What is Amazon DynamoDB?

Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database so that you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling. DynamoDB also offers encryption at rest, which eliminates the operational burden and complexity involved in protecting sensitive data. For more information, see [DynamoDB encryption at rest](#).

With DynamoDB, you can create database tables that can store and retrieve any amount of data and serve any level of request traffic. You can scale up or scale down your tables' throughput capacity without downtime or performance degradation. You can use the AWS Management Console to monitor resource utilization and performance metrics.

DynamoDB provides on-demand backup capability. It allows you to create full backups of your tables for long-term retention and archival for regulatory compliance needs. For more information, see [Using On-Demand backup and restore for DynamoDB](#).

You can create on-demand backups and enable point-in-time recovery for your Amazon DynamoDB tables. Point-in-time recovery helps protect your tables from accidental write or delete operations. With point-in-time recovery, you can restore a table to any point in time during the last 35 days. For more information, see [Point-in-time recovery: How it works](#).

DynamoDB allows you to delete expired items from tables automatically to help you reduce storage usage and the cost of storing data that is no longer relevant. For more information, see [Time to Live \(TTL\)](#).

High availability and durability

DynamoDB automatically spreads the data and traffic for your tables over a sufficient number of servers to handle your throughput and storage requirements, while maintaining consistent and fast performance. All of your data is stored on solid-state disks (SSDs) and is automatically replicated across multiple Availability Zones in an AWS Region, providing built-in high availability and data durability. You can use global tables to keep DynamoDB tables in sync across AWS Regions. For more information, see [Global tables - multi-Region replication for DynamoDB](#).

Getting started with DynamoDB

We recommend that you begin by reading the following sections:

- [Amazon DynamoDB: How it works](#)—To learn essential DynamoDB concepts.
- [Setting up DynamoDB](#)—To learn how to set up DynamoDB (the downloadable version or the web service).
- [Accessing DynamoDB](#)—To learn how to access DynamoDB using the console, AWS CLI, or API.

From there, you have two options to quickly get started with DynamoDB:

- [Getting started with DynamoDB](#)
- [Getting started with DynamoDB and the AWS SDKs](#)

To learn more about application development, see the following:

- [Programming with DynamoDB and the AWS SDKs](#)
- [Working with tables, items, queries, scans, and indexes](#)

To quickly find recommendations for maximizing performance and minimizing throughput costs, see the following: [Best practices for designing and architecting with DynamoDB](#). To learn how to tag DynamoDB resources, see [Adding tags and labels to resources](#).

For best practices, how-to guides, and tools, see [Amazon DynamoDB resources](#).

You can use AWS Database Migration Service (AWS DMS) to migrate data from a relational database or MongoDB to a DynamoDB table. For more information, see the [AWS Database Migration Service User Guide](#).

To learn how to use MongoDB as a migration source, see [Using MongoDB as a source for AWS Database Migration Service](#). To learn how to use DynamoDB as a migration target, see [Using an Amazon DynamoDB database as a target for AWS Database Migration Service](#).

DynamoDB tutorials

The following tutorials present complete end-to-end procedures to familiarize yourself with DynamoDB. These tutorials can be completed with the free tier of AWS and will give you practical experience using DynamoDB.

- [Build an Application Using a NoSQL Key-Value Data Store](#)
- [Create and Query a NoSQL Table with Amazon DynamoDB](#)

Amazon DynamoDB: How it works

The following sections provide an overview of Amazon DynamoDB service components and how they interact.

After you read this introduction, try working through the [Creating tables and loading data for code examples in DynamoDB](#) section, which walks you through the process of creating sample tables, uploading data, and performing some basic database operations.

For language-specific tutorials with sample code, see [Getting started with DynamoDB and the AWS SDKs](#).

Topics

- [Cheat sheet for DynamoDB](#)
- [Core components of Amazon DynamoDB](#)
- [DynamoDB API](#)
- [Supported data types and naming rules in Amazon DynamoDB](#)
- [Read consistency](#)
- [Read/write capacity mode](#)
- [Table classes](#)
- [Partitions and data distribution](#)

Cheat sheet for DynamoDB

This cheat sheet provides a quick reference for working with Amazon DynamoDB and its various AWS SDKs.

Initial setup

1. [Sign up for AWS.](#)
2. [Get an AWS access key](#) to access DynamoDB programmatically.
3. [Configure your DynamoDB credentials.](#)

See also:

- [Setting up DynamoDB \(web service\)](#)
- [Getting started with DynamoDB](#)
- [Basic overview of core components](#)

SDK or CLI

Choose your preferred [SDK](#), or set up the [AWS CLI](#).

 **Note**

When you use the AWS CLI on Windows, a backslash (\) that is not inside a quote is treated as a carriage return. Also, you must escape any quotes and braces inside other quotes. For an example, see the **Windows** tab in "Create a table" in the next section.

Basic actions

This section provides code for basic DynamoDB tasks. For more information about these tasks, see [Getting started with DynamoDB and the AWS SDKs](#).

Create a table

Default

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
   AttributeName=Artist,AttributeType=S \
   AttributeName=SongTitle,AttributeType=S \
--key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
    ReadCapacityUnits=10,WriteCapacityUnits=5
```

Windows

```
aws dynamodb create-table ^
--table-name Music ^
--attribute-definitions ^
   AttributeName=Artist,AttributeType=S ^
   AttributeName=SongTitle,AttributeType=S ^
--key-schema ^
   AttributeName=Artist,KeyType=HASH ^
   AttributeName=SongTitle,KeyType=RANGE ^
--provisioned-throughput ^
    ReadCapacityUnits=10,WriteCapacityUnits=5
```

Write item to a table

```
aws dynamodb put-item \ --table-name Music \ --item file://item.json
```

Read item from a table

```
aws dynamodb get-item \ --table-name Music \ --item file://item.json
```

Delete item from a table

```
aws dynamodb delete-item --table-name Music --key file://key.json
```

Query a table

```
aws dynamodb query --table-name Music  
--key-condition-expression "ArtistName=:Artist and SongName=:Songtitle"
```

Delete a table

```
aws dynamodb delete-table --table-name Music
```

List table names

```
aws dynamodb list-tables
```

Naming rules

- All names must be encoded using UTF-8 and are case sensitive.
- Table names and index names must be between 3 and 255 characters long, and can contain only the following characters:
 - a-z
 - A-Z
 - 0-9
 - _(underscore)
 - -(dash)
 - .(dot)
- Attribute names must be at least one character long, and less than 64 KB in size.

For more information, see [Naming rules](#).

Service quota basics

Read and write units

- **Read capacity unit (RCU)** – One strongly consistent read per second, or two eventually consistent reads per second, for items up to 4 KB in size.
- **Write capacity unit (WCU)** – One write per second, for items up to 1 KB in size.

Table limits

- **Table size** – There is no practical limit on table size. Tables are unconstrained in terms of the number of items or the number of bytes.
- **Number of tables** – For any AWS account, there is an initial quota of 2,500 tables per AWS Region.
- **Page size limit for query and scan** – There is a limit of 1 MB per page, per query or scan. If your query parameters or scan operation on a table result in more than 1 MB of data, DynamoDB returns the initial matching items. It also returns a `LastEvaluatedKey` property that you can use in a new request to read the next page.

Indexes

- **Local secondary indexes (LSIs)** – You can define a maximum of five local secondary indexes. LSIs are primarily useful when an index must have strong consistency with the base table.
- **Global secondary indexes (GSIs)** – There is a default quota of 20 global secondary indexes per table.
- **Projected secondary index attributes per table** – You can project a total of up to 100 attributes into all of a table's local and global secondary indexes. This only applies to user-specified projected attributes.

Partition keys

- The minimum length of a partition key value is 1 byte. The maximum length is 2048 bytes.
- There is no practical limit on the number of distinct partition key values, for tables or for secondary indexes.
- The minimum length of a sort key value is 1 byte. The maximum length is 1024 bytes.
- In general, there is no practical limit on the number of distinct sort key values per partition key value. The exception is for tables with secondary indexes.

For more information on secondary indexes, partition key design, and sort key design, see [Best practices](#).

Limits for commonly used data types

- **String** – The length of a string is constrained by the maximum item size of 400 KB. Strings are Unicode with UTF-8 binary encoding.
- **Number** – A number can have up to 38 digits of precision, and can be positive, negative, or zero.
- **Binary** – The length of a binary is constrained by the maximum item size of 400 KB. Applications that work with binary attributes must encode the data in base64 encoding before sending it to DynamoDB.

For a full list of supported data types, see [Data types](#). For more information, also see [Service quotas](#).

Items, attributes, and expression parameters

The maximum item size in DynamoDB is 400 KB, which includes both attribute name binary length (UTF-8 length) and attribute value binary lengths (UTF-8 length). The attribute name counts towards the size limit.

There is no limit on the number of values in a list, map, or set, as long as the item that contains the values fits within the 400-KB item size limit.

For expression parameters, the maximum length of any expression string is 4 KB.

For more information about item size, attributes, and expression parameters, see [Service quotas](#).

Core components of Amazon DynamoDB

In DynamoDB, tables, items, and attributes are the core components that you work with. A *table* is a collection of *items*, and each item is a collection of *attributes*. DynamoDB uses primary keys to uniquely identify each item in a table and secondary indexes to provide more querying flexibility. You can use DynamoDB Streams to capture data modification events in DynamoDB tables.

There are limits in DynamoDB. For more information, see [Service, account, and table quotas in Amazon DynamoDB](#).

The following video will give you an introductory look at tables, items, and attributes.

Tables, items, and attributes

Tables, items, and attributes

The following are the basic DynamoDB components:

- **Tables** – Similar to other database systems, DynamoDB stores data in tables. A *table* is a collection of data. For example, see the example table called *People* that you could use to store personal contact information about friends, family, or anyone else of interest. You could also have a *Cars* table to store information about vehicles that people drive.
- **Items** – Each table contains zero or more items. An *item* is a group of attributes that is uniquely identifiable among all of the other items. In a *People* table, each item represents a person. For a *Cars* table, each item represents one vehicle. Items in DynamoDB are similar in many ways to rows, records, or tuples in other database systems. In DynamoDB, there is no limit to the number of items you can store in a table.
- **Attributes** – Each item is composed of one or more attributes. An *attribute* is a fundamental data element, something that does not need to be broken down any further. For example, an item in a *People* table contains attributes called *PersonID*, *LastName*, *FirstName*, and so on. For a *Department* table, an item might have attributes such as *DepartmentID*, *Name*, *Manager*, and so on. Attributes in DynamoDB are similar in many ways to fields or columns in other database systems.

The following diagram shows a table named *People* with some example items and attributes.

People

```
{  
    "PersonID": 101,  
    "LastName": "Smith",  
    "FirstName": "Fred",  
    "Phone": "555-4321"  
}  
  
{  
    "PersonID": 102,  
    "LastName": "Jones",  
    "FirstName": "Mary",  
    "Address": {  
        "Street": "123 Main",  
        "City": "Anytown",  
        "State": "OH",  
        "ZIPCode": 12345  
    }  
}  
  
{  
    "PersonID": 103,  
    "LastName": "Stephens",  
    "FirstName": "Howard",  
    "Address": {  
        "Street": "123 Main",  
        "City": "London",  
        "PostalCode": "ER3 5K8"  
    },  
    "FavoriteColor": "Blue"  
}
```

Note the following about the *People* table:

- Each item in the table has a unique identifier, or primary key, that distinguishes the item from all of the others in the table. In the *People* table, the primary key consists of one attribute (*PersonID*).
- Other than the primary key, the *People* table is schemaless, which means that neither the attributes nor their data types need to be defined beforehand. Each item can have its own distinct attributes.
- Most of the attributes are *scalar*, which means that they can have only one value. Strings and numbers are common examples of scalars.

- Some of the items have a nested attribute (*Address*). DynamoDB supports nested attributes up to 32 levels deep.

The following is another example table named *Music* that you could use to keep track of your music collection.

```
Music

{
    "Artist": "No One You Know",
    "SongTitle": "My Dog Spot",
    "AlbumTitle": "Hey Now",
    "Price": 1.98,
    "Genre": "Country",
    "CriticRating": 8.4
}

{
    "Artist": "No One You Know",
    "SongTitle": "Somewhere Down The Road",
    "AlbumTitle": "Somewhat Famous",
    "Genre": "Country",
    "CriticRating": 8.4,
    "Year": 1984
}

{
    "Artist": "The Acme Band",
    "SongTitle": "Still in Love",
    "AlbumTitle": "The Buck Starts Here",
    "Price": 2.47,
    "Genre": "Rock",
    "PromotionInfo": {
        "RadioStationsPlaying": [
            "KHCR",
            "KQBX",
            "WTNR",
            "WJJH"
        ],
        "TourDates": {
            "Seattle": "20150622",
            "London": "20150703"
        }
    }
}
```

```
        "Cleveland": "20150630"
    },
    "Rotation": "Heavy"
}
}

{
    "Artist": "The Acme Band",
    "SongTitle": "Look Out, World",
    "AlbumTitle": "The Buck Starts Here",
    "Price": 0.99,
    "Genre": "Rock"
}
```

Note the following about the *Music* table:

- The primary key for *Music* consists of two attributes (*Artist* and *SongTitle*). Each item in the table must have these two attributes. The combination of *Artist* and *SongTitle* distinguishes each item in the table from all of the others.
- Other than the primary key, the *Music* table is schemaless, which means that neither the attributes nor their data types need to be defined beforehand. Each item can have its own distinct attributes.
- One of the items has a nested attribute (*PromotionInfo*), which contains other nested attributes. DynamoDB supports nested attributes up to 32 levels deep.

For more information, see [Working with tables and data in DynamoDB](#).

Primary key

When you create a table, in addition to the table name, you must specify the primary key of the table. The primary key uniquely identifies each item in the table, so that no two items can have the same key.

DynamoDB supports two different kinds of primary keys:

- **Partition key** – A simple primary key, composed of one attribute known as the *partition key*.

DynamoDB uses the partition key's value as input to an internal hash function. The output from the hash function determines the partition (physical storage internal to DynamoDB) in which the item will be stored.

In a table that has only a partition key, no two items can have the same partition key value.

The *People* table described in [Tables, items, and attributes](#) is an example of a table with a simple primary key (*PersonID*). You can access any item in the *People* table directly by providing the *PersonId* value for that item.

- **Partition key and sort key** – Referred to as a *composite primary key*, this type of key is composed of two attributes. The first attribute is the *partition key*, and the second attribute is the *sort key*.

DynamoDB uses the partition key value as input to an internal hash function. The output from the hash function determines the partition (physical storage internal to DynamoDB) in which the item will be stored. All items with the same partition key value are stored together, in sorted order by sort key value.

In a table that has a partition key and a sort key, it's possible for multiple items to have the same partition key value. However, those items must have different sort key values.

The *Music* table described in [Tables, items, and attributes](#) is an example of a table with a composite primary key (*Artist* and *SongTitle*). You can access any item in the *Music* table directly, if you provide the *Artist* and *SongTitle* values for that item.

A composite primary key gives you additional flexibility when querying data. For example, if you provide only the value for *Artist*, DynamoDB retrieves all of the songs by that artist. To retrieve only a subset of songs by a particular artist, you can provide a value for *Artist* along with a range of values for *SongTitle*.

Note

The partition key of an item is also known as its *hash attribute*. The term *hash attribute* derives from the use of an internal hash function in DynamoDB that evenly distributes data items across partitions, based on their partition key values.

The sort key of an item is also known as its *range attribute*. The term *range attribute* derives from the way DynamoDB stores items with the same partition key physically close together, in sorted order by the sort key value.

Each primary key attribute must be a scalar (meaning that it can hold only a single value). The only data types allowed for primary key attributes are string, number, or binary. There are no such restrictions for other, non-key attributes.

Secondary indexes

You can create one or more secondary indexes on a table. A *secondary index* lets you query the data in the table using an alternate key, in addition to queries against the primary key. DynamoDB doesn't require that you use indexes, but they give your applications more flexibility when querying your data. After you create a secondary index on a table, you can read data from the index in much the same way as you do from the table.

DynamoDB supports two kinds of indexes:

- Global secondary index – An index with a partition key and sort key that can be different from those on the table.
- Local secondary index – An index that has the same partition key as the table, but a different sort key.

In DynamoDB, global secondary indexes (GSIs) are indexes that span the entire table, allowing you to query across all partition keys. Local secondary indexes (LSIs) are indexes that have the same partition key as the base table but a different sort key.

Each table in DynamoDB has a quota of 20 global secondary indexes (default quota) and 5 local secondary indexes.

In the example *Music* table shown previously, you can query data items by *Artist* (partition key) or by *Artist* and *SongTitle* (partition key and sort key). What if you also wanted to query the data by *Genre* and *AlbumTitle*? To do this, you could create an index on *Genre* and *AlbumTitle*, and then query the index in much the same way as you'd query the *Music* table.

The following diagram shows the example *Music* table, with a new index called *GenreAlbumTitle*. In the index, *Genre* is the partition key and *AlbumTitle* is the sort key.

Music Table	GenreAlbumTitle
<pre>"SongTitle": "My Dog Spot", "AlbumTitle": "Hey Now", "Price": 1.98, "Genre": "Country", "CriticRating": 8.4 }</pre>	<pre>"AlbumTitle": "Hey Now", "Artist": "No One You Know", "SongTitle": "My Dog Spot" }</pre>
<pre>{ "Artist": "No One You Know", "SongTitle": "Somewhere Down The Road", "AlbumTitle": "Somewhat Famous", "Genre": "Country", "CriticRating": 8.4, "Year": 1984 }</pre>	<pre>{ "Genre": "Country", "AlbumTitle": "Somewhat Famous", "Artist": "No One You Know", "SongTitle": "Somewhere Down The Road" }</pre>

Music Table	<i>GenreAlbumTitle</i>
<pre>{ "Artist": "The Acme Band", "SongTitle": "Still in Love", "AlbumTitle": "The Buck Starts Here", "Price": 2.47, "Genre": "Rock", "PromotionInfo": { "RadioStationsPlaying": ["KHCR", "KQBX", "WTNR", "WJJH"], "TourDates": { "Seattle": "20150622", "Cleveland": "20150630" }, "Rotation": "Heavy" } }</pre>	<pre>{ "Genre": "Rock", "AlbumTitle": "The Buck Starts Here", "Artist": "The Acme Band", "SongTitle": "Still In Love" }</pre>
<pre>{ "Artist": "The Acme Band", "SongTitle": "Look Out, World", "AlbumTitle": "The Buck Starts Here", "Price": 0.99, "Genre": "Rock" }</pre>	<pre>{ "Genre": "Rock", "AlbumTitle": "The Buck Starts Here", "Artist": "The Acme Band", "SongTitle": "Look Out, World" }</pre>

Note the following about the *GenreAlbumTitle* index:

- Every index belongs to a table, which is called the *base table* for the index. In the preceding example, *Music* is the base table for the *GenreAlbumTitle* index.
- DynamoDB maintains indexes automatically. When you add, update, or delete an item in the base table, DynamoDB adds, updates, or deletes the corresponding item in any indexes that belong to that table.
- When you create an index, you specify which attributes will be copied, or *projected*, from the base table to the index. At a minimum, DynamoDB projects the key attributes from the base table into the index. This is the case with *GenreAlbumTitle*, where only the key attributes from the *Music* table are projected into the index.

You can query the *GenreAlbumTitle* index to find all albums of a particular genre (for example, all *Rock* albums). You can also query the index to find all albums within a particular genre that have certain album titles (for example, all *Country* albums with titles that start with the letter H).

For more information, see [Improving data access with secondary indexes](#).

DynamoDB Streams

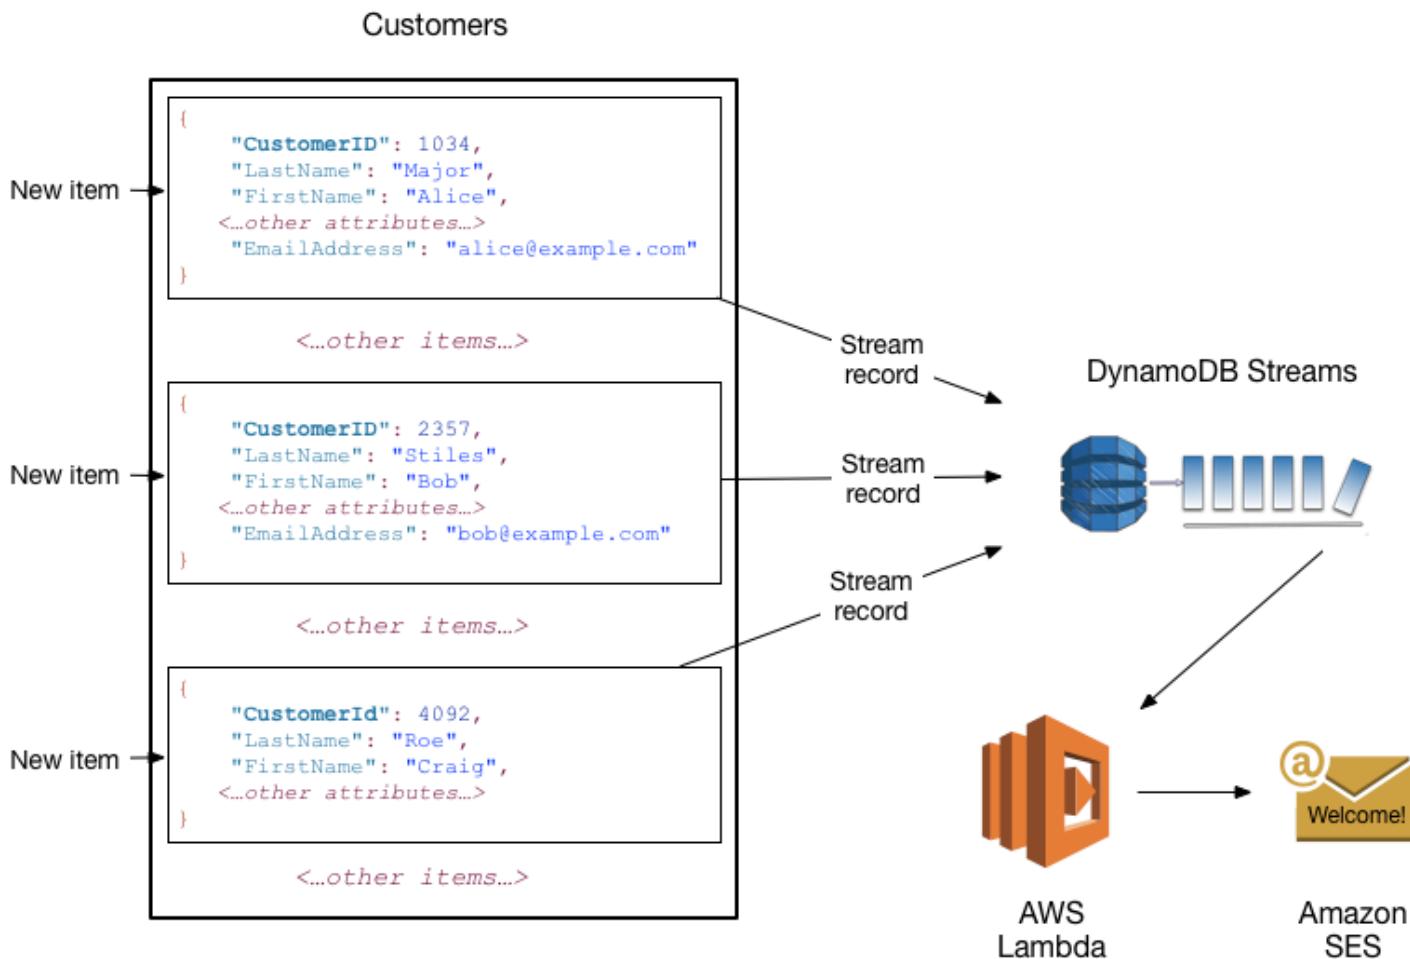

DynamoDB Streams is an optional feature that captures data modification events in DynamoDB tables. The data about these events appear in the stream in near-real time, and in the order that the events occurred.

Each event is represented by a *stream record*. If you enable a stream on a table, DynamoDB Streams writes a stream record whenever one of the following events occurs:

- A new item is added to the table: The stream captures an image of the entire item, including all of its attributes.
- An item is updated: The stream captures the "before" and "after" image of any attributes that were modified in the item.
- An item is deleted from the table: The stream captures an image of the entire item before it was deleted.

Each stream record also contains the name of the table, the event timestamp, and other metadata. Stream records have a lifetime of 24 hours; after that, they are automatically removed from the stream.

You can use DynamoDB Streams together with AWS Lambda to create a *trigger*—code that runs automatically whenever an event of interest appears in a stream. For example, consider a *Customers* table that contains customer information for a company. Suppose that you want to send a "welcome" email to each new customer. You could enable a stream on that table, and then associate the stream with a Lambda function. The Lambda function would run whenever a new stream record appears, but only process new items added to the *Customers* table. For any item that has an *EmailAddress* attribute, the Lambda function would invoke Amazon Simple Email Service (Amazon SES) to send an email to that address.

Note

In this example, the last customer, Craig Roe, will not receive an email because he doesn't have an *EmailAddress*.

In addition to triggers, DynamoDB Streams enables powerful solutions such as data replication within and across AWS Regions, materialized views of data in DynamoDB tables, data analysis using Kinesis materialized views, and much more.

For more information, see [Change data capture for DynamoDB Streams](#).

DynamoDB API

To work with Amazon DynamoDB, your application must use a few simple API operations. The following is a summary of these operations, organized by category.

Note

For a full list of the API operations, see the [Amazon DynamoDB API Reference](#).

Topics

- [Control plane](#)
- [Data plane](#)
- [DynamoDB Streams](#)
- [Transactions](#)

Control plane

Control plane operations let you create and manage DynamoDB tables. They also let you work with indexes, streams, and other objects that are dependent on tables.

- [CreateTable](#) – Creates a new table. Optionally, you can create one or more secondary indexes, and enable DynamoDB Streams for the table.
- [DescribeTable](#) – Returns information about a table, such as its primary key schema, throughput settings, and index information.
- [ListTables](#) – Returns the names of all of your tables in a list.
- [UpdateTable](#) – Modifies the settings of a table or its indexes, creates or removes new indexes on a table, or modifies DynamoDB Streams settings for a table.
- [DeleteTable](#) – Removes a table and all of its dependent objects from DynamoDB.

Data plane

Data plane operations let you perform create, read, update, and delete (also called *CRUD*) actions on data in a table. Some of the data plane operations also let you read data from a secondary index.

You can use [PartiQL - a SQL-compatible query language for Amazon DynamoDB](#), to perform these CRUD operations or you can use DynamoDB's classic CRUD APIs that separates each operation into a distinct API call.

PartiQL - A SQL-compatible query language

- `ExecuteStatement` – Reads multiple items from a table. You can also write or update a single item from a table. When writing or updating a single item, you must specify the primary key attributes.
- `BatchExecuteStatement` – Writes, updates or reads multiple items from a table. This is more efficient than `ExecuteStatement` because your application only needs a single network round trip to write or read the items.

Classic APIs

Creating data

- `PutItem` – Writes a single item to a table. You must specify the primary key attributes, but you don't have to specify other attributes.
- `BatchWriteItem` – Writes up to 25 items to a table. This is more efficient than calling `PutItem` multiple times because your application only needs a single network round trip to write the items.

Reading data

- `GetItem` – Retrieves a single item from a table. You must specify the primary key for the item that you want. You can retrieve the entire item, or just a subset of its attributes.
- `BatchGetItem` – Retrieves up to 100 items from one or more tables. This is more efficient than calling `GetItem` multiple times because your application only needs a single network round trip to read the items.
- `Query` – Retrieves all items that have a specific partition key. You must specify the partition key value. You can retrieve entire items, or just a subset of their attributes. Optionally, you can apply

a condition to the sort key values so that you only retrieve a subset of the data that has the same partition key. You can use this operation on a table, provided that the table has both a partition key and a sort key. You can also use this operation on an index, provided that the index has both a partition key and a sort key.

- **Scan** – Retrieves all items in the specified table or index. You can retrieve entire items, or just a subset of their attributes. Optionally, you can apply a filtering condition to return only the values that you are interested in and discard the rest.

Updating data

- **UpdateItem** – Modifies one or more attributes in an item. You must specify the primary key for the item that you want to modify. You can add new attributes and modify or remove existing attributes. You can also perform conditional updates, so that the update is only successful when a user-defined condition is met. Optionally, you can implement an atomic counter, which increments or decrements a numeric attribute without interfering with other write requests.

Deleting data

- **DeleteItem** – Deletes a single item from a table. You must specify the primary key for the item that you want to delete.
- **BatchWriteItem** – Deletes up to 25 items from one or more tables. This is more efficient than calling `DeleteItem` multiple times because your application only needs a single network round trip to delete the items.

 **Note**

You can use `BatchWriteItem` to both create data and delete data.

DynamoDB Streams

DynamoDB Streams operations let you enable or disable a stream on a table, and allow access to the data modification records contained in a stream.

- **ListStreams** – Returns a list of all your streams, or just the stream for a specific table.
- **DescribeStream** – Returns information about a stream, such as its Amazon Resource Name (ARN) and where your application can begin reading the first few stream records.

- `GetShardIterator` – Returns a *shard iterator*, which is a data structure that your application uses to retrieve the records from the stream.
- `GetRecords` – Retrieves one or more stream records, using a given shard iterator.

Transactions

Transactions provide atomicity, consistency, isolation, and durability (ACID) enabling you to maintain data correctness in your applications more easily.

You can use [PartiQL - a SQL-compatible query language for Amazon DynamoDB](#), to perform transactional operations or you can use DynamoDB's classic CRUD APIs that separates each operation into a distinct API call.

PartiQL - A SQL-compatible query language

- `ExecuteTransaction` – A batch operation that allows CRUD operations to multiple items both within and across tables with a guaranteed all-or-nothing result.

Classic APIs

- `TransactWriteItems` – A batch operation that allows Put, Update, and Delete operations to multiple items both within and across tables with a guaranteed all-or-nothing result.
- `TransactGetItems` – A batch operation that allows Get operations to retrieve multiple items from one or more tables.

Supported data types and naming rules in Amazon DynamoDB

This section describes the Amazon DynamoDB naming rules and the various data types that DynamoDB supports. There are limits that apply to data types. For more information, see [Data types](#).

Topics

- [Naming rules](#)
- [Data types](#)
- [Data type descriptors](#)

Naming rules

Tables, attributes, and other objects in DynamoDB must have names. Names should be meaningful and concise—for example, names such as *Products*, *Books*, and *Authors* are self-explanatory.

The following are the naming rules for DynamoDB:

- All names must be encoded using UTF-8, and are case-sensitive.
- Table names and index names must be between 3 and 255 characters long, and can contain only the following characters:
 - a-z
 - A-Z
 - 0-9
 - _ (underscore)
 - - (dash)
 - . (dot)
- Attribute names must be at least one character long and less than 64 KB in size. It is considered best practice to keep your attribute names as short as possible. This helps reduce read request units consumed, as attribute names are included in metering of storage and throughput usage.

The following are the exceptions. These attribute names must be no greater than 255 characters long:

- Secondary index partition key names
- Secondary index sort key names
- The names of any user-specified projected attributes (applicable only to local secondary indexes)

Reserved words and special characters

DynamoDB has a list of reserved words and special characters. For a complete list, see [Reserved words in DynamoDB](#). Also, the following characters have special meaning in DynamoDB: # (hash) and : (colon).

Although DynamoDB allows you to use these reserved words and special characters for names, we recommend that you avoid doing so because you have to define placeholder variables whenever

you use these names in an expression. For more information, see [Expression attribute names in DynamoDB](#).

Data types

DynamoDB supports many different data types for attributes within a table. They can be categorized as follows:

- **Scalar Types** – A scalar type can represent exactly one value. The scalar types are number, string, binary, Boolean, and null.
 - **Document Types** – A document type can represent a complex structure with nested attributes, such as what you would find in a JSON document. The document types are list and map.
 - **Set Types** – A set type can represent multiple scalar values. The set types are string set, number set, and binary set.

When you create a table or a secondary index, you must specify the names and data types of each primary key attribute (partition key and sort key). Furthermore, each primary key attribute must be defined as type string, number, or binary.

DynamoDB is a NoSQL database and is *schemaless*. This means that other than the primary key attributes, you don't have to define any attributes or data types when you create tables. By comparison, relational databases require you to define the names and data types of each column when you create a table.

The following are descriptions of each data type, along with examples in JSON format.

Scalar types

The scalar types are number, string, binary, Boolean, and null.

Number

Numbers can be positive, negative, or zero. Numbers can have up to 38 digits of precision. Exceeding this results in an exception. If you need greater precision than 38 digits, you can use strings.

In DynamoDB, numbers are represented as variable length. Leading and trailing zeroes are trimmed.

All numbers are sent across the network to DynamoDB as strings to maximize compatibility across languages and libraries. However, DynamoDB treats them as number type attributes for mathematical operations.

You can use the number data type to represent a date or a timestamp. One way to do this is by using epoch time—the number of seconds since 00:00:00 UTC on 1 January 1970. For example, the epoch time 1437136300 represents 12:31:40 PM UTC on 17 July 2015.

For more information, see http://en.wikipedia.org/wiki/Unix_time.

String

Strings are Unicode with UTF-8 binary encoding. The minimum length of a string can be zero, if the attribute is not used as a key for an index or table, and is constrained by the maximum DynamoDB item size limit of 400 KB.

The following additional constraints apply to primary key attributes that are defined as type string:

- For a simple primary key, the maximum length of the first attribute value (the partition key) is 2048 bytes.
- For a composite primary key, the maximum length of the second attribute value (the sort key) is 1024 bytes.

DynamoDB collates and compares strings using the bytes of the underlying UTF-8 string encoding. For example, "a" (0x61) is greater than "A" (0x41), and "ż" (0xC2BF) is greater than "z" (0x7A).

You can use the string data type to represent a date or a timestamp. One way to do this is by using ISO 8601 strings, as shown in these examples:

- 2016-02-15
- 2015-12-21T17:42:34Z
- 20150311T122706Z

For more information, see http://en.wikipedia.org/wiki/ISO_8601.

Note

Unlike conventional relational databases, DynamoDB does not natively support a date and time data type. It can be useful instead to store date and time data as a number data type, using Unix epoch time.

Binary

Binary type attributes can store any binary data, such as compressed text, encrypted data, or images. Whenever DynamoDB compares binary values, it treats each byte of the binary data as unsigned.

The length of a binary attribute can be zero, if the attribute is not used as a key for an index or table, and is constrained by the maximum DynamoDB item size limit of 400 KB.

If you define a primary key attribute as a binary type attribute, the following additional constraints apply:

- For a simple primary key, the maximum length of the first attribute value (the partition key) is 2048 bytes.
- For a composite primary key, the maximum length of the second attribute value (the sort key) is 1024 bytes.

Your applications must encode binary values in base64-encoded format before sending them to DynamoDB. Upon receipt of these values, DynamoDB decodes the data into an unsigned byte array and uses that as the length of the binary attribute.

The following example is a binary attribute, using base64-encoded text.

