amazon.com/datapipeline/>.
2. (Optional) If you want to perform a cross region import, go to the upper right corner of the window and choose the destination region.
3. Choose **Create new pipeline**.
4. On the **Create Pipeline** page, do the following:
 - a. In the **Name** field, type a name for your pipeline. For example: MyDynamoDBImportPipeline.
 - b. For the **Source** parameter, select **Build using a template**. From the drop-down template list, choose **Import DynamoDB backup data from S3**.
 - c. In the **Input S3 Folder** text box, enter an Amazon S3 URI where the export file can be found. For example: s3://mybucket/exports

The format of this URI is `s3://bucketname/folder` where:

- *bucketname* is the name of your Amazon S3 bucket.
- *folder* is the name of the folder that contains the export file.

The import job will expect to find a file at the specified Amazon S3 location. The internal format of the file is described at [Verify data export file in the AWS Data Pipeline Developer Guide](#).

- d. In the **Target DynamoDB table name** field, type the name of the DynamoDB table into which you want to import the data.
- e. In the **S3 location for logs** text box, enter an Amazon S3 URI where the log file for the import will be written. For example: s3://mybucket/logs/

The URI format for **S3 Log Folder** is the same as for **Output S3 Folder**. The URI must resolve to a folder; log files cannot be written to the top level of the S3 bucket.

- f. Add a tag with the Key dynamodbdatapipeline and the Value true.

- When the settings are as you want them, click **Activate**.

Your pipeline will now be created; this process can take several minutes to complete. The import job will begin immediately after the pipeline has been created.

Troubleshooting

This section covers some basic failure modes and troubleshooting for DynamoDB exports.

If an error occurs during an export or import, the pipeline status in the AWS Data Pipeline console will display as **ERROR**. If this happens, click the name of the failed pipeline to go to its detail page. This will show details about all of the steps in the pipeline, and the status of each one. In particular, examine any execution stack traces that you see.

Finally, go to your Amazon S3 bucket and look for any export or import log files that were written there.

The following are some common issues that may cause a pipeline to fail, along with corrective actions. To diagnose your pipeline, compare the errors you have seen with the issues noted below.

- For an import, ensure that the destination table already exists, and the destination table has the same key schema as the source table. These conditions must be met, or the import will fail.
- Ensure that the pipeline has the tag `dynamodbdatipeline`; otherwise, the Amazon EMR API calls will not succeed.
- Ensure that the Amazon S3 bucket you specified has been created, and that you have read and write permissions on it.
- The pipeline might have exceeded its execution timeout. (You set this parameter when you created the pipeline.) For example, you might have set the execution timeout for 1 hour, but the export job might have required more time than this. Try deleting and then re-creating the pipeline, but with a longer execution timeout interval this time.
- Update the manifest file if you restore from a Amazon S3 bucket that is not the original bucket that the export was performed with (contains a copy of the export).
- You might not have the correct permissions for performing an export or import. For more information, see [Prerequisites to export and import data](#).
- You might have reached a resource quota in your AWS account, such as the maximum number of Amazon EC2 instances or the maximum number of AWS Data Pipeline pipelines. For more

information, including how to request increases in these quotas, see [AWS service quotas](#) in the *AWS General Reference*.

 **Note**

For more details on troubleshooting a pipeline, go to [Troubleshooting](#) in the *AWS Data Pipeline Developer Guide*.

Predefined templates for AWS Data Pipeline and DynamoDB

If you would like a deeper understanding of how AWS Data Pipeline works, we recommend that you consult the *AWS Data Pipeline Developer Guide*. This guide contains step-by-step tutorials for creating and working with pipelines; you can use these tutorials as starting points for creating your own pipelines. We recommend that you read the AWS Data Pipeline tutorial, which walks you through the steps required to create an import and export pipeline that you can customize for your requirements. See [Tutorial: Amazon DynamoDB import and export using AWS Data Pipeline](#) in the *AWS Data Pipeline Developer Guide*.

AWS Data Pipeline offers several templates for creating pipelines; the following templates are relevant to DynamoDB.

Exporting data between DynamoDB and Amazon S3

 **Note**

DynamoDB Console now supports its own Export to Amazon S3 flow, however it is not compatible with AWS Data Pipeline import flow. For more information, see [DynamoDB data export to Amazon S3: how it works](#) and the blog post [Export Amazon DynamoDB table data to your data lake in Amazon S3, no code writing required](#).

The AWS Data Pipeline console provides two predefined templates for exporting data between DynamoDB and Amazon S3. For more information about these templates, see the following sections of the *AWS Data Pipeline Developer Guide*:

- [Export DynamoDB to Amazon S3](#)
- [Export Amazon S3 to DynamoDB](#)

Amazon DynamoDB Storage Backend for Titan

The DynamoDB Storage Backend for Titan project has been superseded by the Amazon DynamoDB Storage Backend for JanusGraph, which is available on [GitHub](#).

For up-to-date instructions on the DynamoDB Storage Backend for JanusGraph, see the [README.md](#) file.

Reserved words in DynamoDB

The following keywords are reserved for use by DynamoDB. Do not use any of these words as attribute names in expressions. This list is not case-sensitive.

If you need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word, you can define an expression attribute name to use in the place of the reserved word. For more information, see [Expression attribute names in DynamoDB](#).

Legacy conditional parameters

This section compares the legacy conditional parameters with expression parameters in DynamoDB.

 **Important**

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). Additionally, DynamoDB does not allow mixing legacy conditional parameters and expression parameters in a single call. For example, calling the Query operation with AttributesToGet and ConditionExpression will result in an error.

The following table shows the DynamoDB API operations that still support these legacy parameters, and which expression parameter to use instead. This table can be helpful if you are considering updating your applications so that they use expression parameters instead.

If you use this API operation ... s...	With these legacy parameter s...	Use this expression parameter instead
BatchGetItem	AttributesToGet	ProjectionExpression
DeleteItem	Expected	ConditionExpression
GetItem	AttributesToGet	ProjectionExpression
PutItem	Expected	ConditionExpression
Query	AttributesToGet	ProjectionExpression
	KeyConditions	KeyConditionExpression
	QueryFilter	FilterExpression
Scan	AttributesToGet	ProjectionExpression
	ScanFilter	FilterExpression
UpdateItem	AttributeUpdates	UpdateExpression
	Expected	ConditionExpression

The following sections provide more information about legacy conditional parameters.

Topics

- [AttributesToGet \(legacy\)](#)
- [AttributeUpdates \(legacy\)](#)
- [ConditionalOperator \(legacy\)](#)
- [Expected \(legacy\)](#)
- [KeyConditions \(legacy\)](#)
- [QueryFilter \(legacy\)](#)
- [ScanFilter \(legacy\)](#)
- [Writing conditions with legacy parameters](#)

AttributesToGet (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, [use *ProjectionExpression* instead..](#)

The legacy conditional parameter `AttributesToGet` is an array of one or more attributes to retrieve from DynamoDB. If no attribute names are provided, then all attributes will be returned. If any of the requested attributes are not found, they will not appear in the result.

`AttributesToGet` allows you to retrieve attributes of type List or Map; however, it cannot retrieve individual elements within a List or a Map.

Note that `AttributesToGet` has no effect on provisioned throughput consumption. DynamoDB determines capacity units consumed based on item size, not on the amount of data that is returned to an application.

Use *ProjectionExpression* instead – Example

Suppose you wanted to retrieve an item from the *Music* table, but that you only wanted to return some of the attributes. You could use a `GetItem` request with an `AttributesToGet` parameter, as in this AWS CLI example:

```
aws dynamodb get-item \
--table-name Music \
--attributes-to-get '["Artist", "Genre"]' \
--key '{
    "Artist": {"S":"No One You Know"}, 
    "SongTitle": {"S":"Call Me Today"}
}'
```

You can use a *ProjectionExpression* instead:

```
aws dynamodb get-item \
--table-name Music \
--projection-expression "Artist, Genre" \
```

```
--key '{  
    "Artist": {"S":"No One You Know"},  
    "SongTitle": {"S":"Call Me Today"}  
}'
```

AttributeUpdates (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, [use *UpdateExpression* instead..](#)

In an `UpdateItem` operation, the legacy conditional parameter `AttributeUpdates` contains the names of attributes to be modified, the action to perform on each, and the new value for each. If you are updating an attribute that is an index key attribute for any indexes on that table, the attribute type must match the index key type defined in the `AttributesDefinition` of the table description. You can use `UpdateItem` to update any non-key attributes.

Attribute values cannot be null. String and Binary type attributes must have lengths greater than zero. Set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException` exception.

Each `AttributeUpdates` element consists of an attribute name to modify, along with the following:

- **Value** - The new value, if applicable, for this attribute.
- **Action** - A value that specifies how to perform the update. This action is only valid for an existing attribute whose data type is Number or is a set; do not use ADD for other data types.

If an item with the specified primary key is found in the table, the following values perform the following actions:

- **PUT** - Adds the specified attribute to the item. If the attribute already exists, it is replaced by the new value.
- **DELETE** - Removes the attribute and its value, if no value is specified for DELETE. The data type of the specified value must match the existing value's data type.

If a set of values is specified, then those values are subtracted from the old set. For example, if the attribute value was the set [a, b, c] and the DELETE action specifies [a, c], then the final attribute value is [b]. Specifying an empty set is an error.

- ADD - Adds the specified value to the item, if the attribute does not already exist. If the attribute does exist, then the behavior of ADD depends on the data type of the attribute:
 - If the existing attribute is a number, and if Value is also a number, then Value is mathematically added to the existing attribute. If Value is a negative number, then it is subtracted from the existing attribute.

 **Note**

If you use ADD to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses 0 as the initial value.

Similarly, if you use ADD for an existing item to increment or decrement an attribute value that doesn't exist before the update, DynamoDB uses 0 as the initial value. For example, suppose that the item you want to update doesn't have an attribute named *itemcount*, but you decide to ADD the number 3 to this attribute anyway. DynamoDB will create the *itemcount* attribute, set its initial value to 0, and finally add 3 to it.

The result will be a new *itemcount* attribute, with a value of 3.

- If the existing data type is a set, and if Value is also a set, then Value is appended to the existing set. For example, if the attribute value is the set [1, 2], and the ADD action specified [3], then the final attribute value is [1, 2, 3]. An error occurs if an ADD action is specified for a set attribute and the attribute type specified does not match the existing set type.

Both sets must have the same primitive data type. For example, if the existing data type is a set of strings, Value must also be a set of strings.

If no item with the specified key is found in the table, the following values perform the following actions:

- PUT - Causes DynamoDB to create a new item with the specified primary key, and then adds the attribute.
- DELETE - Nothing happens, because attributes cannot be deleted from a nonexistent item. The operation succeeds, but DynamoDB does not create a new item.
- ADD - Causes DynamoDB to create an item with the supplied primary key and number (or set of numbers) for the attribute value. The only data types allowed are Number and Number Set.

If you provide any attributes that are part of an index key, then the data types for those attributes must match those of the schema in the table's attribute definition.

Use `UpdateExpression` instead – Example

Suppose you wanted to modify an item in the *Music* table. You could use an `UpdateItem` request with an `AttributeUpdates` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \  
  --table-name Music \  
  --key '{  
    "SongTitle": {"S":"Call Me Today"},  
    "Artist": {"S":"No One You Know"}  
' \  
  --attribute-updates '{  
    "Genre": {  
      "Action": "PUT",  
      "Value": {"S":"Rock"}  
    }  
'
```

You can use a `UpdateExpression` instead:

```
aws dynamodb update-item \  
  --table-name Music \  
  --key '{  
    "SongTitle": {"S":"Call Me Today"},  
    "Artist": {"S":"No One You Know"}  
' \  
  --update-expression 'SET Genre = :g' \  
  --expression-attribute-values '{  
    ":g": {"S":"Rock"}  
'
```

For more information about updating attributes, see [Update an item in a DynamoDB table](#).

ConditionalOperator (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#).

The legacy conditional parameter `ConditionalOperator` is a logical operator used to apply to the conditions in a `Expected`, `QueryFilter` or `ScanFilter` map:

- AND - If all of the conditions evaluate to true, then the entire map evaluates to true.
- OR - If at least one of the conditions evaluates to true, then the entire map evaluates to true.

If you omit `ConditionalOperator`, then AND is the default.

The operation will succeed only if the entire map evaluates to true.

Note

This parameter does not support attributes of type List or Map.

Expected (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, see [*ConditionExpression instead..*](#)

The legacy conditional parameter `Expected` is a conditional block for an `UpdateItem` operation. `Expected` is a map of attribute/condition pairs. Each element of the map consists of an attribute name, a comparison operator, and one or more values. DynamoDB compares the attribute with the value(s) you supplied, using the comparison operator. For each `Expected` element, the result of the evaluation is either true or false.

If you specify more than one element in the Expected map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the ConditionalOperator parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

If the Expected map evaluates to true, then the conditional operation succeeds; otherwise, it fails.

Expected contains the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the ComparisonOperator being used.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For type Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes in the AttributeValueList. When performing the comparison, DynamoDB uses strongly consistent reads.

The following comparison operators are available:

EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS |
BEGINS_WITH | IN | BETWEEN

The following are descriptions of each comparison operator.

- EQ : Equal. EQ is supported for all data types, including lists and maps.

AttributeValueList can contain only one AttributeValue element of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S": "6"} does not equal {"N": "6"}. Also, {"N": "6"} does not equal {"NS": ["6", "2", "1"]}.

- NE : Not equal. NE is supported for all data types, including lists and maps.

AttributeValueList can contain only one AttributeValue of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains an AttributeValue of a different type than the one provided in the request, the value does not match. For example,

`{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not equal `{"NS":["6", "2", "1"]}`.

- LE : Less than or equal.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- LT : Less than.

AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- GE : Greater than or equal.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- GT : Greater than.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, `{"S":"6"}` does not equal `{"N":"6"}`. Also, `{"N":"6"}` does not compare to `{"NS":["6", "2", "1"]}`.

- NOT_NULL : The attribute exists. NOT_NULL is supported for all data types, including lists and maps.

 **Note**

This operator tests for the existence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using NOT_NULL, the result is a Boolean

true. This result is because the attribute "a" exists; its data type is not relevant to the NOT_NULL comparison operator.

- **NULL** : The attribute does not exist. NULL is supported for all data types, including lists and maps.

 **Note**

This operator tests for the nonexistence of an attribute, not its data type. If the data type of attribute "a" is null, and you evaluate it using NULL, the result is a Boolean false. This is because the attribute "a" exists; its data type is not relevant to the NULL comparison operator.

- **CONTAINS** : Checks for a subsequence, or value in a set.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is of type String, then the operator checks for a substring match. If the target attribute of the comparison is of type Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it finds an exact match with any member of the set.

CONTAINS is supported for lists: When evaluating "a CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- **NOT_CONTAINS** : Checks for absence of a subsequence, or absence of a value in a set.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operator evaluates to true if it does not find an exact match with any member of the set.

NOT_CONTAINS is supported for lists: When evaluating "a NOT CONTAINS b", "a" can be a list; however, "b" cannot be a set, a map, or a list.

- **BEGINS_WITH** : Checks for a prefix.

AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- IN : Checks for matching elements within two sets.

AttributeValueList can contain one or more AttributeValue elements of type String, Number, or Binary (not a set type). These attributes are compared against an existing set type attribute of an item. If any elements of the input set are present in the item attribute, the expression evaluates to true.

- BETWEEN : Greater than or equal to the first value, and less than or equal to the second value.

AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S": "6"} does not compare to {"N": "6"}. Also, {"N": "6"} does not compare to {"NS": ["6", "2", "1"]}

The following parameters can be used instead of AttributeValueList and ComparisonOperator:

- Value - A value for DynamoDB to compare with an attribute.
- Exists - A Boolean value that causes DynamoDB to evaluate the value before attempting the conditional operation:
 - If Exists is true, DynamoDB will check to see if that attribute value already exists in the table. If it is found, then the condition evaluates to true; otherwise the condition evaluates to false.
 - If Exists is false, DynamoDB assumes that the attribute value does not exist in the table. If in fact the value does not exist, then the assumption is valid and the condition evaluates to true. If the value is found, despite the assumption that it does not exist, the condition evaluates to false.

Note that the default value for Exists is true.

The `Value` and `Exists` parameters are incompatible with `AttributeValueList` and `ComparisonOperator`. Note that if you use both sets of parameters at once, DynamoDB will return a `ValidationException` exception.

 **Note**

This parameter does not support attributes of type List or Map.

Use `ConditionExpression` instead – Example

Suppose you wanted to modify an item in the `Music` table, but only if a certain condition was true. You could use an `UpdateItem` request with an `Expected` parameter, as in this AWS CLI example:

```
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "Artist": {"S":"No One You Know"},
    "SongTitle": {"S":"Call Me Today"}
}' \
  --attribute-updates '{
    "Price": {
      "Action": "PUT",
      "Value": {"N":"1.98"}
    }
}' \
  --expected '{
    "Price": {
      "ComparisonOperator": "LE",
      "AttributeValueList": [ {"N":"2.00"} ]
    }
}'
```

You can use a `ConditionExpression` instead:

```
aws dynamodb update-item \
  --table-name Music \
  --key '{
    "Artist": {"S":"No One You Know"},
    "SongTitle": {"S":"Call Me Today"}
}' \
```

```
--update-expression 'SET Price = :p1' \
--condition-expression 'Price <= :p2' \
--expression-attribute-values '{'
    ":p1": {"N":"1.98"},
    ":p2": {"N":"2.00"}
}'
```

KeyConditions (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, [use KeyConditionExpression instead..](#)

The legacy conditional parameter `KeyConditions` contains selection criteria for a `Query` operation. For a query on a table, you can have conditions only on the table primary key attributes. You must provide the partition key name and value as an EQ condition. You can optionally provide a second condition, referring to the sort key.

Note

If you don't provide a sort key condition, all of the items that match the partition key will be retrieved. If a `FilterExpression` or `QueryFilter` is present, it will be applied after the items are retrieved.

For a query on an index, you can have conditions only on the index key attributes. You must provide the index partition key name and value as an EQ condition. You can optionally provide a second condition, referring to the index sort key.

Each `KeyConditions` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the `ComparisonOperator` being used.

For type `Number`, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on Unicode with UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

- **ComparisonOperator** - A comparator for evaluating attributes. For example: equals, greater than, and less than.

For KeyConditions, only the following comparison operators are supported:

EQ | LE | LT | GE | GT | BEGINS_WITH | BETWEEN

The following are descriptions of these comparison operators.

- EQ : Equal.

AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"}. Also, {"N":"6"} does not equal {"NS":["6", "2", "1"]}.

- LE : Less than or equal.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"}. Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.

- LT : Less than.

AttributeValueList can contain only one AttributeValue of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"}. Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.

- GE : Greater than or equal.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example,

{"S": "6"} does not equal {"N": "6"}. Also, {"N": "6"} does not compare to {"NS": ["6", "2", "1"]}.

- GT : Greater than.

AttributeValueList can contain only one AttributeValue element of type String, Number, or Binary (not a set type). If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S": "6"} does not equal {"N": "6"}. Also, {"N": "6"} does not compare to {"NS": ["6", "2", "1"]}.

- BEGINS_WITH : Checks for a prefix.

AttributeValueList can contain only one AttributeValue of type String or Binary (not a Number or a set type). The target attribute of the comparison must be of type String or Binary (not a Number or a set type).

- BETWEEN : Greater than or equal to the first value, and less than or equal to the second value.

AttributeValueList must contain two AttributeValue elements of the same type, either String, Number, or Binary (not a set type). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an AttributeValue element of a different type than the one provided in the request, the value does not match. For example, {"S": "6"} does not compare to {"N": "6"}. Also, {"N": "6"} does not compare to {"NS": ["6", "2", "1"]}.

Use *KeyConditionExpression* instead – Example

Suppose you wanted to retrieve several items with the same partition key from the *Music* table. You could use a Query request with a KeyConditions parameter, as in this AWS CLI example:

```
aws dynamodb query \
--table-name Music \
--key-conditions '{
    "Artist": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S": "No One You Know"} ]
    },
    "SongTitle": {
        "ComparisonOperator": "BETWEEN",
        "AttributeValueList": [ {"S": "A"}, {"S": "M"} ]
    }
}'
```

```
}
```

You can use a KeyConditionExpression instead:

```
aws dynamodb query \
--table-name Music \
--key-condition-expression 'Artist = :a AND SongTitle BETWEEN :t1 AND :t2' \
--expression-attribute-values '{
    ":a": {"S": "No One You Know"}, 
    ":t1": {"S": "A"}, 
    ":t2": {"S": "M"}'
}'
```

QueryFilter (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, [use FilterExpression instead..](#)

In a Query operation, the legacy conditional parameter `QueryFilter` is a condition that evaluates the query results after the items are read and returns only the desired values.

This parameter does not support attributes of type List or Map.

Note

A `QueryFilter` is applied after the items have already been read; the process of filtering does not consume any additional read capacity units.

If you provide more than one condition in the `QueryFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the [ConditionalOperator \(legacy\)](#) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Note that `QueryFilter` does not allow key attributes. You cannot define a filter condition on a partition key or a sort key.

Each `QueryFilter` element consists of an attribute name to compare, along with the following:

- `AttributeValueList` - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in `ComparisonOperator`.

For type `Number`, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, `a` is greater than `A`, and `a` is greater than `B`.

For type `Binary`, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see [DynamoDB low-level API](#).

- `ComparisonOperator` - A comparator for evaluating attributes. For example: equals, greater than, and less than.

The following comparison operators are available:

`EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS | BEGINS_WITH | IN | BETWEEN`

Use `FilterExpression` instead – Example

Suppose you wanted to query the `Music` table and apply a condition to the matching items. You could use a Query request with a `QueryFilter` parameter, as in this AWS CLI example:

```
aws dynamodb query \
--table-name Music \
--key-conditions '{
    "Artist": {
        "ComparisonOperator": "EQ",
        "AttributeValueList": [ {"S": "No One You Know"} ]
    }
}' \
--query-filter '{
    "Price": {
        "ComparisonOperator": "GT",
        "AttributeValueList": [ {"N": "10.00"} ]
    }
}'
```

```
        "AttributeValueList": [ {"N": "1.00"} ]  
    }  
}'
```

You can use a [FilterExpression](#) instead:

```
aws dynamodb query \  
--table-name Music \  
--key-condition-expression 'Artist = :a' \  
--filter-expression 'Price > :p' \  
--expression-attribute-values '{  
    ":p": {"N": "1.00"},  
    ":a": {"S": "No One You Know"}  
'
```

ScanFilter (legacy)

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#). For specific information on the new parameter replacing this one, [use *FilterExpression* instead..](#)

In a Scan operation, the legacy conditional parameter `ScanFilter` is a condition that evaluates the scan results and returns only the desired values.

Note

This parameter does not support attributes of type List or Map.

If you specify more than one condition in the `ScanFilter` map, then by default all of the conditions must evaluate to true. In other words, the conditions are ANDed together. (You can use the [ConditionalOperator \(legacy\)](#) parameter to OR the conditions instead. If you do this, then at least one of the conditions must evaluate to true, rather than all of them.)

Each `ScanFilter` element consists of an attribute name to compare, along with the following:

- **AttributeValueList** - One or more values to evaluate against the supplied attribute. The number of values in the list depends on the operator specified in **ComparisonOperator**.

For type Number, value comparisons are numeric.

String value comparisons for greater than, equals, or less than are based on UTF-8 binary encoding. For example, a is greater than A, and a is greater than B.

For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values.

For information on specifying data types in JSON, see [DynamoDB low-level API](#).

- **ComparisonOperator** - A comparator for evaluating attributes. For example: equals, greater than, and less than.

The following comparison operators are available:

EQ | NE | LE | LT | GE | GT | NOT_NULL | NULL | CONTAINS | NOT_CONTAINS |
BEGINS_WITH | IN | BETWEEN

Use *FilterExpression* instead – Example

Suppose you wanted to scan the *Music* table and apply a condition to the matching items. You could use a Scan request with a **ScanFilter** parameter, as in this AWS CLI example:

```
aws dynamodb scan \
--table-name Music \
--scan-filter '{
    "Genre": {
        "AttributeValueList": [ {"S": "Rock"} ],
        "ComparisonOperator": "EQ"
    }
}'
```

You can use a **FilterExpression** instead:

```
aws dynamodb scan \
--table-name Music \
--filter-expression 'Genre = :g' \
--expression-attribute-values '{
```

```
":g": {"S":"Rock"}  
}'
```

Writing conditions with legacy parameters

Note

We recommend that you use the new expression parameters instead of these legacy parameters whenever possible. For more information, see [Using expressions in DynamoDB](#).

The following section describes how to write conditions for use with legacy parameters, such as `Expected`, `QueryFilter`, and `ScanFilter`.

Note

New applications should use expression parameters instead. For more information, see [Using expressions in DynamoDB](#).

Simple conditions

With attribute values, you can write conditions for comparisons against table attributes. A condition always evaluates to true or false, and consists of:

- `ComparisonOperator` — greater than, less than, equal to, and so on.
- `AttributeValueList` (optional) — attribute value(s) to compare against. Depending on the `ComparisonOperator` being used, the `AttributeValueList` might contain one, two, or more values; or it might not be present at all.

The following sections describe the various comparison operators, along with examples of how to use them in conditions.

Comparison operators with no attribute values

- `NOT_NULL` - true if an attribute exists.
- `NULL` - true if an attribute does not exist.

Use these operators to check whether an attribute exists, or doesn't exist. Because there is no value to compare against, do not specify AttributeValueList.

Example

The following expression evaluates to true if the *Dimensions* attribute exists.

```
...  
    "Dimensions": {  
        ComparisonOperator: "NOT_NULL"  
    }  
...
```

Comparison operators with one attribute value

- EQ - true if an attribute is equal to a value.

AttributeValueList can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match. For example, the string "3" is not equal to the number 3. Also, the number 3 is not equal to the number set [3, 2, 1].

- NE - true if an attribute is not equal to a value.

AttributeValueList can contain only one value of type String, Number, Binary, String Set, Number Set, or Binary Set. If an item contains a value of a different type than the one specified in the request, the value does not match.

- LE - true if an attribute is less than or equal to a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains an AttributeValue of a different type than the one specified in the request, the value does not match.

- LT - true if an attribute is less than a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- GE - true if an attribute is greater than or equal to a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- GT - true if an attribute is greater than a value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If an item contains a value of a different type than the one specified in the request, the value does not match.

- CONTAINS - true if a value is present within a set, or if one value contains another.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for a substring match. If the target attribute of the comparison is Binary, then the operator looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it finds an exact match with any member of the set.

- NOT_CONTAINS - true if a value is *not* present within a set, or if one value does not contain another value.

AttributeValueList can contain only one value of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operator checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operator checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set, then the operator evaluates to true if it *does not* find an exact match with any member of the set.

- BEGINS_WITH - true if the first few characters of an attribute match the provided value. Do not use this operator for comparing numbers.

AttributeValueList can contain only one value of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).

Use these operators to compare an attribute with a value. You must specify an AttributeValueList consisting of a single value. For most of the operators, this value must be a scalar; however, the EQ and NE operators also support sets.

Examples

The following expressions evaluate to true if:

- A product's price is greater than 100.

```
...  
    "Price": {  
        ComparisonOperator: "GT",  
        AttributeValueList: [ {"N":"100"} ]  
    }  
...
```

- A product category begins with "Bo".

```
...  
    "ProductCategory": {  
        ComparisonOperator: "BEGINS_WITH",  
        AttributeValueList: [ {"S":"Bo"} ]  
    }  
...
```

- A product is available in either red, green, or black:

```
...  
    "Color": {  
        ComparisonOperator: "EQ",  
        AttributeValueList: [  
            [ {"S":"Black"}, {"S":"Red"}, {"S":"Green"} ]  
        ]  
    }  
...
```

 **Note**

When comparing set data types, the order of the elements does not matter. DynamoDB will return only the items with the same set of values, regardless of the order in which you specify them in your request.

Comparison operators with two attribute values

- BETWEEN - true if a value is between a lower bound and an upper bound, endpoints inclusive.

AttributeValueList must contain two elements of the same type, either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains a value of a different type than the one specified in the request, the value does not match.

Use this operator to determine if an attribute value is within a range. The AttributeValueList must contain two scalar elements of the same type - String, Number, or Binary.

Example

The following expression evaluates to true if a product's price is between 100 and 200.

```
...
    "Price": {
        ComparisonOperator: "BETWEEN",
        AttributeValueList: [ {"N":"100"}, {"N":"200"} ]
    }
...

```

Comparison operators with *n* attribute values

- IN - true if a value is equal to any of the values in an enumerated list. Only scalar values are supported in the list, not sets. The target attribute must be of the same type and exact value in order to match.

AttributeValueList can contain one or more elements of type String, Number, or Binary (not a set). These attributes are compared against an existing non-set type attribute of an item. If *any* elements of the input set are present in the item attribute, the expression evaluates to true.

AttributeValueList can contain one or more values of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.

Use this operator to determine whether the supplied value is within an enumerated list. You can specify any number of scalar values in AttributeValueList, but they all must be of the same data type.

Example

The following expression evaluates to true if the value for *Id* is 201, 203, or 205.

```
...  
    "Id": {  
        ComparisonOperator: "IN",  
        AttributeValueList: [ {"N":"201"}, {"N":"203"}, {"N":"205"} ]  
    }  
...
```

Using multiple conditions

DynamoDB lets you combine multiple conditions to form complex expressions. You do this by providing at least two expressions, with an optional [ConditionalOperator \(legacy\)](#).

By default, when you specify more than one condition, *all* of the conditions must evaluate to true in order for the entire expression to evaluate to true. In other words, an implicit *AND* operation takes place.

Example

The following expression evaluates to true if a product is a book that has at least 600 pages. Both of the conditions must evaluate to true, since they are implicitly *ANDed* together.

```
...  
    "ProductCategory": {  
        ComparisonOperator: "EQ",  
        AttributeValueList: [ {"S":"Book"} ]  
    },  
    "PageCount": {  
        ComparisonOperator: "GE",  
        AttributeValueList: [ {"N":600} ]  
    }  
...
```

You can use [ConditionalOperator \(legacy\)](#) to clarify that an *AND* operation will take place. The following example behaves in the same manner as the previous one.

```
...  
    "ConditionalOperator" : "AND",  
    "ProductCategory": {
```

```
    "ComparisonOperator": "EQ",
    "AttributeValueList": [ {"N":"Book"} ]
},
"PageCount": {
    "ComparisonOperator": "GE",
    "AttributeValueList": [ {"N":600} ]
}
...
...
```

You can also set `ConditionalOperator` to *OR*, which means that *at least one* of the conditions must evaluate to true.

Example

The following expression evaluates to true if a product is a mountain bike, if it is a particular brand name, or if its price is greater than 100.

```
...
ConditionalOperator : "OR",
"BicycleType": {
    "ComparisonOperator": "EQ",
    "AttributeValueList": [ {"S":"Mountain" } ]
},
"Brand": {
    "ComparisonOperator": "EQ",
    "AttributeValueList": [ {"S":"Brand-Company A" } ]
},
"Price": {
    "ComparisonOperator": "GT",
    "AttributeValueList": [ {"N":100"} ]
}
...
...
```

Note

In a complex expression, the conditions are processed in order, from the first condition to the last.

You cannot use both AND and OR in a single expression.

Other conditional operators

In previous releases of DynamoDB, the `Expected` parameter behaved differently for conditional writes. Each item in the `Expected` map represented an attribute name for DynamoDB to check, along with the following:

- `Value` — a value to compare against the attribute.
- `Exists` — determine whether the value exists prior to attempting the operation.

The `Value` and `Exists` options continue to be supported in DynamoDB; however, they only let you test for an equality condition, or whether an attribute exists. We recommend that you use `ComparisonOperator` and `AttributeValueList` instead, because these options let you construct a much wider range of conditions.

Example

A `DeleteItem` can check to see whether a book is no longer in publication, and only delete it if this condition is true. Here is an AWS CLI example using a legacy condition:

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{
    "Id": {"N":"600"}
}' \
--expected '{
    "InPublication": {
        "Exists": true,
        "Value": {"BOOL":false}
    }
}'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{
    "Id": {"N":"600"}
}' \
```

```
--expected '{  
    "InPublication": {  
        "ComparisonOperator": "EQ",  
        "AttributeValueList": [ {"BOOL":false} ]  
    }  
'}
```

Example

A PutItem operation can protect against overwriting an existing item with the same primary key attributes. Here is an example using a legacy condition:

```
aws dynamodb put-item \  
--table-name ProductCatalog \  
--item '{  
    "Id": {"N":"500"},  
    "Title": {"S":"Book 500 Title"}  
' \  
--expected '{  
    "Id": { "Exists": false }  
'
```

The following example does the same thing, but does not use a legacy condition:

```
aws dynamodb put-item \  
--table-name ProductCatalog \  
--item '{  
    "Id": {"N":"500"},  
    "Title": {"S":"Book 500 Title"}  
' \  
--expected '{  
    "Id": { "ComparisonOperator": "NULL" }  
'
```

Note

For conditions in the Expected map, do not use the legacy Value and Exists options together with ComparisonOperator and AttributeValueList. If you do this, your conditional write will fail.

Previous low-level API version (2011-12-05)

This section documents the operations available in the previous DynamoDB low-level API version (2011-12-05). This version of the low-level API is maintained for backward compatibility with existing applications.

New applications should use the current API version (2012-08-10). For more information, see [Low-level API reference](#).

Note

We recommend that you migrate your applications to the latest API version (2012-08-10), since new DynamoDB features will not be backported to the previous API version.

BatchGetItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

The BatchGetItem operation returns the attributes for multiple items from multiple tables using their primary keys. The maximum number of items that can be retrieved for a single operation is 100. Also, the number of items retrieved is constrained by a 1 MB size limit. If the response size limit is exceeded or a partial result is returned because the table's provisioned throughput is exceeded, or because of an internal processing failure, DynamoDB returns an UnprocessedKeys value so you can retry the operation starting with the next item to get. DynamoDB automatically adjusts the number of items returned per page to enforce this limit. For example, even if you ask to retrieve 100 items, but each individual item is 50 KB in size, the system returns 20 items and an appropriate UnprocessedKeys value so you can get the next page of results. If desired, your application can include its own logic to assemble the pages of results into one set.

If no items could be processed because of insufficient provisioned throughput on each of the tables involved in the request, DynamoDB returns a ProvisionedThroughputExceededException error.

Note

By default, BatchGetItem performs eventually consistent reads on every table in the request. You can set the ConsistentRead parameter to true, on a per-table basis, if you want consistent reads instead.

BatchGetItem fetches items in parallel to minimize response latencies.

When designing your application, keep in mind that DynamoDB does not guarantee how attributes are ordered in the returned response. Include the primary key values in the AttributesToGet for the items in your request to help parse the response by item.

If the requested items do not exist, nothing is returned in the response for those items. Requests for non-existent items consume the minimum read capacity units according to the type of read. For more information, see [DynamoDB Item sizes and formats](#).

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{"RequestItems":
  {"Table1":
    {"Keys":
      [{"HashKeyElement": {"S":"KeyValue1"}, "RangeKeyElement": {"N":"KeyValue2"}},
       {"HashKeyElement": {"S":"KeyValue3"}, "RangeKeyElement": {"N":"KeyValue4"}},
       {"HashKeyElement": {"S":"KeyValue5"}, "RangeKeyElement": {"N":"KeyValue6"}},
      ],
      "AttributesToGet": ["AttributeName1", "AttributeName2", "AttributeName3"]
    },
    "Table2":
      {"Keys":
        [{"HashKeyElement": {"S":"KeyValue4"}},
         {"HashKeyElement": {"S":"KeyValue5"}},
        ],
        "AttributesToGet": ["AttributeName4", "AttributeName5", "AttributeName6"]
      }
    }
}
```

Name	Description	Required
RequestItems	A container of the table name and corresponding items to get by primary key. While requesting items, each table	Yes

Name	Description	Required
	<p>name can be invoked only once per operation.</p> <p>Type: String</p> <p>Default: None</p>	
Table	<p>The name of the table containing the items to get. The entry is simply a string specifying an existing table with no label.</p> <p>Type: String</p> <p>Default: None</p>	Yes
Table:Keys	<p>The primary key values that define the items in the specified table. For more information about primary keys, see Primary key.</p> <p>Type: Keys</p>	Yes
Table:AttributesToGet	<p>Array of Attribute names within the specified table. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result.</p> <p>Type: Array</p>	No

Name	Description	Required
Table:ConsistentRead	If set to true, then a consistent read is issued, otherwise eventually consistent is used. Type: Boolean	No

    "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]
  }
}

```

Name	Description
Responses	Table names and the respective item attribute s from the tables. Type: Map
Table	The name of the table containing the items. The entry is simply a string specifying the table with no label. Type: String
Items	Container for the attribute names and values meeting the operation parameters. Type: Map of attribute names to and their data types and values.
ConsumedCapacityUnits	The number of read capacity units consumed, for each table. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see

Name	Description
	<p>Managing settings on DynamoDB provisioned capacity tables.</p> <p>Type: Number</p>
UnprocessedKeys	<p>Contains an array of tables and their respective keys that were not processed with the current response, possibly due to reaching a limit on the response size. The UnprocessedKeys value is in the same form as a RequestItems parameter (so the value can be provided directly to a subsequent BatchGetItem operation). For more information, see the above RequestItems parameter.</p> <p>Type: Array</p>
UnprocessedKeys : Table: Keys	<p>The primary key attribute values that define the items and the attributes associated with the items. For more information about primary keys, see Primary key.</p> <p>Type: Array of attribute name-value pairs.</p>
UnprocessedKeys : Table: AttributeNamesToGet	<p>Attribute names within the specified table. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result.</p> <p>Type: Array of attribute names.</p>

Name	Description
UnprocessedKeys : Table: ConsistentRead	If set to true, then a consistent read is used for the specified table, otherwise an eventually consistent read is used. Type: Boolean.

Special errors

Error	Description
ProvisionedThroughputExceededException	Your maximum allowed provisioned throughput has been exceeded.

Examples

The following examples show an HTTP POST request and response using the BatchGetItem operation. For examples using the AWS SDK, see [Working with items and attributes](#).

Sample request

The following sample requests attributes from two different tables.

```
// This header is abbreviated.
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0
content-length: 409

{"RequestItems": {

        "ConsumedCapacityUnits":1}  
    },  
    "UnprocessedKeys":[]  
}
```

BatchWriteItem

⚠ Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

This operation enables you to put or delete several items across multiple tables in a single call.

To upload one item, you can use `PutItem`, and to delete one item, you can use `DeleteItem`. However, when you want to upload or delete large amounts of data, such as uploading large amounts of data from Amazon EMR (Amazon EMR) or migrating data from another database in to DynamoDB, `BatchWriteItem` offers an efficient alternative.

If you use languages such as Java, you can use threads to upload items in parallel. This adds complexity in your application to handle the threads. Other languages don't support threading. For example, if you are using PHP, you must upload or delete items one at a time. In both situations, `BatchWriteItem` provides an alternative where the specified put and delete operations are processed in parallel, giving you the power of the thread pool approach without having to introduce complexity in your application.

Note that each individual put and delete specified in a `BatchWriteItem` operation costs the same in terms of consumed capacity units. However, because `BatchWriteItem` performs the specified operations in parallel, you get lower latency. Delete operations on non-existent items consume 1 write capacity unit. For more information about consumed capacity units, see [Working with tables and data in DynamoDB](#).

When using `BatchWriteItem`, note the following limitations:

- **Maximum operations in a single request**—You can specify a total of up to 25 put or delete operations; however, the total request size cannot exceed 1 MB (the HTTP payload).
- You can use the `BatchWriteItem` operation only to put and delete items. You cannot use it to update existing items.
- **Not an atomic operation**—Individual operations specified in a `BatchWriteItem` are atomic; however `BatchWriteItem` as a whole is a "best-effort" operation and not an atomic operation. That is, in a `BatchWriteItem` request, some operations might succeed and others might fail. The failed operations are returned in an `UnprocessedItems` field in the response. Some of these failures might be because you exceeded the provisioned throughput configured for the table or a transient failure such as a network error. You can investigate and optionally resend the requests. Typically, you call `BatchWriteItem` in a loop and in each iteration check for unprocessed items, and submit a new `BatchWriteItem` request with those unprocessed items.
- **Does not return any items**—The `BatchWriteItem` is designed for uploading large amounts of data efficiently. It does not provide some of the sophistication offered by `PutItem` and

`DeleteItem`. For example, `DeleteItem` supports the `ReturnValues` field in your request body to request the deleted item in the response. The `BatchWriteItem` operation does not return any items in the response.