```
dGhpcyB0ZXh0IGlzIGJhc2U2NC1lbmNvZGVk
```

Boolean

A Boolean type attribute can store either `true` or `false`.

Null

Null represents an attribute with an unknown or undefined state.

Document types

The document types are list and map. These data types can be nested within each other, to represent complex data structures up to 32 levels deep.

There is no limit on the number of values in a list or a map, as long as the item containing the values fits within the DynamoDB item size limit (400 KB).

An attribute value can be an empty string or empty binary value if the attribute is not used for a table or index key. An attribute value cannot be an empty set (string set, number set, or binary set), however, empty lists and maps are allowed. Empty string and binary values are allowed within lists and maps. For more information, see [Attributes](#).

List

A list type attribute can store an ordered collection of values. Lists are enclosed in square brackets:

[...]

A list is similar to a JSON array. There are no restrictions on the data types that can be stored in a list element, and the elements in a list element do not have to be of the same type.

The following example shows a list that contains two strings and a number.

```
FavoriteThings: ["Cookies", "Coffee", 3.14159]
```

Note

DynamoDB lets you work with individual elements within lists, even if those elements are deeply nested. For more information, see [Using expressions in DynamoDB](#).

Map

A map type attribute can store an unordered collection of name-value pairs. Maps are enclosed in curly braces: { ... }

A map is similar to a JSON object. There are no restrictions on the data types that can be stored in a map element, and the elements in a map do not have to be of the same type.

Maps are ideal for storing JSON documents in DynamoDB. The following example shows a map that contains a string, a number, and a nested list that contains another map.

```
{  
    Day: "Monday",  
    UnreadEmails: 42,  
    ItemsOnMyDesk: [  
        "Coffee Cup",  
        "Telephone",  
        {  
            Pens: { Quantity : 3},  
            Pencils: { Quantity : 2},  
            Erasers: { Quantity : 1}  
        }  
    ]  
}
```

Note

DynamoDB lets you work with individual elements within maps, even if those elements are deeply nested. For more information, see [Using expressions in DynamoDB](#).

Sets

DynamoDB supports types that represent sets of number, string, or binary values. All the elements within a set must be of the same type. For example, a Number Set can only contain numbers and a String Set can only contain strings.

There is no limit on the number of values in a set, as long as the item containing the values fits within the DynamoDB item size limit (400 KB).

Each value within a set must be unique. The order of the values within a set is not preserved. Therefore, your applications must not rely on any particular order of elements within the set. DynamoDB does not support empty sets, however, empty string and binary values are allowed within a set.

The following example shows a string set, a number set, and a binary set:

```
["Black", "Green", "Red"]  
  
[42.2, -19, 7.5, 3.14]  
  
["U3Vubnk=", "UmFpbnk=", "U25vd3k="]
```

Data type descriptors

The low-level DynamoDB API protocol uses *Data type descriptors* as tokens that tell DynamoDB how to interpret each attribute.

The following is a complete list of DynamoDB data type descriptors:

- **S** – String
- **N** – Number
- **B** – Binary
- **BOOL** – Boolean
- **NULL** – Null
- **M** – Map
- **L** – List
- **SS** – String Set
- **NS** – Number Set
- **BS** – Binary Set

Read consistency

Amazon DynamoDB reads data from tables, local secondary indexes (LSIs), global secondary indexes (GSIs), and streams. For more information, see [Core components of Amazon DynamoDB](#). Both tables and LSIs provide two read consistency options: *eventually consistent* (default) and *strongly consistent* reads. All reads from GSIs and streams are eventually consistent.

When your application writes data to a DynamoDB table and receives an HTTP 200 response (OK), that means the write completed successfully and has been durably persisted. DynamoDB provides *read-committed* isolation and ensures that read operations always return committed values for an item. The read will never present a view to the item from a write which did not ultimately succeed. Read-committed isolation does not prevent modifications of the item immediately after the read operation.

Eventually Consistent Reads

Eventually consistent is the default read consistent model for all read operations. When issuing eventually consistent reads to a DynamoDB table or an index, the responses may not reflect the

results of a recently completed write operation. If you repeat your read request after a short time, the response should eventually return the more recent item. Eventually consistent reads are supported on tables, local secondary indexes, and global secondary indexes. Also note that all reads from a DynamoDB stream are also eventually consistent.

Eventually consistent reads are half the cost of strongly consistent reads. For more information, see [Amazon DynamoDB pricing](#).

Strongly Consistent Reads

Read operations such as `GetItem`, `Query`, and `Scan` provide an optional `ConsistentRead` parameter. If you set `ConsistentRead` to true, DynamoDB returns a response with the most up-to-date data, reflecting the updates from all prior write operations that were successful. Strongly consistent reads are only supported on tables and local secondary indexes. Strongly consistent reads from a global secondary index or a DynamoDB stream are not supported.

Global tables read consistency

DynamoDB also supports [global tables](#) for multi-active and multi-Region replication. A global table is composed of multiple replica tables in different AWS Regions. Any change made to any item in any replica table is replicated to all the other replicas within the same global table, typically within a second, and are eventually consistent. For more information, see [Consistency and conflict resolution](#).

Read/write capacity mode

Amazon DynamoDB has two read/write capacity modes for processing reads and writes on your tables:

- On-demand
- Provisioned (default, free-tier eligible)

The read/write capacity mode controls how you are charged for read and write throughput and how you manage capacity. You can set the read/write capacity mode when creating a table or you can change it later.

Secondary indexes inherit the read/write capacity mode from the base table. For more information, see [Considerations when changing read/write Capacity Mode](#).

The following video will give you an introductory look at table capacity modes.

[Table capacity modes](#)

For more information on best practices for optimizing costs of your DynamoDB tables, see [Optimizing costs on DynamoDB tables](#).

Topics

- [On-demand mode](#)
- [Provisioned mode](#)

On-demand mode

Amazon DynamoDB on-demand is a flexible billing option capable of serving thousands of requests per second without capacity planning. DynamoDB on-demand offers pay-per-request pricing for read and write requests so that you pay only for what you use.

When you choose on-demand mode, DynamoDB instantly accommodates your workloads as they ramp up or down to any previously reached traffic level. If a workload's traffic level hits a new peak, DynamoDB adapts rapidly to accommodate the workload. Tables that use on-demand mode deliver the same single-digit millisecond latency, service-level agreement (SLA) commitment, and security that DynamoDB already offers. You can choose on-demand for both new and existing tables and you can continue using the existing DynamoDB APIs without changing code.

On-demand mode is a good option if any of the following are true:

- You create new tables with unknown workloads.
- You have unpredictable application traffic.
- You prefer the ease of paying for only what you use.

The request rate is only limited by the DynamoDB throughput default table quotas, but it can be raised upon request. For more information, see [Throughput default quotas](#).

To get started with on-demand, you can create or update a table to use on-demand mode. For more information, see [Basic operations on DynamoDB tables](#).

Tables can be switched to on-demand mode once every 24 hours. Creating a table as on-demand also starts this 24-hour period. Tables can be returned to provisioned capacity mode at any time. For issues to consider when switching read/write capacity modes, see [Considerations when changing read/write Capacity Mode](#).

Topics

- [Read request units and write request units](#)
- [Peak traffic and scaling properties](#)
- [Initial throughput for on-demand capacity mode](#)
- [Table behavior while switching read/write capacity mode](#)
- [Pre-warming a table for on-demand capacity mode](#)

Read request units and write request units

For on-demand mode tables, you don't need to specify how much read and write throughput you expect your application to perform. DynamoDB charges you for the reads and writes that your application performs on your tables in terms of read request units and write request units.

DynamoDB read requests can be either strongly consistent, eventually consistent, or transactional.

- A *strongly consistent* read request of an item up to 4 KB requires one read request unit.
- An *eventually consistent* read request of an item up to 4 KB requires one-half read request unit.
- A *transactional* read request of an item up to 4 KB requires two read request units.

If you need to read an item that is larger than 4 KB, DynamoDB needs additional read request units. The total number of read request units required depends on the item size, and whether you want an eventually consistent or strongly consistent read. For example, if your item size is 8 KB, you require 2 read request units to sustain one strongly consistent read, 1 read request unit if you choose eventually consistent reads, or 4 read request units for a transactional read request.

To learn more about DynamoDB read consistency models, see [Read consistency](#).

Important

If you perform a read operation on an item that *does not exist*, DynamoDB will still consume read throughput as outlined above.

One *write request unit* represents one write for an item up to 1 KB in size. If you need to write an item that is larger than 1 KB, DynamoDB needs to consume additional write request units. Transactional write requests require 2 write request units to perform one write for items up to 1

KB. The total number of write request units required depends on the item size. For example, if your item size is 2 KB, you require 2 write request units to sustain one write request or 4 write request units for a transactional write request.

For detailed pricing examples and to estimate costs using the pricing calculator, see [Amazon DynamoDB Pricing](#).

Peak traffic and scaling properties

DynamoDB tables using on-demand capacity mode automatically adapt to your application's traffic volume. On-demand capacity mode instantly accommodates up to double the previous peak traffic on a table. For example, if your application's traffic pattern varies between 25,000 and 50,000 strongly consistent reads per second where 50,000 reads per second is the previous traffic peak, on-demand capacity mode instantly accommodates sustained traffic of up to 100,000 reads per second. If your application sustains traffic of 100,000 reads per second, that peak becomes your new previous peak, enabling subsequent traffic to reach up to 200,000 reads per second.

If you need more than double your previous peak on table, DynamoDB automatically allocates more capacity as your traffic volume increases to help ensure that your workload does not experience throttling. However, throttling can occur if you exceed double your previous peak within 30 minutes. For example, if your application's traffic pattern varies between 25,000 and 50,000 strongly consistent reads per second where 50,000 reads per second is the previously reached traffic peak, DynamoDB recommends spacing your traffic growth over at least 30 minutes before driving more than 100,000 reads per second.

Initial throughput for on-demand capacity mode

If you recently switched an existing table to on-demand capacity mode for the first time, or if you created a new table with on-demand capacity mode enabled, the table has the following previous peak settings, even though the table has not served traffic previously using on-demand capacity mode:

Following are examples of possible scenarios.

- **A provisioned table configured as 100 WCU and 100 RCU.** When this table is switched to on-demand for the first time, DynamoDB will ensure it is scaled out to instantly sustain at least 4,000 write units/sec and 12,000 read units/sec.
- **A provisioned table configured as 8,000 WCU and 24,000 RCU.** When this table is switched to on-demand, it will continue to be able to sustain at least 8,000 write units/sec and 24,000 read units/sec at any time.

- **A provisioned table configured with 8,000 WCU and 24,000 RCU, that consumed 6,000 write units/sec and 18,000 read units/sec for a sustained period.** When this table is switched to on-demand, it will continue to be able to sustain at least 8,000 write units/sec and 24,000 read units/sec. The previous traffic may further allow the table to sustain much higher levels of traffic without throttling.
- **A table previously provisioned with 10,000 WCU and 10,000 RCU, but currently provisioned with 10 RCU and 10 WCU.** When this table is switched to on-demand, it will be able to sustain at least 10,000 write units/sec and 10,000 read units/sec.

Table behavior while switching read/write capacity mode

When you switch a table from provisioned capacity mode to on-demand capacity mode, DynamoDB makes several changes to the structure of your table and partitions. This process can take several minutes. During the switching period, your table delivers throughput that is consistent with the previously provisioned write capacity unit and read capacity unit amounts. When switching from on-demand capacity mode back to provisioned capacity mode, your table delivers throughput consistent with the previous peak reached when the table was set to on-demand capacity mode.

Pre-warming a table for on-demand capacity mode

With on-demand capacity mode, the requests can burst up to double the previous peak on the table. Note that throttling can occur if the requests spikes to more than double the default capacity or the previously achieved peak request rate within 30 minutes. One solution is to pre-warm the tables to the anticipated peak capacity of the spike.

To pre-warm the table, follow these steps:

1. Make sure to check your account limits and confirm that you can reach the desired capacity in provisioned mode.
2. If you're pre-warming a table that already exists, or a new table in on-demand mode, start this process at least 24 hours before the anticipated peak. You can only switch between on-demand and provisioned mode once per 24 hours.
3. To pre-warm a table that's currently in on-demand mode, switch it to provisioned mode and wait until the table is active. Then go to the next step.

If you want to pre-warm a new table that's in provisioned mode, or has already been in provisioned mode for 24 hours, you can proceed to the next step without waiting.

4. Set the table's write throughput to the desired peak value, and keep it there for several minutes. You will incur cost from this high volume of throughput until you switch back to on-demand.
5. Switch to On-Demand capacity mode. This should sustain the provisioned throughput capacity values.

Provisioned mode

If you choose provisioned mode, you specify the number of reads and writes per second that you require for your application. You can use auto scaling to adjust your table's provisioned capacity automatically in response to traffic changes. This helps you govern your DynamoDB use to stay at or below a defined request rate in order to obtain cost predictability.

Provisioned mode is a good option if any of the following are true:

- You have predictable application traffic.
- You run applications whose traffic is consistent or ramps gradually.
- You can forecast capacity requirements to control costs.

Read capacity units and write capacity units

For provisioned mode tables, you specify throughput capacity in terms of read capacity units (RCUs) and write capacity units (WCUs):

- One *read capacity unit* represents one strongly consistent read per second, or two eventually consistent reads per second, for an item up to 4 KB in size. Transactional read requests require two read capacity units to perform one read per second for items up to 4 KB. If you need to read an item that is larger than 4 KB, DynamoDB must consume additional read capacity units. The total number of read capacity units required depends on the item size, and whether you want an eventually consistent or strongly consistent read. For example, if your item size is 8 KB, you require 2 read capacity units to sustain one strongly consistent read per second, 1 read capacity unit if you choose eventually consistent reads, or 4 read capacity units for a transactional read request. For more information, see [Capacity unit consumption for reads](#).

 **Note**

To learn more about DynamoDB read consistency models, see [Read consistency](#).

- One *write capacity unit* represents one write per second for an item up to 1 KB in size. If you need to write an item that is larger than 1 KB, DynamoDB must consume additional write capacity units. Transactional write requests require 2 write capacity units to perform one write per second for items up to 1 KB. The total number of write capacity units required depends on the item size. For example, if your item size is 2 KB, you require 2 write capacity units to sustain one write request per second or 4 write capacity units for a transactional write request. For more information, see [Capacity unit consumption for writes](#).

 **Important**

When calling `DescribeTable` on an on-demand table, read capacity units and write capacity units are set to 0.

If your application reads or writes larger items (up to the DynamoDB maximum item size of 400 KB), it will consume more capacity units.

For example, suppose that you create a provisioned table with 6 read capacity units and 6 write capacity units. With these settings, your application could do the following:

- Perform strongly consistent reads of up to 24 KB per second ($4 \text{ KB} \times 6 \text{ read capacity units}$).
- Perform eventually consistent reads of up to 48 KB per second (twice as much read throughput).
- Perform transactional read requests of up to 12 KB per second.
- Write up to 6 KB per second ($1 \text{ KB} \times 6 \text{ write capacity units}$).
- Perform transactional write requests of up to 3 KB per second.

For more information, see [Managing settings on DynamoDB provisioned capacity tables](#).

Provisioned throughput is the maximum amount of capacity that an application can consume from a table or index. If your application exceeds your provisioned throughput capacity on a table or index, it is subject to request throttling.

Throttling prevents your application from consuming too many capacity units.

When a request is throttled, it fails with an HTTP 400 code (Bad Request) and a `ProvisionedThroughputExceededException`. The AWS SDKs have built-in support for retrying throttled requests (see [Error retries and exponential backoff](#)), so you do not need to write

this logic yourself. For more information on how to resolve throttling issues, see [Why is my Amazon DynamoDB table being throttled?](#)

You can use the AWS Management Console to monitor your provisioned and actual throughput, and to modify your throughput settings if necessary.

For detailed pricing examples and to estimate costs using the pricing calculator, see [Amazon DynamoDB Pricing](#).

DynamoDB auto scaling

DynamoDB auto scaling actively manages throughput capacity for tables and global secondary indexes. With auto scaling, you define a range (upper and lower limits) for read and write capacity units. You also define a target utilization percentage within that range. DynamoDB auto scaling seeks to maintain your target utilization, even as your application workload increases or decreases.

With DynamoDB auto scaling, a table or a global secondary index can increase its provisioned read and write capacity to handle sudden increases in traffic, without request throttling. When the workload decreases, DynamoDB auto scaling can decrease the throughput so that you don't pay for unused provisioned capacity.

Note

If you use the AWS Management Console to create a table or a global secondary index, DynamoDB auto scaling is enabled by default.

You can manage auto scaling settings at any time by using the console, the AWS CLI, or one of the AWS SDKs.

For more information, see [Managing throughput capacity automatically with DynamoDB auto scaling](#).

Reserved capacity

As a DynamoDB customer, you can purchase *reserved capacity* in advance for tables that use the DynamoDB Standard table class, as described at [Amazon DynamoDB Pricing](#). With reserved capacity, you pay a one-time upfront fee and commit to a minimum provisioned usage level over a period of time. Your reserved capacity is billed at the hourly reserved capacity rate. By reserving your read and write capacity units ahead of time, you realize significant cost savings on your

provisioned capacity costs. Any capacity that you provision in excess of your reserved capacity is billed at standard provisioned capacity rates.

Reserved capacity discounts are applied first to the account that purchased the reserved capacity. Any unused reserved capacity discount is then applied to other accounts in the same AWS organization as the purchasing account. You can turn off Reserved Instance discount sharing on the **Preferences** page on the Billing and Cost Management console. For more information, see [Turning off reserved instances and Savings Plans discount sharing](#).

Note

Reserved capacity is not available for replicated write capacity units. Reserved Capacity is applied only to the region in which it was purchased. Reserved capacity is also not available for tables using the DynamoDB Standard-IA table class or on-demand capacity mode.

To manage reserved capacity, go to the [DynamoDB console](#) and choose **Reserved Capacity**.

Note

You can prevent users from viewing or purchasing reserved capacity, while still allowing them to access the rest of the console. For more information, see "Grant Permissions to Prevent Purchasing of Reserved Capacity Offerings" in [Identity and Access Management for Amazon DynamoDB](#).

For more information about specific pricing see [Amazon DynamoDB Pricing](#).

Table classes

DynamoDB offers two table classes designed to help you optimize for cost. The DynamoDB Standard table class is the default, and is recommended for the vast majority of workloads. The DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class is optimized for tables where storage is the dominant cost. For example, tables that store infrequently accessed data, such as application logs, old social media posts, e-commerce order history, and past gaming achievements, are good candidates for the Standard-IA table class. See [Amazon DynamoDB Pricing](#) for pricing details.

Every DynamoDB table is associated with a table class (DynamoDB Standard by default). All secondary indexes associated with the table use the same table class. Each table class offers different pricing for data storage as well as for read and write requests. You can select the most cost-effective table class for your table based on its storage and throughput usage patterns.

The choice of a table class is not permanent—you can change this setting using the AWS Management Console, AWS CLI, or AWS SDK. DynamoDB also supports managing your table class using AWS CloudFormation for single-Region tables and global tables. To learn more about selecting your table class, see [Considerations when choosing a table class](#).

Partitions and data distribution

Amazon DynamoDB stores data in partitions. A *partition* is an allocation of storage for a table, backed by solid state drives (SSDs) and automatically replicated across multiple Availability Zones within an AWS Region. Partition management is handled entirely by DynamoDB—you never have to manage partitions yourself.

When you create a table, the initial status of the table is CREATING. During this phase, DynamoDB allocates sufficient partitions to the table so that it can handle your provisioned throughput requirements. You can begin writing and reading table data after the table status changes to ACTIVE.

DynamoDB allocates additional partitions to a table in the following situations:

- If you increase the table's provisioned throughput settings beyond what the existing partitions can support.
- If an existing partition fills to capacity and more storage space is required.

Partition management occurs automatically in the background and is transparent to your applications. Your table remains available throughout and fully supports your provisioned throughput requirements.

For more details, see [Partition key design](#).

Global secondary indexes in DynamoDB are also composed of partitions. The data in a global secondary index is stored separately from the data in its base table, but index partitions behave in much the same way as table partitions.

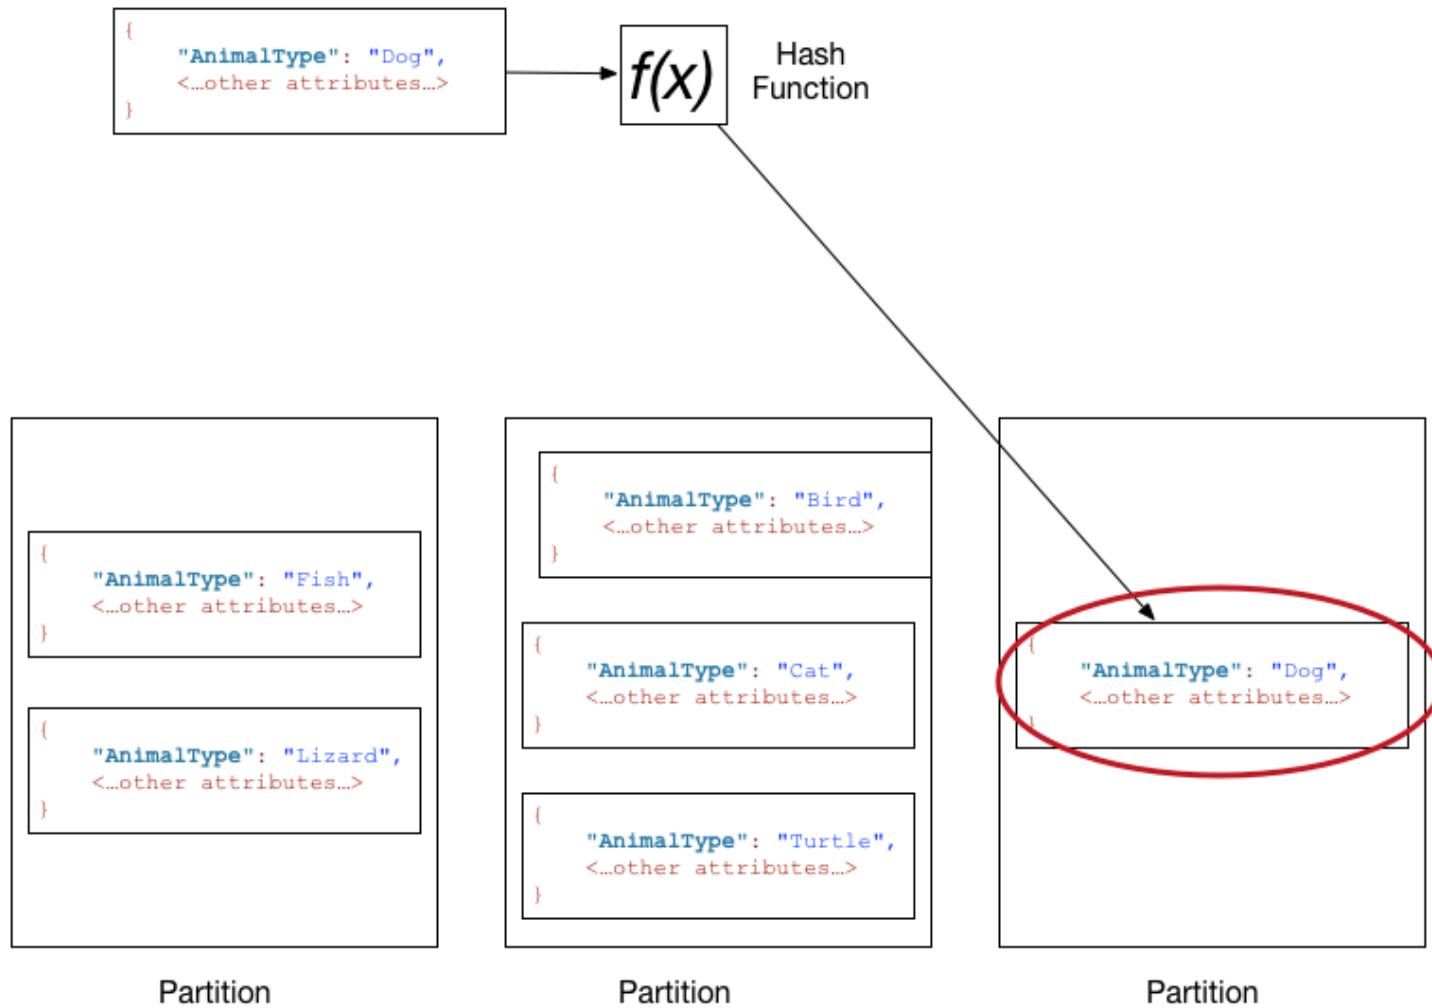

Data distribution: Partition key

If your table has a simple primary key (partition key only), DynamoDB stores and retrieves each item based on its partition key value.

To write an item to the table, DynamoDB uses the value of the partition key as input to an internal hash function. The output value from the hash function determines the partition in which the item will be stored.

To read an item from the table, you must specify the partition key value for the item. DynamoDB uses this value as input to its hash function, yielding the partition in which the item can be found.

The following diagram shows a table named *Pets*, which spans multiple partitions. The table's primary key is *AnimalType* (only this key attribute is shown). DynamoDB uses its hash function to determine where to store a new item, in this case based on the hash value of the string *Dog*. Note that the items are not stored in sorted order. Each item's location is determined by the hash value of its partition key.

Note

DynamoDB is optimized for uniform distribution of items across a table's partitions, no matter how many partitions there may be. We recommend that you choose a partition key that can have a large number of distinct values relative to the number of items in the table.

Data distribution: Partition key and sort key

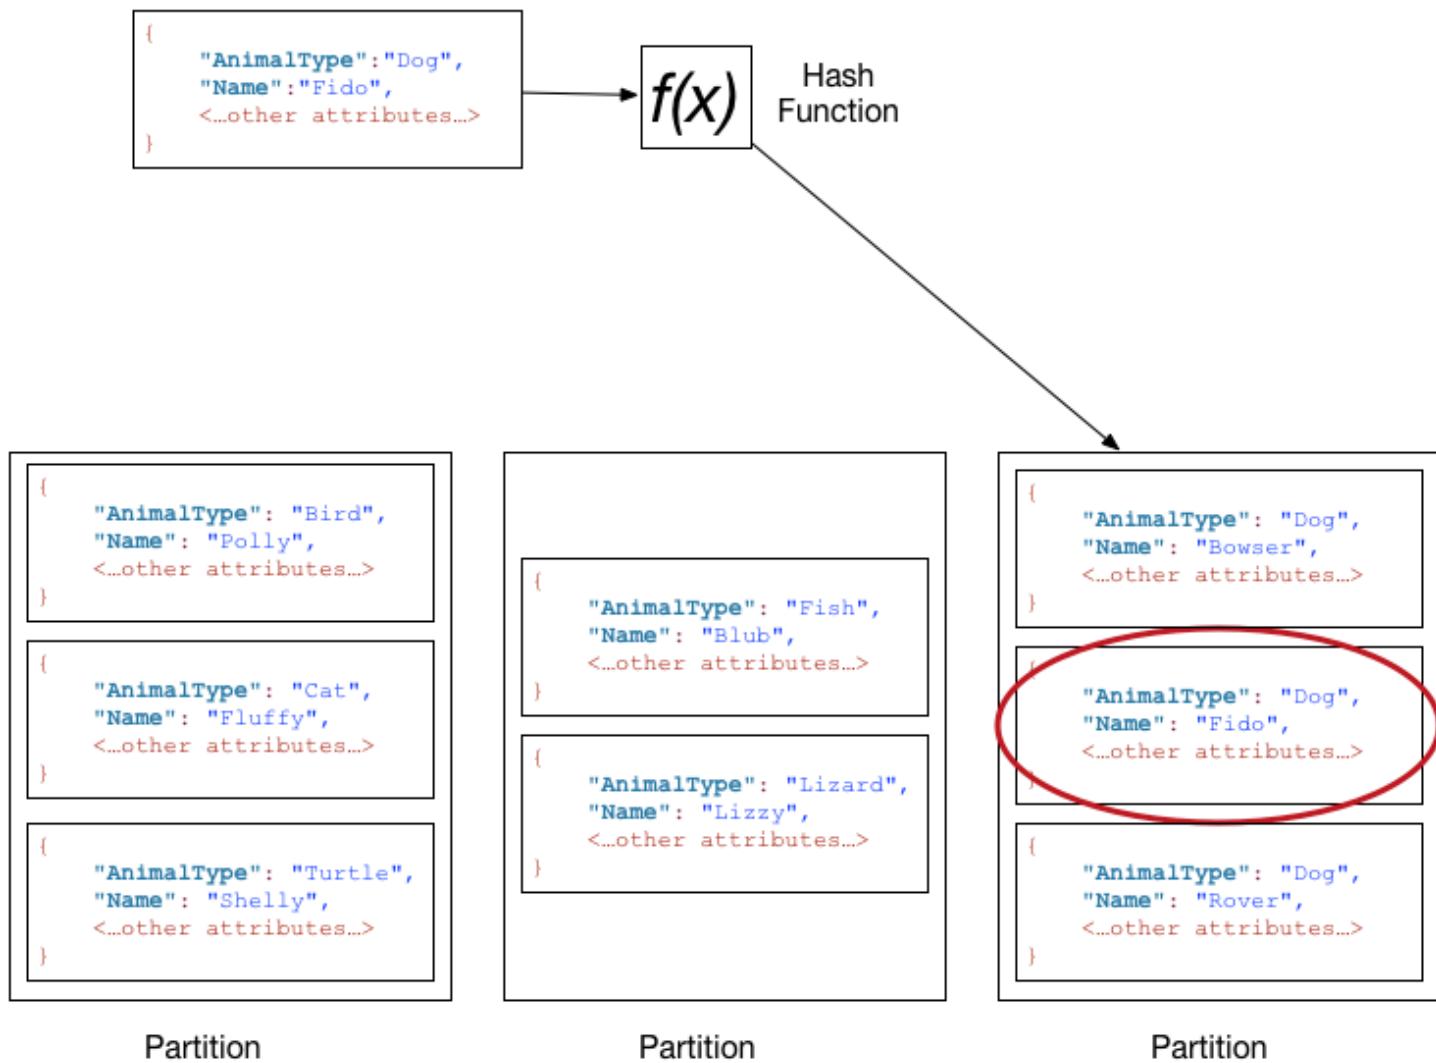

If the table has a composite primary key (partition key and sort key), DynamoDB calculates the hash value of the partition key in the same way as described in [Data distribution: Partition key](#). However, it tends to keep items which have the same value of partition key close together and in sorted order by the sort key attribute's value. The set of items which have the same value of partition key is called an item collection. Item collections are optimized for efficient retrieval of ranges of the items within the collection. If your table doesn't have local secondary indexes, DynamoDB will automatically split your item collection over as many partitions as required to store the data and to serve read and write throughput.

To write an item to the table, DynamoDB calculates the hash value of the partition key to determine which partition should contain the item. In that partition, several items could have the same partition key value. So DynamoDB stores the item among the others with the same partition key, in ascending order by sort key.

To read an item from the table, you must specify its partition key value and sort key value. DynamoDB calculates the partition key's hash value, yielding the partition in which the item can be found.

You can read multiple items from the table in a single operation (Query) if the items you want have the same partition key value. DynamoDB returns all of the items with that partition key value. Optionally, you can apply a condition to the sort key so that it returns only the items within a certain range of values.

Suppose that the *Pets* table has a composite primary key consisting of *AnimalType* (partition key) and *Name* (sort key). The following diagram shows DynamoDB writing an item with a partition key value of *Dog* and a sort key value of *Fido*.

To read that same item from the *Pets* table, DynamoDB calculates the hash value of *Dog*, yielding the partition in which these items are stored. DynamoDB then scans the sort key attribute values until it finds *Fido*.

To read all of the items with an *AnimalType* of *Dog*, you can issue a Query operation without specifying a sort key condition. By default, the items are returned in the order that they are stored (that is, in ascending order by sort key). Optionally, you can request descending order instead.

To query only some of the *Dog* items, you can apply a condition to the sort key (for example, only the *Dog* items where *Name* begins with a letter that is within the range A through K).

Note

In a DynamoDB table, there is no upper limit on the number of distinct sort key values per partition key value. If you needed to store many billions of *Dog* items in the *Pets* table, DynamoDB would allocate enough storage to handle this requirement automatically.

From SQL to NoSQL

If you are an application developer, you might have some experience using a relational database management system (RDBMS) and Structured Query Language (SQL). As you begin working with Amazon DynamoDB, you will encounter many similarities, but also many things that are different. NoSQL is a term used to describe nonrelational database systems that are highly available, scalable, and optimized for high performance. Instead of the relational model, NoSQL databases (like DynamoDB) use alternate models for data management, such as key-value pairs or document storage. For more information, see [What is NoSQL?](#).

Amazon DynamoDB supports [PartiQL](#), an open-source, SQL-compatible query language that makes it easy for you to efficiently query data, regardless of where or in what format it is stored. With PartiQL, you can easily process structured data from relational databases, semi-structured and nested data in open data formats, and even schema-less data in NoSQL or document databases that allow different attributes for different rows. For more information, see [PartiQL query language](#).

The following sections describe common database tasks, comparing and contrasting SQL statements with their equivalent DynamoDB operations.

Note

The SQL examples in this section are compatible with the MySQL RDBMS.

The DynamoDB examples in this section show the name of the DynamoDB operation, along with the parameters for that operation in JSON format. For code examples that use these operations, see [Getting started with DynamoDB and the AWS SDKs](#).

Relational (SQL) or NoSQL?

Today's applications have more demanding requirements than ever before. For example, an online game might start out with just a few users and a very small amount of data. However, if the game becomes successful, it can easily outstrip the resources of the underlying database management system. It is common for web-based applications to have hundreds, thousands, or millions of concurrent users, with terabytes or more of new data generated per day. Databases for such applications must handle tens (or hundreds) of thousands of reads and writes per second.

Amazon DynamoDB is well-suited for these kinds of workloads. As a developer, you can start small and gradually increase your utilization as your application becomes more popular. DynamoDB scales seamlessly to handle very large amounts of data and very large numbers of users.

For more information on traditional relational database modeling and how to adapt it for DynamoDB, see [Best practices for modeling relational data in DynamoDB](#).

The following table shows some high-level differences between a relational database management system (RDBMS) and DynamoDB.

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
Optimal Workloads	Ad hoc queries; data warehousing; OLAP (online analytical processing).	Web-scale applications, including social networks, gaming, media sharing, and Internet of Things (IoT).

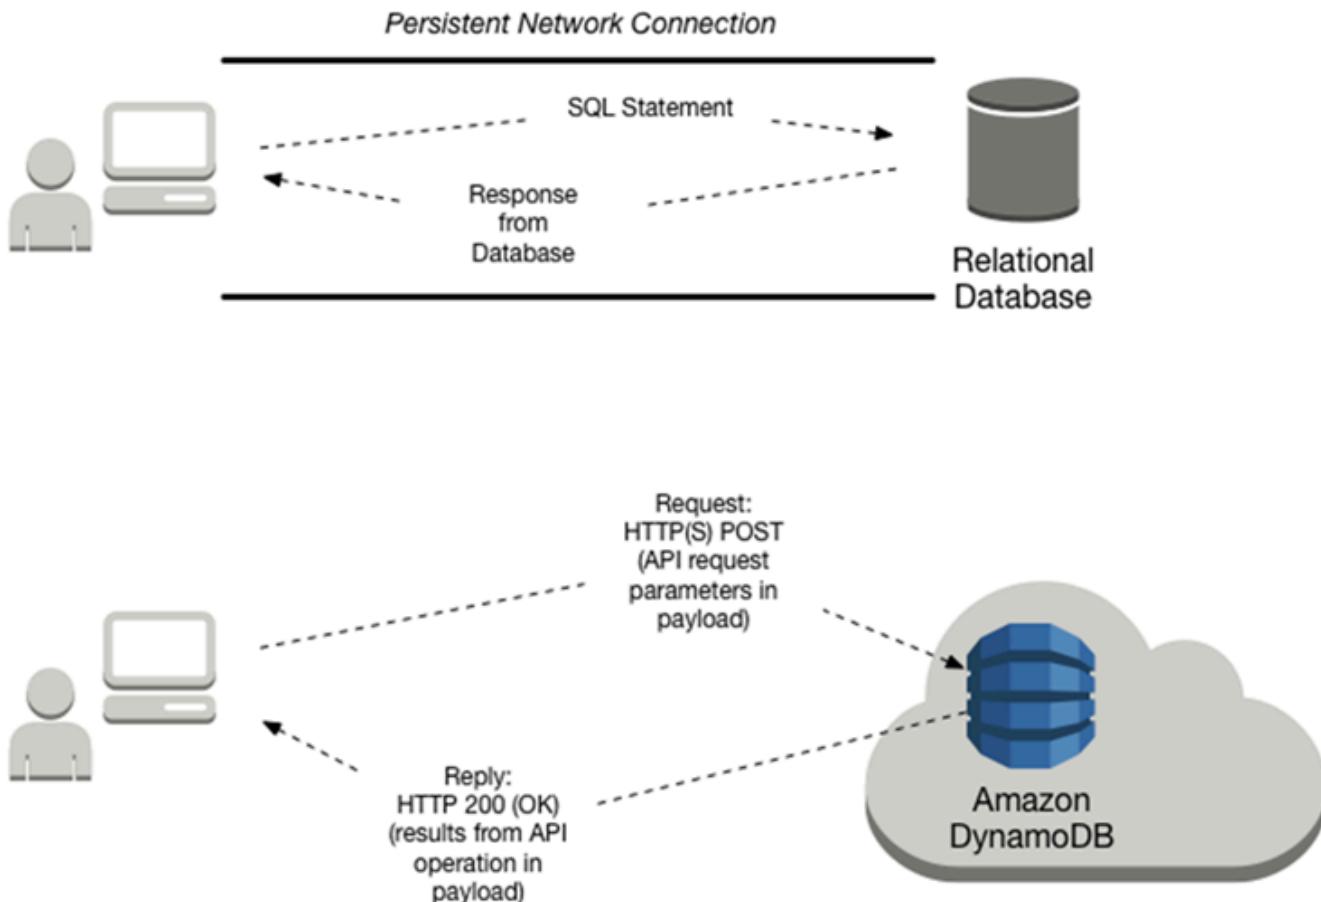

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
Data Model	<p>The relational model requires a well-defined schema, where data is normalized into tables, rows, and columns. In addition, all of the relationships are defined among tables, columns, indexes, and other database elements.</p>	<p>DynamoDB is schemaless. Every table must have a primary key to uniquely identify each data item, but there are no similar constraints on other non-key attributes. DynamoDB can manage structured or semistructured data, including JSON documents.</p>
Data Access	<p>SQL is the standard for storing and retrieving data. Relational databases offer a rich set of tools for simplifying the development of database-driven applications, but all of these tools use SQL.</p>	<p>You can use the AWS Management Console, the AWS CLI, or NoSQL WorkBench to work with DynamoDB and perform ad hoc tasks. PartiQL, a SQL-compatible query language, lets you select, insert, update, and delete data in DynamoDB. Applications can use the AWS software development kits (SDKs) to work with DynamoDB using object-based, document-centric, or low-level interfaces.</p>

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
Performance	<p>Relational databases are optimized for storage, so performance generally depends on the disk subsystem. Developers and database administrators must optimize queries, indexes, and table structures in order to achieve peak performance.</p>	<p>DynamoDB is optimized for compute, so performance is mainly a function of the underlying hardware and network latency. As a managed service, DynamoDB insulates you and your applications from these implementation details, so that you can focus on designing and building robust, high-performance applications.</p>
Scaling	<p>It is easiest to scale up with faster hardware. It is also possible for database tables to span across multiple hosts in a distributed system, but this requires additional investment. Relational databases have maximum sizes for the number and size of files, which imposes upper limits on scalability.</p>	<p>DynamoDB is designed to scale out using distributed clusters of hardware. This design allows increased throughput without increased latency. Customers specify their throughput requirements, and DynamoDB allocates sufficient resources to meet those requirements. There are no upper limits on the number of items per table, nor the total size of that table.</p>

Characteristics of databases

Before your application can access a database, it must be *authenticated* to ensure that the application is allowed to use the database. It must be *authorized* so that the application can perform only the actions for which it has permissions.

The following diagram shows a client's interaction with a relational database and with Amazon DynamoDB.

The following table has more details about client interaction tasks.

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
Tools for Accessing the Database	Most relational databases provide a command line	In most cases, you write application code. You can also

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
	<p>interface (CLI) so that you can enter ad hoc SQL statements and see the results immediately.</p>	<p>use the AWS Management Console, the AWS Command Line Interface (AWS CLI), or NoSQL Workbench to send ad hoc requests to DynamoDB and view the results. PartiQL, a SQL-compatible query language, lets you select, insert, update, and delete data in DynamoDB.</p>
Connecting to the Database	<p>An application program establishes and maintains a network connection with the database. When the application is finished, it terminates the connection.</p>	<p>DynamoDB is a web service, and interactions with it are stateless. Applications do not need to maintain persistent network connections. Instead, interaction with DynamoDB occurs using HTTP(S) requests and responses.</p>
Authentication	<p>An application cannot connect to the database until it is authenticated. The RDBMS can perform the authentication itself, or it can offload this task to the host operating system or a directory service.</p>	<p>Every request to DynamoDB must be accompanied by a cryptographic signature, which authenticates that particular request. The AWS SDKs provide all of the logic necessary for creating signatures and signing requests. For more information, see Signing AWS API requests in the <i>AWS General Reference</i>.</p>

Characteristic	Relational database management system (RDBMS)	Amazon DynamoDB
Authorization	<p>Applications can perform only the actions for which they have been authorized. Database administrators or application owners can use the SQL GRANT and REVOKE statements to control access to database objects (such as tables), data (such as rows within a table), or the ability to issue certain SQL statements.</p>	<p>In DynamoDB, authorization is handled by AWS Identity and Access Management (IAM). You can write an IAM policy to grant permissions on a DynamoDB resource (such as a table), and then allow users and roles to use that policy. IAM also features fine-grained access control for individual data items in DynamoDB tables. For more information, see Identity and Access Management for Amazon DynamoDB.</p>
Sending a Request	<p>The application issues a SQL statement for every database operation that it wants to perform. Upon receipt of the SQL statement, the RDBMS checks its syntax, creates a plan for performing the operation, and then runs the plan.</p>	<p>The application sends HTTP(S) requests to DynamoDB. The requests contain the name of the DynamoDB operation to perform, along with parameters. DynamoDB runs the request immediately.</p>
Receiving a Response	<p>The RDBMS returns the results from the SQL statement. If there is an error, the RDBMS returns an error status and message.</p>	<p>DynamoDB returns an HTTP(S) response containing the results of the operation. If there is an error, DynamoDB returns an HTTP error status and messages.</p>

Creating a table

Tables are the fundamental data structures in relational databases and in Amazon DynamoDB. A relational database management system (RDBMS) requires you to define the table's schema when you create it. In contrast, DynamoDB tables are schemaless—other than the primary key, you do not need to define any extra attributes or data types when you create a table.

The following section compares how you would create a table with SQL to how you would create it with DynamoDB.

Topics

- [Creating a table with SQL](#)
- [Creating a table with DynamoDB](#)

Creating a table with SQL

With SQL you would use the CREATE TABLE statement to create a table, as shown in the following example.

```
CREATE TABLE Music (
    Artist VARCHAR(20) NOT NULL,
    SongTitle VARCHAR(30) NOT NULL,
    AlbumTitle VARCHAR(25),
    Year INT,
    Price FLOAT,
    Genre VARCHAR(10),
    Tags TEXT,
    PRIMARY KEY(Artist, SongTitle)
);
```

The primary key for this table consists of *Artist* and *SongTitle*.

You must define all of the table's columns and data types, and the table's primary key. (You can use the ALTER TABLE statement to change these definitions later, if necessary.)

Many SQL implementations let you define storage specifications for your table, as part of the CREATE TABLE statement. Unless you indicate otherwise, the table is created with default storage settings. In a production environment, a database administrator can help determine the optimal storage parameters.

Creating a table with DynamoDB

Use the `CreateTable` operation to create a provisioned mode table, specifying parameters as shown following:

```
{  
    TableName : "Music",  
    KeySchema: [  
        {  
            AttributeName: "Artist",  
            KeyType: "HASH" //Partition key  
        },  
        {  
            AttributeName: "SongTitle",  
            KeyType: "RANGE" //Sort key  
        }  
    ],  
    AttributeDefinitions: [  
        {  
            AttributeName: "Artist",  
            AttributeType: "S"  
        },  
        {  
            AttributeName: "SongTitle",  
            AttributeType: "S"  
        }  
    ],  
    ProvisionedThroughput: {           // Only specified if using provisioned mode  
        ReadCapacityUnits: 1,  
        WriteCapacityUnits: 1  
    }  
}
```

The primary key for this table consists of *Artist* (partition key) and *SongTitle* (sort key).

You must provide the following parameters to `CreateTable`:

- `TableName` – Name of the table.
- `KeySchema` – Attributes that are used for the primary key. For more information, see [Tables, items, and attributes](#) and [Primary key](#).
- `AttributeDefinitions` – Data types for the key schema attributes.

- **ProvisionedThroughput** (for provisioned tables) – Number of reads and writes per second that you need for this table. DynamoDB reserves sufficient storage and system resources so that your throughput requirements are always met. You can use the `UpdateTable` operation to change these later, if necessary. You do not need to specify a table's storage requirements because storage allocation is managed entirely by DynamoDB.

 **Note**

For code examples that use `CreateTable`, see [Getting started with DynamoDB and the AWS SDKs](#).

Getting information about a table

You can verify that a table has been created according to your specifications. In a relational database, all of the table's schema is shown. Amazon DynamoDB tables are schemaless, so only the primary key attributes are shown.

Topics

- [Getting information about a table with SQL](#)
- [Getting information about a table in DynamoDB](#)

Getting information about a table with SQL

Most relational database management systems (RDBMS) allow you to describe a table's structure—columns, data types, primary key definition, and so on. There is no standard way to do this in SQL. However, many database systems provide a `DESCRIBE` command. The following is an example from MySQL.

```
DESCRIBE Music;
```

This returns the structure of your table, with all of the column names, data types, and sizes.

Field	Type	Null	Key	Default	Extra
Artist	varchar(20)	NO	PRI	NULL	

SongTitle varchar(30) NO	PRI	NULL		
AlbumTitle varchar(25) YES		NULL		
Year int(11) YES		NULL		
Price float YES		NULL		
Genre varchar(10) YES		NULL		
Tags text YES		NULL		
+-----+-----+-----+-----+				

The primary key for this table consists of *Artist* and *SongTitle*.

Getting information about a table in DynamoDB

DynamoDB has a `DescribeTable` operation, which is similar. The only parameter is the table name.

```
{  
    TableName : "Music"  
}
```

The reply from `DescribeTable` looks like the following.

```
{  
    "Table": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "Music",  
        "KeySchema": [  
            {  
                "AttributeName": "Artist",  
                "KeyType": "HASH" //Partition key  
            },  
            {  
                "AttributeName": "SongTitle",  
                "KeyType": "RANGE" //Sort key  
            }  
        ]  
    }  
}
```

```
 }  
 ],  
  
 ...
```

DescribeTable also returns information about indexes on the table, provisioned throughput settings, an approximate item count, and other metadata.

Writing data to a table

Relational database tables contain *rows* of data. Rows are composed of *columns*. Amazon DynamoDB tables contain *items*. Items are composed of *attributes*.

This section describes how to write one row (or item) to a table.

Topics

- [Writing data to a table with SQL](#)
- [Writing data to a table in DynamoDB](#)

Writing data to a table with SQL

A table in a relational database is a two-dimensional data structure composed of rows and columns. Some database management systems also provide support for semistructured data, usually with native JSON or XML data types. However, the implementation details vary among vendors.

In SQL, you would use the INSERT statement to add a row to a table.

```
INSERT INTO Music  
  (Artist, SongTitle, AlbumTitle,  
   Year, Price, Genre,  
   Tags)  
VALUES(  
  'No One You Know', 'Call Me Today', 'Somewhat Famous',  
  2015, 2.14, 'Country',  
  '{"Composers": ["Smith", "Jones", "Davis"], "LengthInSeconds": 214}'  
)
```

The primary key for this table consists of *Artist* and *SongTitle*. You must specify values for these columns.

Note

This example uses the *Tags* column to store semistructured data about the songs in the *Music* table. The *Tags* column is defined as type TEXT, which can store up to 65,535 characters in MySQL.

Writing data to a table in DynamoDB

In Amazon DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to add an item to a table.

DynamoDB API

With the DynamoDB API, you use the PutItem operation to add an item to a table.

```
{  
    TableName: "Music",  
    Item: {  
        "Artist": "No One You Know",  
        "SongTitle": "Call Me Today",  
        "AlbumTitle": "Somewhat Famous",  
        "Year": 2015,  
        "Price": 2.14,  
        "Genre": "Country",  
        "Tags": {  
            "Composers": [  
                "Smith",  
                "Jones",  
                "Davis"  
            ],  
            "LengthInSeconds": 214  
        }  
    }  
}
```

The primary key for this table consists of *Artist* and *SongTitle*. You must specify values for these attributes.

Here are some key things to know about this PutItem example:

- DynamoDB provides native support for documents, using JSON. This makes DynamoDB ideal for storing semistructured data, such as *Tags*. You can also retrieve and manipulate data from within JSON documents.
- The *Music* table does not have any predefined attributes, other than the primary key (*Artist* and *SongTitle*).
- Most SQL databases are transaction oriented. When you issue an INSERT statement, the data modifications are not permanent until you issue a COMMIT statement. With Amazon DynamoDB, the effects of a PutItem operation are permanent when DynamoDB replies with an HTTP 200 status code (OK).

 **Note**

For code examples using PutItem, see [Getting started with DynamoDB and the AWS SDKs](#).

The following are some other PutItem examples.