- Unlike `PutItem` and `DeleteItem`, `BatchWriteItem` does not allow you to specify conditions on individual write requests in the operation.
- Attribute values must not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests that have empty values will be rejected with a `ValidationException`.

DynamoDB rejects the entire batch write operation if any one of the following is true:

- If one or more tables specified in the `BatchWriteItem` request does not exist.
- If primary key attributes specified on an item in the request does not match the corresponding table's primary key schema.
- If you try to perform multiple operations on the same item in the same `BatchWriteItem` request. For example, you cannot put and delete the same item in the same `BatchWriteItem` request.
- If the total request size exceeds the 1 MB request size (the HTTP payload) limit.
- If any individual item in a batch exceeds the 64 KB item size limit.

Requests

Syntax

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.BatchGetItem
content-type: application/x-amz-json-1.0

{
    "RequestItems" : RequestItems
}

RequestItems
{
    "TableName1" : [ Request, Request, ... ],
    "TableName2" : [ Request, Request, ... ],
}
```

```
    ...
}

Request ::=  
  PutRequest | DeleteRequest

PutRequest ::=  
{  
  "PutRequest" : {  
    "Item" : {  
      "Attribute-Name1" : Attribute-Value,  
      "Attribute-Name2" : Attribute-Value,  
      ...  
    }  
  }  
}

DeleteRequest ::=  
{  
  "DeleteRequest" : {  
    "Key" : PrimaryKey-Value  
  }  
}

PrimaryKey-Value ::= HashTypePK | HashAndRangeTypePK

HashTypePK ::=  
{  
  "HashKeyElement" : Attribute-Value  
}

HashAndRangeTypePK  
{  
  "HashKeyElement" : Attribute-Value,  
  "RangeKeyElement" : Attribute-Value,  
}

Attribute-Value ::= String | Numeric | Binary | StringSet | NumericSet | BinarySet

Numeric ::=  
{  
  "N": "Number"  
}
```

```
String ::=  
{  
    "S": "String"  
}  
  
Binary ::=  
{  
    "B": "Base64 encoded binary data"  
}  
  
StringSet ::=  
{  
    "SS": [ "String1", "String2", ... ]  
}  
  
NumberSet ::=  
{  
    "NS": [ "Number1", "Number2", ... ]  
}  
  
BinarySet ::=  
{  
    "BS": [ "Binary1", "Binary2", ... ]  
}
```

In the request body, the `RequestItems` JSON object describes the operations that you want to perform. The operations are grouped by tables. You can use `BatchWriteItem` to update or delete several items across multiple tables. For each specific write request, you must identify the type of request (`PutItem`, `DeleteItem`) followed by detail information about the operation.

- For a `PutRequest`, you provide the item, that is, a list of attributes and their values.
- For a `DeleteRequest`, you provide the primary key name and value.

Responses

Syntax

The following is the syntax of the JSON body returned in the response.

{

```
"Responses" : ConsumedCapacityUnitsByTable  
"UnprocessedItems" : RequestItems  
}  
  
ConsumedCapacityUnitsByTable  
{  
  "TableName1" : { "ConsumedCapacityUnits" : NumericValue },  
  "TableName2" : { "ConsumedCapacityUnits" : NumericValue },  
  ...  
}
```

RequestItems

This syntax is identical to the one described in the JSON syntax in the request.

Special errors

No errors specific to this operation.

Examples

The following example shows an HTTP POST request and the response of a BatchWriteItem operation. The request specifies the following operations on the Reply and the Thread tables:

- Put an item and delete an item from the Reply table
- Put an item into the Thread table

For examples using the AWS SDK, see [Working with items and attributes](#).

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.BatchGetItem  
content-type: application/x-amz-json-1.0  
  
{  
  "RequestItems":{  
    "Reply": [  
      {  
        "PutRequest":{  
          "Item":{
```

Sample response

The following example response shows a put operation on both the Thread and Reply tables succeeded and a delete operation on the Reply table failed (for reasons such as throttling that is

caused when you exceed the provisioned throughput on the table). Note the following in the JSON response:

- The Responses object shows one capacity unit was consumed on both the Thread and Reply tables as a result of the successful put operation on each of these tables.
- The UnprocessedItems object shows the unsuccessful delete operation on the Reply table. You can then issue a new BatchWriteItem call to address these unprocessed requests.

```

                            "S": "oops - accidental row"
                        }
                    }
                }
            ]
        }
    }
}
```

CreateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

The CreateTable operation adds a new table to your account.

The table name must be unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-2.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data.

The CreateTable operation triggers an asynchronous workflow to begin creating the table. DynamoDB immediately returns the state of the table (CREATING) until the table is in the ACTIVE state. Once the table is in the ACTIVE state, you can perform data plane operations.

Use the [DescribeTables](#) operation to check the status of the table.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.CreateTable  
content-type: application/x-amz-json-1.0  
  
{"TableName": "Table1",  
 "KeySchema":  
     {"HashKeyElement": {"AttributeName": "AttributeName1", "AttributeType": "S"},  
      "RangeKeyElement": {"AttributeName": "AttributeName2", "AttributeType": "N"}},  
 "ProvisionedThroughput": {"ReadCapacityUnits": 5, "WriteCapacityUnits": 10}}
```

}

Name	Description	Required
TableName	<p>The name of the table to create.</p> <p>Allowed characters are a-z, A-Z, 0-9, '_' (underscore), '-' (dash), and '.' (dot). Names can be between 3 and 255 characters long.</p> <p>Type: String</p>	Yes
KeySchema	<p>The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). For more information about primary keys, see Primary key.</p> <p>Primary key element names can be between 1 and 255 characters long with no character restrictions.</p> <p>Possible values for the AttributeType are "S" (string), "N" (numeric), or "B" (binary).</p> <p>Type: Map of HashKeyElement , or HashKeyEl</p>	Yes

Name	Description	Required
	ement and RangeKeyE lement for a composite primary key.	
ProvisionedThrough put	New throughput for the specified table, consisting of values for ReadCapac ityUnits and WriteCapa cityUnits . For details, see Managing settings on DynamoDB provisioned capacity tables .	Yes

 **Note**

For current
maximum/minimum
values, see [Service,
account, and table
quotas in Amazon
DynamoDB](#).

Type: Array

Name	Description	Required
ProvisionedThroughput : ReadCapacityUnits	<p>Sets the minimum number of consistent ReadCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations.</p> <p>Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.</p> <p>Type: Number</p>	Yes
ProvisionedThroughput : WriteCapacityUnits	<p>Sets the minimum number of WriteCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations.</p> <p>Type: Number</p>	Yes

Responses

DeleteItem

A Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Deletes a single item in a table by primary key. You can perform a conditional delete operation that deletes the item if it exists, or if it has an expected attribute value.

Note

If you specify `DeleteItem` without attributes or values, all the attributes for the item are deleted.

Unless you specify conditions, the `DeleteItem` is an idempotent operation; running it multiple times on the same item or attribute does *not* result in an error response.

Conditional deletes are useful for only deleting items and attributes if specific conditions are met. If the conditions are met, DynamoDB performs the delete. Otherwise, the item is not deleted.

You can perform the expected conditional check on one attribute per operation.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.DeleteItem  
content-type: application/x-amz-json-1.0  
  
{"TableName": "Table1",  
 "Key":  
     {"HashKeyElement": {"S": "AttributeValue1"}, "RangeKeyElement":  
      {"N": "AttributeValue2"}},  
     "Expected": {"AttributeName3": {"Value": {"S": "AttributeValue3"}},  
     "ReturnValues": "ALL_OLD"}  
}
```

Name	Description	Required
TableName	The name of the table containing the item to delete. Type: String	Yes
Key	The primary key that defines the item. For more informati	Yes

Name	Description	Required
	<p>on about primary keys, see Primary key.</p> <p>Type: Map of HashKeyElement to its value and RangeKeyElement to its value.</p>	
Expected	<p>Designates an attribute for a conditional delete. The Expected parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute has a particular value before deleting it.</p> <p>Type: Map of attribute names.</p>	No
Expected:AttributeName	<p>The name of the attribute for the conditional put.</p> <p>Type: String</p>	No

Name	Description	Required
Expected:Attribute Name: ExpectedA ttributeValue	<p>Use this parameter to specify whether or not a value already exists for the attribute name-value pair.</p> <p>The following JSON notation deletes the item if the "Color" attribute doesn't exist for that item:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" : {"Color": {"Exists": false}}</pre></div> <p>The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before deleting the item:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" : {"Color": {"Exists": true}, {"Value": {"S": "Yellow"}}}</pre></div> <p>By default, if you use the Expected parameter and provide a Value, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify {"Exists":true} , because it is implied. You can shorten the request to:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" :</pre></div>	No

Name	Description	Required
	<pre>{"Color":{"Value": "S":"Yellow"}}}</pre> <p>Note If you specify <code>{"Exists":true}</code> without an attribute value to check, DynamoDB returns an error.</p>	
ReturnValues	<p>Use this parameter if you want to get the attribute name-value pairs before they were deleted. Possible parameter values are NONE (default) or ALL_OLD. If ALL_OLD is specified, the content of the old item is returned. If this parameter is not provided or is NONE, nothing is returned.</p> <p>Type: String</p>	No

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CS0C7TJPLR000KIRLG0HVAICUFVV4KQNS05AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 353
Date: Tue, 12 Jul 2011 21:31:03 GMT
```

```
{"Attributes":  
  {"AttributeName3":{"SS":["AttributeValue3","AttributeValue4","AttributeValue5"]},  
   "AttributeName2":{"S":"AttributeValue2"},  
   "AttributeName1":{"N":"AttributeValue1"}  
 },  
 "ConsumedCapacityUnits":1  
}
```

Name	Description
Attributes	If the <code>ReturnValues</code> parameter is provided as <code>ALL_OLD</code> in the request, DynamoDB returns an array of attribute name-value pairs (essentially, the deleted item). Otherwise, the response contains an empty set. Type: Array of attribute name-value pairs.
ConsumedCapacityUnits	The number of write capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Delete requests on non-existent items consume 1 write capacity unit. For more information see Managing settings on DynamoDB provisioned capacity tables . Type: Number

Special errors

Error	Description
ConditionalCheckFailedException	Conditional check failed. An expected attribute value was not found.

Examples

Sample request

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.

- [PutItem](#)

DeleteTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

The DeleteTable operation deletes a table and all of its items. After a DeleteTable request, the specified table is in the DELETING state until DynamoDB completes the deletion. If the table is in the ACTIVE state, you can delete it. If a table is in CREATING or UPDATING states, then DynamoDB returns a ResourceInUseException error. If the specified table does not exist, DynamoDB returns a ResourceNotFoundException. If table is already in the DELETING state, no error is returned.

Note

DynamoDB might continue to accept data plane operation requests, such as GetItem and PutItem, on a table in the DELETING state until the table deletion is complete.

Tables are unique among those associated with the AWS Account issuing the request, and the AWS region that receives the request (such as dynamodb.us-west-1.amazonaws.com). Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-west-1.amazonaws.com, they are completely independent and do not share any data; deleting one does not delete the other.

Use the [DescribeTables](#) operation to check the status of the table.

DescribeTables

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Returns information about the table, including the current status of the table, the primary key schema and when the table was created. `DescribeTable` results are eventually consistent. If you use `DescribeTable` too early in the process of creating a table, DynamoDB returns a `ResourceNotFoundException`. If you use `DescribeTable` too early in the process of updating a table, the new values might not be immediately available.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.DescribeTable  
content-type: application/x-amz-json-1.0  
  
{"TableName": "Table1"}
```

Name	Description	Required
TableName	The name of the table to describe. Type: String	Yes

Responses

Syntax

```
HTTP/1.1 200  
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375  
content-type: application/x-amz-json-1.0  
Content-Length: 543  
  
{"Table":  
    {"CreationDateTime":1.309988345372E9,  
     "ItemCount":1,  
     "KeySchema":  
         {"HashKeyElement":{"AttributeName":"AttributeName1","AttributeType":"S"},  
          "RangeKeyElement":{"AttributeName":"AttributeName2","AttributeType":"N"}},  
     "ProvisionedThroughput": {"LastIncreaseDateTime": Date, "LastDecreaseDateTime": Date, "ReadCapacityUnits":10,"WriteCapacityUnits":10},  
     "TableName": "Table1",  
     "TableSizeBytes":1,  
     "TableStatus": "ACTIVE"}
```

```
}
```

Name	Description
Table	Container for the table being described. Type: String
CreationDateTime	Date when the table was created in UNIX epoch time .
ItemCount	Number of items in the specified table. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
KeySchema	The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separately (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key .
ProvisionedThroughput	Throughput for the specified table, consisting of values for LastIncreaseDateTime (if applicable), LastDecreaseDateTime (if applicable), ReadCapacityUnits and WriteCapacityUnits . If the throughput for the table has never been increased or decreased, DynamoDB does not return values

Name	Description
	for those elements. See Managing settings on DynamoDB provisioned capacity tables .
	Type: Array
TableName	The name of the requested table. Type: String
TableSizeBytes	Total size of the specified table, in bytes. DynamoDB updates this value approximately every six hours. Recent changes might not be reflected in this value. Type: Number
TableStatus	The current state of the table (CREATING, ACTIVE, DELETING or UPDATING). Once the table is in the ACTIVE state, you can add data.

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the `DescribeTable` operation for a table named "comp-table". The table has a composite primary key.

Sample Request

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.DescribeTable  
content-type: application/x-amz-json-1.0  
  
{"TableName": "users"}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 543

{"Table":
  {"CreationDateTime":1.309988345372E9,
   "ItemCount":23,
   "KeySchema":
     {"HashKeyElement":{"AttributeName":"user","AttributeType":"S"},
      "RangeKeyElement":{"AttributeName":"time","AttributeType":"N"}},
   "ProvisionedThroughput":{"LastIncreaseDateTime": 1.309988345384E9,
    "ReadCapacityUnits":10,"WriteCapacityUnits":10},
   "TableName":"users",
   "TableSizeBytes":949,
   "TableStatus":"ACTIVE"
  }
}
```

GetItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

The GetItem operation returns a set of Attributes for an item that matches the primary key. If there is no matching item, GetItem does not return any data.

The GetItem operation provides an eventually consistent read by default. If eventually consistent reads are not acceptable for your application, use ConsistentRead. Although this operation might take longer than a standard read, it always returns the last updated value. For more information, see [Read consistency](#).

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.GetItem  
content-type: application/x-amz-json-1.0  
  
{"TableName":"Table1",  
 "Key":  
 {"HashKeyElement": {"S":"AttributeValue1"},  
 "RangeKeyElement": {"N":"AttributeValue2"}  
 },  
 "AttributesToGet":["AttributeName3","AttributeName4"],  
 "ConsistentRead":Boolean  
}
```

Name	Description	Required
TableName	The name of the table containing the requested item. Type: String	Yes
Key	The primary key values that define the item. For more information about primary keys, see Primary key .	Yes

Name	Description	Required
	Type: Map of HashKeyElement to its value and RangeKeyElement to its value.	
AttributesToGet	<p>Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result.</p> <p>Type: Array</p>	No
ConsistentRead	<p>If set to true, then a consistent read is issued, otherwise eventually consistent is used.</p> <p>Type: Boolean</p>	No

Responses

Syntax

```

HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 144

{"Item": {
    "AttributeName3": {"S": "AttributeValue3"}, 
    "AttributeName4": {"N": "AttributeValue4"}, 
    "AttributeName5": {"B": "dmFsdWU="}
},
"ConsumedCapacityUnits": 0.5
}

```

Name	Description
Item	Contains the requested attributes. Type: Map of attribute name-value pairs.
ConsumedCapacityUnits	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. Requests for non-existent items consume the minimum read capacity units, depending on the type of read. For more information see Managing settings on DynamoDB provisioned capacity tables . Type: Number

Special errors

No errors specific to this operation.

Examples

For examples using the AWS SDK, see [Working with items and attributes](#).

Sample request

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.GetItem  
content-type: application/x-amz-json-1.0  
  
{"TableName": "comptable",  
 "Key":  
 {"HashKeyElement": {"S": "Julie"},  
 "RangeKeyElement": {"N": "1307654345"}},  
 "AttributesToGet": ["status", "friends"],  
 "ConsistentRead": true  
}
```

Sample response

Notice the ConsumedCapacityUnits value is 1, because the optional parameter ConsistentRead is set to true. If ConsistentRead is set to false (or not specified) for the same request, the response is eventually consistent and the ConsumedCapacityUnits value would be 0.5.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 72

{"Item":
 {"friends":{"SS":["Lynda, Aaron"]},
 "status":{"S":"online"}
 },
 "ConsumedCapacityUnits": 1
}
```

ListTables

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Returns an array of all the tables associated with the current account and endpoint.

Each DynamoDB endpoint is entirely independent. For example, if you have two tables called "MyTable," one in dynamodb.us-west-2.amazonaws.com and one in dynamodb.us-east-1.amazonaws.com, they are completely independent and do not share any data. The ListTables operation returns all of the table names associated with the account making the request, for the endpoint that receives the request.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.ListTables  
content-type: application/x-amz-json-1.0  
  
{"ExclusiveStartTableName": "Table1", "Limit": 3}
```

The ListTables operation, by default, requests all of the table names associated with the account making the request, for the endpoint that receives the request.

Name	Description	Required
Limit	A number of maximum table names to return. Type: Integer	No
ExclusiveStartTableName	The name of the table that starts the list. If you already ran a ListTables operation and received an LastEvaluatedTableName value in the response, use that value here to continue the list. Type: String	No

Responses

Syntax

```
HTTP/1.1 200 OK  
x-amzn-RequestId: S1LEK2DPQP80JNHVHL80U2M7KRVV4KQNS05AEMVJF66Q9ASUAAJG  
content-type: application/x-amz-json-1.0
```

```
content-length: 81  
Date: Fri, 21 Oct 2011 20:35:38 GMT
```

```
{"TableNames":["Table1","Table2","Table3"], "LastEvaluatedTableName":"Table3"}
```

Name	Description
TableNames	The names of the tables associated with the current account at the current endpoint. Type: Array
LastEvaluatedTableName	The name of the last table in the current list, only if some tables for the account and endpoint have not been returned. This value does not exist in a response if all table names are already returned. Use this value as the ExclusiveStartTableName in a new request to continue the list until all the table names are returned. Type: String

Special errors

No errors are specific to this operation.

Examples

The following examples show an HTTP POST request and response using the ListTables operation.

Sample request

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.ListTables  
content-type: application/x-amz-json-1.0
```

```
{"ExclusiveStartTableName": "comp2", "Limit": 3}
```

Sample response

```
HTTP/1.1 200 OK
x-amzn-RequestId: S1LEK2DPQP80JNHVHL80U2M7KRVV4KQNS05AEMVJF66Q9ASUAAJG
content-type: application/x-amz-json-1.0
content-length: 81
Date: Fri, 21 Oct 2011 20:35:38 GMT
```

```
{"LastEvaluatedTableName": "comp5", "TableNames": ["comp3", "comp4", "comp5"]}
```

PutItem

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Creates a new item, or replaces an old item with a new item (including all the attributes). If an item already exists in the specified table with the same primary key, the new item completely replaces the existing item. You can perform a conditional put (insert a new item if one with the specified primary key doesn't exist), or replace an existing item if it has certain attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

Note

To ensure that a new item does not replace an existing item, use a conditional put operation with `Exists` set to `false` for the primary key attribute, or attributes.

For more information about using `PutItem`, see [Working with items and attributes](#).