```
{  
    TableName: "Music",  
    Item: {  
        "Artist": "No One You Know",  
        "SongTitle": "My Dog Spot",  
        "AlbumTitle": "Hey Now",  
        "Price": 1.98,  
        "Genre": "Country",  
        "CriticRating": 8.4  
    }  
}
```

```
{  
    TableName: "Music",  
    Item: {  
        "Artist": "No One You Know",  
        "SongTitle": "Somewhere Down The Road",  
        "AlbumTitle": "Somewhat Famous",  
        "Genre": "Country",  
        "CriticRating": 8.4,  
        "Year": 1984  
    }  
}
```

```
    }  
}
```

```
{  
    TableName: "Music",  
    Item: {  
        "Artist": "The Acme Band",  
        "SongTitle": "Still In Love",  
        "AlbumTitle": "The Buck Starts Here",  
        "Price": 2.47,  
        "Genre": "Rock",  
        "PromotionInfo": {  
            "RadioStationsPlaying": [  
                "KHCR", "KBQX", "WTNR", "WJJH"  
            ],  
            "TourDates": {  
                "Seattle": "20150625",  
                "Cleveland": "20150630"  
            },  
            "Rotation": "Heavy"  
        }  
    }  
}
```

```
{  
    TableName: "Music",  
    Item: {  
        "Artist": "The Acme Band",  
        "SongTitle": "Look Out, World",  
        "AlbumTitle": "The Buck Starts Here",  
        "Price": 0.99,  
        "Genre": "Rock"  
    }  
}
```

Note

In addition to PutItem, DynamoDB supports a BatchWriteItem operation for writing multiple items at the same time.

PartiQL for DynamoDB

With PartiQL, you use the `ExecuteStatement` operation to add an item to a table, using the PartiQL Insert statement.

```
INSERT into Music value {  
    'Artist': 'No One You Know',  
    'SongTitle': 'Call Me Today',  
    'AlbumTitle': 'Somewhat Famous',  
    'Year' : '2015',  
    'Genre' : 'Acme'  
}
```

The primary key for this table consists of *Artist* and *SongTitle*. You must specify values for these attributes.

 **Note**

For code examples using Insert and `ExecuteStatement`, see [PartiQL insert statements for DynamoDB](#).

Key differences between SQL and DynamoDB when reading data from a table

With SQL, you use the `SELECT` statement to retrieve one or more rows from a table. You use the `WHERE` clause to determine the data that is returned to you.

This is different than using Amazon DynamoDB which provides the following operations for reading data:

- `ExecuteStatement` retrieves a single or multiple items from a table.
`BatchExecuteStatement` retrieves multiple items from different tables in a single operation.
Both of these operations use [PartiQL](#), a SQL-compatible query language.
- `GetItem` – Retrieves a single item from a table. This is the most efficient way to read a single item because it provides direct access to the physical location of the item. (DynamoDB also provides the `BatchGetItem` operation, allowing you to perform up to 100 `GetItem` calls in a single operation.)

- **Query** – Retrieves all of the items that have a specific partition key. Within those items, you can apply a condition to the sort key and retrieve only a subset of the data. Query provides quick, efficient access to the partitions where the data is stored. (For more information, see [Partitions and data distribution](#).)
- **Scan** – Retrieves all of the items in the specified table. (This operation should not be used with large tables because it can consume large amounts of system resources.)

Note

With a relational database, you can use the SELECT statement to join data from multiple tables and return the results. Joins are fundamental to the relational model. To ensure that joins run efficiently, the database and its applications should be performance-tuned on an ongoing basis. DynamoDB is a non-relational NoSQL database that does not support table joins. Instead, applications read data from one table at a time.

The following sections describe different use cases for reading data, and how to perform these tasks with a relational database and with DynamoDB.

Topics

- [Reading an item using its primary key](#)
- [Querying a table](#)
- [Scanning a table](#)

Reading an item using its primary key

One common access pattern for databases is to read a single item from a table. You have to specify the primary key of the item you want.

Topics

- [Reading an item using its primary key with SQL](#)
- [Reading an item using its primary key in DynamoDB](#)

Reading an item using its primary key with SQL

In SQL, you would use the SELECT statement to retrieve data from a table. You can request one or more columns in the result (or all of them, if you use the * operator). The WHERE clause determines which rows to return.

The following is a SELECT statement to retrieve a single row from the *Music* table. The WHERE clause specifies the primary key values.

```
SELECT *
FROM Music
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today'
```

You can modify this query to retrieve only a subset of the columns.

```
SELECT AlbumTitle, Year, Price
FROM Music
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today'
```

Note that the primary key for this table consists of *Artist* and *SongTitle*.

Reading an item using its primary key in DynamoDB

In Amazon DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to read an item from a table.

DynamoDB API

With the DynamoDB API, you use the PutItem operation to add an item to a table.

DynamoDB provides the GetItem operation for retrieving an item by its primary key. GetItem is highly efficient because it provides direct access to the physical location of the item. (For more information, see [Partitions and data distribution](#).)

By default, GetItem returns the entire item with all of its attributes.

```
{
  TableName: "Music",
  Key: {
    "Artist": "No One You Know",
```

```
        "SongTitle": "Call Me Today"
    }
}
```

You can add a `ProjectionExpression` parameter to return only some of the attributes.

```
{
    TableName: "Music",
    Key: {
        "Artist": "No One You Know",
        "SongTitle": "Call Me Today"
    },
    "ProjectionExpression": "AlbumTitle, Year, Price"
}
```

Note that the primary key for this table consists of `Artist` and `SongTitle`.

The DynamoDB `GetItem` operation is very efficient. It uses the primary key values to determine the exact storage location of the item in question, and retrieves it directly from there. The SQL `SELECT` statement is similarly efficient, in the case of retrieving items by primary key values.

The SQL `SELECT` statement supports many kinds of queries and table scans. DynamoDB provides similar functionality with its `Query` and `Scan` operations, which are described in [Querying a table](#) and [Scanning a table](#).

The SQL `SELECT` statement can perform table joins, allowing you to retrieve data from multiple tables at the same time. Joins are most effective where the database tables are normalized and the relationships among the tables are clear. However, if you join too many tables in one `SELECT` statement application performance can be affected. You can work around such issues by using database replication, materialized views, or query rewrites.

DynamoDB is a nonrelational database and doesn't support table joins. If you are migrating an existing application from a relational database to DynamoDB, you need to denormalize your data model to eliminate the need for joins.

 **Note**

For code examples that use `GetItem`, see [Getting started with DynamoDB and the AWS SDKs](#).

PartiQL for DynamoDB

With PartiQL, you use the `ExecuteStatement` operation to read an item from a table, using the PartiQL Select statement.

```
SELECT AlbumTitle, Year, Price  
FROM Music  
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today'
```

Note that the primary key for this table consists of Artist and SongTitle.

 **Note**

The select PartiQL statement can also be used to Query or Scan a DynamoDB table

For code examples using Select and `ExecuteStatement`, see [PartiQL select statements for DynamoDB](#).

Querying a table

Another common access pattern is reading multiple items from a table, based on your query criteria.

Topics

- [Querying a table with SQL](#)
- [Querying a table in DynamoDB](#)

Querying a table with SQL

When using SQL the `SELECT` statement lets you query on key columns, non-key columns, or any combination. The `WHERE` clause determines which rows are returned, as shown in the following examples.

```
/* Return a single song, by primary key */  
  
SELECT * FROM Music  
WHERE Artist='No One You Know' AND SongTitle = 'Call Me Today';
```

```
/* Return all of the songs by an artist */  
  
SELECT * FROM Music  
WHERE Artist='No One You Know';
```

```
/* Return all of the songs by an artist, matching first part of title */  
  
SELECT * FROM Music  
WHERE Artist='No One You Know' AND SongTitle LIKE 'Call%';
```

```
/* Return all of the songs by an artist, with a particular word in the title...  
...but only if the price is less than 1.00 */
```

```
SELECT * FROM Music  
WHERE Artist='No One You Know' AND SongTitle LIKE '%Today%'  
AND Price < 1.00;
```

Note that the primary key for this table consists of *Artist* and *SongTitle*.

Querying a table in DynamoDB

In Amazon DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to query an item from a table.

DynamoDB API

With Amazon DynamoDB, you can use the `Query` operation to retrieve data in a similar fashion. The `Query` operation provides quick, efficient access to the physical locations where the data is stored. For more information, see [Partitions and data distribution](#).

You can use `Query` with any table or secondary index. You must specify an equality condition for the partition key's value, and you can optionally provide another condition for the sort key attribute if it is defined.

The `KeyConditionExpression` parameter specifies the key values that you want to query. You can use an optional `FilterExpression` to remove certain items from the results before they are returned to you.

In DynamoDB, you must use `ExpressionAttributeValues` as placeholders in expression parameters (such as `KeyConditionExpression` and `FilterExpression`). This is analogous

to the use of *bind variables* in relational databases, where you substitute the actual values into the SELECT statement at runtime.

Note that the primary key for this table consists of *Artist* and *SongTitle*.

The following are some DynamoDB Query examples.

```
// Return a single song, by primary key

{
    TableName: "Music",
    KeyConditionExpression: "Artist = :a and SongTitle = :t",
    ExpressionAttributeValues: {
        ":a": "No One You Know",
        ":t": "Call Me Today"
    }
}
```

```
// Return all of the songs by an artist

{
    TableName: "Music",
    KeyConditionExpression: "Artist = :a",
    ExpressionAttributeValues: {
        ":a": "No One You Know"
    }
}
```

```
// Return all of the songs by an artist, matching first part of title

{
    TableName: "Music",
    KeyConditionExpression: "Artist = :a and begins_with(SongTitle, :t)",
    ExpressionAttributeValues: {
        ":a": "No One You Know",
        ":t": "Call"
    }
}
```

Note

For code examples that use Query, see [Getting started with DynamoDB and the AWS SDKs](#).

PartiQL for DynamoDB

With PartiQL, you can perform a query by using the ExecuteStatement operation and the Select statement on the partition key.

```
SELECT AlbumTitle, Year, Price  
FROM Music  
WHERE Artist='No One You Know'
```

Using the SELECT statement in this way returns all the songs associated with this particular Artist.

For code examples using Select and ExecuteStatement, see [PartiQL select statements for DynamoDB](#).

Scanning a table

In SQL, a SELECT statement without a WHERE clause will return every row in a table. In Amazon DynamoDB, the Scan operation does the same thing. In both cases, you can retrieve all of the items or just some of them.

Whether you are using a SQL or a NoSQL database, scans should be used sparingly because they can consume large amounts of system resources. Sometimes a scan is appropriate (such as scanning a small table) or unavoidable (such as performing a bulk export of data). However, as a general rule, you should design your applications to avoid performing scans. For more information, see [Query operations in DynamoDB](#).

Note

Doing a bulk export also creates at least 1 file per partition. All of the items in each file are from that particular partition's hashed keyspace.

Topics

- [Scanning a table with SQL](#)
- [Scanning a table in DynamoDB](#)

Scanning a table with SQL

When using SQL you can scan a table and retrieve all of its data by using a SELECT statement without specifying a WHERE clause. You can request one or more columns in the result. Or you can request all of them if you use the wildcard character (*).

The following are examples of using a SELECT statement.

```
/* Return all of the data in the table */
SELECT * FROM Music;
```

```
/* Return all of the values for Artist and Title */
SELECT Artist, Title FROM Music;
```

Scanning a table in DynamoDB

In Amazon DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to perform a scan on a table.

DynamoDB API

With the DynamoDB API, you use the Scan operation to return one or more items and item attributes by accessing every item in a table or a secondary index.

```
// Return all of the data in the table
{
    TableName: "Music"
}
```

```
// Return all of the values for Artist and Title
{
    TableName: "Music",
    ProjectionExpression: "Artist, Title"
}
```

The Scan operation also provides a `FilterExpression` parameter, which you can use to discard items that you do not want to appear in the results. A `FilterExpression` is applied after the scan is performed, but before the results are returned to you. (This is not recommended with large tables. You are still charged for the entire Scan, even if only a few matching items are returned.)

 **Note**

For code examples that use Scan, see [Getting started with DynamoDB and the AWS SDKs](#).

PartiQL for DynamoDB

With PartiQL, you perform a scan by using the `ExecuteStatement` operation to return all the contents for a table using the `Select` statement.

```
SELECT AlbumTitle, Year, Price  
FROM Music
```

Note that this statement will return all items for in the Music table.

For code examples using Select and `ExecuteStatement`, see [PartiQL select statements for DynamoDB](#).

Managing indexes

Indexes give you access to alternate query patterns, and can speed up queries. This section compares and contrasts index creation and usage in SQL and Amazon DynamoDB.

Whether you are using a relational database or DynamoDB, you should be judicious with index creation. Whenever a write occurs on a table, all of the table's indexes must be updated. In a write-heavy environment with large tables, this can consume large amounts of system resources. In a read-only or read-mostly environment, this is not as much of a concern. However, you should ensure that the indexes are actually being used by your application, and not simply taking up space.

Topics

- [Creating an index](#)

- [Querying and scanning an index](#)

Creating an index

Compare the CREATE INDEX statement in SQL with the UpdateTable operation in Amazon DynamoDB.

Topics

- [Creating an index with SQL](#)
- [Creating an index in DynamoDB](#)

Creating an index with SQL

In a relational database, an index is a data structure that lets you perform fast queries on different columns in a table. You can use the CREATE INDEX SQL statement to add an index to an existing table, specifying the columns to be indexed. After the index has been created, you can query the data in the table as usual, but now the database can use the index to quickly find the specified rows in the table instead of scanning the entire table.

After you create an index, the database maintains it for you. Whenever you modify data in the table, the index is automatically modified to reflect changes in the table.

In MySQL, you would create an index like the following.

```
CREATE INDEX GenreAndPriceIndex  
ON Music (genre, price);
```

Creating an index in DynamoDB

In DynamoDB, you can create and use a *secondary index* for similar purposes.

Indexes in DynamoDB are different from their relational counterparts. When you create a secondary index, you must specify its key attributes—a partition key and a sort key. After you create the secondary index, you can Query it or Scan it just as you would with a table. DynamoDB does not have a query optimizer, so a secondary index is only used when you Query it or Scan it.

DynamoDB supports two different kinds of indexes:

- Global secondary indexes – The primary key of the index can be any two attributes from its table.

- Local secondary indexes – The partition key of the index must be the same as the partition key of its table. However, the sort key can be any other attribute.

DynamoDB ensures that the data in a secondary index is eventually consistent with its table. You can request strongly consistent Query or Scan operations on a table or a local secondary index. However, global secondary indexes support only eventual consistency.

You can add a global secondary index to an existing table, using the UpdateTable operation and specifying GlobalSecondaryIndexUpdates.

```
{  
    TableName: "Music",  
    AttributeDefinitions:[  
        {AttributeName: "Genre", AttributeType: "S"},  
        {AttributeName: "Price", AttributeType: "N"}  
    ],  
    GlobalSecondaryIndexUpdates: [  
        {  
            Create: {  
                IndexName: "GenreAndPriceIndex",  
                KeySchema: [  
                    {AttributeName: "Genre", KeyType: "HASH"}, //Partition key  
                    {AttributeName: "Price", KeyType: "RANGE"} //Sort key  
                ],  
                Projection: {  
                    "ProjectionType": "ALL"  
                },  
                ProvisionedThroughput: {  
                    "ReadCapacityUnits": 1,"WriteCapacityUnits": 1  
                }  
            }  
        }  
    ]  
}
```

You must provide the following parameters to UpdateTable:

- TableName – The table that the index will be associated with.
- AttributeDefinitions – The data types for the key schema attributes of the index.
- GlobalSecondaryIndexUpdates – Details about the index you want to create:

- `IndexName` – A name for the index.
- `KeySchema` – The attributes that are used for the index's primary key.
- `Projection` – Attributes from the table that are copied to the index. In this case, `ALL` means that all of the attributes are copied.
- `ProvisionedThroughput` (for provisioned tables) – The number of reads and writes per second that you need for this index. (This is separate from the provisioned throughput settings of the table.)

Part of this operation involves backfilling data from the table into the new index. During backfilling, the table remains available. However, the index is not ready until its `Backfilling` attribute changes from true to false. You can use the `DescribeTable` operation to view this attribute.

 **Note**

For code examples that use `UpdateTable`, see [Getting started with DynamoDB and the AWS SDKs](#).

Querying and scanning an index

Compare querying and scanning an index using the `SELECT` statement in SQL with the `Query` and `Scan` operations in Amazon DynamoDB.

Topics

- [Querying and scanning an index with SQL](#)
- [Querying and scanning an index in DynamoDB](#)

Querying and scanning an index with SQL

In a relational database, you do not work directly with indexes. Instead, you query tables by issuing `SELECT` statements, and the query optimizer can make use of any indexes.

A *query optimizer* is a relational database management system (RDBMS) component that evaluates the available indexes and determines whether they can be used to speed up a query. If the indexes can be used to speed up a query, the RDBMS accesses the index first and then uses it to locate the data in the table.

Here are some SQL statements that can use *GenreAndPriceIndex* to improve performance. We assume that the *Music* table has enough data in it that the query optimizer decides to use this index, rather than simply scanning the entire table.

```
/* All of the rock songs */
```

```
SELECT * FROM Music  
WHERE Genre = 'Rock';
```

```
/* All of the cheap country songs */
```

```
SELECT Artist, SongTitle, Price FROM Music  
WHERE Genre = 'Country' AND Price < 0.50;
```

Querying and scanning an index in DynamoDB

In DynamoDB, you perform Query and Scan operations directly on the index, in the same way that you would on a table. You can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to query or scan the index. You must specify both TableName and IndexName.

The following are some queries on *GenreAndPriceIndex* in DynamoDB. (The key schema for this index consists of *Genre* and *Price*.)

DynamoDB API

```
// All of the rock songs  
  
{  
    TableName: "Music",  
    IndexName: "GenreAndPriceIndex",  
    KeyConditionExpression: "Genre = :genre",  
    ExpressionAttributeValues: {  
        ":genre": "Rock"  
    },  
};
```

This example uses a `ProjectionExpression` to indicate that you only want some of the attributes, rather than all of them, to appear in the results.

```
// All of the cheap country songs
```

```
{  
    TableName: "Music",  
    IndexName: "GenreAndPriceIndex",  
    KeyConditionExpression: "Genre = :genre and Price < :price",  
    ExpressionAttributeValues: {  
        ":genre": "Country",  
        ":price": 0.50  
    },  
    ProjectionExpression: "Artist, SongTitle, Price"  
};
```

The following is a scan on *GenreAndPriceIndex*.

```
// Return all of the data in the index  
  
{  
    TableName: "Music",  
    IndexName: "GenreAndPriceIndex"  
}
```

PartiQL for DynamoDB

With PartiQL, you use the PartiQL Select statement to perform queries and scans on the index.

```
// All of the rock songs  
  
SELECT *  
FROM Music.GenreAndPriceIndex  
WHERE Genre = 'Rock'
```

```
// All of the cheap country songs  
  
SELECT *  
FROM Music.GenreAndPriceIndex  
WHERE Genre = 'Rock' AND Price < 0.50
```

The following is a scan on *GenreAndPriceIndex*.

```
// Return all of the data in the index  
  
SELECT *
```

```
FROM Music.GenreAndPriceIndex
```

Note

For code examples using Select, see [PartiQL select statements for DynamoDB](#).

Modifying data in a table

The SQL language provides the UPDATE statement for modifying data. Amazon DynamoDB uses the UpdateItem operation to accomplish similar tasks.

Topics

- [Modifying data in a table with SQL](#)
- [Modifying data in a table in DynamoDB](#)

Modifying data in a table with SQL

In SQL, you would use the UPDATE statement to modify one or more rows. The SET clause specifies new values for one or more columns, and the WHERE clause determines which rows are modified. The following is an example.

```
UPDATE Music
SET RecordLabel = 'Global Records'
WHERE Artist = 'No One You Know' AND SongTitle = 'Call Me Today';
```

If no rows match the WHERE clause, the UPDATE statement has no effect.

Modifying data in a table in DynamoDB

In DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to modify a single item. If you want to modify multiple items, you must use multiple operations.

DynamoDB API

With the DynamoDB API, you use the UpdateItem operation to modify a single item.

```
{
```

```
TableName: "Music",
Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
},
UpdateExpression: "SET RecordLabel = :label",
ExpressionAttributeValues: {
    ":label": "Global Records"
}
}
```

You must specify the Key attributes of the item to be modified and an UpdateExpression to specify attribute values. UpdateItem behaves like an "upsert" operation. The item is updated if it exists in the table, but if not, a new item is added (inserted).

UpdateItem supports *conditional writes*, where the operation succeeds only if a specific ConditionExpression evaluates to true. For example, the following UpdateItem operation does not perform the update unless the price of the song is greater than or equal to 2.00.

```
{
  TableName: "Music",
  Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
  },
  UpdateExpression: "SET RecordLabel = :label",
  ConditionExpression: "Price >= :p",
  ExpressionAttributeValues: {
    ":label": "Global Records",
    ":p": 2.00
  }
}
```

UpdateItem also supports *atomic counters*, or attributes of type Number that can be incremented or decremented. Atomic counters are similar in many ways to sequence generators, identity columns, or autoincrement fields in SQL databases.

The following is an example of an UpdateItem operation to initialize a new attribute (*Plays*) to keep track of the number of times a song has been played.

```
{
```

```
TableName: "Music",
Key: {
    "Artist":"No One You Know",
    "SongTitle":"Call Me Today"
},
UpdateExpression: "SET Plays = :val",
ExpressionAttributeValues: {
    ":val": 0
},
ReturnValues: "UPDATED_NEW"
}
```

The `ReturnValues` parameter is set to `UPDATED_NEW`, which returns the new values of any attributes that were updated. In this case, it returns 0 (zero).

Whenever someone plays this song, we can use the following `UpdateItem` operation to increment `Plays` by one.

```
{
    TableName: "Music",
    Key: {
        "Artist":"No One You Know",
        "SongTitle":"Call Me Today"
    },
    UpdateExpression: "SET Plays = Plays + :incr",
    ExpressionAttributeValues: {
        ":incr": 1
    },
    ReturnValues: "UPDATED_NEW"
}
```

Note

For code examples that use `UpdateItem`, see [Getting started with DynamoDB and the AWS SDKs](#).

PartiQL for DynamoDB

With PartiQL, you use the `ExecuteStatement` operation to modify an item in a table, using the PartiQL `Update` statement.

The primary key for this table consists of *Artist* and *SongTitle*. You must specify values for these attributes.

```
UPDATE Music
SET RecordLabel = 'Global Records'
WHERE Artist='No One You Know' AND SongTitle='Call Me Today'
```

You can also modify multiple fields at once, such as in the following example.

```
UPDATE Music
SET RecordLabel = 'Global Records'
SET AwardsWon = 10
WHERE Artist = 'No One You Know' AND SongTitle='Call Me Today'
```

Update also supports *atomic counters*, or attributes of type Number that can be incremented or decremented. Atomic counters are similar in many ways to sequence generators, identity columns, or autoincrement fields in SQL databases.

The following is an example of an Update statement to initialize a new attribute (*Plays*) to keep track of the number of times a song has been played.

```
UPDATE Music
SET Plays = 0
WHERE Artist='No One You Know' AND SongTitle='Call Me Today'
```

Whenever someone plays this song, we can use the following Update statement to increment *Plays* by one.

```
UPDATE Music
SET Plays = Plays + 1
WHERE Artist='No One You Know' AND SongTitle='Call Me Today'
```

Note

For code examples using Update and ExecuteStatement, see [PartiQL update statements for DynamoDB](#).

Deleting data from a table

In SQL, the DELETE statement removes one or more rows from a table. Amazon DynamoDB uses the DeleteItem operation to delete one item at a time.

Topics

- [Deleting data from a table with SQL](#)
- [Deleting data from a table in DynamoDB](#)

Deleting data from a table with SQL

In SQL, you use the DELETE statement to delete one or more rows. The WHERE clause determines the rows that you want to modify. The following is an example.

```
DELETE FROM Music  
WHERE Artist = 'The Acme Band' AND SongTitle = 'Look Out, World';
```

You can modify the WHERE clause to delete multiple rows. For example, you could delete all of the songs by a particular artist, as shown in the following example.

```
DELETE FROM Music WHERE Artist = 'The Acme Band'
```

Note

If you omit the WHERE clause, the database attempts to delete all of the rows from the table.

Deleting data from a table in DynamoDB

In DynamoDB, you can use either the DynamoDB API or [PartiQL](#) (a SQL-compatible query language) to delete a single item. If you want to modify multiple items, you must use multiple operations.

DynamoDB API

With the DynamoDB API, you use the DeleteItem operation to delete data from a table, one item at a time. You must specify the item's primary key values.

```
{  
    TableName: "Music",  
    Key: {  
        Artist: "The Acme Band",  
        SongTitle: "Look Out, World"  
    }  
}
```

Note

In addition to `DeleteItem`, Amazon DynamoDB supports a `BatchWriteItem` operation for deleting multiple items at the same time.

`DeleteItem` supports *conditional writes*, where the operation succeeds only if a specific `ConditionExpression` evaluates to true. For example, the following `DeleteItem` operation deletes the item only if it has a `RecordLabel` attribute.

```
{  
    TableName: "Music",  
    Key: {  
        Artist: "The Acme Band",  
        SongTitle: "Look Out, World"  
    },  
    ConditionExpression: "attribute_exists(RecordLabel)"  
}
```

Note

For code examples that use `DeleteItem`, see [Getting started with DynamoDB and the AWS SDKs](#).

PartiQL for DynamoDB

With PartiQL, you use the `Delete` statement through the `ExecuteStatement` operation to delete data from a table, one item at a time. You must specify the item's primary key values.

The primary key for this table consists of `Artist` and `SongTitle`. You must specify values for these attributes.

```
DELETE FROM Music  
WHERE Artist = 'Acme Band' AND SongTitle = 'PartiQL Rocks'
```

You can also specify additional conditions for the operation. The following DELETE operation only deletes the item if it has more than 11 Awards.

```
DELETE FROM Music  
WHERE Artist = 'Acme Band' AND SongTitle = 'PartiQL Rocks' AND Awards > 11
```

Note

For code examples using DELETE and ExecuteStatement, see [PartiQL delete statements for DynamoDB](#).

Removing a table

In SQL, you use the DROP TABLE statement to remove a table. In Amazon DynamoDB, you use the DeleteTable operation.

Topics

- [Removing a table with SQL](#)
- [Removing a table in DynamoDB](#)

Removing a table with SQL

When you no longer need a table and want to discard it permanently, you would use the DROP TABLE statement in SQL.

```
DROP TABLE Music;
```

After a table is dropped, it cannot be recovered. (Some relational databases do allow you to undo a DROP TABLE operation, but this is vendor-specific functionality and it is not widely implemented.)

Removing a table in DynamoDB

In DynamoDB, DeleteTable is a similar operation. In the following example, the table is permanently deleted.

```
{  
    TableName: "Music"  
}
```

Note

For code examples that use `DeleteTable`, see [Getting started with DynamoDB and the AWS SDKs](#).

Additional resources for Amazon DynamoDB

You can use the following additional resources to understand and work with DynamoDB.

- [AWS re:Invent 2020: DynamoDB advanced design patterns – Part 2](#)
- [DynamoDB Office Hours on Twitch](#)

 **Note**

Each session covers different use cases and examples.

Training courses

There are many different training courses and educational options for learning more about DynamoDB. Here are some current examples:

- [Developing with Amazon DynamoDB](#) – Designed by AWS to take you from beginner to expert in developing real-world applications with data modeling for Amazon DynamoDB.
- [DynamoDB deep-dive course](#) – A course from A Cloud Guru.
- [Amazon DynamoDB: Building NoSQL database-driven applications](#) – A course from the AWS Training and Certification team hosted on edX.

Setting up DynamoDB

In addition to the Amazon DynamoDB web service, AWS provides a downloadable version of DynamoDB that you can run on your computer. The downloadable version is helpful for developing and testing your code. It lets you write and test applications locally without accessing the DynamoDB web service.

The topics in this section describe how to set up DynamoDB (downloadable version) and the DynamoDB web service.

Topics

- [Setting up DynamoDB local \(downloadable version\)](#)
- [Setting up DynamoDB \(web service\)](#)

Setting up DynamoDB local (downloadable version)

With the downloadable version of Amazon DynamoDB, you can develop and test applications without accessing the DynamoDB web service. Instead, the database is self-contained on your computer. When you're ready to deploy your application in production, you remove the local endpoint in the code, and then it points to the DynamoDB web service.

Having this local version helps you save on throughput, data storage, and data transfer fees. In addition, you don't need an internet connection while you develop your application.

DynamoDB local is available as a [download](#) (requires JRE), as an [Apache Maven dependency](#), or as a [Docker image](#).

If you prefer to use the Amazon DynamoDB web service instead, see [Setting up DynamoDB \(web service\)](#).

Topics

- [Deploying DynamoDB locally on your computer](#)
- [DynamoDB local usage notes](#)
- [Release history for DynamoDB local](#)
- [Telemetry in DynamoDB local](#)

Deploying DynamoDB locally on your computer

Important

DynamoDB local jar can be downloaded from our AWS CloudFront distribution links referenced here. Starting January 1, 2025, the old S3 distribution buckets will no longer be active and DynamoDB local will be distributed through CloudFront distribution links only.

There are two major versions of DynamoDB local available: DynamoDB local v2.x (Current) and DynamoDB local v1.x (Legacy). Customers should use version 2.x (Current) when possible, as it supports the latest versions of the Java Runtime Environment and is compatible with the jakarta.* namespace for Maven project. DynamoDB local v1.x will reach end of standard support starting on January 1, 2025. After this date, v1.x will no longer receive updates or bug fixes.

Note

DynamoDB local AWS_ACCESS_KEY_ID can contain only letters (A–Z, a–z) and numbers (0–9).

Download DynamoDB local

Follow these steps to set up and run DynamoDB on your computer.

To set up DynamoDB on your computer

1. Download DynamoDB local for free from one of the following locations.

Download Links	Checksums
.tar.gz .zip	.tar.gz.sha256 .zip.sha256

⚠ Important

To run DynamoDB v2.3.0 or greater on your computer, you must have the Java Runtime Environment (JRE) version 17.x or newer. The application doesn't run on earlier JRE versions.

2. After you download the archive, extract the contents and copy the extracted directory to a location of your choice.
3. To start DynamoDB on your computer, open a command prompt window, navigate to the directory where you extracted DynamoDBLocal.jar, and enter the following command.

```
java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -sharedDb
```

ⓘ Note

If you're using Windows PowerShell, be sure to enclose the parameter name or the entire name and value like this:

```
java -D"java.library.path=./DynamoDBLocal_lib" -jar  
DynamoDBLocal.jar
```

DynamoDB processes incoming requests until you stop it. To stop DynamoDB, press Ctrl+C at the command prompt.

DynamoDB uses port 8000 by default. If port 8000 is unavailable, this command throws an exception. For a complete list of DynamoDB runtime options, including –port, enter this command.

```
java -Djava.library.path=./DynamoDBLocal_lib -jar  
DynamoDBLocal.jar -help
```

4. Before you can access DynamoDB programmatically or through the AWS Command Line Interface (AWS CLI), you must configure your credentials to enable authorization for your applications. Downloadable DynamoDB requires any credentials to work, as shown in the following example.

```
AWS Access Key ID: "fakeMyKeyId"  
AWS Secret Access Key: "fakeSecretAccessKey"  
Default Region Name: "fakeRegion"
```

You can use the `aws configure` command of the AWS CLI to set up credentials. For more information, see [Using the AWS CLI](#).

5. Start writing applications. To access DynamoDB running locally with the AWS CLI, use the `--endpoint-url` parameter. For example, use the following command to list DynamoDB tables.

```
aws dynamodb list-tables --endpoint-url http://localhost:8000
```

Run DynamoDB local as Docker image

The downloadable version of Amazon DynamoDB is available as a Docker image. For more information, see [dynamodb-local](#). To see your current DynamoDB local version, enter the following command:

```
java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar -version
```

For an example of using DynamoDB local as part of a REST application built on the AWS Serverless Application Model (AWS SAM), see [SAM DynamoDB application for managing orders](#). This sample application demonstrates how to use DynamoDB local for testing.

If you want to run a multi-container application that also uses the DynamoDB local container, use Docker Compose to define and run all the services in your application, including DynamoDB local.

To install and run DynamoDB local with Docker compose:

1. Download and install [Docker desktop](#).
2. Copy the following code to a file and save it as `docker-compose.yml`.

```
version: '3.8'
services:
  dynamodb-local:
    command: "-jar DynamoDBLocal.jar -sharedDb -dbPath ./data"
    image: "amazon/dynamodb-local:latest"
    container_name: dynamodb-local
    ports:
      - "8000:8000"
    volumes:
      - "./docker/dynamodb:/home/dynamodblocal/data"
```

```
working_dir: /home/dynamodblocal
```

If you want your application and DynamoDB local to be in separate containers, use the following yaml file.

```
version: '3.8'
services:
  dynamodb-local:
    command: "-jar DynamoDBLocal.jar -sharedDb -dbPath ./data"
    image: "amazon/dynamodb-local:latest"
    container_name: dynamodb-local
    ports:
      - "8000:8000"
    volumes:
      - "./docker/dynamodb:/home/dynamodblocal/data"
    working_dir: /home/dynamodblocal
  app-node:
    depends_on:
      - dynamodb-local
    image: amazon/aws-cli
    container_name: app-node
    ports:
      - "8080:8080"
    environment:
      AWS_ACCESS_KEY_ID: 'DUMMYIDEXAMPLE'
      AWS_SECRET_ACCESS_KEY: 'DUMMYEXAMPLEKEY'
    command:
      dynamodb describe-limits --endpoint-url http://dynamodb-local:8000 --region us-west-2
```

This docker-compose.yml script creates an app-node container and a dynamodb-local container. The script runs a command in the app-node container that uses the AWS CLI to connect to the dynamodb-local container and describes the account and table limits.

To use with your own application image, replace the `image` value in the example below with that of your application.

```
version: '3.8'
services:
  dynamodb-local:
    command: "-jar DynamoDBLocal.jar -sharedDb -dbPath ./data"
```

```
image: "amazon/dynamodb-local:latest"
container_name: dynamodb-local
ports:
  - "8000:8000"
volumes:
  - "./docker/dynamodb:/home/dynamodblocal/data"
working_dir: /home/dynamodblocal
app-node:
  image: location-of-your-dynamodb-demo-app:latest
  container_name: app-node
  ports:
    - "8080:8080"
  depends_on:
    - "dynamodb-local"
links:
  - "dynamodb-local"
environment:
  AWS_ACCESS_KEY_ID: 'DUMMYIDEXAMPLE'
  AWS_SECRET_ACCESS_KEY: 'DUMMYEXAMPLEKEY'
  REGION: 'eu-west-1'
```

Note

The YAML scripts require that you specify an AWS access key and an AWS secret key, but they are not required to be valid AWS keys for you to access DynamoDB local.

3. Run the following command-line command:

```
docker-compose up
```

Run DynamoDB local as an Apache Maven dependency

Follow these steps to use Amazon DynamoDB in your application as a dependency.

To deploy DynamoDB as an Apache Maven repository

1. Download and install Apache Maven. For more information, see [Downloading Apache Maven](#) and [Installing Apache Maven](#).
2. Add the DynamoDB Maven repository to your application's Project Object Model (POM) file.

```
<!--Dependency:-->
<dependencies>
    <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>DynamoDBLocal</artifactId>
        <version>2.3.0</version>
    </dependency>
</dependencies>
```

Example template for use with Spring Boot 3 and/or Spring Framework 6:

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://
maven.apache.org/xsd/maven-4.0.0.xsd">
<modelVersion>4.0.0</modelVersion>

<groupId>org.example</groupId>
<artifactId>SpringMavenDynamoDB</artifactId>
<version>1.0-SNAPSHOT</version>

<properties>
    <spring-boot.version>3.0.1</spring-boot.version>
    <maven.compiler.source>17</maven.compiler.source>
    <maven.compiler.target>17</maven.compiler.target>
    <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
</properties>

<parent>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-parent</artifactId>
    <version>3.0.1</version>
</parent>

<dependencies>
    <dependency>
        <groupId>com.amazonaws</groupId>
        <artifactId>DynamoDBLocal</artifactId>
        <version>2.3.0</version>
    </dependency>
    <!-- Spring Boot -->
```

```
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter</artifactId>
    <version>${spring-boot.version}</version>
</dependency>
<!-- Spring Web -->
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-web</artifactId>
    <version>${spring-boot.version}</version>
</dependency>
<!-- Spring Data JPA -->
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-data-jpa</artifactId>
    <version>${spring-boot.version}</version>
</dependency>
<!-- Other Spring dependencies -->
<!-- Replace the version numbers with the desired version -->
<dependency>
    <groupId>org.springframework</groupId>
    <artifactId>spring-context</artifactId>
    <version>6.0.0</version>
</dependency>
<dependency>
    <groupId>org.springframework</groupId>
    <artifactId>spring-core</artifactId>
    <version>6.0.0</version>
</dependency>
<!-- Add other Spring dependencies as needed -->
<!-- Add any other dependencies your project requires -->
</dependencies>
</project>
```

 **Note**

You can also use the [Maven central repository](#) URL.

For an example of a sample project that showcases multiple approaches to set up and use DynamoDB local, including downloading JAR files, running it as a Docker image, and using it as a Maven dependency, see [DynamoDB Local Sample Java Project](#).

DynamoDB local usage notes

Except for the endpoint, applications that run with the downloadable version of Amazon DynamoDB should also work with the DynamoDB web service. However, when using DynamoDB locally, you should be aware of the following:

- If you use the `-sharedDb` option, DynamoDB creates a single database file named *shared-local-instance.db*. Every program that connects to DynamoDB accesses this file. If you delete the file, you lose any data that you have stored in it.
- If you omit `-sharedDb`, the database file is named *myaccesskeyid_region.db*, with the AWS access key ID and AWS Region as they appear in your application configuration. If you delete the file, you lose any data that you have stored in it.
- If you use the `-inMemory` option, DynamoDB doesn't write any database files at all. Instead, all data is written to memory, and the data is not saved when you terminate DynamoDB.
- If you use the `-inMemory` option, the `-sharedDb` option is also required.
- If you use the `-optimizeDbBeforeStartup` option, you must also specify the `-dbPath` parameter so that DynamoDB can find its database file.
- The AWS SDKs for DynamoDB require that your application configuration specify an access key value and an AWS Region value. Unless you're using the `-sharedDb` or the `-inMemory` option, DynamoDB uses these values to name the local database file. These values don't have to be valid AWS values to run locally. However, you might find it convenient to use valid values so that you can run your code in the cloud later by changing the endpoint you're using.
- DynamoDB local always returns null for `billingModeSummary`.
- DynamoDB local `AWS_ACCESS_KEY_ID` can contain only letters (A–Z, a–z) and numbers (0–9).

Topics

- [Command line options](#)
- [Setting the local endpoint](#)
- [Differences between downloadable DynamoDB and the DynamoDB web service](#)

Command line options

You can use the following command line options with the downloadable version of DynamoDB:

- **-cors value** — Enables support for cross-origin resource sharing (CORS) for JavaScript. You must provide a comma-separated "allow" list of specific domains. The default setting for **-cors** is an asterisk (*), which allows public access.
- **-dbPath value** — The directory where DynamoDB writes its database file. If you don't specify this option, the file is written to the current directory. You can't specify both **-dbPath** and **-inMemory** at once.
- **-delayTransientStatuses** — Causes DynamoDB to introduce delays for certain operations. DynamoDB (downloadable version) can perform some tasks almost instantaneously, such as create/update/delete operations on tables and indexes. However, the DynamoDB service requires more time for these tasks. Setting this parameter helps DynamoDB running on your computer simulate the behavior of the DynamoDB web service more closely. (Currently, this parameter introduces delays only for global secondary indexes that are in either *CREATING* or *DELETING* status.)
- **-help** — Prints a usage summary and options.
- **-inMemory** — DynamoDB runs in memory instead of using a database file. When you stop DynamoDB, none of the data is saved. You can't specify both **-dbPath** and **-inMemory** at once.
- **-optimizeDbBeforeStartup** — Optimizes the underlying database tables before starting DynamoDB on your computer. You also must specify **-dbPath** when you use this parameter.
- **-port value** — The port number that DynamoDB uses to communicate with your application. If you don't specify this option, the default port is 8000.

 **Note**

DynamoDB uses port 8000 by default. If port 8000 is unavailable, this command throws an exception. You can use the **-port** option to specify a different port number. For a complete list of DynamoDB runtime options, including **-port**, type this command:

```
java -Djava.library.path=./DynamoDBLocal_lib -jar DynamoDBLocal.jar  
-help
```

- **-sharedDb** — If you specify **-sharedDb**, DynamoDB uses a single database file instead of separate files for each credential and Region.
- **-disableTelemetry** — When specified, DynamoDB local will not send any telemetry.
- **-version** — Prints the version of DynamoDB local.

Setting the local endpoint

By default, the AWS SDKs and tools use endpoints for the Amazon DynamoDB web service. To use the SDKs and tools with the downloadable version of DynamoDB, you must specify the local endpoint:

`http://localhost:8000`

AWS Command Line Interface

You can use the AWS Command Line Interface (AWS CLI) to interact with downloadable DynamoDB. For example, you can use it to perform all the steps in [Creating tables and loading data for code examples in DynamoDB](#).

To access DynamoDB running locally, use the `--endpoint-url` parameter. The following is an example of using the AWS CLI to list the tables in DynamoDB on your computer.

```
aws dynamodb list-tables --endpoint-url http://localhost:8000
```

Note

The AWS CLI can't use the downloadable version of DynamoDB as a default endpoint. Therefore, you must specify `--endpoint-url` with each AWS CLI command.

AWS SDKs

The way you specify an endpoint depends on the programming language and AWS SDK you're using. The following sections describe how to do this:

- [Java: Setting the AWS Region and endpoint](#) (DynamoDB local supports the AWS SDK for Java V1 and V2)
- [.NET: Setting the AWS Region and endpoint](#)

Note

For examples in other programming languages, see [Getting started with DynamoDB and the AWS SDKs](#).

Differences between downloadable DynamoDB and the DynamoDB web service

The downloadable version of DynamoDB is intended for development and testing purposes only. By comparison, the DynamoDB web service is a managed service with scalability, availability, and durability features that make it ideal for production use.

The downloadable version of DynamoDB differs from the web service in the following ways:

- AWS Regions and distinct AWS accounts are not supported at the client level.
- Provisioned throughput settings are ignored in downloadable DynamoDB, even though the `CreateTable` operation requires them. For `CreateTable`, you can specify any numbers you want for provisioned read and write throughput, even though these numbers are not used. You can call `UpdateTable` as many times as you want per day. However, any changes to provisioned throughput values are ignored.
- Scan operations are performed sequentially. Parallel scans are not supported. The `Segment` and `TotalSegments` parameters of the `Scan` operation are ignored.
- The speed of read and write operations on table data is limited only by the speed of your computer. `CreateTable`, `UpdateTable`, and `DeleteTable` operations occur immediately, and table state is always ACTIVE. `UpdateTable` operations that change only the provisioned throughput settings on tables or global secondary indexes occur immediately. If an `UpdateTable` operation creates or deletes any global secondary indexes, then those indexes transition through normal states (such as CREATING and DELETING, respectively) before they become an ACTIVE state. The table remains ACTIVE during this time.
- Read operations are eventually consistent. However, due to the speed of DynamoDB running on your computer, most reads appear to be strongly consistent.
- Item collection metrics and item collection sizes are not tracked. In operation responses, nulls are returned instead of item collection metrics.
- In DynamoDB, there is a 1 MB limit on data returned per result set. Both the DynamoDB web service and the downloadable version enforce this limit. However, when querying an index, the DynamoDB service calculates only the size of the projected key and attributes. By contrast, the downloadable version of DynamoDB calculates the size of the entire item.
- If you're using DynamoDB Streams, the rate at which shards are created might differ. In the DynamoDB web service, shard-creation behavior is partially influenced by table partition activity. When you run DynamoDB locally, there is no table partitioning. In either case, shards are ephemeral, so your application should not be dependent on shard behavior.

- `TransactionConflictExceptions` aren't thrown by downloadable DynamoDB for transactional APIs. We recommend that you use a Java mocking framework to simulate `TransactionConflictExceptions` in the DynamoDB handler to test how your application responds to conflicting transactions.
- In the DynamoDB web service, whether being accessed via the console or the AWS CLI, table names are case sensitive. A table named `Authors` and one named `authors` can both exist as separate tables. In the downloadable version, table names are case insensitive, and attempting to create these two tables would result in an error.
- Tagging is not supported in the downloadable version of DynamoDB.
- The downloadable version of DynamoDB ignores the [Limit](#) parameter in [ExecuteStatement](#).

Release history for DynamoDB local

The following table describes the important changes in each release of *DynamoDB local*.

Version	Change	Description	Date
2.3.0	Jetty and JDK Upgrade	<ul style="list-style-type: none">Upgrading to Jetty 12.0.2Upgrading to JDK 17Upgrading ANTLR4 to 4.10.1	March 14, 2024
2.2.0	Added support for table deletion protection and the <code>ReturnValuesOnConditionCheckFailure</code> parameter	<ul style="list-style-type: none">Added support of Table delete protectionAdded support for <code>ReturnValuesOnConditionCheckFailure</code>Added support for -version flag	December 14, 2023
2.1.0	Support for SQLite Native Libraries for	<ul style="list-style-type: none">Adding telemetry to DynamoDB local	October 23, 2023

1.18.0	Upgraded log4j-core and Jackson-core	Upgraded log4j-core to 2.17.1 and Jackson-core 2.10.x to 2.12.0	January 10, 2022
1.17.2	Upgraded log4j-core	Upgraded log4j-core dependency to version 2.16	January 16, 2021

Version	Change	Description	Date
1.17.1	Upgraded log4j-core	Updated log4j-core dependency to patch zero-day exploit to prevent remote code execution - Log4Shell	January 10, 2021
1.17.0	Deprecated Javascript Web Shell	<ul style="list-style-type: none">• Updated the AWS SDK dependency to AWS SDK for Java 1.12.x• Deprecated Javascript Web Shell	January 8, 2021

Telemetry in DynamoDB local

At AWS, we develop and launch services based on what we learn from interactions with customers, and we use customer feedback to iterate on our products. Telemetry is additional information that helps us to better understand our customers needs, diagnose issues, and deliver features that improve the customer experience.

DynamoDB local collects telemetry, such as generic usage metrics, systems and environment information, and errors. For details about the types of telemetry collected, see [Types of information collected](#).

DynamoDB local does not collect personal information, such as user names or email addresses. It also does not extract sensitive project-level information.

As a customer, you control whether telemetry is turned on, and you can change your settings at any point in time. If telemetry remains on, DynamoDB local sends telemetry data in the background without requiring any additional customer interaction.

Turn off telemetry using command line options

You can turn off telemetry using command line options when starting DynamoDB local using the option `-disableTelemetry`. For more information, see [Command line options](#)

Turn off telemetry for a single session

In macOS and Linux operating systems, you can turn off telemetry for a single session. To turn off telemetry for your current session, run the following command to set the environment variable DDB_LOCAL_TELEMETRY to false. Repeat the command for each new terminal or session.

```
export DDB_LOCAL_TELEMETRY=0
```

Turn off telemetry for your profile in all sessions

Run the following commands to turn off telemetry for all sessions when you're running DynamoDB local on your operating system.

To turn off telemetry in Linux

1. Run:

```
echo "export DDB_LOCAL_TELEMETRY=0" >>~/.profile
```

2. Run:

```
source ~/.profile
```

To turn off telemetry in macOS

1. Run:

```
echo "export DDB_LOCAL_TELEMETRY=0" >>~/.profile
```

2. Run:

```
source ~/.profile
```

To turn off telemetry in Windows

1. Run:

```
setx DDB_LOCAL_TELEMETRY 0
```

2. Run:

```
refreshenv
```

Types of information collected

- **Usage information** — The generic telemetry like server start/stop and the API or Operation called.
- **System and environment information** — The Java version, operating system (Windows, Linux or macOS), the environment in which DynamoDB local runs (for example, Stand alone JAR, Docker container, or as a Maven Dependency), and hash values of usage attributes.

Learn more

The telemetry data that DynamoDB local collects adheres to the AWS data privacy policies. For more information, see the following:

- [AWS service terms](#)
- [Data privacy FAQ](#)

Setting up DynamoDB (web service)

To use the Amazon DynamoDB web service:

1. [Sign up for AWS](#).
2. [Get an AWS access key](#) (used to access DynamoDB programmatically).

 **Note**

If you plan to interact with DynamoDB only through the AWS Management Console, you don't need an AWS access key, and you can skip ahead to [Using the console](#).

3. [Configure your credentials](#) (used to access DynamoDB programmatically).

Signing up for AWS

To use the DynamoDB service, you must have an AWS account. If you don't already have an account, you are prompted to create one when you sign up. You're not charged for any AWS services that you sign up for unless you use them.

To sign up for AWS

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

Granting programmatic access

Before you can access DynamoDB programmatically or through the AWS Command Line Interface (AWS CLI), you must have programmatic access. You don't need programmatic access if you plan to use the DynamoDB console only.

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use.

Which user needs programmatic access?	To	By
		<ul style="list-style-type: none">For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center in the <i>AWS Command Line Interface User Guide</i>.For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the <i>AWS SDKs and Tools Reference Guide</i>.
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions in Using temporary credentials with AWS resources in the <i>IAM User Guide</i> .

Which user needs programmatic access?	To	By
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use. <ul style="list-style-type: none">• For the AWS CLI, see Authenticating using IAM user credentials in the <i>AWS Command Line Interface User Guide</i>.• For AWS SDKs and tools, see Authenticate using long-term credentials in the <i>AWS SDKs and Tools Reference Guide</i>.• For AWS APIs, see Managing access keys for IAM users in the <i>IAM User Guide</i>.

Configuring your credentials

Before you can access DynamoDB programmatically or through the AWS CLI, you must configure your credentials to enable authorization for your applications.

There are several ways to do this. For example, you can manually create the credentials file to store your access key ID and secret access key. You also can use the AWS CLI command `aws configure` to automatically create the file. Alternatively, you can use environment variables. For more information about configuring your credentials, see the programming-specific AWS SDK developer guide.

To install and configure the AWS CLI, see [Using the AWS CLI](#).

Integrating with other DynamoDB services

You can integrate DynamoDB with many other AWS services. For more information, see the following:

- [Using DynamoDB with other AWS services](#)
- [AWS CloudFormation for DynamoDB](#)
- [Using AWS Backup with DynamoDB](#)
- [AWS Identity and Access Management \(IAM\)](#)
- [Using AWS Identity and Access Management with DynamoDB](#)

Accessing DynamoDB

You can access Amazon DynamoDB using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API.

Topics

- [Using the console](#)
- [Using the AWS CLI](#)
- [Using the API](#)
- [Using the NoSQL workbench for DynamoDB](#)
- [IP address ranges](#)

Using the console

You can access the AWS Management Console for Amazon DynamoDB at <https://console.aws.amazon.com/dynamodb/home>.

You can use the console to do the following in DynamoDB:

- Monitor recent alerts, total capacity, service health, and the latest DynamoDB news on the DynamoDB dashboard.
- Create, update, and delete tables. The capacity calculator provides estimates of how many capacity units to request based on the usage information you provide.
- Manage streams.
- View, add, update, and delete items that are stored in tables. Manage Time to Live (TTL) to define when items in a table expire so that they can be automatically deleted from the database.
- Query and scan a table.
- Set up and view alarms to monitor your table's capacity usage. View your table's top monitoring metrics on real-time graphs from CloudWatch.
- Modify a table's provisioned capacity.
- Modify a table's table class.
- Create and delete global secondary indexes.

- Create triggers to connect DynamoDB streams to AWS Lambda functions.
- Apply tags to your resources to help organize and identify them.
- Purchase reserved capacity.

The console displays an introductory screen that prompts you to create your first table. To view your tables, in the navigation pane on the left side of the console, choose **Tables**.

Here's a high-level overview of the actions available per table within each navigation tab:

- **Overview** – View table details, including item count and metrics.
- **Indexes** – Manage global and local secondary indexes.
- **Monitor** – View alarms, CloudWatch Contributor Insights, and Cloudwatch metrics.
- **Global tables** – Manage table replicas.
- **Backups** – Manage point-in-time recovery and on-demand backups.
- **Exports and streams** – Export your table to Amazon S3 and manage DynamoDB Streams and Kinesis Data Streams.
- **Additional settings** – Manage read/write capacity, Time to Live settings, encryption, and tags.

Using the AWS CLI

You can use the AWS Command Line Interface (AWS CLI) to control multiple AWS services from the command line and automate them through scripts. You can use the AWS CLI for ad hoc operations, such as creating a table. You can also use it to embed Amazon DynamoDB operations within utility scripts.

Before you can use the AWS CLI with DynamoDB, you must get an access key ID and secret access key. For more information, see [Granting programmatic access](#).

For a complete listing of all the commands available for DynamoDB in the AWS CLI, see the [AWS CLI command reference](#).

Topics

- [Downloading and configuring the AWS CLI](#)
- [Using the AWS CLI with DynamoDB](#)
- [Using the AWS CLI with DynamoDB local](#)

Downloading and configuring the AWS CLI

The AWS CLI is available at <http://aws.amazon.com/cli>. It runs on Windows, macOS, or Linux. After you download the AWS CLI, follow these steps to install and configure it:

1. Go to the [AWS Command Line Interface User Guide](#).
2. Follow the instructions for [Installing the AWS CLI](#) and [Configuring the AWS CLI](#).

Using the AWS CLI with DynamoDB

The command line format consists of a DynamoDB operation name followed by the parameters for that operation. The AWS CLI supports a shorthand syntax for the parameter values, as well as JSON.

For example, the following command creates a table named *Music*. The partition key is *Artist*, and the sort key is *SongTitle*. (For easier readability, long commands in this section are broken into separate lines.)

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions \
    AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
  --key-schema AttributeName=Artist,KeyType=HASH
  AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput ReadCapacityUnits=1,WriteCapacityUnits=1 \
  --table-class STANDARD
```

The following commands add new items to the table. These examples use a combination of shorthand syntax and JSON.

```
aws dynamodb put-item \
  --table-name Music \
  --item \
    '{"Artist": {"S": "No One You Know"}, "SongTitle": {"S": "Call Me Today"}, \
    "AlbumTitle": {"S": "Somewhat Famous"}}' \
  --return-consumed-capacity TOTAL

aws dynamodb put-item \
  --table-name Music \
```

```
--item '{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"},  
    "AlbumTitle": {"S": "Songs About Life"} }' \  
--return-consumed-capacity TOTAL
```

On the command line, it can be difficult to compose valid JSON. However, the AWS CLI can read JSON files. For example, consider the following JSON code snippet, which is stored in a file named *key-conditions.json*.

```
{  
    "Artist": {  
        "AttributeValueList": [  
            {  
                "S": "No One You Know"  
            }  
        ],  
        "ComparisonOperator": "EQ"  
    },  
    "SongTitle": {  
        "AttributeValueList": [  
            {  
                "S": "Call Me Today"  
            }  
        ],  
        "ComparisonOperator": "EQ"  
    }  
}
```

You can now issue a Query request using the AWS CLI. In this example, the contents of the *key-conditions.json* file are used for the --key-conditions parameter.

```
aws dynamodb query --table-name Music --key-conditions file://key-conditions.json
```

Using the AWS CLI with DynamoDB local

The AWS CLI can also interact with DynamoDB local (downloadable version) that runs on your computer. To enable this, add the following parameter to each command:

```
--endpoint-url http://localhost:8000
```

The following example uses the AWS CLI to list the tables in a local database.