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.PutItem  
content-type: application/x-amz-json-1.0  
  
{"TableName":"Table1",  
 "Item":{  
     "AttributeName1":{"S":"AttributeValue1"},  
     "AttributeName2":{"N":"AttributeValue2"},  
     "AttributeName5":{"B":"dmFsdWU="}  
 },  
 "Expected":{"AttributeName3":{"Value": {"S":"AttributeValue"}, "Exists":Boolean}},  
 "ReturnValues":ReturnValuesConstant"}
```

Name	Description	Required
TableName	The name of the table to contain the item. Type: String	Yes
Item	A map of the attributes for the item, and must include the primary key values that define the item. Other attribute name-value pairs can be provided for the item.	Yes

Name	Description	Required
	<p>For more information about primary keys, see Primary key.</p> <p>Type: Map of attribute names to attribute values.</p>	
Expected	<p>Designates an attribute for a conditional put. The Expected parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it.</p> <p>Type: Map of an attribute names to an attribute value, and whether it exists.</p>	No
Expected:AttributeName	<p>The name of the attribute for the conditional put.</p> <p>Type: String</p>	No

Name	Description	Required
Expected:Attribute Name: ExpectedA ttributeValue	<p>Use this parameter to specify whether or not a value already exists for the attribute name-value pair.</p> <p>The following JSON notation replaces the item if the "Color" attribute doesn't already exist for that item:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" : {"Color": {"Exists": false}}</pre></div> <p>The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before replacing the item:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" : {"Color": {"Exists": true, "Value": {"S": "Yellow"}}}</pre></div> <p>By default, if you use the Expected parameter and provide a Value, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify {"Exists":true} , because it is implied. You can shorten the request to:</p> <div style="border: 1px solid #ccc; padding: 10px; width: fit-content; margin-left: auto; margin-right: auto;"><pre>"Expected" :</pre></div>	No

Name	Description	Required
	<pre>{"Color":{"Value": "S":"Yellow"}}}</pre> <p>Note If you specify <code>{"Exists":true}</code> without an attribute value to check, DynamoDB returns an error.</p>	
ReturnValues	<p>Use this parameter if you want to get the attribute name-value pairs before they were updated with the PutItem request. Possible parameter values are NONE (default) or ALL_OLD. If ALL_OLD is specified, and PutItem overwrote an attribute name-value pair, the content of the old item is returned. If this parameter is not provided or is NONE, nothing is returned.</p> <p>Type: String</p>	No

Responses

Syntax

The following syntax example assumes the request specified a `ReturnValues` parameter of `ALL_OLD`; otherwise, the response has only the `ConsumedCapacityUnits` element.

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 85
```

```
{"Attributes":
  {"AttributeName3":{"S":"AttributeValue3"},
   "AttributeName2":{"SS":"AttributeValue2"},
   "AttributeName1":{"SS":"AttributeValue1"},
  },
  "ConsumedCapacityUnits":1
}
```

Name	Description
Attributes	<p>Attribute values before the put operation, but only if the <code>ReturnValues</code> parameter is specified as <code>ALL_OLD</code> in the request.</p> <p>Type: Map of attribute name-value pairs.</p>
ConsumedCapacityUnits	<p>The number of write capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. For more information see Managing settings on DynamoDB provisioned capacity tables.</p> <p>Type: Number</p>

Special errors

Error	Description
ConditionalCheckFailedException	Conditional check failed. An expected attribute value was not found.
ResourceNotFoundException	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see [Working with items and attributes](#).

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.PutItem
content-type: application/x-amz-json-1.0

{"TableName":"comp5",
 "Item":
  {"time":{"N":"300"},
   "feeling":{"S":"not surprised"},
   "user":{"S":"Riley"}
  },
 "Expected":
  {"feeling":{"Value":{"S":"surprised"}, "Exists":true}}
 "ReturnValues":"ALL_OLD"
}
```

Sample response

```
HTTP/1.1 200
x-amzn-RequestId: 8952fa74-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 84

{"Attributes":
 {"feeling":{"S":"surprised"},
  "time":{"N":"300"},
  "user":{"S":"Riley"}},
 "ConsumedCapacityUnits":1
}
```

Query

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

A Query operation gets the values of one or more items and their attributes by primary key (Query is only available for hash-and-range primary key tables). You must provide a specific HashKeyValue, and can narrow the scope of the query using comparison operators on the RangeKeyValue of the primary key. Use the ScanIndexForward parameter to get results in forward or reverse order by range key.

Queries that do not return results consume the minimum read capacity units according to the type of read.

Note

If the total number of items meeting the query parameters exceeds the 1MB limit, the query stops and results are returned to the user with a LastEvaluatedKey to continue the query in a subsequent operation. Unlike a Scan operation, a Query operation never returns an empty result set *and* a LastEvaluatedKey. The LastEvaluatedKey is only provided if the results exceed 1MB, or if you have used the Limit parameter.

The result can be set for a consistent read using the ConsistentRead parameter.

Requests

Syntax

```
// This header is abbreviated.
```

```
// For a sample of a complete header, see DynamoDB low-level API.
POST / HTTP/1.1
x-amz-target: DynamoDB_20111205.Query
content-type: application/x-amz-json-1.0

{"TableName":"Table1",
 "Limit":2,
 "ConsistentRead":true,
 "HashKeyValue":{"S":"AttributeValue1"}, 
 "RangeKeyCondition": {"AttributeValueList":
 [{"N":"AttributeValue2"}]}, "ComparisonOperator":"GT"}
 "ScanIndexForward":true,
 "ExclusiveStartKey":{ 
 "HashKeyElement":{"S":"AttributeName1"}, 
 "RangeKeyElement":{"N":"AttributeName2"}},
 },
 "AttributesToGet":["AttributeName1", "AttributeName2", "AttributeName3"]},
}
```

Name	Description	Required
TableName	The name of the table containing the requested items. Type: String	Yes
AttributesToGet	Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result. Type: Array	No
Limit	The maximum number of items to return (not necessarily the number of matching items). If Dynamo	No

Name	Description	Required
	<p>DB processes the number of items up to the limit while querying the table, it stops the query and returns the matching values up to that point, and a <code>LastEvaluatedKey</code> to apply in a subsequent operation to continue the query. Also, if the result set size exceeds 1MB before DynamoDB hits this limit, it stops the query and returns the matching values, and a <code>LastEvaluatedKey</code> to apply in a subsequent operation to continue the query.</p> <p>Type: Number</p>	
ConsistentRead	<p>If set to true, then a consistent read is issued, otherwise eventually consistent is used.</p> <p>Type: Boolean</p>	No

Name	Description	Required
Count	<p>If set to true, DynamoDB returns a total number of items that match the query parameters, instead of a list of the matching items and their attributes. You can apply the <code>Limit</code> parameter to count-only queries.</p> <p>Do not set <code>Count</code> to true while providing a list of <code>AttributesToGet</code> ; otherwise, DynamoDB returns a validation error. For more information, see Counting the items in the results.</p> <p>Type: Boolean</p>	No
HashKeyValue	<p>Attribute value of the hash component of the composite primary key.</p> <p>Type: String, Number, or Binary</p>	Yes

Name	Description	Required
RangeKeyCondition	A container for the attribute values and comparison operators to use for the query. A query request does not require a RangeKeyCondition . If you provide only the HashKeyValue , DynamoDB returns all items with the specified hash key element value. Type: Map	No
RangeKeyCondition : AttributeValueList	The attribute values to evaluate for the query parameters. The AttributeValueList contains one attribute value, unless a BETWEEN comparison is specified. For the BETWEEN comparison, the AttributeValueList contains two attribute values. Type: A map of AttributeValue to a ComparisonOperator .	No

Name	Description	Required
RangeKeyCondition : ComparisonOperator	<p>The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a Query operation.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.</p><p>For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions.</p></div> <p>Type: String or Binary</p>	No

Name	Description	Required
	<p>EQ : Equal.</p> <p>For EQ, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not equal {"NS":["6", "2", "1"]}.</p>	
	<p>LE : Less than or equal.</p> <p>For LE, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
	<p>LT : Less than.</p> <p>For LT, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	
	<p>GE : Greater than or equal.</p> <p>For GE, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
	<p>GT : Greater than.</p> <p>For GT, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	
	<p>BEGINS_WITH : checks for a prefix.</p> <p>For BEGINS_WITH , AttributeValueList can contain only oneAttributeValue of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).</p>	

Name	Description	Required
	<p>BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value.</p> <p>For BETWEEN, Attribute ValueList must contain two AttributeValue elements of the same type , either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
ScanIndexForward	<p>Specifies ascending or descending traversal of the index. DynamoDB returns results reflecting the requested order determined by the range key: If the data type is Number, the results are returned in numeric order; otherwise, the traversal is based on ASCII character code values.</p> <p>Type: Boolean</p> <p>Default is true (ascending).</p>	No
ExclusiveStartKey	<p>Primary key of the item from which to continue an earlier query. An earlier query might provide this value as the LastEvaluatedKey if that query operation was interrupted before completing the query; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new query request to continue the operation from that point.</p> <p>Type: HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.</p>	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 308

Scan

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

The Scan operation returns one or more items and its attributes by performing a full scan of a table. Provide a ScanFilter to get more specific results.

Note

If the total number of scanned items exceeds the 1MB limit, the scan stops and results are returned to the user with a LastEvaluatedKey to continue the scan in a subsequent operation. The results also include the number of items exceeding the limit. A scan can result in no table data meeting the filter criteria.

The result set is eventually consistent.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.Scan  
content-type: application/x-amz-json-1.0  
  
{"TableName": "Table1",  
 "Limit": 2,  
 "ScanFilter":{  
     "AttributeName1": {"AttributeValueList":  
         [{"S": "AttributeValue"}]},  
     "ComparisonOperator": "EQ"  
 },  
 "ExclusiveStartKey":{  
     "HashKeyElement": {"S": "AttributeName1"},  
     "RangeKeyElement": {"N": "AttributeName2"}  
 },  
 "AttributesToGet": ["AttributeName1", "AttributeName2", "AttributeName3"]}  
}
```

Name	Description	Required
TableName	<p>The name of the table containing the requested items.</p> <p>Type: String</p>	Yes
AttributesToGet	<p>Array of Attribute names. If attribute names are not specified then all attributes will be returned. If some attributes are not found, they will not appear in the result.</p> <p>Type: Array</p>	No
Limit	<p>The maximum number of items to evaluate (not necessarily the number of matching items). If Dynamo DB processes the number of items up to the limit while processing the results, it stops and returns the matching values up to that point, and a <code>LastEvaluatedKey</code> to apply in a subsequent operation to continue retrieving items. Also, if the scanned data set size exceeds 1MB before DynamoDB reaches this limit, it stops the scan and returns the matching values up to the limit, and a <code>LastEvaluatedKey</code> to apply in a</p>	No

Name	Description	Required
	<p>subsequent operation to continue the scan.</p> <p>Type: Number</p>	
Count	<p>If set to true, DynamoDB returns a total number of items for the Scan operation, even if the operation has no matching items for the assigned filter. You can apply the Limit parameter to count-only scans.</p> <p>Do not set Count to true while providing a list of AttributesToGet , otherwise DynamoDB returns a validation error. For more information, see Counting the items in the results.</p> <p>Type: Boolean</p>	No
ScanFilter	<p>Evaluates the scan results and returns only the desired values. Multiple conditions are treated as "AND" operations: all conditions must be met to be included in the results.</p> <p>Type: A map of attribute names to values with comparison operators.</p>	No

Name	Description	Required
ScanFilter :Attribute ValueList	<p>The values and conditions to evaluate the scan results for the filter.</p> <p>Type: A map of Attribute Value to a Condition .</p>	No

Name	Description	Required
ScanFilter : ComparisonOperator	<p>The criteria for evaluating the provided attributes, such as equals, greater-than, etc. The following are valid comparison operators for a scan operation.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"><p>Note</p><p>String value comparisons for greater than, equals, or less than are based on ASCII character code values. For example, a is greater than A, and aa is greater than B. For a list of code values, see http://en.wikipedia.org/wiki/ASCII#ASCII_printable_characters.</p><p>For Binary, DynamoDB treats each byte of the binary data as unsigned when it compares binary values, for example when evaluating query expressions.</p></div> <p>Type: String or Binary</p>	No

Name	Description	Required
	<p>EQ : Equal.</p> <p>For EQ, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not equal {"NS":["6", "2", "1"]}.</p>	
	<p>NE : Not Equal.</p> <p>For NE, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not equal {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
	<p>LE : Less than or equal.</p> <p>For LE, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	
	<p>LT : Less than.</p> <p>For LT, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
	<p>GE : Greater than or equal.</p> <p>For GE, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	
	<p>GT : Greater than.</p> <p>For GT, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not equal {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
	NOT_NULL : Attribute exists. NULL : Attribute does not exist.	
	CONTAINS : checks for a subsequence, or value in a set. For CONTAINS, Attribute ValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for a substring match. If the target attribute of the comparison is Binary, then the operation looks for a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operation checks for a member of the set (not as a substring).	

Name	Description	Required
	<p>NOT_CONTAINS : checks for absence of a subsequence, or absence of a value in a set.</p> <p>For NOT_CONTAINS , AttributeValueList can contain only oneAttributeValue of type String, Number, or Binary (not a set). If the target attribute of the comparison is a String, then the operation checks for the absence of a substring match. If the target attribute of the comparison is Binary, then the operation checks for the absence of a subsequence of the target that matches the input. If the target attribute of the comparison is a set ("SS", "NS", or "BS"), then the operation checks for the absence of a member of the set (not as a substring).</p>	

Name	Description	Required
	<p><code>BEGINS_WITH</code> : checks for a prefix.</p> <p>For <code>BEGINS_WITH</code> , <code>AttributeValueList</code> can contain only one <code>AttributeValue</code> of type String or Binary (not a Number or a set). The target attribute of the comparison must be a String or Binary (not a Number or a set).</p>	
	<p><code>IN</code> : checks for exact matches.</p> <p>For <code>IN</code>, <code>AttributeValueList</code> can contain more than one <code>AttributeValue</code> of type String, Number, or Binary (not a set). The target attribute of the comparison must be of the same type and exact value to match. A String never matches a String set.</p>	

Name	Description	Required
	<p>BETWEEN : Greater than, or equal to, the first value and less than, or equal to, the second value.</p> <p>For BETWEEN, Attribute ValueList must contain two AttributeValue elements of the same type , either String, Number, or Binary (not a set). A target attribute matches if the target value is greater than, or equal to, the first element and less than, or equal to, the second element. If an item contains an Attribute Value of a different type than the one specified in the request, the value does not match. For example, {"S":"6"} does not compare to {"N":"6"} . Also, {"N":"6"} does not compare to {"NS":["6", "2", "1"]}.</p>	

Name	Description	Required
ExclusiveStartKey	<p>Primary key of the item from which to continue an earlier scan. An earlier scan might provide this value if that scan operation was interrupted before scanning the entire table; either because of the result set size or the Limit parameter. The LastEvaluatedKey can be passed back in a new scan request to continue the operation from that point.</p> <p>Type: HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.</p>	No

Responses

Syntax

```
HTTP/1.1 200
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
content-type: application/x-amz-json-1.0
content-length: 229
```

```
{"Count":2,"Items":[{"AttributeNames1":{"S":"AttributeValue1"}, "AttributeNames2":{"S":"AttributeValue2"}, "AttributeNames3":{"S":"AttributeValue3"}}, {"AttributeNames1":{"S":"AttributeValue4"}, "AttributeNames2":{"S":"AttributeValue5"}, "AttributeNames3":{"S":"AttributeValue6"}, "AttributeNames5":{"B":"dmFsdWU="}}]
```

```

}],  

"LastEvaluatedKey":  

{"HashKeyElement":{"S":"AttributeName1"},  

"RangeKeyElement":{"N":"AttributeName2"},  

"ConsumedCapacityUnits":1,  

"ScannedCount":2}  

}

```

Name	Description
Items	<p>Container for the attributes meeting the operation parameters.</p> <p>Type: Map of attribute names to and their data types and values.</p>
Count	<p>Number of items in the response. For more information, see Counting the items in the results.</p> <p>Type: Number</p>
ScannedCount	<p>Number of items in the complete scan before any filters are applied. A high ScannedCount value with few, or no, Count results indicates an inefficient Scan operation. For more information, see Counting the items in the results.</p> <p>Type: Number</p>
LastEvaluatedKey	<p>Primary key of the item where the scan operation stopped. Provide this value in a subsequent scan operation to continue the operation from that point.</p> <p>The LastEvaluatedKey is null when the entire scan result set is complete (i.e. the operation processed the “last page”).</p>

Name	Description
ConsumedCapacityUnits	The number of read capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. For more information see Managing settings on DynamoDB provisioned capacity tables . Type: Number

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.

Examples

For examples using the AWS SDK, see [Working with scans in DynamoDB](#).

Sample request

```
// This header is abbreviated. For a sample of a complete header, see DynamoDB low-level API.

UpdateItem

⚠ Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Edits an existing item's attributes. You can perform a conditional update (insert a new attribute name-value pair if it doesn't exist, or replace an existing name-value pair if it has certain expected attribute values).

Note

You cannot update the primary key attributes using `UpdateItem`. Instead, delete the item and use `PutItem` to create a new item with new attributes.

The `UpdateItem` operation includes an `Action` parameter, which defines how to perform the update. You can put, delete, or add attribute values.

Attribute values may not be null; string and binary type attributes must have lengths greater than zero; and set type attributes must not be empty. Requests with empty values will be rejected with a `ValidationException`.

If an existing item has the specified primary key:

- **PUT**— Adds the specified attribute. If the attribute exists, it is replaced by the new value.
- **DELETE**— If no value is specified, this removes the attribute and its value. If a set of values is specified, then the values in the specified set are removed from the old set. So if the attribute value contains [a,b,c] and the delete action contains [a,c], then the final attribute value is [b]. The type of the specified value must match the existing value type. Specifying an empty set is not valid.
- **ADD**— Only use the add action for numbers or if the target attribute is a set (including string sets). ADD does not work if the target attribute is a single string value or a scalar binary value. The specified value is added to a numeric value (incrementing or decrementing the existing numeric value) or added as an additional value in a string set. If a set of values is specified, the values are added to the existing set. For example if the original set is [1,2] and supplied value is [3], then after the add operation the set is [1,2,3], not [4,5]. An error occurs if an Add action is specified for a set attribute and the attribute type specified does not match the existing set type.

If you use ADD for an attribute that does not exist, the attribute and its values are added to the item.

If no item matches the specified primary key:

- **PUT**— Creates a new item with specified primary key. Then adds the specified attribute.
- **DELETE**— Nothing happens.

- **ADD**— Creates an item with supplied primary key and number (or set of numbers) for the attribute value. Not valid for a string or a binary type.

Note

If you use ADD to increment or decrement a number value for an item that doesn't exist before the update, DynamoDB uses `0` as the initial value. Also, if you update an item using ADD to increment or decrement a number value for an attribute that doesn't exist before the update (but the item does) DynamoDB uses `0` as the initial value. For example, you use ADD to add `+3` to an attribute that did not exist before the update. DynamoDB uses `0` for the initial value, and the value after the update is `3`.

For more information about using this operation, see [Working with items and attributes](#).

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.UpdateItem  
content-type: application/x-amz-json-1.0  
  
{"TableName": "Table1",  
 "Key":  
     {"HashKeyElement": {"S": "AttributeValue1"},  
      "RangeKeyElement": {"N": "AttributeValue2"}},  
     "AttributeUpdates": {"AttributeName3": {"Value":  
         {"S": "AttributeValue3_New"}, "Action": "PUT"}},  
     "Expected": {"AttributeName3": {"Value": {"S": "AttributeValue3_Current"}},  
     "ReturnValues": "ReturnValuesConstant"  
}
```

Name	Description	Required
TableName	<p>The name of the table containing the item to update.</p> <p>Type: String</p>	Yes
Key	<p>The primary key that defines the item. For more information about primary keys, see Primary key.</p> <p>Type: Map of HashKeyElement to its value and RangeKeyElement to its value.</p>	Yes
AttributeUpdates	<p>Map of attribute name to the new value and action for the update. The attribute names specify the attributes to modify, and cannot contain any primary key attributes.</p> <p>Type: Map of attribute name, value, and an action for the attribute update.</p>	
AttributeUpdates :Action	<p>Specifies how to perform the update. Possible values: PUT (default), ADD or DELETE. The semantics are explained in the UpdateItem description.</p> <p>Type: String</p>	No

Name	Description	Required
	Default: PUT	
Expected	<p>Designates an attribute for a conditional update. The Expected parameter allows you to provide an attribute name, and whether or not DynamoDB should check to see if the attribute value already exists; or if the attribute value exists and has a particular value before changing it.</p> <p>Type: Map of attribute names.</p>	No
Expected:AttributeName	<p>The name of the attribute for the conditional put.</p> <p>Type: String</p>	No

Name	Description	Required
Expected:Attribute Name: ExpectedA ttributeValue	<p>Use this parameter to specify whether or not a value already exists for the attribute name-value pair.</p> <p>The following JSON notation updates the item if the "Color" attribute doesn't already exist for that item:</p> <pre>"Expected" : {"Color":{"Exists":false}}</pre> <p>The following JSON notation checks to see if the attribute with name "Color" has an existing value of "Yellow" before updating the item:</p> <pre>"Expected" : {"Color":{"Exists":true}, {"Value": {"S":"Yellow"}}}</pre> <p>By default, if you use the Expected parameter and provide a Value, DynamoDB assumes the attribute exists and has a current value to be replaced. So you don't have to specify {"Exists":true} , because it is implied. You can shorten the request to:</p> <pre>"Expected" :</pre>	No

Name	Description	Required
	<pre>{"Color":{"Value": {"S":"Yellow"}}}</pre> <p>Note If you specify <code>{"Exists":true}</code> without an attribute value to check, DynamoDB returns an error.</p>	

Name	Description	Required
ReturnValues	<p>Use this parameter if you want to get the attribute name-value pairs before they were updated with the <code>UpdateItem</code> request. Possible parameter values are <code>NONE</code> (default) or <code>ALL_OLD</code>, <code>UPDATED_OLD</code>, <code>ALL_NEW</code> or <code>UPDATED_NEW</code>. If <code>ALL_OLD</code> is specified, and <code>UpdateItem</code> overwrote an attribute name-value pair, the content of the old item is returned. If this parameter is not provided or is <code>NONE</code>, nothing is returned. If <code>ALL_NEW</code> is specified, then all the attributes of the new version of the item are returned. If <code>UPDATED_NEW</code> is specified, then the new versions of only the updated attributes are returned.</p> <p>Type: String</p>	No

Responses

Syntax

The following syntax example assumes the request specified a `ReturnValues` parameter of `ALL_OLD`; otherwise, the response has only the `ConsumedCapacityUnits` element.

```
HTTP/1.1 200
```

```
x-amzn-RequestId: 8966d095-71e9-11e0-a498-71d736f27375
```

```
content-type: application/x-amz-json-1.0
content-length: 140

{"Attributes": {
    "AttributeName1": {"S": "AttributeValue1"},
    "AttributeName2": {"S": "AttributeValue2"},
    "AttributeName3": {"S": "AttributeValue3"},
    "AttributeName5": {"B": "dmFsdWU="}
},
"ConsumedCapacityUnits": 1
}
```

Name	Description
Attributes	A map of attribute name-value pairs, but only if the <code>ReturnValues</code> parameter is specified as something other than <code>NONE</code> in the request. Type: Map of attribute name-value pairs.
ConsumedCapacityUnits	The number of write capacity units consumed by the operation. This value shows the number applied toward your provisioned throughput. For more information see Managing settings on DynamoDB provisioned capacity tables . Type: Number

Special errors

Error	Description
ConditionalCheckFailedException	Conditional check failed. Attribute ("+ name +") value is ("+ value +") but was expected ("+ expValue +")
ResourceNotFoundExceptions	The specified item or attribute was not found.

Examples

For examples using the AWS SDK, see [Working with items and attributes](#).

UpdateTable

Important

This section refers to API version 2011-12-05, which is deprecated and should not be used for new applications.

For documentation on the current low-level API, see the [Amazon DynamoDB API Reference](#).

Description

Updates the provisioned throughput for the given table. Setting the throughput for a table helps you manage performance and is part of the provisioned throughput feature of DynamoDB. For more information, see [Managing settings on DynamoDB provisioned capacity tables](#).

The provisioned throughput values can be upgraded or downgraded based on the maximums and minimums listed in [Service, account, and table quotas in Amazon DynamoDB](#).

The table must be in the ACTIVE state for this operation to succeed. UpdateTable is an asynchronous operation; while executing the operation, the table is in the UPDATING state. While the table is in the UPDATING state, the table still has the provisioned throughput from before the call. The new provisioned throughput setting is in effect only when the table returns to the ACTIVE state after the UpdateTable operation.

Requests

Syntax

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.UpdateTable  
content-type: application/x-amz-json-1.0  
  
{"TableName":"Table1",  
 "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":15}  
}
```

Name	Description	Required
TableName	<p>The name of the table to update.</p> <p>Type: String</p>	Yes
ProvisionedThroughput	<p>New throughput for the specified table, consisting of values for ReadCapacityUnits and WriteCapacityUnits . See Managing settings on DynamoDB provisioned capacity tables.</p> <p>Type: Array</p>	Yes
ProvisionedThroughput :ReadCapacityUnits	<p>Sets the minimum number of consistent ReadCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations.</p> <p>Eventually consistent read operations require less effort than a consistent read operation, so a setting of 50 consistent ReadCapacityUnits per second provides 100 eventually consistent ReadCapacityUnits per second.</p> <p>Type: Number</p>	Yes

Name	Description	Required
ProvisionedThroughput put :WriteCapacityUnits	Sets the minimum number of WriteCapacityUnits consumed per second for the specified table before DynamoDB balances the load with other operations. Type: Number	Yes

Responses

Syntax

```
HTTP/1.1 200 OK
x-amzn-RequestId: CS0C7TJPLR000KIRLG0HVAICUFVV4KQNS05AEMVJF66Q9ASUAAJG

  "TableStatus":"UPDATING"}}
```

Name	Description
CreationDateTime	Date when the table was created.

Name	Description
	Type: Number
KeySchema	<p>The primary key (simple or composite) structure for the table. A name-value pair for the HashKeyElement is required, and a name-value pair for the RangeKeyElement is optional (only required for composite primary keys). The maximum hash key size is 2048 bytes. The maximum range key size is 1024 bytes. Both limits are enforced separately (i.e. you can have a combined hash + range 2048 + 1024 key). For more information about primary keys, see Primary key.</p> <p>Type: Map of HashKeyElement , or HashKeyElement and RangeKeyElement for a composite primary key.</p>
ProvisionedThroughput	<p>Current throughput settings for the specified table, including values for LastIncreaseDateTime (if applicable), LastDecreaseDateTime (if applicable),</p> <p>Type: Array</p>
TableName	<p>The name of the updated table.</p> <p>Type: String</p>
TableStatus	<p>The current state of the table (CREATING, ACTIVE, DELETING or UPDATING), which should be UPDATING.</p> <p>Use the DescribeTables operation to check the status of the table.</p> <p>Type: String</p>

Special errors

Error	Description
ResourceNotFoundException	The specified table was not found.
ResourceInUseException	The table is not in the ACTIVE state.

Examples

Sample request

```
// This header is abbreviated.  
// For a sample of a complete header, see DynamoDB low-level API.  
POST / HTTP/1.1  
x-amz-target: DynamoDB_20111205.UpdateTable  
content-type: application/x-amz-json-1.0  
  
{"TableName":"comp1",  
 "ProvisionedThroughput":{"ReadCapacityUnits":5,"WriteCapacityUnits":15}  
}
```

Sample response

```
HTTP/1.1 200 OK  
content-type: application/x-amz-json-1.0  
content-length: 390  
Date: Sat, 19 Nov 2011 00:46:47 GMT  
  
{"TableDescription":

AWS SDK for Java 1.x examples

This section contains example code for DAX applications using SDK for Java 1.x.

Topics

- [Using DAX with AWS SDK for Java 1.x](#)
- [Modifying an existing SDK for Java 1.x application to use DAX](#)
- [Querying global secondary indexes with SDK for Java 1.x](#)

Using DAX with AWS SDK for Java 1.x

Follow this procedure to run the Java sample for Amazon DynamoDB Accelerator (DAX) on your Amazon EC2 instance.

Note

These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see [Java and DAX](#).

To run the Java sample for DAX

1. Install the Java Development Kit (JDK).

```
sudo yum install -y java-devel
```

2. Download the AWS SDK for Java (.zip file), and then extract it.

```
wget http://sdk-for-java.amazonwebservices.com/latest/aws-java-sdk.zip
```

```
unzip aws-java-sdk.zip
```

3. Download the latest version of the DAX Java client (.jar file).

```
wget http://dax-sdk.s3-website-us-west-2.amazonaws.com/java/DaxJavaClient-latest.jar
```

 **Note**

The client for the DAX SDK for Java is available on Apache Maven. For more information, see [Using the client as an Apache Maven dependency](#).

4. Set your CLASSPATH variable. In this example, replace *sdkVersion* with the actual version number of the AWS SDK for Java (for example, 1.11.112).

```
export SDKVERSION=sdkVersion  
  
export CLASSPATH=$(pwd)/TryDax/java:$(pwd)/DaxJavaClient-latest.jar:$(pwd)/aws-java-sdk-$SDKVERSION/lib/aws-java-sdk-$SDKVERSION.jar:$(pwd)/aws-java-sdk-$SDKVERSION/third-party/lib/*
```

5. Download the sample program source code (.zip file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

6. Navigate to the Java code directory and compile the code as follows.

```
cd TryDax/java/  
javac TryDax*.java
```

7. Run the program.

```
java TryDax
```

You should see output similar to the following.

Creating a DynamoDB client

```
Attempting to create table; please wait...
Successfully created table. Table status: ACTIVE

Total time: 10.736 ms - Avg time: 2.147 ms
Total time: 12.122 ms - Avg time: 2.424 ms
Scan test - all items in the table
Total time: 58.952 ms - Avg time: 11.790 ms
Total time: 25.507 ms - Avg time: 5.101 ms
Total time: 37.660 ms - Avg time: 7.532 ms
Total time: 26.781 ms - Avg time: 5.356 ms
Total time: 46.076 ms - Avg time: 9.215 ms
```

```
Attempting to delete table; please wait...
```

```
Successfully deleted table.
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

8. In the previous step, you ran the program against the DynamoDB endpoint. Now run the program again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{  
    "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",  
    "Port": 8111,  
    "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"  
}
```

Now run the program again, but this time, specify the cluster endpoint as a command line parameter.

```
java TryDax dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

For more information about this program, see the following sections:

- [TryDax.java](#)

- [TryDaxHelper.java](#)
- [TryDaxTests.java](#)

Using the client as an Apache Maven dependency

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

To use the client as a Maven dependency

1. Download and install Apache Maven. For more information, see [Downloading Apache Maven](#) and [Installing Apache Maven](#).
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace x.x.x.x with the actual version number of the client (for example, 1.0.200704.0).

```
<!--Dependency:-->
<dependencies>
    <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>amazon-dax-client</artifactId>
        <version>x.x.x.x</version>
    </dependency>
</dependencies>
```

TryDax.java

The TryDax.java file contains the main method. If you run the program with no command line parameters, it creates an Amazon DynamoDB client and uses that client for all API operations. If you specify a DynamoDB Accelerator (DAX) cluster endpoint on the command line, the program also creates a DAX client and uses it for GetItem, Query, and Scan operations.

You can modify the program in several ways:

- Use the DAX client instead of the DynamoDB client. For more information, see [Java and DAX](#).
- Choose a different name for the test table.
- Modify the number of items written by changing the helper.writeData parameters. The second parameter is the number of partition keys, and the third parameter is the number of sort

keys. By default, the program uses 1–10 for partition key values and 1–10 for sort key values, for a total of 100 items written to the table. For more information, see [TryDaxHelper.java](#).

- Modify the number of GetItem, Query, and Scan tests, and modify their parameters.
- Comment out the lines containing helper.createTable and helper.deleteTable (if you don't want to create and delete the table each time you run the program).

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see [Using the client as an Apache Maven dependency](#).

Alternatively, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See [Java and DAX](#) for an example of setting your CLASSPATH variable.

```
public class TryDax {  
  
    public static void main(String[] args) throws Exception {  
  
        TryDaxHelper helper = new TryDaxHelper();  
        TryDaxTests tests = new TryDaxTests();  
  
        DynamoDB ddbClient = helper.getDynamoDBClient();  
        DynamoDB daxClient = null;  
        if (args.length >= 1) {  
            daxClient = helper.getDaxClient(args[0]);  
        }  
  
        String tableName = "TryDaxTable";  
  
        System.out.println("Creating table...");  
        helper.createTable(tableName, ddbClient);  
        System.out.println("Populating table...");  
        helper.writeData(tableName, ddbClient, 10, 10);  
  
        DynamoDB testClient = null;  
        if (daxClient != null) {
```

```
        testClient = daxClient;
    } else {
        testClient = ddbClient;
    }

    System.out.println("Running GetItem, Scan, and Query tests...");
    System.out.println("First iteration of each test will result in cache misses");
    System.out.println("Next iterations are cache hits\n");

    // GetItem
    tests.getItemTest(tableName, testClient, 1, 10, 5);

    // Query
    tests.queryTest(tableName, testClient, 5, 2, 9, 5);

    // Scan
    tests.scanTest(tableName, testClient, 5);

    helper.deleteTable(tableName, ddbClient);
}

}
```

TryDaxHelper.java

The TryDaxHelper.java file contains utility methods.

The getDynamoDBClient and getDaxClient methods provide Amazon DynamoDB and DynamoDB Accelerator (DAX) clients. For control plane operations (CreateTable, DeleteTable) and write operations, the program uses the DynamoDB client. If you specify a DAX cluster endpoint, the main program creates a DAX client for performing read operations (GetItem, Query, Scan).

The other TryDaxHelper methods (createTable, writeData, deleteTable) are for setting up and tearing down the DynamoDB table and its data.

You can modify the program in several ways:

- Use different provisioned throughput settings for the table.
- Modify the size of each item written (see the stringSize variable in the writeData method).
- Modify the number of GetItem, Query, and Scan tests and their parameters.

- Comment out the lines containing `helper.CreateTable` and `helper.DeleteTable` (if you don't want to create and delete the table each time you run the program).

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see [Using the client as an Apache Maven dependency](#).

Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See [Java and DAX](#) for an example of setting your CLASSPATH variable.

    try {
        System.out.println("\nAttempting to delete table; please wait...");
        table.delete();
        table.waitForDelete();
        System.out.println("Successfully deleted table.");
    } catch (Exception e) {
        System.err.println("Unable to delete table: ");
        e.printStackTrace();
    }
}
}
```

TryDaxTests.java

The TryDaxTests.java file contains methods that perform read operations against a test table in Amazon DynamoDB. These methods are not concerned with how they access the data (using either the DynamoDB client or the DAX client), so there is no need to modify the application logic.

You can modify the program in several ways:

- Modify the queryTest method so that it uses a different KeyConditionExpression.
- Add a ScanFilter to the scanTest method so that only some of the items are returned to you.

Note

To run this program, you can set up Maven to use the client for the DAX SDK for Java and the AWS SDK for Java as dependencies. For more information, see [Using the client as an Apache Maven dependency](#).

Or, you can download and include both the DAX Java client and the AWS SDK for Java in your classpath. See [Java and DAX](#) for an example of setting your CLASSPATH variable.

    valueMap.put(":skval1", sk1);
    valueMap.put(":skval2", sk2);

    QuerySpec spec = new QuerySpec()
        .withKeyConditionExpression("pk = :pkval and sk between :skval1 and :skval2")
        .WithValueMap(valueMap);

    for (int i = 0; i < iterations; i++) {
        startTime = System.nanoTime();
        ItemCollection<QueryOutcome> items = table.query(spec);

        try {
            Iterator<Item> iter = items.iterator();
            while (iter.hasNext()) {
                iter.next();
            }
        } catch (Exception e) {
            System.err.println("Unable to query table:");
            e.printStackTrace();
        }
        endTime = System.nanoTime();
        printTime(startTime, endTime, iterations);
    }
}

void scanTest(String tableName, DynamoDB client, int iterations) {
    long startTime, endTime;
    System.out.println("Scan test - all items in the table");
    Table table = client.getTable(tableName);

    for (int i = 0; i < iterations; i++) {
```

```
startTime = System.nanoTime();
ItemCollection<ScanOutcome> items = table.scan();
try {

    Iterator<Item> iter = items.iterator();
    while (iter.hasNext()) {
        iter.next();
    }
} catch (Exception e) {
    System.err.println("Unable to scan table:");
    e.printStackTrace();
}
endTime = System.nanoTime();
printTime(startTime, endTime, iterations);
}

public void printTime(long startTime, long endTime, int iterations) {
    System.out.format("\tTotal time: %.3f ms - ", (endTime - startTime) /
(1000000.0));
    System.out.format("Avg time: %.3f ms\n", (endTime - startTime) / (iterations *
1000000.0));
}
```

Modifying an existing SDK for Java 1.x application to use DAX

If you already have a Java application that uses Amazon DynamoDB, you have to modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java.

Note

These instructions are for applications using AWS SDK for Java 1.x. For applications using AWS SDK for Java 2.x, see [Modifying an existing application to use DAX](#).

Suppose that you have a DynamoDB table named `Music`. The partition key for the table is `Artist`, and its sort key is `SongTitle`. The following program reads an item directly from the `Music` table.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class GetMusicItem {

    public static void main(String[] args) throws Exception {

        // Create a DynamoDB client
        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music").withKey(key);

        try {
            System.out.println("Attempting to read the item...");
            GetItemResult result = client.getItem(request);
            System.out.println("GetItem succeeded: " + result);

        } catch (Exception e) {
            System.err.println("Unable to read item");
            System.err.println(e.getMessage());
        }
    }
}
```

To modify the program, replace the DynamoDB client with a DAX client.

```
import java.util.HashMap;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;
```

```
public class GetMusicItem {  
  
    public static void main(String[] args) throws Exception {  
  
        //Create a DAX client  
  
        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();  
        daxClientBuilder.withRegion("us-  
east-1").withEndpointConfiguration("mydaxcluster.2cmrw1.clustercfg.dax.use1.cache.amazonaws.com");  
        AmazonDynamoDB client = daxClientBuilder.build();  
  
        /*  
         * ...  
         * Remaining code omitted (it is identical)  
         * ...  
        */  
  
    }  
}
```

Using the DynamoDB document API

The AWS SDK for Java provides a document interface for DynamoDB. The document API acts as a wrapper around the low-level DynamoDB client. For more information, see [Document interfaces](#).

The document interface can also be used with the low-level DAX client, as shown in the following example.

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;  
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;  
import com.amazonaws.services.dynamodbv2.document.DynamoDB;  
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;  
import com.amazonaws.services.dynamodbv2.document.Table;  
  
public class GetMusicItemWithDocumentApi {  
  
    public static void main(String[] args) throws Exception {  
  
        //Create a DAX client  
  
        AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();
```

```
daxClientBuilder.withRegion("us-east-1").withEndpointConfiguration("mydaxcluster.2cmrw1.clustercfg.dax.use1.cache.amazonaws.com");
AmazonDynamoDB client = daxClientBuilder.build();

// Document client wrapper
DynamoDB docClient = new DynamoDB(client);

Table table = docClient.getTable("Music");

try {
    System.out.println("Attempting to read the item...");
    GetItemOutcome outcome = table.tgetItemOutcome(
        "Artist", "No One You Know",
        "SongTitle", "Scared of My Shadow");
    System.out.println(outcome.getItem());
    System.out.println("GetItem succeeded: " + outcome);
} catch (Exception e) {
    System.err.println("Unable to read item");
    System.err.println(e.getMessage());
}

}

}
```

DAX async client

The AmazonDaxClient is synchronous. For a long-running DAX API operation, such as a Scan of a large table, this can block program execution until the operation is complete. If your program needs to perform other work while a DAX API operation is in progress, you can use ClusterDaxAsyncClient instead.

The following program shows how to use ClusterDaxAsyncClient, along with Java Future, to implement a non-blocking solution.