```
aws dynamodb list-tables --endpoint-url http://localhost:8000
```

If DynamoDB is using a port number other than the default (8000), modify the `--endpoint-url` value accordingly.

 **Note**

The AWS CLI can't use the DynamoDB local (downloadable version) as a default endpoint. Therefore, you must specify `--endpoint-url` with each command.

Using the API

You can use the AWS Management Console and the AWS Command Line Interface to work interactively with Amazon DynamoDB. However, to get the most out of DynamoDB, you can write application code using the AWS SDKs.

The AWS SDKs provide broad support for DynamoDB in [Java](#), [JavaScript in the browser](#), [.NET](#), [Node.js](#), [PHP](#), [Python](#), [Ruby](#), [C++](#), [Go](#), [Android](#), and [iOS](#). To get started quickly with these languages, see [Getting started with DynamoDB and the AWS SDKs](#).

Before you can use the AWS SDKs with DynamoDB, you must get an AWS access key ID and secret access key. For more information, see [Setting up DynamoDB \(web service\)](#).

For a high-level overview of DynamoDB application programming with the AWS SDKs, see [Programming with DynamoDB and the AWS SDKs](#).

Using the NoSQL workbench for DynamoDB

You can also access DynamoDB by downloading and using the [NoSQL Workbench for DynamoDB](#).

NoSQL Workbench for Amazon DynamoDB is a cross-platform, client-side GUI application that you can use for modern database development and operations. It's available for Windows, macOS, and Linux. NoSQL Workbench is a visual development tool that provides data modeling, data visualization, and query development features to help you design, create, query, and manage DynamoDB tables. NoSQL Workbench now includes DynamoDB local as an optional part of the installation process, which makes it easier to model your data in DynamoDB local. To learn more

about DynamoDB local and its requirements, see [Setting up DynamoDB local \(downloadable version\)](#).

Note

The NoSQL Workbench for DynamoDB currently doesn't support AWS logins that are configured with two-factor authentication (2FA).

Data modeling

With NoSQL Workbench for DynamoDB, you can build new data models from, or design models based on, existing data models that satisfy your application's data access patterns. You can also import and export the designed data model at the end of the process. For more information, see [Building data models with NoSQL Workbench](#).

Data visualization

The data model visualizer provides a canvas where you can map queries and visualize the access patterns (facets) of the application without having to write code. Every facet corresponds to a different access pattern in DynamoDB. You can autogenerate sample data for use in your data model. For more information, see [Visualizing data access patterns](#).

Operation building

NoSQL Workbench provides a rich graphical user interface for you to develop and test queries. You can use the *operation builder* to view, explore, and query live datasets. You can also use the structured operation builder to build and perform data plane operations. It supports projection and condition expression, and lets you generate sample code in multiple languages. For more information, see [Exploring datasets and building operations with NoSQL Workbench](#).

IP address ranges

Amazon Web Services (AWS) publishes its current IP address ranges in JSON format. To view the current ranges, download [ip-ranges.json](#). For more information, see [AWS IP address ranges](#) in the AWS General Reference.

To find the IP address ranges that you can use to [access to DynamoDB tables and indexes](#), search the ip-ranges.json file for the following string: "service": "DYNAMODB".

Note

The IP address ranges do not apply to DynamoDB Streams or DynamoDB Accelerator (DAX).

Getting started with DynamoDB

Use the hands-on tutorials in this section to help you get started and learn more about Amazon DynamoDB.

Topics

- [Basic concepts in DynamoDB](#)
- [Prerequisites - getting started tutorial](#)
- [Step 1: Create a table](#)
- [Step 2: Write data to a table using the console or AWS CLI](#)
- [Step 3: Read data from a table](#)
- [Step 4: Update data in a table](#)
- [Step 5: Query data in a table](#)
- [Step 6: Create a global secondary index](#)
- [Step 7: Query the global secondary index](#)
- [Step 8: \(Optional\) clean up resources](#)
- [Getting started with DynamoDB: Next steps](#)

Basic concepts in DynamoDB

Before you begin, you should familiarize yourself with the basic concepts in Amazon DynamoDB. For more information, see [DynamoDB core components](#).

Then continue on to [Prerequisites](#) to learn about setting up DynamoDB.

Prerequisites - getting started tutorial

Before starting the Amazon DynamoDB tutorial, follow the steps in [Setting up DynamoDB](#). Then continue on to [Step 1: Create a table](#).

Note

- If you plan to interact with DynamoDB only through the AWS Management Console, you don't need an AWS access key. Complete the steps in [Signing up for AWS](#), and then continue on to [Step 1: Create a table](#).
- If you don't want to sign up for a free tier account, you can set up [DynamoDB local \(downloadable version\)](#). Then continue on to [Step 1: Create a table](#).
- There are differences when working with CLI commands in terminals on Linux and Windows. The following guide presents commands formatted for Linux terminals (this includes macOS), and commands formatted for Windows CMD. Choose the command that best fits the terminal application you are using.

Step 1: Create a table

In this step, you create a Music table in Amazon DynamoDB. The table has the following details:

- Partition key — Artist
- Sort key — SongTitle

For more information about table operations, see [Working with tables and data in DynamoDB](#).

Note

Before you begin, make sure that you followed the steps in [Prerequisites - getting started tutorial](#).

AWS Management Console

To create a new Music table using the DynamoDB console:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Dashboard**.
3. On the right side of the console, choose **Create Table**.

Create a table

Create an Amazon DynamoDB table for fast and predictable database performance at any scale.

[Learn more !\[\]\(f5f6fa381223eb14fa65a973ea1d362f_img.jpg\)](#)

Create table

4. Enter the table details as follows:
 - a. For the table name, enter **Music**.
 - b. For the partition key, enter **Artist**.
 - c. Enter **SongTitle** as the sort key.
 - d. Leave **Default settings** selected.
5. Choose **Create** to create the table.

Create table

Table details Info

DynamoDB is a schemaless database that requires only a table name and a primary key when you create the table.

Table name

This will be used to identify your table.

Between 3 and 255 characters, containing only letters, numbers, underscores (_), hyphens (-), and periods (.).

Partition key

The partition key is part of the table's primary key. It is a hash value that is used to retrieve items from your table and allocate data across hosts for scalability and availability.

1 to 255 characters and case sensitive.

Sort key - optional

You can use a sort key as the second part of a table's primary key. The sort key allows you to sort or search among all items sharing the same partition key.

1 to 255 characters and case sensitive.

Settings

Default settings

The fastest way to create your table. You can modify these settings now or after your table has been created.

Customize settings

Use these advanced features to make DynamoDB work better for your needs.

Default settings

Read/write capacity Info

Using provisioned capacity mode. Read and write capacity are set to 5 units each with auto scaling enabled.

Secondary indexes Info

No secondary indexes have been created. Queries will be run by using the table's partition key and sort key only.

Key management for encryption at rest Info

Using the AWS owned customer master key. This key is managed by DynamoDB at no extra cost.

Tags

Tags are pairs of keys and optional values, that you can assign to AWS resources. You can use tags to control access to your resources or track your AWS spending.

6. Once the table is in ACTIVE status, it's considered best practice to enable [Point-in-time recovery for DynamoDB](#) on the table by performing the following steps:

- a. Click the table name to open the table.
- b. Click **Backups**.
- c. Click the **Edit** button in the Point-in-time recovery section.
- d. Click the checkbox to turn on point-in-time recovery, then click the **Save changes** button.

Point-in-time recovery is now enabled for your newly created Music table.

AWS CLI

The following AWS CLI example creates a new Music table using `create-table`.

Linux

```
aws dynamodb create-table \
--table-name Music \
--attribute-definitions \
   AttributeName=Artist,AttributeType=S \
   AttributeName=SongTitle,AttributeType=S \
--key-schema \
   AttributeName=Artist,KeyType=HASH \
   AttributeName=SongTitle,KeyType=RANGE \
--provisioned-throughput \
    ReadCapacityUnits=5,WriteCapacityUnits=5 \
--table-class STANDARD
```

Windows CMD

```
aws dynamodb create-table ^
--table-name Music ^
--attribute-definitions ^
   AttributeName=Artist,AttributeType=S ^
   AttributeName=SongTitle,AttributeType=S ^
--key-schema ^
   AttributeName=Artist,KeyType=HASH ^
   AttributeName=SongTitle,KeyType=RANGE ^
--provisioned-throughput ^
    ReadCapacityUnits=5,WriteCapacityUnits=5 ^
```

```
--table-class STANDARD
```

Using `create-table` returns the following sample result.

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "Music",  
        "KeySchema": [  
            {  
                "AttributeName": "Artist",  
                "KeyType": "HASH"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "KeyType": "RANGE"  
            }  
        ],  
        "TableStatus": "CREATING",  
        "CreationDateTime": "2023-03-29T12:11:43.379000-04:00",  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "ReadCapacityUnits": 5,  
            "WriteCapacityUnits": 5  
        },  
        "TableSizeBytes": 0,  
        "ItemCount": 0,  
        "TableArn": "arn:aws:dynamodb:us-east-1:111122223333:table/Music",  
        "TableId": "60abf404-1839-4917-a89b-a8b0ab2a1b87",  
        "TableClassSummary": {  
            "TableClass": "STANDARD"  
        }  
    }  
}
```

```
}
```

Note that the value of the TableStatus field is set to CREATING.

To verify that DynamoDB has finished creating the Music table, use the describe-table command.

Linux

```
aws dynamodb describe-table --table-name Music | grep TableStatus
```

Windows CMD

```
aws dynamodb describe-table --table-name Music | findstr TableStatus
```

This command returns the following result. When DynamoDB finishes creating the table, the value of the TableStatus field is set to ACTIVE.

```
"TableStatus": "ACTIVE",
```

Once the table is in ACTIVE status, it's considered best practice to enable [Point-in-time recovery for DynamoDB](#) on the table by running the following command:

Linux

```
aws dynamodb update-continuous-backups \
  --table-name Music \
  --point-in-time-recovery-specification \
    PointInTimeRecoveryEnabled=true
```

Windows CMD

```
aws dynamodb update-continuous-backups --table-name Music --point-in-time-recovery-
specification PointInTimeRecoveryEnabled=true
```

This command returns the following result.

```
{  
    "ContinuousBackupsDescription": {  
        "ContinuousBackupsStatus": "ENABLED",  
        "PointInTimeRecoveryDescription": {  
            "PointInTimeRecoveryStatus": "ENABLED",  
            "EarliestRestorableDateTime": "2023-03-29T12:18:19-04:00",  
            "LatestRestorableDateTime": "2023-03-29T12:18:19-04:00"  
        }  
    }  
}
```

Note

There are cost implications to enabling continuous backups with point-in-time recovery. For more information about pricing, see [Amazon DynamoDB pricing](#).

After creating the new table, proceed to [Step 2: Write data to a table using the console or AWS CLI](#).

Step 2: Write data to a table using the console or AWS CLI

In this step, you insert several items into the Music table that you created in [Step 1: Create a table](#).

For more information about write operations, see [Writing an item](#).

AWS Management Console

Follow these steps to write data to the Music table using the DynamoDB console.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. In the table list, choose the **Music** table.

DynamoDB

Actions ▾ Create item

Find items

< 1 > ⚙️ ✎

6. Choose **Add new attribute**, and then choose **Number**. Name the field **Awards**.

7. Repeat this process to create an **AlbumTitle** of type **String**.
8. Enter the following values for your item:
 - a. For **Artist**, enter **No One You Know** as the value.
 - b. For **SongTitle**, enter **Call Me Today**.
 - c. For **AlbumTitle**, enter **Somewhat Famous**.
 - d. For **Awards**, enter **1**.

9. Choose **Create item**.

Create item

Attributes

Attribute name	Value	Type
Artist - <i>Partition key</i>	No One You Know	String
SongTitle - <i>Sort key</i>	Call Me Today	String
Awards	1	Number
AlbumTitle	Somewhat Famous	String

Add new attribute ▾

Cancel **Create Item**

10. Repeat this process and create another item with the following values:

- For **Artist**, enter **Acme Band**.
- For **SongTitle** enter **Happy Day**.
- For **AlbumTitle**, enter **Songs About Life**.
- For **Awards**, enter **10**.

11. Do this one more time to create another item with the same **Artist** as the previous step, but different values for the other attributes:

- For **Artist**, enter **Acme Band**.
- For **SongTitle** enter **PartiQL Rocks**.
- For **AlbumTitle**, enter **Another Album Title**.
- For **Awards**, enter **8**.

AWS CLI

The following AWS CLI example creates several new items in the Music table. You can do this either through the DynamoDB API or [PartiQL](#), a SQL-compatible query language for DynamoDB.

DynamoDB API

Linux

```
aws dynamodb put-item \
--table-name Music \
--item \
'{"Artist": {"S": "No One You Know"}, "SongTitle": {"S": "Call Me Today"}, \
"AlbumTitle": {"S": "Somewhat Famous"}, "Awards": {"N": "1"}}'

aws dynamodb put-item \
--table-name Music \
--item \
'{"Artist": {"S": "No One You Know"}, "SongTitle": {"S": "Howdy"}, \
"AlbumTitle": {"S": "Somewhat Famous"}, "Awards": {"N": "2"}}'

aws dynamodb put-item \
--table-name Music \
--item \
'{"Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"}, \
"AlbumTitle": {"S": "Songs About Life"}, "Awards": {"N": "10"}}'

aws dynamodb put-item \
--table-name Music \
--item \
'{"Artist": {"S": "Acme Band"}, "SongTitle": {"S": "PartiQL Rocks"}, \
"AlbumTitle": {"S": "Another Album Title"}, "Awards": {"N": "8"}}'
```

Windows CMD

```
aws dynamodb put-item ^
--table-name Music ^
--item ^
'{"\\"Artist\\": {\\"S\\": \"No One You Know\"}, \\"SongTitle\\": {\\"S\\": \"Call \
Me Today\"}, \\"AlbumTitle\\": {\\"S\\": \"Somewhat Famous\"}, \\"Awards\\": {\\"N\\": \
\"1\"}}'

aws dynamodb put-item ^
--table-name Music ^
--item ^
'{"\\"Artist\\": {\\"S\\": \"No One You Know\"}, \\"SongTitle\\": {\\"S\\": \"Howdy\"}, \
\\"AlbumTitle\\": {\\"S\\": \"Somewhat Famous\"}, \\"Awards\\": {\\"N\\": \"2\"}}'

aws dynamodb put-item ^
--table-name Music ^
--item ^
```

```
"{\"Artist\": {\"S\": \"Acme Band\"}, \"SongTitle\": {\"S\": \"Happy Day\"},  
\"AlbumTitle\": {\"S\": \"Songs About Life\"}, \"Awards\": {\"N\": \"10\"}}"  
  
aws dynamodb put-item ^  
  --table-name Music ^  
  --item ^  
    "{\"Artist\": {\"S\": \"Acme Band\"}, \"SongTitle\": {\"S\": \"PartiQL Rocks\"},  
\"AlbumTitle\": {\"S\": \"Another Album Title\"}, \"Awards\": {\"N\": \"8\"}}"
```

PartiQL for DynamoDB

Linux

```
aws dynamodb execute-statement --statement "INSERT INTO Music \
    VALUE \
        {'Artist':'No One You Know','SongTitle':'Call Me Today',
'AlbumTitle':'Somewhat Famous', 'Awards':'1'}"

aws dynamodb execute-statement --statement "INSERT INTO Music \
    VALUE \
        {'Artist':'No One You Know','SongTitle':'Howdy',
'AlbumTitle':'Somewhat Famous', 'Awards':'2'}"

aws dynamodb execute-statement --statement "INSERT INTO Music \
    VALUE \
        {'Artist':'Acme Band','SongTitle':'Happy Day', 'AlbumTitle':'Songs
About Life', 'Awards':'10'}"

aws dynamodb execute-statement --statement "INSERT INTO Music \
    VALUE \
        {'Artist':'Acme Band','SongTitle':'PartiQL Rocks',
'AlbumTitle':'Another Album Title', 'Awards':'8'}"
```

Windows CMD

```
aws dynamodb execute-statement --statement "INSERT INTO Music VALUE {'Artist':'No One You Know', 'SongTitle':'Call Me Today', 'AlbumTitle':'Somewhat Famous', 'Awards':'1'}"  
  
aws dynamodb execute-statement --statement "INSERT INTO Music VALUE {'Artist':'No One You Know', 'SongTitle':'Howdy', 'AlbumTitle':'Somewhat Famous', 'Awards':'2'}"
```

```
aws dynamodb execute-statement --statement "INSERT INTO Music VALUE {'Artist':'Acme Band', 'SongTitle':'Happy Day', 'AlbumTitle':'Songs About Life', 'Awards':'10'}"  
  
aws dynamodb execute-statement --statement "INSERT INTO Music VALUE {'Artist':'Acme Band', 'SongTitle':'PartiQL Rocks', 'AlbumTitle':'Another Album Title', 'Awards':'8'}"
```

For more information about writing data with PartiQL, see [PartiQL insert statements](#).

For more information about supported data types in DynamoDB, see [Data types](#).

For more information about how to represent DynamoDB data types in JSON, see [Attribute values](#).

After writing data to your table, proceed to [Step 3: Read data from a table](#).

Step 3: Read data from a table

In this step, you will read back an item that was created in [Step 2: Write data to a table using the console or AWS CLI](#). You can use the DynamoDB console or the AWS CLI to read an item from the Music table by specifying Artist and SongTitle.

For more information about read operations in DynamoDB, see [Reading an item](#).

AWS Management Console

Follow these steps to read data from the Music table using the DynamoDB console.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Select the **Explore table items**.
5. On the **Items** tab, view the list of items stored in the table, sorted by Artist and SongTitle. The first item in the list is the one with the Artist **Acme Band** and the SongTitle **Happy Day**.

The screenshot shows the Amazon DynamoDB Items page. At the top, there's a breadcrumb navigation: DynamoDB > Items. To the right of the breadcrumb is an "Autopreview" button with a blue circular icon. Below the navigation, the word "Items" is followed by an "Info" link. On the left, there's a sidebar with a back arrow and a dropdown menu showing "Music". The main area has tabs for "Query" (which is selected) and "Scan". A "View table details" button is in the top right corner. The "Table or index" dropdown is set to "Music". Under "Artist (Partition key)", there's a text input field with placeholder text "Enter partition key value". Under "SongTitle (Sort key)", there's a dropdown menu set to "Equal to" with a "▼" arrow, an input field for "Enter sort key value", and a checkbox for "Sort descending". Below these fields is a "▶ Filters" button. At the bottom of the query section are "Run" and "Reset" buttons. A green checkmark icon indicates the query is completed with "Read capacity units consumed: 0.5". The results section is titled "Items returned (2)" with "Actions" and "Create item" buttons. It includes a search bar with "Find items" placeholder text and navigation controls for pages 1, 2, and 3. The table headers are "Artist", "SongTitle", "AlbumTitle", and "Awards". The data rows are:

	Artist	SongTitle	AlbumTitle	Awards
<input type="checkbox"/>	Acme Band	Happy Day	Songs Abou...	10
<input type="checkbox"/>	No One You...	Call Me Today	Somewhat ...	1

AWS CLI

The following AWS CLI example reads an item from the Music. You can do this either through the DynamoDB API or [PartiQL](#), a SQL-compatible query language for DynamoDB.

DynamoDB API

Note

The default behavior for DynamoDB is eventually consistent reads. The `consistent-read` parameter is used below to demonstrate strongly consistent reads.

Linux

```
aws dynamodb get-item --consistent-read \
--table-name Music \
--key '{ "Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"} }'
```

Windows CMD

```
aws dynamodb get-item --consistent-read ^
--table-name Music ^
--key "{\"Artist\": {\"S\": \"Acme Band\"}, \"SongTitle\": {\"S\": \"Happy Day\"}}"
```

Using `get-item` returns the following sample result.

```
{
  "Item": {
    "AlbumTitle": {
      "S": "Songs About Life"
    },
    "Awards": {
      "S": "10"
    },
    "Artist": {
      "S": "Acme Band"
    },
    "SongTitle": {
      "S": "Happy Day"
    }
  }
}
```

PartiQL for DynamoDB

Linux

```
aws dynamodb execute-statement --statement "SELECT * FROM Music \n WHERE Artist='Acme Band' AND SongTitle='Happy Day'"
```

Windows CMD

```
aws dynamodb execute-statement --statement "SELECT * FROM Music WHERE Artist='Acme\nBand' AND SongTitle='Happy Day'"
```

Using the PartiQL Select statement returns the following sample result.

```
{\n    "Items": [\n        {\n            "AlbumTitle": {\n                "S": "Songs About Life"\n            },\n            "Awards": {\n                "S": "10"\n            },\n            "Artist": {\n                "S": "Acme Band"\n            },\n            "SongTitle": {\n                "S": "Happy Day"\n            }\n        }\n    ]\n}
```

For more information about reading data with PartiQL, see [PartiQL select statements](#).

To update the data in your table, proceed to [Step 4: Update data in a table](#).

Step 4: Update data in a table

In this step, you update an item that you created in [Step 2: Write data to a table using the console or AWS CLI](#). You can use the DynamoDB console or the AWS CLI to update the **AlbumTitle** of an item in the **Music** table by specifying **Artist**, **SongTitle**, and the updated **AlbumTitle**.

For more information about write operations, see [Writing an item](#).

AWS Management Console

You can use the DynamoDB console to update data in the **Music** table.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Choose **View items**.
5. Choose the item whose **Artist** value is **Acme Band** and **SongTitle** value is **Happy Day**.
6. Update the **AlbumTitle** value to **Updated Album Title**, and then choose **Save**.

The following image shows the updated item on the console.

Item editor

Form JSON

Attributes		Type
<input type="button" value="Attribute name"/> Artist - Partition key	Acme Band	New String
<input type="button" value="SongTitle - Sort key"/>	Happy Day	New String
<input type="button" value="AlbumTitle"/>	Updated Album Title	String <input type="button" value="Remove"/>
<input type="button" value="Awards"/>	10	Number <input type="button" value="Remove"/>
<input type="button" value="Add new attribute ▾"/>		
		<input type="button" value="Cancel"/> <input type="button" value="Save changes"/>

AWS CLI

The following AWS CLI example updates an item in the Music table. You can do this either through the DynamoDB API or [PartiQL](#), a SQL-compatible query language for DynamoDB.

DynamoDB API

Linux

```
aws dynamodb update-item \  
  --table-name Music \  
  --key '{ "Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"} }' \  
  --update-expression "SET AlbumTitle = :newval" \  
  --expression-attribute-values '{":newval":{"S":"Updated Album Title"}}' \  
  --return-values ALL_NEW
```

Windows CMD

```
aws dynamodb update-item ^  
  --table-name Music ^  
  --key "{\"Artist\": {\"S\": \"Acme Band\"}, \"SongTitle\": {\"S\": \"Happy Day\"}}" ^  
  --update-expression "SET AlbumTitle = :newval" ^  
  --expression-attribute-values "{\":newval\":{\"S\":\"Updated Album Title\"}}" ^  
  --return-values ALL_NEW
```

Using `update-item` returns the following sample result because `return-values ALL_NEW` was specified.

```
{  
  "Attributes": {  
    "AlbumTitle": {  
      "S": "Updated Album Title"  
    },  
    "Awards": {  
      "S": "10"  
    },  
    "Artist": {  
      "S": "Acme Band"  
    },  
    "SongTitle": {  
      "S": "Happy Day"  
    }  
  }  
}
```

```
        "S": "Happy Day"
    }
}
}
```

PartiQL for DynamoDB

Linux

```
aws dynamodb execute-statement --statement "UPDATE Music \
SET AlbumTitle='Updated Album Title' \
WHERE Artist='Acme Band' AND SongTitle='Happy Day' \
RETURNING ALL NEW *"
```

Windows CMD

```
aws dynamodb execute-statement --statement "UPDATE Music SET AlbumTitle='Updated
Album Title' WHERE Artist='Acme Band' AND SongTitle='Happy Day' RETURNING ALL NEW
*"
```

Using the Update statement returns the following sample result because RETURNING ALL NEW * was specified.

```
{
  "Items": [
    {
      "AlbumTitle": {
        "S": "Updated Album Title"
      },
      "Awards": {
        "S": "10"
      },
      "Artist": {
        "S": "Acme Band"
      },
      "SongTitle": {
        "S": "Happy Day"
      }
    }
  ]
}
```

For more information about updating data with PartiQL, see [PartiQL update statements](#).

To query the data in the Music table, proceed to [Step 5: Query data in a table](#).

Step 5: Query data in a table

In this step, you query the data that you wrote to the Music table in [the section called "Step 2: Write data"](#) by specifying Artist. This will display all songs that are associated with the partition key: Artist.

For more information about query operations, see [Query operations in DynamoDB](#).

AWS Management Console

Follow these steps to use the DynamoDB console to query data in the Music table.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Choose **Explore table items**.
5. Choose **Query**.
6. For **Partition key**, enter **Acme Band**, and then choose **Run**.

The screenshot shows the 'Items' page in the Amazon DynamoDB console. At the top, there's a breadcrumb navigation: 'DynamoDB > Items'. On the right, there's an 'Autopreview' button with a blue circular icon. Below the navigation, the table name 'Music' is selected under 'Table or index'. The 'Artist (Partition key)' is set to 'Acme Band'. Under 'SongTitle (Sort key)', there's a dropdown set to 'Equal to' with the value 'Enter sort key value'. A checkbox for 'Sort descending' is unchecked. At the bottom, there are 'Run' and 'Reset' buttons.

AWS CLI

The following AWS CLI example queries an item in the `Music` table. You can do this either through the DynamoDB API or [PartiQL](#), a SQL-compatible query language for DynamoDB.

DynamoDB API

You query an item through the DynamoDB API by using `query` and providing the partition key.

Linux

```
aws dynamodb query \
--table-name Music \
--key-condition-expression "Artist = :name" \
--expression-attribute-values '{":name":{"S":"Acme Band"}}'
```

Windows CMD

```
aws dynamodb query ^
--table-name Music ^
--key-condition-expression "Artist = :name" ^
--expression-attribute-values "{\":name\":{\"S\":\"Acme Band\"}}"
```

Using query returns all the songs associated with this particular Artist.

```
{
  "Items": [
    {
      "AlbumTitle": {
        "S": "Updated Album Title"
      },
      "Awards": {
        "N": "10"
      },
      "Artist": {
        "S": "Acme Band"
      },
      "SongTitle": {
        "S": "Happy Day"
      }
    },
    {
      "AlbumTitle": {
        "S": "Another Album Title"
      },
      "Awards": {
        "N": "8"
      },
      "Artist": {
        "S": "Acme Band"
      },
      "SongTitle": {
        "S": "PartiQL Rocks"
      }
    }
  ],
  "Count": 2,
  "ScannedCount": 2,
  "ConsumedCapacity": null
}
```

PartiQL for DynamoDB

You query an item through PartiQL by using the `Select` statement and providing the partition key.

Linux

```
aws dynamodb execute-statement --statement "SELECT * FROM Music \
WHERE Artist='Acme Band'"
```

Windows CMD

```
aws dynamodb execute-statement --statement "SELECT * FROM Music WHERE Artist='Acme
Band'"
```

Using the `Select` statement in this way returns all the songs associated with this particular Artist.

```
{
  "Items": [
    {
      "AlbumTitle": {
        "S": "Updated Album Title"
      },
      "Awards": {
        "S": "10"
      },
      "Artist": {
        "S": "Acme Band"
      },
      "SongTitle": {
        "S": "Happy Day"
      }
    },
    {
      "AlbumTitle": {
        "S": "Another Album Title"
      },
      "Awards": {
        "S": "8"
      },
      "Artist": {
```

```
        "S": "Acme Band"
    },
    "SongTitle": {
        "S": "PartiQL Rocks"
    }
}
}
```

For more information about querying data with PartiQL, see [PartiQL select statements](#).

To create a global secondary index for your table, proceed to [Step 6: Create a global secondary index](#).

Step 6: Create a global secondary index

In this step, you create a global secondary index for the Music table that you created in [Step 1: Create a table](#).

For more information about global secondary indexes, see [Using Global Secondary Indexes in DynamoDB](#).

AWS Management Console

To use the Amazon DynamoDB console to create a global secondary index AlbumTitle-index for the Music table:

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Choose the **Indexes** tab for the Music table.
5. Choose **Create index**.

6. For the **Partition key**, enter **AlbumTitle**.
7. For **Index name**, enter **AlbumTitle-index**.
8. Leave the other settings on their default values and choose **Create index**.

Create global secondary index [Info](#)

Global secondary indexes allow you to perform queries on attributes that are not part of a table's primary key. Note that global secondary index read and write capacity settings are separate from those of the table, and they will incur additional costs.

Index details [Info](#)

Partition key Data type

1 to 255 characters.

Sort key - optional Data type

1 to 255 characters.

Index name

Between 3 and 255 characters. Only A–Z, a–z, 0–9, underscore characters, hyphens, and periods allowed.

Index capacity [Info](#)

Read capacity

Read capacity settings

- Copy from base table
- Customize settings

Auto scaling [Info](#)

Dynamically adjusts provisioned throughput capacity on your behalf in response to actual traffic patterns.

- On
- Off

Minimum capacity units

Maximum capacity units

Target utilization (%)

Write capacity

Write capacity settings

- Copy from base table

Auto scaling [Info](#)

Dynamically adjusts provisioned throughput capacity on your behalf in response to actual traffic patterns.

- On

AWS CLI

The following AWS CLI example creates a global secondary index `AlbumTitle-index` for the `Music` table using `update-table`.