```
import java.util.concurrent.ExecutionException;
import java.util.concurrent.Future;

import com.amazon.dax.client.dynamodbv2.ClientConfig;
import com.amazon.dax.client.dynamodbv2.ClusterDaxAsyncClient;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.handlers.AsyncHandler;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBAsync;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
```

```
import com.amazonaws.services.dynamodbv2.model.GetItemRequest;
import com.amazonaws.services.dynamodbv2.model.GetItemResult;

public class DaxAsyncClientDemo {
    public static void main(String[] args) throws Exception {

        ClientConfig daxConfig = new ClientConfig().withCredentialsProvider(new
ProfileCredentialsProvider())
            .withEndpoints("mydaxcluster.2cmrw1.clustercfg.dax.use1.cache.amazonaws.com:8111");

        AmazonDynamoDBAsync client = new ClusterDaxAsyncClient(daxConfig);

        HashMap<String, AttributeValue> key = new HashMap<String, AttributeValue>();
        key.put("Artist", new AttributeValue().withS("No One You Know"));
        key.put("SongTitle", new AttributeValue().withS("Scared of My Shadow"));

        GetItemRequest request = new GetItemRequest()
            .withTableName("Music").withKey(key);

        // Java Futures
        Future<GetItemResult> call = client.getItemAsync(request);
        while (!call.isDone()) {
            // Do other processing while you're waiting for the response
            System.out.println("Doing something else for a few seconds...");
            Thread.sleep(3000);
        }
        // The results should be ready by now

        try {
            call.get();

        } catch (ExecutionException ee) {
            // Futures always wrap errors as an ExecutionException.
            // The *real* exception is stored as the cause of the
            // ExecutionException
            Throwable exception = ee.getCause();
            System.out.println("Error getting item: " + exception.getMessage());
        }

        // Async callbacks
        call = client.getItemAsync(request, new AsyncHandler<GetItemRequest, GetItemResult>()
{
    @Override
```

```
public void onSuccess(GetItemRequest request, GetItemResult getItemResult) {
    System.out.println("Result: " + getItemResult);
}

@Override
public void onError(Exception e) {
    System.out.println("Unable to read item");
    System.err.println(e.getMessage());
    // Callers can also test if exception is an instance of
    // AmazonServiceException or AmazonClientException and cast
    // it to get additional information
}

});

call.get();

}
}
```

Querying global secondary indexes with SDK for Java 1.x

You can use Amazon DynamoDB Accelerator (DAX) to query [global secondary indexes](#) using DynamoDB [programmatic interfaces](#).

The following example demonstrates how to use DAX to query the CreateDateIndex global secondary index that is created in [Example: Global secondary indexes using the AWS SDK for Java document API](#).

The DAXClient class instantiates the client objects that are needed to interact with the DynamoDB programming interfaces.

```
import com.amazon.dax.client.dynamodbv2.AmazonDaxClientBuilder;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.util.EC2MetadataUtils;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;

public class DaxClient {

    private static final String region = EC2MetadataUtils.getEC2InstanceRegion();

    DynamoDB getDaxDocClient(String daxEndpoint) {
```

```
System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
AmazonDynamoDB client = daxClientBuilder.build();

return new DynamoDB(client);
}

DynamoDBMapper getDaxMapperClient(String daxEndpoint) {
    System.out.println("Creating a DAX client with cluster endpoint " + daxEndpoint);
    AmazonDaxClientBuilder daxClientBuilder = AmazonDaxClientBuilder.standard();

    daxClientBuilder.withRegion(region).withEndpointConfiguration(daxEndpoint);
    AmazonDynamoDB client = daxClientBuilder.build();

    return new DynamoDBMapper(client);
}
}
```

You can query a global secondary index in the following ways:

- Use the `queryIndex` method on the `QueryIndexDax` class defined in the following example. The `QueryIndexDax` takes as a parameter the `client` object that is returned by the `getDaxDocClient` method on the `DaxClient` class.
- If you are using the [object persistence interface](#), use the `queryIndexMapper` method on the `QueryIndexDax` class defined in the following example. The `queryIndexMapper` takes as a parameter the `client` object that is returned by the `getDaxMapperClient` method defined on the `DaxClient` class.

```
import java.util.Iterator;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import java.util.List;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBQueryExpression;
import com.amazonaws.services.dynamodbv2.model.AttributeValue;
import java.util.HashMap;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.utils.ValueMap;
import com.amazonaws.services.dynamodbv2.document.spec.QuerySpec;
import com.amazonaws.services.dynamodbv2.document.QueryOutcome;
import com.amazonaws.services.dynamodbv2.document.ItemCollection;
```

```
import com.amazonaws.services.dynamodbv2.document.Index;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;

public class QueryIndexDax {

    //This is used to query Index using the low-level interface.
    public static void queryIndex(DynamoDB client, String tableName, String indexName) {
        Table table = client.getTable(tableName);

        System.out.println("\n*****");
        System.out.print("Querying index " + indexName + "...");

        Index index = table.getIndex(indexName);

        ItemCollection<QueryOutcome> items = null;

        QuerySpec querySpec = new QuerySpec();

        if (indexName == "CreateDateIndex") {
            System.out.println("Issues filed on 2013-11-01");
            querySpec.withKeyConditionExpression("CreateDate = :v_date and
begins_with(IssueId, :v_issue)")
                .WithValueMap(new ValueMap().withString(":v_date",
"2013-11-01").withString(":v_issue", "A-"));
            items = index.query(querySpec);
        } else {
            System.out.println("\nNo valid index name provided");
            return;
        }

        Iterator<Item> iterator = items.iterator();

        System.out.println("Query: printing results...");

        while (iterator.hasNext()) {
            System.out.println(iterator.next().toJSONPretty());
        }

    }

    //This is used to query Index using the high-level mapper interface.
```

```
public static void queryIndexMapper(DynamoDBMapper mapper, String tableName, String indexName) {
    HashMap<String,AttributeValue> eav = new HashMap<String,AttributeValue>();
    eav.put(":v_date", new AttributeValue().withS("2013-11-01"));
    eav.put(":v_issue", new AttributeValue().withS("A-"));
    DynamoDBQueryExpression<CreateDate> queryExpression = new
    DynamoDBQueryExpression<CreateDate>()
        .withIndexName("CreateDateIndex").withConsistentRead(false)
        .withKeyConditionExpression("CreateDate = :v_date and
begins_with(IssueId, :v_issue)")
        .withExpressionAttributeValues(eav);

    List<CreateDate> items = mapper.query(CreateDate.class, queryExpression);
    Iterator<CreateDate> iterator = items.iterator();

    System.out.println("Query: printing results...");

    while (iterator.hasNext()) {
        CreateDate iterObj = iterator.next();
        System.out.println(iterObj.getCreateDate());
        System.out.println(iterObj.getIssueId());
    }
}
```

The class definition below represents the Issues table and is used in the queryIndexMapper method.

```
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIndexRangeKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;

@DynamoDBTable(tableName = "Issues")
public class CreateDate {
    private String createDate;
    @DynamoDBHashKey(attributeName = "IssueId")
    private String issueId;

    @DynamoDBIndexHashKey(globalSecondaryIndexName = "CreateDateIndex", attributeName =
    "CreateDate")
    public String getCreateDate() {
        return createDate;
```

```
}

public void setCreateDate(String createDate) {
    this.createDate = createDate;
}

@DynamoDBIndexRangeKey(globalSecondaryIndexName = "CreateDatePicker", attributeName =
"IssueId")
public String getIssueId() {
    return issueId;
}

public void setIssueId(String issueId) {
    this.issueId = issueId;
}
}
```

Document history for DynamoDB

The following table describes the important changes in each release of the *DynamoDB Developer Guide* from July 3, 2018 onward. For notification about updates to this documentation, you can subscribe to the RSS feed (at the top left corner of this page).

Change	Description	Date
<u>Resource-based policies for Amazon DynamoDB resources</u>	DynamoDB now supports resource-based policies for tables, indexes, and streams. Resource-based policies let you define access permissions by specifying who has access to each resource, and the actions they are allowed to perform on each resource. For more information, see <u>Using resource-based policies for DynamoDB</u> .	March 20, 2024
<u>DynamoDB managed policy update</u>	Added a new permission dynamodb:GetResourcePolicy to the AmazonDynamoDBReadOnlyAccess managed policy. This permission provides access to read resource-based policies attached to DynamoDB resources. For more information, see <u>AWS managed policy: AmazonDynamoDBReadOnlyAccess</u> .	March 20, 2024
<u>AWS PrivateLink for Amazon DynamoDB</u>	Amazon DynamoDB now supports AWS PrivateLi	March 19, 2024

nk. With AWS PrivateLink, you can simplify private network connectivity between virtual private clouds (VPCs), DynamoDB, and your on-premises data centers using interface VPC endpoints and private IP addresses. For more information, see [AWS PrivateLink for DynamoDB](#).

[Programming with JavaScript guide](#)

Amazon DynamoDB presents a programming guide for AWS SDK for JavaScript. Learn about the AWS SDK for JavaScript, abstraction layers, configuring connection, handling errors, defining retry policies, managing keep-alive, and more. For more information, see [Programming with JavaScript](#).

[Programming with AWS SDK for Java 2.x guide](#)

Created a new programming guide that goes in depth about high-level, low-level, and document interfaces, HTTP clients and their configuration, error handling, and addresses the most common configuration settings that you should consider when using the SDK for Java 2.x. For more information, see [Programming Amazon DynamoDB with AWS SDK for Java 2.x](#).

<u>Clone tables with NoSQL Workbench</u>	Allow developers to use NoSQL Workbench to copy or clone tables between development environments and regions (DynamoDB Local and DynamoDB web). For more information, see <u>Cloning tables with NoSQL Workbench</u> .	February 26, 2024
<u>Programming with Python guide</u>	Created a new guide that goes in depth about both high level and low level libraries and addresses the most common configuration settings that one should consider when using the Python SDK. For more information, see <u>Programming with Python</u> .	January 5, 2024
<u>Time to live (TTL) topic rewrite</u>	Completely rewrote the TTL section of the guide. The new guide helps you get started with TTL by providing ready-to-use code snippets along the way. The current code snippets provided are in Python and Javascript. For more information, see <u>TTL</u> .	December 20, 2023
<u>Best Practices for Understanding your AWS Billing and Usage Reports</u>	Added a new section that clarifies various usage types and the charges for those usage types in DynamoDB. For more information, see <u>Billing and usage reports</u> .	December 15, 2023

<u>Amazon DynamoDB zero-ETL integration with Amazon OpenSearch Service</u>	Amazon DynamoDB now supports zero-ETL integration with Amazon OpenSearch Service, which lets you perform a search on your DynamoDB data by automatically replicating and transforming it without custom code or infrastructure. For more information, see <u>DynamoDB zero-ETL integration with Amazon OpenSearch Service</u> .	November 28, 2023
<u>Migrating to DynamoDB from a relational database</u>	Created a <u>migration guide</u> to help users understand how to migrate to DynamoDB from a relational database.	November 27, 2023
<u>Generate sample data with NoSQL Workbench</u>	NoSQL Workbench for Amazon DynamoDB now supports creating data models directly from <u>sample data model templates</u> to help you design data schemas for your workloads. You can use this feature to get familiar with NoSQL data modeling best practices when building your applications on DynamoDB.	September 28, 2023

[Incremental Export to S3](#)

You can now export data that was inserted, updated or deleted, in small increments. With [incremental export](#), you can export changed data ranging from a few megabytes to terabytes with a few clicks in the AWS Management Console, an API call, or the AWS Command Line Interface.

September 26, 2023

[Data modeling for DynamoDB](#)

You can now learn more about [data modeling](#) with DynamoDB examples that focus on specific use cases, their access patterns, and step-by-step guidance in realizing those access patterns.

July 14, 2023

[Troubleshooting section](#)

You can now find [troubleshooting content](#) for latency and throttling issues that might occur in your DynamoDB tables.

March 13, 2023

[Deletion protection for Amazon DynamoDB](#)

Deletion protection is now available for Amazon DynamoDB tables in all AWS Regions. DynamoDB now makes it possible for you to protect your tables from accidental deletion when performing regular table management operations.

March 8, 2023

<u>AWS CloudFormation support for KDSD in global tables</u>	Amazon Kinesis Data Streams for DynamoDB now supports AWS CloudFormation for DynamoDB global tables, which means you can enable streaming to an Amazon Kinesis Data Streams on your DynamoDB global tables with CloudFormation templates.	February 15, 2023
<u>DynamoDB local supports 100 actions per transaction</u>	You can now perform up to 100 actions in a single transaction on DynamoDB local.	February 9, 2023
<u>Using the DynamoDB Well-Architected Lens to optimize your DynamoDB workload</u>	You can now use the <u>DynamoDB Well-Architected Lens</u> , a collection of design principles and guidance that you can use for designing well-architected DynamoDB workloads.	February 3, 2023
<u>PartiQL GovCloud availability</u>	<u>PartiQL—a SQL-compatible query language for Amazon DynamoDB</u> is now supported in AWS GovCloud (US-East) and AWS GovCloud (US-West)	December 21, 2022
<u>Single installation suite for NoSQL Workbench and DynamoDB local</u>	<u>NoSQL Workbench for DynamoDB</u> now includes a guided <u>DynamoDB local</u> installation process to streamline setting up your DynamoDB local development environment.	December 6, 2022

[Bulk import from S3](#)

Amazon DynamoDB now makes it easier for you to migrate and load data into new DynamoDB tables by [supporting bulk data imports from Amazon S3](#).

August 18, 2022

[Enhanced integration with Service Quotas](#)

[Service Quotas](#) now enables you to proactively manage your account and table quotas. You can view current values, set alarms for when your utilization of a quota exceeds a configurable threshold, and more.

June 15, 2022

[NoSQL Workbench adds table and GSI support](#)

You can now use NoSQL Workbench for table and global secondary index (GSI) [control plane operations](#) such as CreateTable, UpdateTable, and DeleteTable.

June 2, 2022

[Standard-infrequent access table class now available in China](#)

Amazon DynamoDB Standard-Infrequent Access table class is available in China Regions. Reduce your [DynamoDB costs by up to 60 percent](#), by using this new table class for tables that store infrequently accessed data.

April 18, 2022

<u>Increase in default service quotas and table management operations</u>	<u>DynamoDB increased the default quota for the number of tables per account and Region</u> from 256 to 2,500 tables, and increased the number of concurrent table management operations from 50 to 500.	March 9, 2022
<u>Optional limiting of items with PartiQL for DynamoDB</u>	DynamoDB can <u>limit the number of items processed in PartiQL</u> for DynamoDB operations as an optional parameter on each request.	March 8, 2022
<u>AWS Backup integration available in China (Beijing and Ningxia) Regions</u>	<u>AWS Backup</u> now integrates with DynamoDB in the China (Beijing and Ningxia) Regions. You can meet compliance and business continuity requirements more easily through enhanced backup features in AWS Backup, such as cross-account and cross-Region backups.	January 26, 2022
<u>Throughput capacity information through PartiQL API calls</u>	DynamoDB can return the throughput capacity consumed by <u>PartiQL API</u> calls to help you optimize your queries and throughput costs.	January 18, 2022

<u>AWS Backup integration</u>	DynamoDB now helps you meet compliance and business continuity requirements more easily through enhanced backup features in <u>AWS Backup</u> , such as cross-account and cross-Region backups.	November 24, 2021
<u>NoSQL Workbench import/export datasets in CSV</u>	<u>NoSQL Workbench for Amazon DynamoDB</u> now enables you to import and automatically populate sample data to help build and visualize your data models.	October 11, 2021
<u>Filter and retrieve Amazon DynamoDB Streams data-plane activity with AWS CloudTrail</u>	Amazon DynamoDB now provides you more granular control of audit logging by enabling you to <u>filter Streams data-plane API activity in AWS CloudTrail</u> .	September 22, 2021
<u>Updated console</u>	The <u>DynamoDB console</u> is now your default console to help you manage data more easily, simplify your common tasks, and give you faster access to resources and features.	August 25, 2021

[DAX SDK For Java 2.x is now available](#)

[DynamoDB Accelerator \(DAX\) SDK for Java 2.x](#) is now available and is compatible with the AWS SDK for Java 2.x. You can benefit from the latest features, including non-blocking I/O.

July 29, 2021

[NoSQL Workbench feature updates including control plane operations](#)

[NoSQL Workbench for Amazon DynamoDB](#) now helps you run frequent operations more easily to modify and access table data.

July 28, 2021

[DynamoDB global tables are now available in the Asia Pacific Region](#)

[DynamoDB global tables](#) are now available in the Asia Pacific (Osaka) Region. Replicate your DynamoDB tables automatically across your choice of 22 AWS Regions.

July 28, 2021

[DAX is now available in China](#)

[DynamoDB Accelerator \(DAX\)](#) is now available in the China (Beijing) Region, operated by Sinnet.

July 28, 2021

[DAX encryption in transit](#)

[DynamoDB Accelerator \(DAX\)](#) now supports encryption in transit of data between your applications and DAX clusters, and between the nodes within a DAX cluster.

July 24, 2021

[CloudFormation and CloudTrail integration](#)[Integration with AWS](#)

June 18, 2021

[CloudFormation](#) and security enhancements with CloudFormation data-plane logging.

[CloudFormation now supported for global tables](#)[Amazon DynamoDB global](#)

May 14, 2021

tables now support [AWS CloudFormation](#), which means you can create global tables and manage their settings with CloudFormation templates.

[Amazon DynamoDB local support for Java 2.x](#)[You now can use the AWS](#)

May 3, 2021

[SDK for Java 2.x](#) with [DynamoDB local](#), the downloadable version of Amazon DynamoDB. With DynamoDB local, you can develop and test applications by using a version of DynamoDB running in your local development environment without incurring any additional costs.

[NoSQL Workbench now supports AWS CloudFormation](#)[NoSQL Workbench for](#)

April 22, 2021

[Amazon DynamoDB](#) now supports [AWS CloudFormation](#), so you can manage and modify DynamoDB data models with CloudFormation templates. In addition, you now can configure table capacity settings in NoSQL Workbench.

[DynamoDB and AWS Amplify now feature integration](#)

[AWS Amplify](#) now orchestrates multiple DynamoDB global secondary index updates in a single deployment.

April 20, 2021

[AWS CloudTrail to log Amazon DynamoDB Streams data-plane APIs](#)

You now can use [AWS CloudTrail](#) to log [Amazon DynamoDB Streams](#) data-plane API activity, and monitor and investigate item-level changes in your DynamoDB tables.

April 20, 2021

[Amazon Kinesis Data Streams for Amazon DynamoDB now supports AWS CloudFormation](#)

[Amazon Kinesis Data Streams](#) for [Amazon DynamoDB](#) now supports AWS CloudFormation, which means you can enable streaming to an Amazon Kinesis data stream on your DynamoDB tables with CloudFormation templates. By streaming your DynamoDB data changes to a Kinesis data stream, you can build advanced streaming applications with AAmazon Kinesis services.

April 12, 2021

[Amazon Keyspaces now offers FIPS 140-2 compliant endpoints](#)

[Amazon Keyspaces \(for Apache Cassandra\) now offers Federal Information Processing Standards \(FIPS\) 140-2 compliant endpoints](#) to help you run highly regulated workloads more easily. FIPS 140-2 is a US and Canadian government standard that specifies the security requirements for cryptographic modules that protect sensitive information.

April 8, 2021

[Amazon EC2 T3 instances for DAX](#)

DAX now supports [Amazon EC2 T3 instance types](#), which provide a baseline level of CPU performance with the ability to burst above the baseline when needed.

February 15, 2021

[NoSQL Workbench for Amazon DynamoDB support for PartiQL](#)

You now can use the [NoSQL Workbench for DynamoDB](#) to build [PartiQL](#) statements for DynamoDB.

December 4, 2020

[PartiQL for DynamoDB](#)

You now can use [PartiQL for DynamoDB](#)—a SQL-compatible query language—to interact with DynamoDB tables and run ad hoc queries by using the AWS Management Console, AWS Command Line Interface, and DynamoDB APIs for PartiQL.

November 23, 2020

<u>Amazon Kinesis Data Streams for Amazon DynamoDB</u>	You now can use <u>Amazon Kinesis Data Streams for Amazon DynamoDB</u> with your DynamoDB tables to capture item-level changes and replicate them to a Kinesis data stream.	November 23, 2020
<u>DynamoDB table export</u>	You can now <u>export your DynamoDB tables to Amazon S3</u> , enabling you to perform analytics and complex queries on your data with services like Athena, AWS Glue, and Lake Formation.	November 9, 2020
<u>Support for empty values</u>	DynamoDB now supports empty values for non-key String and Binary attributes in DynamoDB tables. Empty value support gives you greater flexibility to use attributes for a broader set of use cases without having to transform such attributes before sending them to DynamoDB. List, Map, and Set data types also support empty String and Binary values.	May 18, 2020
<u>NoSQL Workbench for Amazon DynamoDB support for Linux</u>	NoSQL Workbench for Amazon DynamoDB is now supported on <u>Linux- Ubuntu, Fedora and Debian</u> .	May 4, 2020

[CloudWatch Contributor Insights for DynamoDB – GA](#)

[CloudWatch Contributor Insights for DynamoDB](#)

April 2, 2020

is generally available.
CloudWatch Contributor Insights for DynamoDB is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).

[Upgrading global tables](#)

You now can update your global tables from version 2017.11.29 to the [latest version of global tables \(2019.11.21\)](#), with a few clicks in the DynamoDB Console. By upgrading the version of your global tables, you can increase the availability of your DynamoDB tables easily by extending your existing tables into additional AWS Regions, with no table rebuilds required.

March 16, 2020

[NoSQL Workbench for Amazon DynamoDB – GA](#)

[NoSQL Workbench for Amazon DynamoDB](#) is generally available. Use the NoSQL Workbench to design, create, query, and manage DynamoDB tables.

March 2, 2020

<u>DAX cache cluster metrics</u>	DAX support for new <u>CloudWatch metrics</u> , that allow you to better understand your DAX cluster's performance.	February 6, 2020
<u>CloudWatch Contributor Insights for DynamoDB – Preview</u>	<u>CloudWatch Contributor Insights for DynamoDB</u> is a diagnostic tool that provides an at-a-glance view of your DynamoDB table's traffic trends and helps you identify your table's most frequently accessed keys (also known as hot keys).	November 26, 2019
<u>Adaptive capacity support for imbalanced workload</u>	Amazon DynamoDB adaptive capacity now <u>handles</u> imbalanced workloads better by isolating frequently accessed items automatically. If your application drives disproportionately high traffic to one or more items, DynamoDB will rebalance your partitions such that frequently accessed items do not reside on the same partition.	November 26, 2019
<u>Support for customer managed keys</u>	DynamoDB now <u>supports customer managed keys</u> , which means you can have full control over how you encrypt and manage the security of your DynamoDB data.	November 25, 2019

<u>NoSQL Workbench support for DynamoDB local (Downloadable Version)</u>	The NoSQL Workbench now supports connecting to <u>DynamoDB local (Downloadable Version)</u> to design, create, query, and manage DynamoDB tables.	November 8, 2019
<u>NoSQL Workbench - Preview</u>	This is the initial release of NoSQL Workbench for DynamoDB. Use NoSQL Workbench to design, create, query, and manage DynamoDB tables. For more information, see <u>NoSQL Workbench for Amazon DynamoDB (Preview)</u> .	September 16, 2019
<u>DAX adds support for transactional operations using Python and .NET</u>	DAX supports the <code>TransactWriteItems</code> and <code>TransactGetItems</code> APIs for applications written in Go, Java, .NET, Node.js, and Python. For more information, see <u>In-Memory Acceleration with DAX</u> .	February 14, 2019

<u>Amazon DynamoDB local (Downloadable Version) Updates</u>	DynamoDB local (Downloadable Version) now supports transactional APIs, on-demand read/write capacity, capacity reporting for read and write operations, and 20 global secondary indexes. For more information, see <u>Differences Between Downloadable DynamoDB and the DynamoDB Web Service</u> .	February 4, 2019
<u>Amazon DynamoDB On-Demand</u>	DynamoDB on-demand is a flexible billing option capable of serving thousands of requests per second without capacity planning. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use. For more information, see <u>Read/Write Capacity Mode</u> .	November 28, 2018
<u>Amazon DynamoDB Transactions</u>	DynamoDB transactions make coordinated, all-or-nothing changes to multiple items both within and across tables, providing atomicity, consistency, isolation, and durability (ACID) in DynamoDB. For more information, see <u>Amazon DynamoDB Transactions</u> .	November 27, 2018

[Amazon DynamoDB encrypts all customer data at rest](#)

DynamoDB encryption at rest provides an additional layer of data protection by securing your data in the encrypted table, including its primary key, local and global secondary indexes, streams, global tables, backups, and DAX clusters whenever the data is stored in durable media. For more information, see [Amazon DynamoDB Encryption at Rest](#).

[Use Amazon DynamoDB Local More Easily with the New Docker Image](#)

Now, it's easier to use DynamoDB local, the downloadable version of DynamoDB, to help you develop and test your DynamoDB applications by using the new DynamoDB local Docker image. For more information, see [DynamoDB \(Downloadable Version\) and Docker](#).

November 15, 2018

August 22, 2018

<u>DynamoDB Accelerator (DAX)</u>	DynamoDB Accelerator (DAX) now supports encryption at rest for new DAX clusters to help you accelerate reads from Amazon DynamoDB tables in security-sensitive applications that are subject to strict compliance and regulatory requirements. For more information, see <u>DAX Encryption at Rest</u> .	August 9, 2018
<u>DynamoDB point-in-time recovery (PITR) adds support for restoring deleted tables</u>	If you delete a table with point-in-time recovery enabled, a system backup is automatically created and is retained for 35 days (at no additional cost). For more information, see <u>Before You Begin Using Point In Time Recovery</u> .	August 7, 2018
<u>Updates now available over RSS</u>	You can now subscribe to the <u>RSS feed</u> (at the top left corner of this page) to receive notifications about updates to the Amazon DynamoDB Developer Guide.	July 3, 2018

Earlier updates

The following table describes important changes of the *DynamoDB Developer Guide* before July 3, 2018.

Change	Description	Date Changed
Go support for DAX	Now, you can enable microsecond read performance for Amazon DynamoDB tables in your applications written in the Go programming language by using the new DynamoDB Accelerator (DAX) SDK for Go. For more information, see DAX SDK for Go .	June 26, 2018
DynamoDB announces SLA	DynamoDB has released a public availability SLA. For more information, see Amazon DynamoDB Service Level Agreement .	June 19, 2018
DynamoDB continuous backups and Point-In-Time Recovery (PITR)	Point-in-time recovery helps protect your Amazon DynamoDB tables from accidental write or delete operations. With point in time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. DynamoDB maintains incremental backups of your	April 25, 2018

Change	Description	Date Changed
	<p>table. For more information, see Point-in-time recovery for DynamoDB.</p>	
Encryption at rest for DynamoDB	<p>DynamoDB encryption at rest, available for new DynamoDB tables, helps you secure your application data in Amazon DynamoDB tables by using AWS-managed encryption keys stored in AWS Key Management Service. For more information, see DynamoDB encryption at rest.</p>	February 8, 2018
DynamoDB Backup and restore	<p>On-Demand Backup allows you to create full backups of your DynamoDB tables data for data archival, helping you meet your corporate and governmental regulatory requirements. You can backup tables from a few megabytes to hundreds of terabytes of data, with no impact on performance and availability to your production applications. For more information, see Using On-Demand backup and restore for DynamoDB.</p>	November 29, 2017

Change	Description	Date Changed
DynamoDB Global tables	<p>Global Tables builds upon DynamoDB's global footprint to provide you with a fully managed, multi-region, and multi-active database that provides fast, local, read and write performance for massively scaled, global applications. Global Tables replicates your Amazon DynamoDB tables automatically across your choice of AWS regions. For more information, see Global tables - multi-Region replication for DynamoDB.</p>	November 29, 2017
Node.js support for DAX	<p>Node.js developers can leverage DynamoDB Accelerator (DAX), using the DAX client for Node.js. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX).</p>	October 5, 2017

Change	Description	Date Changed
VPC Endpoints for DynamoDB	<p>DynamoDB endpoints allow Amazon EC2 instances in your Amazon VPC to access DynamoDB, without exposure to the public Internet.</p> <p>Network traffic between your VPC and DynamoDB does not leave the Amazon network.</p> <p>For more information, see Using Amazon VPC endpoints to access DynamoDB.</p>	August 16, 2017
Auto Scaling for DynamoDB	<p>DynamoDB auto scaling eliminates the need for manually defining or adjusting provisioned throughput settings. Instead, DynamoDB auto scaling dynamically adjusts read and write capacity in response to actual traffic patterns. This allows a table or a global secondary index to increase its provisioned read and write capacity to handle sudden increases in traffic, without throttling.</p> <p>When the workload decreases, DynamoDB auto scaling decreases the provisioned capacity. For more information, see Managing throughput capacity automatically with DynamoDB auto scaling.</p>	June 14, 2017

Change	Description	Date Changed
DynamoDB Accelerator (DAX)	DynamoDB Accelerator (DAX) is a fully managed, highly available, in-memory cache for DynamoDB that delivers up to a 10x performance improvement – from milliseconds to microseconds – even at millions of requests per second. For more information, see In-memory acceleration with DynamoDB Accelerator (DAX) .	April 19, 2017
DynamoDB now supports automatic item expiration with Time to Live (TTL)	Amazon DynamoDB Time to Live (TTL) enables you to automatically delete expired items from your tables, at no additional cost. For more information, see Time to Live (TTL) .	Feb 27, 2017
DynamoDB now supports Cost Allocation Tags	You can now add tags to your Amazon DynamoDB tables for improved usage categorization and more granular cost reporting. For more information, see Adding tags and labels to resources .	Jan 19, 2017

Change	Description	Date Changed
New DynamoDB <code>DescribeLimits</code> API	<p>The <code>DescribeLimits</code> API returns the current provisioned capacity limits for your AWS account in a region, both for the region as a whole and for any one DynamoDB table that you create there. It lets you determine what your current account-level limits are so that you can compare them to the provisioned capacity that you are currently using, and have plenty of time to apply for an increase before you hit a limit.</p> <p>For more information, see Service, account, and table quotas in Amazon DynamoDB and the DescribeLimits in the <i>Amazon DynamoDB API Reference</i>.</p>	March 1, 2016

Change	Description	Date Changed
DynamoDB Console Update and New Terminology for Primary Key Attributes	<p>The DynamoDB management console has been redesigned to be more intuitive and easy to use. As part of this update, we are introducing new terminology for primary key attributes:</p> <ul style="list-style-type: none">• Partition Key—also known as a <i>hash attribute</i>.• Sort Key—also known as a <i>range attribute</i>. <p>Only the names have changed; the functionality remains the same.</p> <p>When you create a table or a secondary index, you can choose either a simple primary key (partition key only), or a composite primary key (partition key and sort key). The DynamoDB documentation has been updated to reflect these changes.</p>	November 12, 2015

Change	Description	Date Changed
Amazon DynamoDB Storage Backend for Titan	<p>The DynamoDB Storage Backend for Titan is a storage backend for the Titan graph database implemented on top of Amazon DynamoDB. When using the DynamoDB Storage Backend for Titan, your data benefits from the protection of DynamoDB, which runs across Amazon's high-availability data centers. The plugin is available for Titan version 0.4.4 (primarily for compatibility with existing applications) and Titan version 0.5.4 (recommended for new applications). Like other storage backends for Titan, this plugin supports the Tinkerpop stack (versions 2.4 and 2.5), including the Blueprints API and the Gremlin shell. For more information, see Amazon DynamoDB Storage Backend for Titan.</p>	August 20, 2015

Change	Description	Date Changed
DynamoDB Streams, Cross-Region Replication, and Scan with Strongly Consistent Reads	<p>DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table, and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near real time. For more information, see Change data capture for DynamoDB Streams and the DynamoDB Streams API Reference.</p> <p>DynamoDB cross-region replication is a client-side solution for maintaining identical copies of DynamoDB tables across different AWS regions, in near real time. You can use cross region replication to back up DynamoDB tables, or to provide low-latency access to data where users are geographically distributed.</p> <p>The DynamoDB Scan operation uses eventually consistent reads, by default. You can use strongly consistent reads instead by setting the Consisten</p>	July 16, 2015

Change	Description	Date Changed
	<p>Set the <code>Read</code> parameter to true.</p> <p>For more information, see Read consistency for scan and Scan in the Amazon DynamoDB API Reference.</p>	
AWS CloudTrail support for Amazon DynamoDB	<p>DynamoDB is now integrated with CloudTrail. CloudTrail captures API calls made from the DynamoDB console or from the DynamoDB API and tracks them in log files.</p> <p>For more information, see Logging DynamoDB operations by using AWS CloudTrail and the AWS CloudTrail User Guide.</p>	May 28, 2015

Change	Description	Date Changed
Improved support for Query expressions	<p>This release adds a new <code>KeyConditionExpression</code> parameter to the Query API. A Query reads items from a table or an index using primary key values. The <code>KeyConditionExpression</code> parameter is a string that identifies primary key names, and conditions to be applied to the key values; the Query retrieves only those items that satisfy the expression. The syntax of <code>KeyConditionExpression</code> is similar to that of other expression parameters in DynamoDB, and allows you to define substitution variables for names and values within the expression. For more information, see Query operations in DynamoDB.</p>	April 27, 2015

Change	Description	Date Changed
New comparison functions for conditional writes	<p>In DynamoDB, the <code>ConditionExpression</code> parameter determines whether a <code>PutItem</code>, <code>UpdateItem</code>, or <code>DeleteItem</code> succeeds: The item is written only if the condition evaluates to true. This release adds two new functions, <code>attribute_type</code> and <code>size</code>, for use with <code>ConditionExpression</code>. These functions allow you to perform a conditional writes based on the data type or size of an attribute in a table. For more information, see Condition expressions.</p>	April 27, 2015

Change	Description	Date Changed
Scan API for secondary indexes	<p>In DynamoDB, a Scan operation reads all of the items in a table, applies user-defined filtering criteria, and returns the selected data items to the application. This same capability is now available for secondary indexes too. To scan a local secondary index or a global secondary index, you specify the index name and the name of its parent table. By default, an index Scan returns all of the data in the index; you can use a filter expression to narrow the results that are returned to the application. For more information, see Working with scans in DynamoDB.</p>	February 10, 2015

Change	Description	Date Changed
Online operations for global secondary indexes	<p>Online indexing lets you add or remove global secondary indexes on existing tables. With online indexing, you do not need to define all of a table's indexes when you create a table; instead, you can add a new index at any time. Similarly, if you decide you no longer need an index, you can remove it at any time. Online indexing operations are non-blocking, so that the table remains available for read and write activity while indexes are being added or removed. For more information, see Managing Global Secondary Indexes.</p>	January 27, 2015

Change	Description	Date Changed
Document model support with JSON	<p>DynamoDB allows you to store and retrieve documents with full support for document models. New data types are fully compatible with the JSON standard and allow you to nest document elements within one another. You can use document path dereference operators to read and write individual elements, without having to retrieve the entire document. This release also introduces new expression parameters for specifying projections, conditions and update actions when reading or writing data items. To learn more about document model support with JSON, see Data types and Using expressions in DynamoDB.</p>	October 7, 2014
Flexible scaling	<p>For tables and global secondary indexes, you can increase provisioned read and write throughput capacity by any amount, provided that you stay within your per-table and per-account limits. For more information, see Service, account, and table quotas in Amazon DynamoDB.</p>	October 7, 2014

Change	Description	Date Changed
Larger item sizes	<p>The maximum item size in DynamoDB has increased from 64 KB to 400 KB.</p> <p>For more information, see Service, account, and table quotas in Amazon DynamoDB.</p>	October 7, 2014

Change	Description	Date Changed
Improved conditional expressions	<p>DynamoDB expands the operators that are available for conditional expressions, giving you additional flexibility for conditional puts, updates, and deletes. The newly available operators let you check whether an attribute does or does not exist, is greater than or less than a particular value, is between two values, begins with certain characters, and much more. DynamoDB also provides an optional <i>OR</i> operator for evaluating multiple conditions. By default, multiple conditions in an expression are ANDed together, so the expression is true only if all of its conditions are true. If you specify <i>OR</i> instead, the expression is true if one or more one conditions are true. For more information, see Working with items and attributes.</p>	April 24, 2014

Change	Description	Date Changed
Query filter	<p>The DynamoDB Query API supports a new <code>QueryFilter</code> option. By default, a Query finds items that match a specific partition key value and an optional sort key condition. A Query filter applies conditional expressions to other, non-key attributes; if a Query filter is present, then items that do not match the filter conditions are discarded before the Query results are returned to the application. For more information, see Query operations in DynamoDB.</p>	April 24, 2014

Change	Description	Date Changed
Data export and import using the AWS Management Console	<p>The DynamoDB console has been enhanced to simplify exports and imports of data in DynamoDB tables. With just a few clicks, you can set up an AWS Data Pipeline to orchestrate the workflow, and an Amazon Elastic MapReduce cluster to copy data from DynamoDB tables to an Amazon S3 bucket, or vice-versa. You can perform an export or import one time only, or set up a daily export job. You can even perform cross-region exports and imports, copying DynamoDB data from a table in one AWS region to a table in another AWS region. For more information, see Exporting and importing DynamoDB data using AWS Data Pipeline.</p>	March 6, 2014

Change	Description	Date Changed
Reorganized higher-level API documentation	<p>Information about the following APIs is now easier to find:</p> <ul style="list-style-type: none">• Java: DynamoDBMapper• .NET: Document model and object-persistence model <p>These higher-level APIs are now documented here: <u>Higher-level programming interfaces for DynamoDB.</u></p>	January 20, 2014

Change	Description	Date Changed
Global secondary indexes	DynamoDB adds support for global secondary indexes. As with a local secondary index, you define a global secondary index by using an alternate key from a table and then issuing Query requests on the index. Unlike a local secondary index, the partition key for the global secondary index does not have to be the same as that of the table; it can be any scalar attribute from the table. The sort key is optional and can also be any scalar table attribute. A global secondary index also has its own provisioned throughput settings, which are separate from those of the parent table. For more information, see Improving data access with secondary indexes and Using Global Secondary Indexes in DynamoDB .	December 12, 2013

Change	Description	Date Changed
Fine-grained access control	<p>DynamoDB adds support for fine-grained access control. This feature allows customers to specify which principals (users, groups, or roles) can access individual items and attributes in a DynamoDB table or secondary index. Applications can also leverage web identity federation to offload the task of user authentication to a third-party identity provider, such as Facebook, Google, or Login with Amazon. In this way, applications (including mobile apps) can handle very large numbers of users, while ensuring that no one can access DynamoDB data items unless they are authorized to do so. For more information, see Using IAM policy conditions for fine-grained access control.</p>	October 29, 2013

Change	Description	Date Changed
4 KB read capacity unit size	<p>The capacity unit size for reads has increased from 1 KB to 4 KB. This enhancement can reduce the number of provisioned read capacity units required for many applications. For example, prior to this release, reading a 10 KB item would consume 10 read capacity units; now that same 10 KB read would consume only 3 units (10 KB / 4 KB, rounded up to the next 4 KB boundary). For more information, see Read/write capacity mode.</p>	May 14, 2013
Parallel scans	<p>DynamoDB adds support for parallel Scan operations. Applications can now divide a table into logical segments and scan all of the segments simultaneously. This feature reduces the time required for a Scan to complete, and fully utilizes a table's provisioned read capacity. For more information, see Working with scans in DynamoDB.</p>	May 14, 2013

Change	Description	Date Changed
Local secondary indexes	<p>DynamoDB adds support for local secondary indexes. You can define sort key indexes on non-key attributes, and then use these indexes in Query requests. With local secondary indexes, applications can efficiently retrieve data items across multiple dimensions. For more information, see Local Secondary Indexes.</p>	April 18, 2013
New API version	<p>With this release, DynamoDB introduces a new API version (2012-08-10). The previous API version (2011-12-05) is still supported for backward compatibility with existing applications. New applications should use the new API version 2012-08-10. We recommend that you migrate your existing applications to API version 2012-08-10, since new DynamoDB features (such as local secondary indexes) will not be backported to the previous API version. For more information on API version 2012-08-10, see the Amazon DynamoDB API Reference.</p>	April 18, 2013

Change	Description	Date Changed
IAM policy variable support	<p>The IAM access policy language now supports variables. When a policy is evaluated, any policy variables are replaced with values that are supplied by context-based information from the authenticated user's session. You can use policy variables to define general purpose policies without explicitly listing all the components of the policy.</p> <p>For more information about policy variables, go to Policy Variables in the <i>AWS Identity and Access Management Using IAM</i> guide.</p> <p>For examples of policy variables in DynamoDB, see Identity and Access Management for Amazon DynamoDB.</p>	April 4, 2013
PHP code examples updated for AWS SDK for PHP version 2	<p>Version 2 of the AWS SDK for PHP is now available. The PHP code examples in the Amazon DynamoDB Developer Guide have been updated to use this new SDK.</p> <p>For more information on Version 2 of the SDK, see AWS SDK for PHP.</p>	January 23, 2013

Change	Description	Date Changed
New endpoint	DynamoDB expands to the AWS GovCloud (US-West) region. For the current list of service endpoints and protocols, see Regions and Endpoints .	December 3, 2012
New endpoint	DynamoDB expands to the South America (São Paulo) region. For the current list of supported endpoints, see Regions and Endpoints .	December 3, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Sydney) region. For the current list of supported endpoints, see Regions and Endpoints .	November 13, 2012

Change	Description	Date Changed
DynamoDB implements support for CRC32 checksums, supports strongly consistent batch gets, and removes restrictions on concurrent table updates.	<ul style="list-style-type: none">DynamoDB calculates a CRC32 checksum of the HTTP payload and returns this checksum in a new header, <code>x-amz-crc32</code>. For more information, see DynamoDB low-level API.By default, read operations performed by the <code>BatchGetItem</code> API are eventually consistent. A new <code>ConsistentRead</code> parameter in <code>BatchGetItem</code> lets you choose strong read consistency instead, for any table(s) in the request. For more information, see Description.This release removes some restrictions when updating many tables simultaneously. The total number of tables that can be updated at once is still 10; however, these tables can now be any combination of <code>CREATING</code>, <code>UPDATING</code> or <code>DELETING</code> status. Additionally, there is no longer any minimum amount for increasing or reducing the <code>ReadCapacityUnits</code> or <code>WriteCapacityUnits</code> for a	November 2, 2012

Change	Description	Date Changed
BatchWriteItem API support	<p>DynamoDB now supports a batch write API that enables you to put and delete several items from one or more tables in a single API call. For more information about the DynamoDB batch write API, see BatchWriteItem.</p> <p>For information about working with items and using batch write feature using AWS SDKs, see Working with items and attributes and .NET code examples.</p>	April 19, 2012
Documented more error codes	For more information, see Error handling with DynamoDB .	April 5, 2012
New endpoint	DynamoDB expands to the Asia Pacific (Tokyo) region. For the current list of supported endpoints, see Regions and Endpoints .	February 29, 2012

Change	Description	Date Changed
ReturnedItemCount metric added	A new metric, <code>ReturnedItemCount</code> , provides the number of items returned in the response of a Query or Scan operation for DynamoDB is available for monitoring through CloudWatch. For more information, see Logging and monitoring in DynamoDB .	February 24, 2012
Added examples for incrementing values	DynamoDB supports incrementing and decrementing existing numeric values. Examples show adding to existing values in the "Updating an Item" sections at: Working with items: Java. Working with items: .NET.	January 25, 2012
Initial product release	DynamoDB is introduced as a new service in Beta release.	January 18, 2012

Legacy features of DynamoDB

The following topics are legacy features that DynamoDB still supports. No active development is made on these features.

Topics

- [Global tables version 2017.11.29 \(Legacy\)](#)

Global tables version 2017.11.29 (Legacy)

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21 \(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

Topics

- [Global tables: How it works](#)
- [Best practices and requirements for managing global tables](#)
- [Creating a global table](#)
- [Monitoring global tables](#)
- [Using IAM with global tables](#)

Global tables: How it works

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21](#)

[\(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

The following sections help you understand the concepts and behavior of global tables in Amazon DynamoDB.

Global table concepts for Version 2017.11.29 (Legacy)

A *global table* is a collection of one or more replica tables, all owned by a single AWS account.

A *replica table* (or *replica*, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region.

The following is a conceptual overview of how a global table is created.

1. Create an ordinary DynamoDB table, with DynamoDB Streams enabled, in an AWS Region.
2. Repeat step 1 for every other Region where you want to replicate your data.
3. Define a DynamoDB global table based on the tables that you have created.

The AWS Management Console automates these tasks, so you can create a global table more quickly and easily. For more information, see [Creating a global table](#).

The resulting DynamoDB global table consists of multiple replica tables, one per Region, that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB automatically propagates the write to the other replica tables in the other AWS Regions.

Important

To keep your table data in sync, global tables automatically create the following attributes for every item:

- `aws:rep:deleting`
- `aws:rep:updatetime`

- `aws:rep:updateregion`

Do not modify these attributes or create attributes with the same name.

You can add replica tables to the global table so that it can be available in additional Regions. (To do this, the global table must be empty. In other words, none of the replica tables can have any data in them.)

You can also remove a replica table from a global table. If you do this, the table is completely disassociated from the global table. This newly independent table no longer interacts with the global table, and data is no longer propagated to or from the global table.

Warning

Be aware that removing a replica is not an atomic process. To ensure consistent behavior and known state, you may want to consider diverting your application write traffic away from the replica to be removed ahead of time. After removing it, wait until all replica region endpoints show the replica as disassociated before making any further writes to it as its own isolated regional table.

Common tasks

Common tasks for global tables work as follows.

You can delete a global table's replica table the same as a regular table. This will stop replication to that Region and delete the table copy kept in that Region. You cannot sever the replication and have copies of the table exist as independent entities.

Note

You won't be able to delete a source table until at least 24 hours after it's used to initiate a new Region. If you try to delete it too soon you will receive an error.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a "last writer wins" method

to reconcile between concurrent updates. All the replicas will agree on the latest update and converge toward a state in which they all have identical data.

Note

There are several ways to avoid conflicts, including:

- Using an IAM policy to only allow writes to the table in one region.
- Using an IAM policy to route users to only one region and keeping the other as an idle standby, or alternately routing odd users to one region and even users to another region.
- Avoiding the use of non-idempotent updates such as `Bookmark = Bookmark + 1`, in favor of static updates such as `Bookmark=25`.

Monitoring global tables

You can use CloudWatch to observe the metric `ReplicationLatency`. This metric tracks the elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source-Region and destination-Region pair. This is the only CloudWatch metric provided by Global Tables v2.

The latencies you will observe depend on the distance between your chosen Regions, as well as other variables. Latencies in the 0.5 to 2.5 second range for Regions can be common within the same geographic area.

Time To Live (TTL)

You can use Time To Live (TTL) to specify an attribute name whose value indicates the time of expiration for the item. This value is specified as a number in seconds since the start of the Unix epoch.

With global tables legacy version, the TTL deletes are not automatically replicated across other replicas. When an item is deleted via a TTL rule, that work is performed without consuming Write Units.

Be aware that if the source and target table have very low Provisioned write capacity, this may cause throttling as the TTL deletes require write capacity.

Streams and transactions with global tables

Each global table produces an independent stream based on all its writes, regardless of the origination point for those writes. You can choose to consume this DynamoDB stream in one Region or in all Regions independently.

If you want processed local writes but not replicated writes, you can add your own region attribute to each item. Then you can use a Lambda event filter to invoke only the Lambda for writes in the local Region.

Transactional operations provide ACID (Atomicity, Consistency, Isolation, and Durability) guarantees ONLY within the Region where the write is made originally. Transactions are not supported across Regions in global tables.

For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a `TransactWriteItems` operation in the US East (Ohio) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other Regions once they have been committed in the source Region.

Note

- Global tables “write around” DynamoDB Accelerator by updating DynamoDB directly. As a result DAX will not be aware it is holding stale data. The DAX cache will only be refreshed when the cache’s TTL expires.
- Tags on global tables do not automatically propagate.

Read and write throughput

Global tables manage read and write throughput in the following ways.

- The write capacity must be the same on all table instances across Regions.
- With Version 2019.11.21 (Current, if the table is set to support autoscaling or is in on-demand mode then the write capacity is automatically kept in sync. The current amount of write capacity provisioned in each Region will rise and fall independently within those synchronized autoscaling settings. If the table is placed in on-demand mode, that mode will sync to the other replicas.

- Read capacity can differ between Regions because reads may not be equal. When adding a global replica to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity for one replica, and this new setting is not transferred to the other side.

Consistency and conflict resolution

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within seconds.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. DynamoDB supports eventually consistent reads across Regions, but does not support strongly consistent reads across Regions. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads then it must perform all the strongly consistent reads and writes in the same Region. Otherwise, if you write to one Region and read from another Region then the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a *last writer wins* reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.

Availability and durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have been performed but have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region

that is now back online. All previously successful writes will be propagated eventually no matter how long the Region is isolated.

Best practices and requirements for managing global tables

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21 \(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

Topics

- [Global tables version](#)
- [Requirements for adding a new replica table](#)
- [Best practices and requirements for managing capacity](#)

Global tables version

There are two versions of DynamoDB global tables available: [Global Tables version 2019.11.21 \(Current\)](#) and [Global tables version 2017.11.29 \(Legacy\)](#). Customers should use Global Tables version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from Version 2017.11.29 (Legacy) to Version 2019.11.21 (Current), see [Upgrading global tables](#).

Requirements for adding a new replica table

If you want to add a new replica table to a global table, each of the following conditions must be true:

- The table must have the same partition key as all of the other replicas.
- The table must have the same write capacity management settings specified.
- The table must have the same name as all of the other replicas.
- The table must have DynamoDB Streams enabled, with the stream containing both the new and the old images of the item.
- None of the new or existing replica tables in the global table can contain any data.

If global secondary indexes are specified, the following conditions must also be met:

- The global secondary indexes must have the same name.
- The global secondary indexes must have the same partition key and sort key (if present).

Important

Write capacity settings should be set consistently across all of your global tables' replica tables and matching secondary indexes. To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see [UpdateGlobalTableSettings](#) in the [Amazon DynamoDB API Reference](#).

We strongly recommend that you enable auto scaling to manage provisioned write capacity settings. If you prefer to manage write capacity settings manually, you should provision equal replicated write capacity units to all of your replica tables. Also provision equal replicated write capacity units to matching secondary indexes across your global table. You must also have appropriate AWS Identity and Access Management (IAM) permissions. For more information, see [Using IAM with global tables](#).

Best practices and requirements for managing capacity

Consider the following when managing capacity settings for replica tables in DynamoDB.

Using DynamoDB auto scaling

Using DynamoDB auto scaling is the recommended way to manage throughput capacity settings for replica tables that use the provisioned mode. DynamoDB auto scaling automatically adjusts read capacity units (RCUs) and write capacity units (WCUs) for each replica table based upon your actual application workload. For more information, see [Managing throughput capacity automatically with DynamoDB auto scaling](#).

If you create your replica tables using the AWS Management Console, auto scaling is enabled by default for each replica table, with default auto scaling settings for managing read capacity units and write capacity units.

Changes to auto scaling settings for a replica table or secondary index made through the DynamoDB console or using the `UpdateGlobalTableSettings` call are applied to all of the replica tables and matching secondary indexes in the global table automatically. These changes overwrite any existing auto scaling settings. This ensures that provisioned write capacity settings are consistent across the replica tables and secondary indexes in your global table. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` calls, you should apply the change to each replica table and matching secondary index individually.

Note

If auto scaling doesn't satisfy your application's capacity changes (unpredictable workload), or if you don't want to configure its settings (target settings for minimum, maximum, or utilization threshold), you can use on-demand mode to manage capacity for your global tables. For more information, see [On-demand mode](#).

If you enable on-demand mode on a global table, your consumption of replicated write request units (rWCUs) will be consistent with how rWCUs are provisioned. For example, if you perform 10 writes to a local table that is replicated in two additional Regions, you will consume 60 write request units ($10 + 10 + 10 = 30$; $30 \times 2 = 60$). The consumed 60 write request units include the extra write consumed by global tables Version 2017.11.29 (Legacy) to update the `aws:rep:deleting`, `aws:rep:updatetime`, and `aws:rep:updateregion` attributes.

Managing capacity manually

If you decide not to use DynamoDB auto scaling, you must manually set the read capacity and write capacity settings on each replica table and secondary index.

The provisioned replicated write capacity units (rWCUs) on every replica table should be set to the total number of rWCUs needed for application writes across all Regions multiplied by two. This accommodates application writes that occur in the local Region and replicated application writes coming from other Regions. For example, suppose that you expect 5 writes per second to your replica table in Ohio and 5 writes per second to your replica table in N. Virginia. In this case, you should provision 20 rWCUs to each replica table ($5 + 5 = 10$; $10 \times 2 = 20$).

To update write capacity settings for your global table, we strongly recommend using the DynamoDB console or the `UpdateGlobalTableSettings` API operation. `UpdateGlobalTableSettings` applies changes to write capacity settings to all replica tables and matching secondary indexes in a global table automatically. If you use the `UpdateTable`, `RegisterScalableTarget`, or `PutScalingPolicy` operations, you should apply the change to each replica table and matching secondary index individually. For more information, see [Amazon DynamoDB API Reference](#).

Note

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions. For more information, see [Using IAM with global tables](#).

Creating a global table

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21 \(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics

- [Creating a global table \(console\)](#)
- [Creating a global table \(AWS CLI\)](#)

Creating a global table (console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/home>. For this example, choose the us-east-2 (US East Ohio) Region.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**.

For **Table name**, enter **Music**.

For **Primary key** enter **Artist**. Choose **Add sort key**, and enter **SongTitle**. (**Artist** and **SongTitle** should both be strings.)

To create the table, choose **Create**. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.

4. Choose the **Global Tables** tab, and then choose **Create a Version 2017.11.29 (Legacy) replica**.

The screenshot shows the 'Global tables' tab selected in the navigation bar. Under the 'Replicas' section, it says '(0)' and 'Other AWS Regions to which you have replicated this table.' There are three buttons: a 'C' icon, 'Delete replica', and 'Create replica'. Below this, it says 'No replicas' and has another 'Create replica' button. A note on the left says: 'You are using global tables version 2019.11.21. If you need to use version 2017.11.29 instead, choose "Create version 2017.11.29 replica." You can create a version 2017.11.29 replica only if you have an empty table.' To the right of this note is a button 'Create a version 2017.11.29 replica.', which is circled in red.

5. From the **Available replication Regions** dropdown, choose **US West (Oregon)**.

The console checks to ensure that a table with the same name doesn't exist in the selected Region. If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.

6. Choose **Create Replica**. This starts the table creation process in US West (Oregon);

The **Global Table** tab for the selected table (and for any other replica tables) shows that the table has been replicated in multiple Regions.

7. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **Europe (Frankfurt)** instead of **US West (Oregon)**.
8. You should still be using the AWS Management Console in the US East (Ohio) Region. Select **Items** in the left navigation menu, select the **Music** table, then choose **Create Item**.
 - a. For **Artist**, enter **item_1**.
 - b. For **SongTitle**, enter **Song Value 1**.
 - c. To write the item, choose **Create item**.

9. After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The Music table in Europe (Frankfurt) should contain the new item.
10. Repeat step 9 and choose **US West (Oregon)** to verify replication in that region.

Creating a global table (AWS CLI)

Follow these steps to create a global table Music using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (Music) in US East (Ohio), with DynamoDB Streams enabled (NEW_AND_OLD_IMAGES).

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
   AttributeName=Artist,AttributeType=S \
   AttributeName=SongTitle,AttributeType=S \
  --key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
    ReadCapacityUnits=10,WriteCapacityUnits=5 \
  --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
  --region us-east-2
```