Linux

```
aws dynamodb update-table \
--table-name Music \
--attribute-definitions AttributeName=AlbumTitle,AttributeType=S \
--global-secondary-index-updates \
"[{\\"Create\\":{\\\"IndexName\\\": \\"AlbumTitle-index\\\",\\\"KeySchema\\\": \
[{\\"AttributeName\\\":\\\"AlbumTitle\\\",\\\"KeyType\\\":\\\"HASH\\\"}], \
\\\"ProvisionedThroughput\\\": {\\\"ReadCapacityUnits\\\": 10, \\\"WriteCapacityUnits\\\": \
5},\\\"Projection\\\":{\\\"ProjectionType\\\":\\\"ALL\\\"}}}]"
```

Windows CMD

```
aws dynamodb update-table ^
--table-name Music ^
--attribute-definitions AttributeName=AlbumTitle,AttributeType=S ^
--global-secondary-index-updates "[{\\"Create\\":{\\\"IndexName\\\": \\"AlbumTitle-
index\\\",\\\"KeySchema\\\": [{\\\"AttributeName\\\":\\\"AlbumTitle\\\",\\\"KeyType\\\":\\\"HASH\\\"}], \
\\\"ProvisionedThroughput\\\": {\\\"ReadCapacityUnits\\\": 10, \\\"WriteCapacityUnits\\\": 5}, \
\\\"Projection\\\":{\\\"ProjectionType\\\":\\\"ALL\\\"}}}]"
```

Using `update-table` returns the following sample result.

```
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-west-2:111122223333:table/Music",
    "AttributeDefinitions": [
      {
        "AttributeName": "AlbumTitle",
        "AttributeType": "S"
      },
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "IndexDefinitions": [
      {
        "IndexName": "AlbumTitle-index",
        "KeySchema": [
          {
            "AttributeName": "AlbumTitle",
            "KeyType": "HASH"
          }
        ],
        "ProjectionType": "ALL"
      }
    ],
    "TableStatus": "ACTIVE",
    "ItemCount": 0,
    "TableSizeBytes": 0
  }
}
```

```
        },
    ],
    "GlobalSecondaryIndexes": [
        {
            "IndexSizeBytes": 0,
            "IndexName": "AlbumTitle-index",
            "Projection": {
                "ProjectionType": "ALL"
            },
            "ProvisionedThroughput": {
                "NumberOfDecreasesToday": 0,
                "WriteCapacityUnits": 5,
                "ReadCapacityUnits": 10
            },
            "IndexStatus": "CREATING",
            "Backfilling": false,
            "KeySchema": [
                {
                    "KeyType": "HASH",
                    "AttributeName": "AlbumTitle"
                }
            ],
            "IndexArn": "arn:aws:dynamodb:us-west-2:111122223333:table/Music/index/AlbumTitle-index",
            "ItemCount": 0
        }
    ],
    "ProvisionedThroughput": {
        "NumberOfDecreasesToday": 0,
        "WriteCapacityUnits": 5,
        "ReadCapacityUnits": 10
    },
    "TableSizeBytes": 0,
    "TableName": "Music",
    "TableStatus": "UPDATING",
    "TableId": "a04b7240-0a46-435b-a231-b54091ab1017",
    "KeySchema": [
        {
            "KeyType": "HASH",
            "AttributeName": "Artist"
        },
        {
            "KeyType": "RANGE",
            "AttributeName": "SongTitle"
        }
    ]
}
```

```
        },
    ],
    "ItemCount": 0,
    "CreationDateTime": 1558028402.69
}
}
```

Note that the value of the IndexStatus field is set to CREATING.

To verify that DynamoDB has finished creating the AlbumTitle-index global secondary index, use the describe-table command.

Linux

```
aws dynamodb describe-table --table-name Music | grep IndexStatus
```

Windows CMD

```
aws dynamodb describe-table --table-name Music | findstr IndexStatus
```

This command returns the following result. The index is ready for use when the value of the IndexStatus field returned is set to ACTIVE.

```
"IndexStatus": "ACTIVE",
```

Next, you can query the global secondary index. For details, see [Step 7: Query the global secondary index](#).

Step 7: Query the global secondary index

In this step, you query a global secondary index on the Music table using the Amazon DynamoDB console or the AWS CLI.

For more information about global secondary indexes, see [Using Global Secondary Indexes in DynamoDB](#).

AWS Management Console

Follow these steps to use the DynamoDB console to query data through the AlbumTitle-index global secondary index.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Music** table from the table list.
4. Select the **View items**.
5. Choose **Query**.
6. In the drop-down list under **Query**, choose **AlbumTitle-index**.

For **AlbumTitle**, enter **Somewhat Famous**, and then choose **Run**.

The screenshot shows the 'Items' page for the 'Music' table. At the top, there's a 'Query' button highlighted in grey, indicating it's selected. Below it is a dropdown menu labeled 'Table or index' containing the following options:

- AlbumTitle-index (highlighted with a blue border)
- Table
- Music
- Index
- AlbumTitle-index (highlighted with a blue border)

AWS CLI

The following AWS CLI example queries a global secondary index `AlbumTitle-index` on the `Music` table. You can do this either through the DynamoDB API or [PartiQL](#), a SQL-compatible query language for DynamoDB.

DynamoDB API

You query the global secondary index through the DynamoDB API by using `query` and providing the index name.

Linux

```
aws dynamodb query \
--table-name Music \
--index-name AlbumTitle-index \
```

```
--key-condition-expression "AlbumTitle = :name" \
--expression-attribute-values  '{"":name":{"S":"Somewhat Famous"}}'
```

Windows CMD

```
aws dynamodb query ^
--table-name Music ^
--index-name AlbumTitle-index ^
--key-condition-expression "AlbumTitle = :name" ^
--expression-attribute-values  "{\"":name\":{\"S\":\"Somewhat Famous\"}}"
```

Using query returns the following sample result.

```
{
  "Items": [
    {
      "AlbumTitle": {
        "S": "Somewhat Famous"
      },
      "Awards": {
        "S": "1"
      },
      "Artist": {
        "S": "No One You Know"
      },
      "SongTitle": {
        "S": "Call Me Today"
      }
    },
    {
      "AlbumTitle": {
        "S": "Somewhat Famous"
      },
      "Awards": {
        "N": "2"
      },
      "Artist": {
        "S": "No One You Know"
      },
      "SongTitle": {
        "S": "Howdy"
      }
    }
  ]
}
```

```
],  
"Count": 2,  
"ScannedCount": 2,  
"ConsumedCapacity": null  
}
```

PartiQL for DynamoDB

You query the global secondary index through PartiQL by using the `Select` statement and providing the index name.

Note

You'll need to escape the double quotes around `Music` and `AlbumTitle-index` since you're doing this through the CLI.

Linux

```
aws dynamodb execute-statement --statement "SELECT * FROM \"Music\".\"AlbumTitle-  
index\"  \  
WHERE AlbumTitle='Somewhat Famous'"
```

Windows CMD

```
aws dynamodb execute-statement --statement "SELECT * FROM \"Music\".\"AlbumTitle-  
index\" WHERE AlbumTitle='Somewhat Famous'"
```

Using the `Select` statement in this way returns the following sample result.

```
{  
    "Items": [  
        {  
            "AlbumTitle": {  
                "S": "Somewhat Famous"  
            },  
            "Awards": {  
                "S": "1"  
            },  
            "Artist": {  
                "S": "The Artist"  
            }  
        }  
    ]  
}
```

```
        "S": "No One You Know"
    },
    "SongTitle": {
        "S": "Call Me Today"
    }
},
{
    "AlbumTitle": {
        "S": "Somewhat Famous"
    },
    "Awards": {
        "S": "2"
    },
    "Artist": {
        "S": "No One You Know"
    },
    "SongTitle": {
        "S": "Howdy"
    }
}
]
```

For more information about querying data with PartiQL, see [PartiQL select statements](#).

Step 8: (Optional) clean up resources

If you no longer need the Amazon DynamoDB table that you created for the tutorial, you can delete it. This step helps ensure that you aren't charged for resources that you aren't using. You can use the DynamoDB console or the AWS CLI to delete the Music table that you created in [Step 1: Create a table](#).

For more information about table operations in DynamoDB, see [Working with tables and data in DynamoDB](#).

AWS Management Console

To delete the Music table using the console:

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.

3. Choose the **Music** table from the table list.
4. Choose the **Indexes** tab for the Music table.
5. Choose **Delete table**.

The screenshot shows the 'Actions' dropdown menu for the 'Music' table. The menu items are: Actions ▲, View items, Edit capacity, Create index, Create access control policy, and Delete table. The 'Delete table' option is circled in red.

AWS CLI

The following AWS CLI example deletes the `Music` table using `delete-table`.

```
aws dynamodb delete-table --table-name Music
```

Getting started with DynamoDB: Next steps

For more information about using Amazon DynamoDB, see the following topics:

- [Working with tables and data in DynamoDB](#)
- [Working with items and attributes](#)
- [Query operations in DynamoDB](#)
- [Using Global Secondary Indexes in DynamoDB](#)
- [Working with transactions](#)
- [In-memory acceleration with DynamoDB Accelerator \(DAX\)](#)
- [Getting started with DynamoDB and the AWS SDKs](#)
- [Programming with DynamoDB and the AWS SDKs](#)

Getting started with DynamoDB and the AWS SDKs

Use the hands-on tutorials in this section to get started with Amazon DynamoDB and the AWS SDKs. You can run the code examples on either the downloadable version of DynamoDB or the DynamoDB web service.

Topics

- [Create a DynamoDB table](#)
- [Write an item to a DynamoDB table](#)
- [Read an item from a DynamoDB table](#)
- [Update an item in a DynamoDB table](#)
- [Delete an item in a DynamoDB table](#)
- [Query a DynamoDB table](#)
- [Scan a DynamoDB table](#)
- [Using DynamoDB with an AWS SDK](#)

Create a DynamoDB table

You can create a table using the AWS Management Console, the AWS CLI, or an AWS SDK. For more information on tables, see [Core components of Amazon DynamoDB](#).

Create a DynamoDB table using an AWS SDK

The following code examples show how to create a DynamoDB table using an AWS SDK.

.NET

AWS SDK for .NET

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Creates a new Amazon DynamoDB table and then waits for the new
/// table to become active.
/// </summary>
/// <param name="client">An initialized Amazon DynamoDB client object.</param>
/// <param name="tableName">The name of the table to create.</param>
/// <returns>A Boolean value indicating the success of the operation.</returns>
public static async Task<bool> CreateMovieTableAsync(AmazonDynamoDBClient
client, string tableName)
{
    var response = await client.CreateTableAsync(new CreateTableRequest
    {
        TableName = tableName,
        AttributeDefinitions = new List<AttributeDefinition>()
        {
            new AttributeDefinition
            {
                AttributeName = "title",
                AttributeType = ScalarAttributeType.S,
            },
            new AttributeDefinition
            {
                AttributeName = "year",
                AttributeType = ScalarAttributeType.N,
            },
        },
        KeySchema = new List<KeySchemaElement>()
        {
            new KeySchemaElement
            {
                AttributeName = "year",
                KeyType = KeyType.HASH,
            },
            new KeySchemaElement
            {
                AttributeName = "title",
                KeyType = KeyType.RANGE,
            },
        },
        ProvisionedThroughput = new ProvisionedThroughput
        {
            ReadCapacityUnits = 5,
```

```
        WriteCapacityUnits = 5,
    },
});

// Wait until the table is ACTIVE and then report success.
Console.WriteLine("Waiting for table to become active...");

var request = new DescribeTableRequest
{
    TableName = response.TableDescription.TableName,
};

TableStatus status;

int sleepDuration = 2000;

do
{
    System.Threading.Thread.Sleep(sleepDuration);

    var describeTableResponse = await
client.DescribeTableAsync(request);
    status = describeTableResponse.Table.TableStatus;

    Console.WriteLine(".");
}
while (status != "ACTIVE");

return status == TableStatus.ACTIVE;
}
```

- For API details, see [CreateTable](#) in *AWS SDK for .NET API Reference*.

Bash

AWS CLI with Bash script

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
#####
# function dynamodb_create_table
#
# This function creates an Amazon DynamoDB table.
#
# Parameters:
#   -n table_name -- The name of the table to create.
#   -a attribute_definitions -- JSON file path of a list of attributes and
#     their types.
#   -k key_schema -- JSON file path of a list of attributes and their key
#     types.
#   -p provisioned_throughput -- Provisioned throughput settings for the
#     table.
#
# Returns:
#   0 - If successful.
#   1 - If it fails.
#####
function dynamodb_create_table() {
    local table_name attribute_definitions key_schema provisioned_throughput
    response
    local option OPTARG # Required to use getopt command in a function.

    #####
    # Function usage explanation
    #####

CLI

AWS CLI

Example 1: To create a table with tags

The following `create-table` example uses the specified attributes and key schema to create a table named `MusicCollection`. This table uses provisioned throughput and is

encrypted at rest using the default AWS owned CMK. The command also applies a tag to the table, with a key of Owner and a value of blueTeam.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --tags Key=Owner,Value=blueTeam
```

Output:

```
{
  "TableDescription": {
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 5,
      "ReadCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "TableName": "MusicCollection",
    "TableStatus": "CREATING",
    "KeySchema": [
      {
        "KeyType": "HASH",
        "AttributeName": "Artist"
      },
      {
        "KeyType": "RANGE",
        "AttributeName": "SongTitle"
      }
    ]
  }
}
```

```
        ],
        "ItemCount": 0,
        "CreationDateTime": "2020-05-26T16:04:41.627000-07:00",
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111"
    }
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To create a table in On-Demand Mode

The following example creates a table called MusicCollection using on-demand mode, rather than provisioned throughput mode. This is useful for tables with unpredictable workloads.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
    --billing-mode PAY_PER_REQUEST
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "TableName": "MusicCollection",
        "KeySchema": [
            {

```

```
        "AttributeName": "Artist",
        "KeyType": "HASH"
    },
    {
        "AttributeName": "SongTitle",
        "KeyType": "RANGE"
    }
],
"TableStatus": "CREATING",
"CreationDateTime": "2020-05-27T11:44:10.807000-07:00",
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "ReadCapacityUnits": 0,
    "WriteCapacityUnits": 0
},
"TableSizeBytes": 0,
"ItemCount": 0,
"TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection",
"TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
"BillingModeSummary": {
    "BillingMode": "PAY_PER_REQUEST"
}
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To create a table and encrypt it with a Customer Managed CMK

The following example creates a table named MusicCollection and encrypts it using a customer managed CMK.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
    --key-schema AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --sse-specification Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-abcd-1234-a123-ab1234a1b234
```

Output:

```
{  
    "TableDescription": {  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "TableName": "MusicCollection",  
        "KeySchema": [  
            {  
                "AttributeName": "Artist",  
                "KeyType": "HASH"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "KeyType": "RANGE"  
            }  
        ],  
        "TableStatus": "CREATING",  
        "CreationDateTime": "2020-05-27T11:12:16.431000-07:00",  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "ReadCapacityUnits": 5,  
            "WriteCapacityUnits": 5  
        },  
        "TableSizeBytes": 0,  
        "ItemCount": 0,  
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/  
MusicCollection",  
        "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",  
        "SSEDescription": {  
            "Status": "ENABLED",  
            "SSEType": "KMS",  
            "KMSMasterKeyArn": "arn:aws:kms:us-west-2:123456789012:key/abcd1234-  
abcd-1234-a123-ab1234a1b234"  
        }  
    }  
}
```

{}

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 4: To create a table with a Local Secondary Index

The following example uses the specified attributes and key schema to create a table named MusicCollection with a Local Secondary Index named AlbumTitleIndex.

```
aws dynamodb create-table \
    --table-name MusicCollection \
    --attribute-definitions AttributeName=Artist,AttributeType=S
    AttributeName=SongTitle,AttributeType=S AttributeName=AlbumTitle,AttributeType=S
\
    --key-schema AttributeName=Artist,KeyType=HASH
    AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --local-secondary-indexes \
    "[
        {
            \"IndexName\": \"AlbumTitleIndex\",
            \"KeySchema\": [
                {\"AttributeName\": \"Artist\", \"KeyType\": \"HASH\"},
                {\"AttributeName\": \"AlbumTitle\", \"KeyType\": \"RANGE\"}
            ],
            \"Projection\": {
                \"ProjectionType\": \"INCLUDE\",
                \"NonKeyAttributes\": [\"Genre\", \"Year\"]"
            }
        }
    ]"
```

Output:

```
{ "TableDescription": { "AttributeDefinitions": [ { "AttributeName": "AlbumTitle", "AttributeType": "S" }, { "AttributeName": "SongTitle", "AttributeType": "S" } ], "IndexDescriptions": [ { "IndexName": "AlbumTitleIndex", "KeySchema": [ { "AttributeName": "Artist", "KeyType": "HASH" }, { "AttributeName": "AlbumTitle", "KeyType": "RANGE" } ], "Projection": { "ProjectionType": "INCLUDE", "NonKeyAttributes": [ "Genre", "Year" ] } } ], "TableStatus": "ACTIVE", "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/MusicCollection", "ItemCount": 0, "TableSizeBytes": 0, "BillingMode": "PAY_PER_REQUEST" } }
```

```
        "AttributeName": "Artist",
        "AttributeType": "S"
    },
    {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
    }
],
"TableName": "MusicCollection",
"KeySchema": [
    {
        "AttributeName": "Artist",
        "KeyType": "HASH"
    },
    {
        "AttributeName": "SongTitle",
        "KeyType": "RANGE"
    }
],

        },
        "IndexSizeBytes": 0,
        "ItemCount": 0,
        "IndexArn": "arn:aws:dynamodb:us-west-2:123456789012:table/MusicCollection/index/AlbumTitleIndex"
    }
]
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 5: To create a table with a Global Secondary Index

The following example creates a table named GameScores with a Global Secondary Index called GameTitleIndex. The base table has a partition key of UserId and a sort key of GameTitle, allowing you to find an individual user's best score for a specific game efficiently, whereas the GSI has a partition key of GameTitle and a sort key of TopScore, allowing you to quickly find the overall highest score for a particular game.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S \
    AttributeName=GameTitle,AttributeType=S AttributeName=TopScore,AttributeType=N \
    --key-schema AttributeName=UserId,KeyType=HASH \
        AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --global-secondary-indexes \
    "[
        {
            \"IndexName\": \"GameTitleIndex\",
            \"KeySchema\": [
                {\"AttributeName\": \"GameTitle\", \"KeyType\": \"HASH\"},
                {\"AttributeName\": \"TopScore\", \"KeyType\": \"RANGE\"}
            ],
            \"Projection\": {
```

```
\\"ProjectionType\\":\\"INCLUDE\\",
\\"NonKeyAttributes\\":[\\"UserId\\"]
},
\\"ProvisionedThroughput\\": {
    \\"ReadCapacityUnits\\": 10,
    \\"WriteCapacityUnits\\": 5
}
}"
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "TopScore",
                "AttributeType": "N"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",

            "ItemCount": 0,
            "IndexArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/index/GameTitleIndex"
        }
    ]
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 6: To create a table with multiple Global Secondary Indexes at once

The following example creates a table named GameScores with two Global Secondary Indexes. The GSI schemas are passed via a file, rather than on the command line.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S
    AttributeName=GameTitle,AttributeType=S AttributeName=TopScore,AttributeType=N
    AttributeName=Date,AttributeType=S \
    --key-schema AttributeName=UserId,KeyType=HASH
    AttributeName=GameTitle,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --global-secondary-indexes file://gsi.json
```

Contents of gsi.json:

```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 7: To create a table with Streams enabled

The following example creates a table called GameScores with DynamoDB Streams enabled. Both new and old images of each item will be written to the stream.

```
aws dynamodb create-table \
    --table-name GameScores \
    --attribute-definitions AttributeName=UserId,AttributeType=S \
    AttributeName=GameTitle,AttributeType=S \
```

```
--key-schema AttributeName=UserId,KeyType=HASH
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--stream-specification StreamEnabled=TRUE,StreamViewType=NEW_AND_OLD_IMAGES
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "GameTitle",
                "KeyType": "RANGE"
            }
        ],
        "TableStatus": "CREATING",
        "CreationDateTime": "2020-05-27T10:49:34.056000-07:00",
        "ProvisionedThroughput": {
            "NumberOfDecreasesToday": 0,
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        },
        "TableSizeBytes": 0,
        "ItemCount": 0,
        "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",

        "StreamSpecification": {
            "StreamEnabled": true,
```

```
        "StreamViewType": "NEW_AND_OLD_IMAGES"
    },
    "LatestStreamLabel": "2020-05-27T17:49:34.056",
    "LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/2020-05-27T17:49:34.056"
}
}
```

For more information, see [Basic Operations for Tables](#) in the *Amazon DynamoDB Developer Guide*.

Example 8: To create a table with Keys-Only Stream enabled

The following example creates a table called GameScores with DynamoDB Streams enabled. Only the key attributes of modified items are written to the stream.

```
aws dynamodb create-table \
--table-name GameScores \
--attribute-definitions AttributeName=UserId,AttributeType=S
AttributeName=GameTitle,AttributeType=S \
--key-schema AttributeName=UserId,KeyType=HASH
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--stream-specification StreamEnabled=TRUE,StreamViewType=KEYS_ONLY
```

Output:

```
{
    "TableDescription": {
        "AttributeDefinitions": [
            {
                "AttributeName": "GameTitle",
                "AttributeType": "S"
            },
            {
                "AttributeName": "UserId",
                "AttributeType": "S"
            }
        ],
        "TableName": "GameScores",
        "KeySchema": [
            {
                "AttributeName": "UserId",

```

```
        "KeyType": "HASH"
    },
    {
        "AttributeName": "GameTitle",
        "KeyType": "RANGE"
    }
],
"TableStatus": "CREATING",
"CreationDateTime": "2023-05-25T18:45:34.140000+00:00",
"ProvisionedThroughput": {
    "NumberOfDecreasesToday": 0,
    "ReadCapacityUnits": 10,
    "WriteCapacityUnits": 5
},
"TableSizeBytes": 0,
"ItemCount": 0,
"TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
"TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
"StreamSpecification": {
    "StreamEnabled": true,
    "StreamViewType": "KEYS_ONLY"
},
"LatestStreamLabel": "2023-05-25T18:45:34.140",
"LatestStreamArn": "arn:aws:dynamodb:us-west-2:123456789012:table/
GameScores/stream/2023-05-25T18:45:34.140",
"DeletionProtectionEnabled": false
}
}
```

For more information, see [Change data capture for DynamoDB Streams](#) in the *Amazon DynamoDB Developer Guide*.

Example 9: To create a table with the Standard Infrequent Access class

The following example creates a table called GameScores and assigns the Standard-Infrequent Access (DynamoDB Standard-IA) table class. This table class is optimized for storage being the dominant cost.

```
aws dynamodb create-table \
--table-name GameScores \
--attribute-definitions AttributeName=UserId,AttributeType=S \
AttributeType=S \
AttributeType=S \
```

```
--key-schema AttributeName=UserId,KeyType=HASH
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--table-class STANDARD_INFREQUENT_ACCESS
```

Output:

```
{
  "TableDescription": {
    "AttributeDefinitions": [
      {
        "AttributeName": "GameTitle",
        "AttributeType": "S"
      },
      {
        "AttributeName": "UserId",
        "AttributeType": "S"
      }
    ],
    "TableName": "GameScores",
    "KeySchema": [
      {
        "AttributeName": "UserId",
        "KeyType": "HASH"
      },
      {
        "AttributeName": "GameTitle",
        "KeyType": "RANGE"
      }
    ],
    "TableStatus": "CREATING",
    "CreationDateTime": "2023-05-25T18:33:07.581000+00:00",
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "ReadCapacityUnits": 10,
      "WriteCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "ItemCount": 0,
    "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
    "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "TableClassSummary": {
      "TableClass": "STANDARD_INFREQUENT_ACCESS"
    }
}
```

```
    },
    "DeletionProtectionEnabled": false
}
}
```

For more information, see [Table classes](#) in the *Amazon DynamoDB Developer Guide*.

Example 10: To Create a table with Delete Protection enabled

The following example creates a table called GameScores and enables deletion protection.

```
aws dynamodb create-table \
--table-name GameScores \
--attribute-definitions AttributeName=UserId,AttributeType=S \
AttributeName=GameTitle,AttributeType=S \
--key-schema AttributeName=UserId,KeyType=HASH \
AttributeName=GameTitle,KeyType=RANGE \
--provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
--deletion-protection-enabled
```

Output:

```
{
  "TableDescription": {
    "AttributeDefinitions": [
      {
        "AttributeName": "GameTitle",
        "AttributeType": "S"
      },
      {
        "AttributeName": "UserId",
        "AttributeType": "S"
      }
    ],
    "TableName": "GameScores",
    "KeySchema": [
      {
        "AttributeName": "UserId",
        "KeyType": "HASH"
      },
      {
        "AttributeName": "GameTitle",
        "KeyType": "RANGE"
      }
    ]
  }
}
```

```
        },
    ],
    "TableStatus": "CREATING",
    "CreationDateTime": "2023-05-25T23:02:17.093000+00:00",
    "ProvisionedThroughput": {
        "NumberOfDecreasesToday": 0,
        "ReadCapacityUnits": 10,
        "WriteCapacityUnits": 5
    },
    "TableSizeBytes": 0,
    "ItemCount": 0,
    "TableArn": "arn:aws:dynamodb:us-west-2:123456789012:table/GameScores",
    "TableId": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
    "DeletionProtectionEnabled": true
}
}
```

For more information, see [Using deletion protection](#) in the *Amazon DynamoDB Developer Guide*.

Aws::DynamoDB::Model::AttributeValue().SetS(
        albumTitleValue));
    putItemRequest.AddItem(awardsKey,

Aws::DynamoDB::Model::AttributeValue().SetS(awardsValue));
    putItemRequest.AddItem(songTitleKey,

Aws::DynamoDB::Model::AttributeValue().SetS(songTitleValue));

    const Aws::DynamoDB::Model::PutItemOutcome outcome = dynamoClient.PutItem(
        putItemRequest);
    if (outcome.IsSuccess()) {
        std::cout << "Successfully added Item!" << std::endl;
    }
    else {
        std::cerr << outcome.GetError().GetMessage() << std::endl;
    }

    return outcome.IsSuccess();
}
```

- For API details, see [PutItem](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To add an item to a table

The following `put-item` example adds a new item to the *MusicCollection* table.

```
aws dynamodb put-item \  
  --table-name MusicCollection \  
  --item file://item.json \  
  --return-consumed-capacity TOTAL \  
  --return-item-collection-metrics SIZE
```

Contents of `item.json`:

```
{  
    "Artist": {"S": "No One You Know"},  
    "SongTitle": {"S": "Call Me Today"},  
    "AlbumTitle": {"S": "Greatest Hits"}  
}
```

Output:

```
{  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 1.0  
    },  
    "ItemCollectionMetrics": {  
        "ItemCollectionKey": {  
            "Artist": {  
                "S": "No One You Know"  
            }  
        },  
        "SizeEstimateRangeGB": [  
            0.0,  
            1.0  
        ]  
    }  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To conditionally overwrite an item in a table

The following put-item example overwrites an existing item in the MusicCollection table only if that existing item has an AlbumTitle attribute with a value of Greatest Hits. The command returns the previous value of the item.

```
aws dynamodb put-item \  
  --table-name MusicCollection \  
  --item file://item.json \  
  --condition-expression "#A = :A" \  
  --expression-attribute-names file://names.json \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_OLD
```

Contents of item.json:

```
{  
    "Artist": {"S": "No One You Know"},  
    "SongTitle": {"S": "Call Me Today"},  
    "AlbumTitle": {"S": "Somewhat Famous"}  
}
```

Contents of names.json:

```
{  
    "#A": "AlbumTitle"  
}
```

Contents of values.json:

```
{  
    ":A": {"S": "Greatest Hits"}  
}
```

Output:

```
{  
    "Attributes": {  
        "AlbumTitle": {  
            "S": "Greatest Hits"  
        },  
    },  
}
```

```
        "Artist": {  
            "S": "No One You Know"  
        },  
        "SongTitle": {  
            "S": "Call Me Today"  
        }  
    }  
}
```

If the key already exists, you should see the following output:

A client error (ConditionalCheckFailedException) occurred when calling the PutItem operation: The conditional request failed.

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

- For API details, see [PutItem](#) in *AWS CLI Command Reference*.

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

This example uses the document client to simplify working with items in DynamoDB. For API details see [PutCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { PutCommand, DynamoDBDocumentClient } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
    const command = new PutCommand({
        TableName: "HappyAnimals",
        Item: {
            CommonName: "Shiba Inu",
        },
    });
}

const response = await docClient.send(command);
console.log(response);
return response;
```

```
};
```

- For API details, see [PutItem](#) in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Put an item in a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "CUSTOMER_LIST",
  Item: {
    CUSTOMER_ID: { N: "001" },
    CUSTOMER_NAME: { S: "Richard Roe" },
  },
};

// Call DynamoDB to add the item to the table
ddb.putItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Put an item in a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Item: {
    HASHKEY: VALUE,
    ATTRIBUTE_1: "STRING_VALUE",
    ATTRIBUTE_2: VALUE_2,
  },
};

docClient.put(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

#####
# function dynamodb_get_item
#
# This function gets an item from a DynamoDB table.
#
# Parameters:
#     -n table_name -- The name of the table.
#     -k keys -- Path to json file containing the keys that identify the item
#               to get.
#     [-q query] -- Optional JMESPath query expression.
#
# Returns:
#     The item as text output.
# And:
#     0 - If successful.
#     1 - If it fails.
#####
function dynamodb_get_item() {
    local table_name keys query response
    local option OPTARG # Required to use getopt command in a function.