2. Create an identical Music table in US East (N. Virginia).

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
   AttributeName=Artist,AttributeType=S \
   AttributeName=SongTitle,AttributeType=S \
  --key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
    ReadCapacityUnits=10,WriteCapacityUnits=5 \
  --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
  --region us-east-1
```

3. Create a global table (`Music`) consisting of replica tables in the `us-east-2` and `us-east-1` Regions.

```
aws dynamodb create-global-table \
--global-table-name Music \
--replication-group RegionName=us-east-2 RegionName=us-east-1 \
--region us-east-2
```

 **Note**

The global table name (`Music`) must match the name of each of the replica tables (`Music`). For more information, see [Best practices and requirements for managing global tables](#).

4. Create another table in Europe (Ireland), with the same settings as those you created in step 1 and step 2.

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
  AttributeName=Artist,AttributeType=S \
  AttributeName=SongTitle,AttributeType=S \
--key-schema \
  AttributeName=Artist,KeyType=HASH \
  AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
  ReadCapacityUnits=10,WriteCapacityUnits=5 \
--stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
--region eu-west-1
```

After doing this step, add the new table to the `Music` global table.

```
aws dynamodb update-global-table \
--global-table-name Music \
--replica-updates 'Create={RegionName=eu-west-1}' \
--region us-east-2
```

5. To verify that replication is working, add a new item to the `Music` table in US East (Ohio).

```
aws dynamodb put-item \
```

```
--table-name Music \
--item '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region us-east-2
```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

```
aws dynamodb get-item \
--table-name Music \
--key '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region us-east-1
```

```
aws dynamodb get-item \
--table-name Music \
--key '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region eu-west-1
```

Monitoring global tables

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21 \(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes `ReplicationLatency` and `PendingReplicationCount` metrics for each replica in the global table.

- **ReplicationLatency**—The elapsed time between when an updated item appears in the DynamoDB stream for one replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source- and destination-Region pair.

During normal operation, `ReplicationLatency` should be fairly constant. An elevated value for `ReplicationLatency` could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables *falling behind* because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in [Global tables version](#).

`ReplicationLatency` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

- **PendingReplicationCount**—The number of item updates that are written to one replica table, but that have not yet been written to another replica in the global table. `PendingReplicationCount` is expressed in number of items and is emitted for every source-and destination-Region pair.

During normal operation, `PendingReplicationCount` should be very low. If `PendingReplicationCount` increases for extended periods, investigate whether your replica tables' provisioned write capacity settings are sufficient for your current workload.

`PendingReplicationCount` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

For more information, see [DynamoDB Metrics and dimensions](#).

Using IAM with global tables

Important

This documentation is for version 2017.11.29 (Legacy) of global tables, which should be avoided for new global tables. Customers should use [Global Tables version 2019.11.21 \(Current\)](#) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy).

To determine which version you are using, see [Determining the global table version you are using](#). To update existing global tables from version 2017.11.29 (Legacy) to version 2019.11.21 (Current), see [Upgrading global tables](#).

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named [AWSServiceRoleForDynamoDBReplication](#), and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, then all of your global tables will no longer function.

For more information about service-linked roles, see [Using service-linked roles in the IAM User Guide](#).

To create and maintain global tables in DynamoDB, you must have the `dynamodb:CreateGlobalTable` permission to access each of the following:

- The replica table that you want to add.
- Each existing replica that's already part of the global table.
- The global table itself.

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling:DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The `application-autoscaling:DeleteScalingPolicy` and `application-autoscaling:DeregisterScalableTarget` permissions are required when updating an existing scaling policy. This is so that the global tables service can remove the old scaling policy before attaching the new policy to the table or secondary index.

If you use an IAM policy to manage access to one replica table, you should apply an identical policy to all other replicas within that global table. This practice helps you maintain a consistent permissions model across all of the replica tables.

By using identical IAM policies on all replicas in a global table, you can also avoid granting unintended read and write access to your global table data. For example, consider a user who

has access to only one replica in a global table. If that user can write to this replica, DynamoDB propagates the write to all of the other replica tables. In effect, the user can (indirectly) write to all of the other replicas in the global table. This scenario can be avoided by using consistent IAM policies on all of the replica tables.

Example: Allow the CreateGlobalTable action

Before you can add a replica to a global table, you must have the `dynamodb:CreateGlobalTable` permission for the global table and for each of its replica tables.

The following IAM policy grants permissions to allow the `CreateGlobalTable` action on all tables.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb:CreateGlobalTable"],  
            "Resource": "*"  
        }  
    ]  
}
```

Example: Allow the UpdateGlobalTable, DescribeLimits, application-autoscaling>DeleteScalingPolicy, and application-autoscaling:DeregisterScalableTarget actions

To update the settings (`UpdateGlobalTableSettings`) for a global table in DynamoDB, you must have the `dynamodb:UpdateGlobalTable`, `dynamodb:DescribeLimits`, `application-autoscaling>DeleteScalingPolicy`, and `application-autoscaling:DeregisterScalableTarget` permissions.

The following IAM policy grants permissions to allow the `UpdateGlobalTableSettings` action on all tables.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb:UpdateGlobalTableSettings"],  
            "Resource": "*"  
        }  
    ]  
}
```

```
        "Effect": "Allow",
        "Action": [
            "dynamodb:UpdateGlobalTable",
            "dynamodb:DescribeLimits",
            "application-autoscaling:DeleteScalingPolicy",
            "application-autoscaling:DeregisterScalableTarget"
        ],
        "Resource": "*"
    }
]
```

Example: Allow the CreateGlobalTable action for a specific global table name with replicas allowed in certain regions only

The following IAM policy grants permissions to allow the CreateGlobalTable action to create a global table named `Customers` with replicas in two Regions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb>CreateGlobalTable",
            "Resource": [
                "arn:aws:dynamodb::123456789012:global-table/Customers",
                "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
                "arn:aws:dynamodb:us-west-1:123456789012:table/Customers"
            ]
        }
    ]
}
```