CLI

AWS CLI

Example 1: To read an item in a table

The following get-item example retrieves an item from the MusicCollection table. The table has a hash-and-range primary key (Artist and SongTitle), so you must specify both of these attributes. The command also requests information about the read capacity consumed by the operation.

```
aws dynamodb get-item \
--table-name MusicCollection \
--key file://key.json \
--return-consumed-capacity TOTAL
```

Contents of key.json:

```
{
    "Artist": {"S": "Acme Band"},
    "SongTitle": {"S": "Happy Day"}
}
```

Output:

```
{  
    "Item": {  
        "AlbumTitle": {  
            "S": "Songs About Life"  
        },  
        "SongTitle": {  
            "S": "Happy Day"  
        },  
        "Artist": {  
            "S": "Acme Band"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 0.5  
    }  
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To read an item using a consistent read

The following example retrieves an item from the MusicCollection table using strongly consistent reads.

```
aws dynamodb get-item \  
  --table-name MusicCollection \  
  --key file://key.json \  
  --consistent-read \  
  --return-consumed-capacity TOTAL
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Output:

```
{  
    "Item": {  
        "AlbumTitle": {  
            "S": "Songs About Life"  
        },  
        "SongTitle": {  
            "S": "Happy Day"  
        },  
        "Artist": {  
            "S": "Acme Band"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 1.0  
    }  
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To retrieve specific attributes of an item

The following example uses a projection expression to retrieve only three attributes of the desired item.

```
aws dynamodb get-item \  
  --table-name ProductCatalog \  
  --key '{"Id": {"N": "102"}}' \  
  --projection-expression "#T, #C, #P" \  
  --expression-attribute-names file://names.json
```

Contents of names.json:

```
{  
    "#T": "Title",  
    "#C": "ProductCategory",  
    "#P": "Price"  
}
```

Output:

```
{
```

```
"Item": {  
    "Price": {  
        "N": "20"  
    },  
    "Title": {  
        "S": "Book 102 Title"  
    },  
    "ProductCategory": {  
        "S": "Book"  
    }  
}
```

For more information, see [Reading an Item](#) in the *Amazon DynamoDB Developer Guide*.

- For API details, see [GetItem](#) in *AWS CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

 **Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

This example uses the document client to simplify working with items in DynamoDB. For API details see [GetCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { DynamoDBDocumentClient, GetCommand } from "@aws-sdk/lib-dynamodb";

const client = new DynamoDBClient({});
const docClient = DynamoDBDocumentClient.from(client);

export const main = async () => {
  const command = new GetCommand({
    TableName: "AngryAnimals",
    Key: {
      CommonName: "Shoebill",
    },
  });

  const response = await docClient.send(command);
  console.log(response);
  return response;
};
```

- For API details, see [GetItem](#) in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Get an item from a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });
```

```
var params = {
    TableName: "TABLE",
    Key: {
        KEY_NAME: { N: "001" },
    },
    ProjectionExpression: "ATTRIBUTE_NAME",
};

// Call DynamoDB to read the item from the table
ddb.getItem(params, function (err, data) {
    if (err) {
        console.log("Error", err);
    } else {
        console.log("Success", data.Item);
    }
});
```

Get an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
    TableName: "EPISODES_TABLE",
    Key: { KEY_NAME: VALUE },
};

docClient.get(params, function (err, data) {
    if (err) {
        console.log("Error", err);
    } else {
        console.log("Success", data.Item);
    }
});
```

}

return outcome.IsSuccess();
}
```

- For API details, see [UpdateItem](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To update an item in a table

The following update-item example updates an item in the MusicCollection table. It adds a new attribute (Year) and modifies the AlbumTitle attribute. All of the attributes in the item, as they appear after the update, are returned in the response.

```
aws dynamodb update-item \  
  --table-name MusicCollection \  
  --key file://key.json \  
  --update-expression "SET #Y = :y, #AT = :t" \  
  --expression-attribute-names file://expression-attribute-names.json \  
  --expression-attribute-values file://expression-attribute-values.json \  
  --return-values ALL_NEW \  
  --return-consumed-capacity TOTAL \  
  --return-item-collection-metrics SIZE
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Contents of expression-attribute-names.json:

```
{  
    "#Y":"Year", "#AT":"AlbumTitle"  
}
```

Contents of expression-attribute-values.json:

```
{  
    ":y":{"N": "2015"},  
    ":t":{"S": "Louder Than Ever"}  
}
```

Output:

```
{  
    "Attributes": {  
        "AlbumTitle": {  
            "S": "Louder Than Ever"  
        },  
        "Awards": {  
            "N": "10"  
        },  
        "Artist": {  
            "S": "Acme Band"  
        },  
        "Year": {  
            "N": "2015"  
        },  
        "SongTitle": {  
            "S": "Happy Day"  
        }  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 3.0  
    "ItemCollectionMetrics": {  
        "ItemCollectionKey": {  
            "Artist": {  
                "S": "Acme Band"  
            }  
        "SizeEstimateRangeGB": [  
            0.0,  
            1.0  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To update an item conditionally

The following example updates an item in the MusicCollection table, but only if the existing item does not already have a Year attribute.

```
aws dynamodb update-item \
```

```
--table-name MusicCollection \
--key file://key.json \
--update-expression "SET #Y = :y, #AT = :t" \
--expression-attribute-names file://expression-attribute-names.json \
--expression-attribute-values file://expression-attribute-values.json \
--condition-expression "attribute_not_exists(#Y)"
```

Contents of key.json:

```
{  
    "Artist": {"S": "Acme Band"},  
    "SongTitle": {"S": "Happy Day"}  
}
```

Contents of expression-attribute-names.json:

```
{  
    "#Y": "Year",  
    "#AT": "AlbumTitle"  
}
```

Contents of expression-attribute-values.json:

```
{  
    ":y": {"N": "2015"},  
    ":t": {"S": "Louder Than Ever"}  
}
```

If the item already has a Year attribute, DynamoDB returns the following output.

An error occurred (ConditionalCheckFailedException) when calling the UpdateItem operation: The conditional request failed

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

}
```

- For API details, see [DeleteItem](#) in *AWS SDK for C++ API Reference*.

CLI

AWS CLI

Example 1: To delete an item

The following `delete-item` example deletes an item from the `MusicCollection` table and requests details about the item that was deleted and the capacity used by the request.

```
aws dynamodb delete-item \
    --table-name MusicCollection \
    --key file://key.json \
    --return-values ALL_OLD \
    --return-consumed-capacity TOTAL \
    --return-item-collection-metrics SIZE
```

Contents of `key.json`:

```
{  
    "Artist": {"S": "No One You Know"},  
    "SongTitle": {"S": "Scared of My Shadow"}  
}
```

Output:

```
{  
    "Attributes": {  
        "AlbumTitle": {  
            "S": "Blue Sky Blues"  
        },  
        "Artist": {  
            "S": "No One You Know"  
        },  
        "SongTitle": {  
            "S": "Scared of My Shadow"  
        }  
    },  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 2.0  
    },  
    "ItemCollectionMetrics": {  
        "ItemCollectionKey": {  
    }
```

```
        "Artist": {  
            "S": "No One You Know"  
        },  
        "SizeEstimateRangeGB": [  
            0.0,  
            1.0  
        ]  
    }  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To delete an item conditionally

The following example deletes an item from the ProductCatalog table only if its ProductCategory is either Sporting Goods or Gardening Supplies and its price is between 500 and 600. It returns details about the item that was deleted.

```
aws dynamodb delete-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"456"}}' \  
  --condition-expression "(ProductCategory IN (:cat1, :cat2)) and (#P  
between :lo and :hi)" \  
  --expression-attribute-names file://names.json \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_OLD
```

Contents of names.json:

```
{  
    "#P": "Price"  
}
```

Contents of values.json:

```
{  
    ":cat1": {"S": "Sporting Goods"},  
    ":cat2": {"S": "Gardening Supplies"},  
    ":lo": {"N": "500"},  
    ":hi": {"N": "600"}  
}
```

Output:

```
{  
    "Attributes": {  
        "Id": {  
            "N": "456"  
        },  
        "Price": {  
            "N": "550"  
        },  
        "ProductCategory": {  
            "S": "Sporting Goods"  
        }  
    }  
}
```

For more information, see [Writing an Item](#) in the *Amazon DynamoDB Developer Guide*.

- For API details, see [DeleteItem](#) in *AWS CLI Command Reference*.

This example uses the document client to simplify working with items in DynamoDB. For API details see [DeleteCommand](#).

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";  
import { DynamoDBDocumentClient, DeleteCommand } from "@aws-sdk/lib-dynamodb";  
  
const client = new DynamoDBClient({});  
const docClient = DynamoDBDocumentClient.from(client);  
  
export const main = async () => {  
  const command = new DeleteCommand({  
    TableName: "Sodas",  
    Key: {  
      Flavor: "Cola",  
    },  
  });  
  
  const response = await docClient.send(command);  
  console.log(response);  
  return response;  
};
```

- For more information, see [AWS SDK for JavaScript Developer Guide](#).
- For API details, see [DeleteItem](#) in *AWS SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

Delete an item from a table.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create the DynamoDB service object
var ddb = new AWS.DynamoDB({ apiVersion: "2012-08-10" });

var params = {
  TableName: "TABLE",
  Key: {
    KEY_NAME: { N: "VALUE" },
  },
};

// Call DynamoDB to delete the item from the table
ddb.deleteItem(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

Delete an item from a table using the DynamoDB document client.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });
```

```
// Create DynamoDB document client
var docClient = new AWS.DynamoDB.DocumentClient({ apiVersion: "2012-08-10" });

var params = {
  Key: {
    HASH_KEY: VALUE,
  },
  TableName: "TABLE",
};

docClient.delete(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

- For more information, see [AWS SDK for JavaScript Developer Guide](#).
- For API details, see [DeleteItem](#) in *AWS SDK for JavaScript API Reference*.

Query a DynamoDB table

You can perform a query on a DynamoDB table using the AWS Management Console, the AWS CLI, or an AWS SDK. For more information on queries, see [Query operations in DynamoDB](#).

Query a DynamoDB table using an AWS SDK

The following code examples show how to query a DynamoDB table using an AWS SDK.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
/// <summary>
/// Queries the table for movies released in a particular year and
/// then displays the information for the movies returned.
/// </summary>
/// <param name="client">The initialized DynamoDB client object.</param>
/// <param name="tableName">The name of the table to query.</param>
/// <param name="year">The release year for which we want to
/// view movies.</param>
/// <returns>The number of movies that match the query.</returns>
public static async Task<int> QueryMoviesAsync(AmazonDynamoDBClient
client, string tableName, int year)
{
    var movieTable = Table.LoadTable(client, tableName);
    var filter = new QueryFilter("year", QueryOperator.Equal, year);

    Console.WriteLine("\nFind movies released in: {year}:");

    var config = new QueryOperationConfig()
    {
        Limit = 10, // 10 items per page.
        Select = SelectValues.SpecificAttributes,
        AttributesToGet = new List<string>
        {
            "title",
            "year",
        },
        ConsistentRead = true,
        Filter = filter,
    };

    // Value used to track how many movies match the
```

```
// supplied criteria.  
var moviesFound = 0;  
  
Search search = movieTable.Query(config);  
do  
{  
    var movieList = await search.GetNextSetAsync();  
    moviesFound += movieList.Count;  
  
    foreach (var movie in movieList)  
    {  
        DisplayDocument(movie);  
    }  
}  
while (!search.IsDone);  
  
return moviesFound;  
}
```

- For API details, see [Query](#) in *AWS SDK for .NET API Reference*.

The utility functions used in this example.

```
#####
# function errecho
#
# This function outputs everything sent to it to STDERR (standard error output).
#####
function errecho() {
    printf "%s\n" "$*" 1>&2
}

#####
# function aws_cli_error_log()
#
# This function is used to log the error messages from the AWS CLI.
#
# See https://docs.aws.amazon.com/cli/latest/topic/return-codes.html#cli-aws-help-return-codes.
#
# The function expects the following argument:
#     $1 - The error code returned by the AWS CLI.
#
# Returns:
#     0: - Success.
#
#####
function aws_cli_error_log() {
```

```
local err_code=$1
errecho "Error code : $err_code"
if [ "$err_code" == 1 ]; then
    errecho " One or more S3 transfers failed."
elif [ "$err_code" == 2 ]; then
    errecho " Command line failed to parse."

CLI

AWS CLI

Example 1: To query a table

The following query example queries items in the MusicCollection table. The table has a hash-and-range primary key (Artist and SongTitle), but this query only specifies the hash key value. It returns song titles by the artist named "No One You Know".

```
aws dynamodb query \  
    --table-name MusicCollection \  
    --projection-expression "SongTitle" \  
    --key-condition-expression "Artist = :v1" \  
    --expression-attribute-values file://expression-attributes.json \  
    --return-consumed-capacity TOTAL
```

Contents of expression-attributes.json:

```
{  
    ":v1": {"S": "No One You Know"}  
}
```

Output:

```
{  
    "Items": [  
        {  
            "SongTitle": {  
                "S": "Call Me Today"  
            },  
            "SongTitle": {  
                "S": "Scared of My Shadow"  
            }  
        }  
    ],  
    "Count": 2,  
    "ScannedCount": 2,  
    "ConsumedCapacity": {
```

```
        "TableName": "MusicCollection",
        "CapacityUnits": 0.5
    }
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 2: To query a table using strongly consistent reads and traverse the index in descending order

The following example performs the same query as the first example, but returns results in reverse order and uses strongly consistent reads.

```
aws dynamodb query \
--table-name MusicCollection \
--projection-expression "SongTitle" \
--key-condition-expression "Artist = :v1" \
--expression-attribute-values file://expression-attributes.json \
--consistent-read \
--no-scan-index-forward \
--return-consumed-capacity TOTAL
```

Contents of expression-attributes.json:

```
{
  ":v1": {"S": "No One You Know"}
}
```

Output:

```
{
  "Items": [
    {
      "SongTitle": {
        "S": "Scared of My Shadow"
      }
    },
    {
      "SongTitle": {
        "S": "Call Me Today"
      }
    }
  ]
}
```

```
        }
    ],
    "Count": 2,
    "ScannedCount": 2,
    "ConsumedCapacity": {
        "TableName": "MusicCollection",
        "CapacityUnits": 1.0
    }
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 3: To filter out specific results

The following example queries the MusicCollection but excludes results with specific values in the AlbumTitle attribute. Note that this does not affect the ScannedCount or ConsumedCapacity, because the filter is applied after the items have been read.

```
aws dynamodb query \
--table-name MusicCollection \
--key-condition-expression "#n1 = :v1" \
--filter-expression "NOT (#n2 IN (:v2, :v3))" \
--expression-attribute-names file://names.json \
--expression-attribute-values file://values.json \
--return-consumed-capacity TOTAL
```

Contents of values.json:

```
{
    ":v1": {"S": "No One You Know"},
    ":v2": {"S": "Blue Sky Blues"},
    ":v3": {"S": "Greatest Hits"}
}
```

Contents of names.json:

```
{
    "#n1": "Artist",
    "#n2": "AlbumTitle"
}
```

```
}
```

Output:

```
{  
    "Items": [  
        {  
            "AlbumTitle": {  
                "S": "Somewhat Famous"  
            },  
            "Artist": {  
                "S": "No One You Know"  
            },  
            "SongTitle": {  
                "S": "Call Me Today"  
            }  
        }  
    ],  
    "Count": 1,  
    "ScannedCount": 2,  
    "ConsumedCapacity": {  
        "TableName": "MusicCollection",  
        "CapacityUnits": 0.5  
    }  
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 4: To retrieve only an item count

The following example retrieves a count of items matching the query, but does not retrieve any of the items themselves.

```
aws dynamodb query \  
    --table-name MusicCollection \  
    --select COUNT \  
    --key-condition-expression "Artist = :v1" \  
    --expression-attribute-values file://expression-attributes.json
```

Contents of expression-attributes.json:

```
{  
  ":v1": {"S": "No One You Know"}  
}
```

Output:

```
{  
  "Count": 2,  
  "ScannedCount": 2,  
  "ConsumedCapacity": null  
}
```

For more information, see [Working with Queries in DynamoDB](#) in the *Amazon DynamoDB Developer Guide*.

Example 5: To query an index

The following example queries the local secondary index `AlbumTitleIndex`. The query returns all attributes from the base table that have been projected into the local secondary index. Note that when querying a local secondary index or global secondary index, you must also provide the name of the base table using the `table-name` parameter.

```
aws dynamodb query \  
  --table-name MusicCollection \  
  --index-name AlbumTitleIndex \  
  --key-condition-expression "Artist = :v1" \  
  --expression-attribute-values file://expression-attributes.json \  
  --select ALL_PROJECTED_ATTRIBUTES \  
  --return-consumed-capacity INDEXES
```

Contents of `expression-attributes.json`:

```
{  
  ":v1": {"S": "No One You Know"}  
}
```

Output:

```
{
```

```
"Items": [
    {
        "AlbumTitle": {
            "S": "Blue Sky Blues"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Scared of My Shadow"
        }
    },
    {
        "AlbumTitle": {
            "S": "Somewhat Famous"
        },
        "Artist": {
            "S": "No One You Know"
        },
        "SongTitle": {
            "S": "Call Me Today"
        }
    }
],
"Count": 2,
"ScannedCount": 2,
"ConsumedCapacity": {
    "TableName": "MusicCollection",
    "CapacityUnits": 0.5,
    "Table": {
        "CapacityUnits": 0.0
    },
    "LocalSecondaryIndexes": {
        "AlbumTitleIndex": {
            "CapacityUnits": 0.5
        }
    }
}
}
```

CLI

AWS CLI

To scan a table

The following scan example scans the entire MusicCollection table, and then narrows the results to songs by the artist "No One You Know". For each item, only the album title and song title are returned.

```
aws dynamodb scan \
    --table-name MusicCollection \
    --filter-expression "Artist = :a" \
    --projection-expression "#ST, #AT" \
    --expression-attribute-names file://expression-attribute-names.json \
    --expression-attribute-values file://expression-attribute-values.json
```

Contents of expression-attribute-names.json:

```
{  
    "#ST": "SongTitle",  
    "#AT": "AlbumTitle"  
}
```

Contents of expression-attribute-values.json:

```
{  
    ":a": {"S": "No One You Know"}  
}
```

Output:

```
{  
    "Count": 2,  
    "Items": [  
        {  
            "SongTitle": {  
                "S": "Call Me Today"  
            },  
            "AlbumTitle": {  
                "S": "Somewhat Famous"  
            }  
        },  
        {  
            "SongTitle": {  
                "S": "Scared of My Shadow"  
            },  
            "AlbumTitle": {  
                "S": "Blue Sky Blues"  
            }  
        }  
    ],  
}
```

```
        "ScannedCount": 3,  
        "ConsumedCapacity": null  
    }
```

    guard let client = self.ddbClient else {  
        throw MoviesError.UninitializedClient  
    }  
  
    let input = ScanInput(  
        consistentRead: true,  
        exclusiveStartKey: startKey,  
        expressionAttributeNames: [  
            "#y": "year"           // `year` is a reserved word, so use `#y`  
instead.  
        ],  
        expressionAttributeValues: [  
            ":y1": .n(String(firstYear)),  
            ":y2": .n(String(lastYear))  
        ],  
        filterExpression: "#y BETWEEN :y1 AND :y2",  
        tableName: self.tableName  
    )  
  
    let output = try await client.scan(input: input)  
  
    guard let items = output.items else {  
        return movieList  
    }  
  
    // Build an array of `Movie` objects for the returned items.  
  
    for item in items {  
        let movie = try Movie(withItem: item)  
        movieList.append(movie)  
    }  
  
    // Call this function recursively to continue collecting matching  
    // movies, if necessary.  
  
    if output.lastEvaluatedKey != nil {
```

```
        let movies = try await self.getMovies(firstYear: firstYear, lastYear:  
lastYear,  
                                         startKey: output.lastEvaluatedKey)  
        movieList += movies  
    }  
    return movieList  
}
```

- For API details, see [Scan](#) in [AWS SDK for Swift API reference](#).

For more DynamoDB examples, see [Code examples for DynamoDB using AWS SDKs](#).

Using DynamoDB with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples

SDK documentation	Code examples
AWS SDK for SAP ABAP	AWS SDK for SAP ABAP code examples
AWS SDK for Swift	AWS SDK for Swift code examples

For examples specific to DynamoDB, see [Code examples for DynamoDB using AWS SDKs](#).

 **Example availability**

Programming with DynamoDB and the AWS SDKs

This section covers developer-related topics. If you want to run code examples instead, see [Running the code examples in this Developer Guide](#).

Note

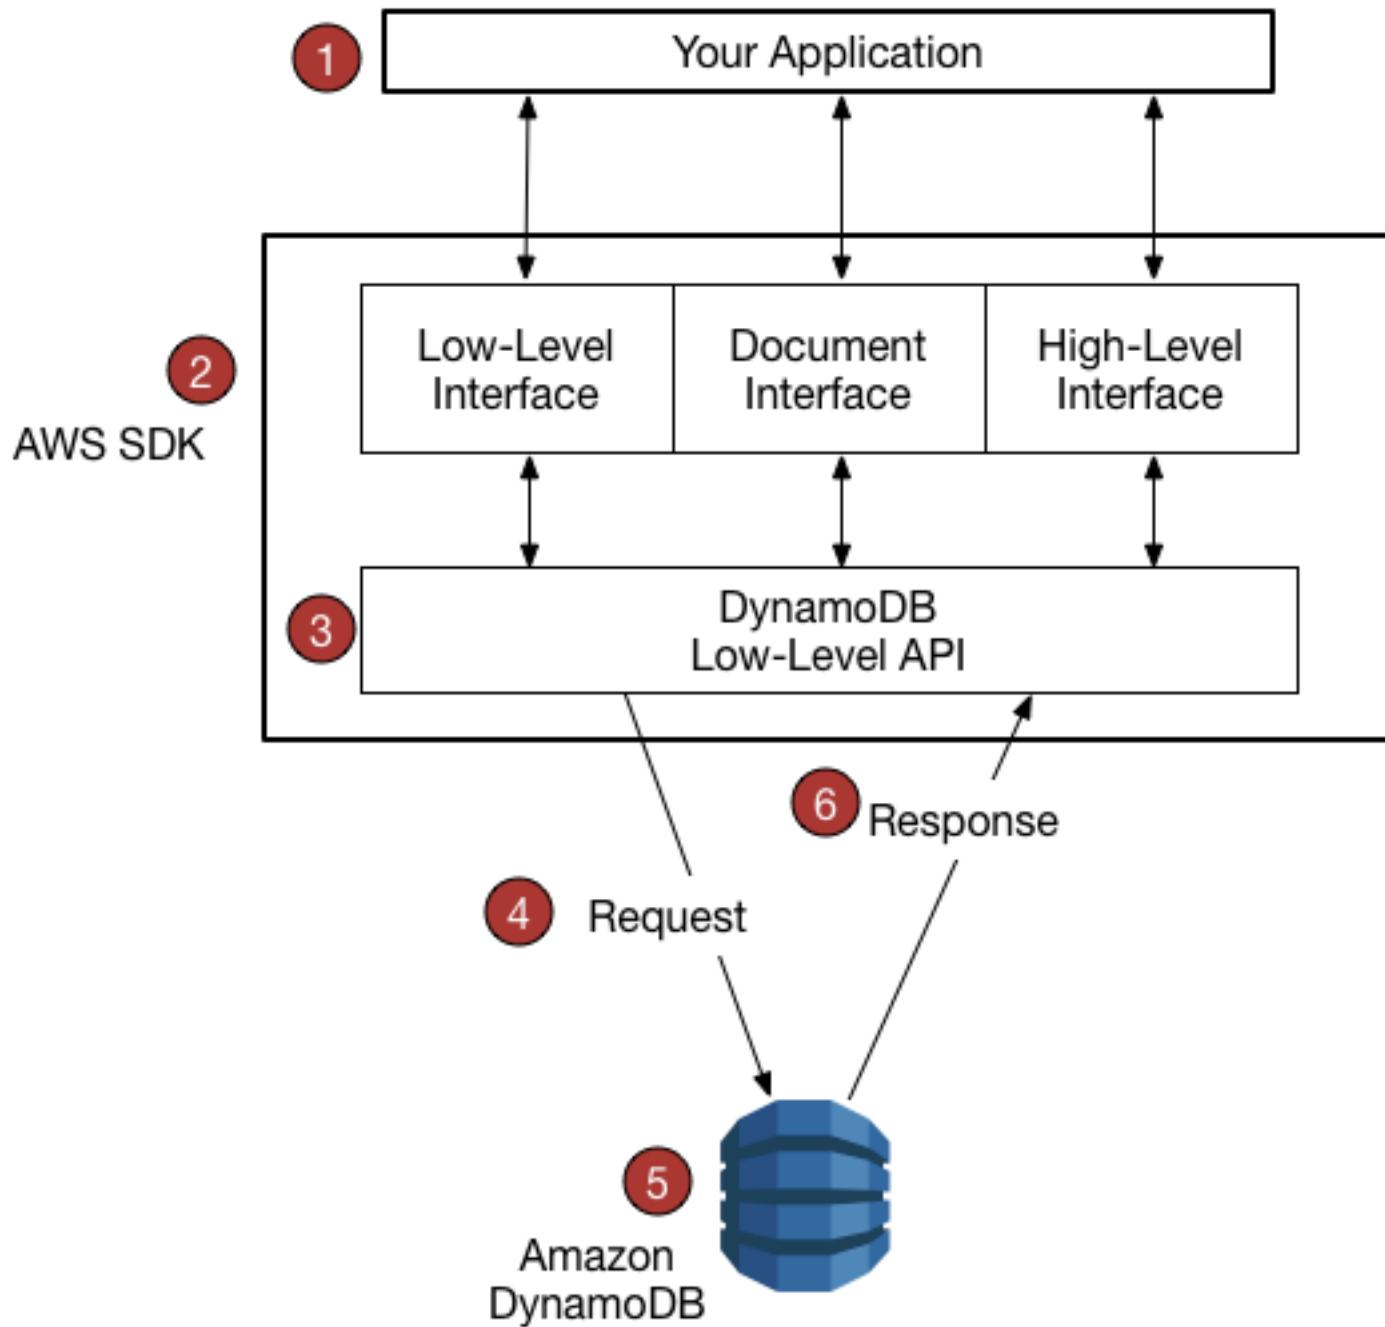

In December 2017, AWS began the process of migrating all Amazon DynamoDB endpoints to use secure certificates issued by Amazon Trust Services (ATS). For more information, see [Troubleshooting SSL/TLS connection establishment issues](#).

Topics

- [Overview of AWS SDK support for DynamoDB](#)
- [Higher-level programming interfaces for DynamoDB](#)
- [Running the code examples in this Developer Guide](#)
- [Programming Amazon DynamoDB with Python and Boto3](#)
- [Programming Amazon DynamoDB with JavaScript](#)
- [Programming Amazon DynamoDB with AWS SDK for Java 2.x](#)

Overview of AWS SDK support for DynamoDB

The following diagram provides a high-level overview of Amazon DynamoDB application programming using the AWS SDKs.

1. You write an application using an AWS SDK for your programming language.
2. Each AWS SDK provides one or more programmatic interfaces for working with DynamoDB. The specific interfaces available depend on which programming language and AWS SDK you use. Options include:
 - [Low-level interfaces](#)
 - [Document interfaces](#)
 - [Object persistence interface](#)

- [High Level Interfaces](#)

3. The AWS SDK constructs HTTP(S) requests for use with the low-level DynamoDB API.
4. The AWS SDK sends the request to the DynamoDB endpoint.
5. DynamoDB runs the request. If the request is successful, DynamoDB returns an HTTP 200 response code (OK). If the request is unsuccessful, DynamoDB returns an HTTP error code and an error message.
6. The AWS SDK processes the response and propagates it back to your application.

Each of the AWS SDKs provides important services to your application, including the following:

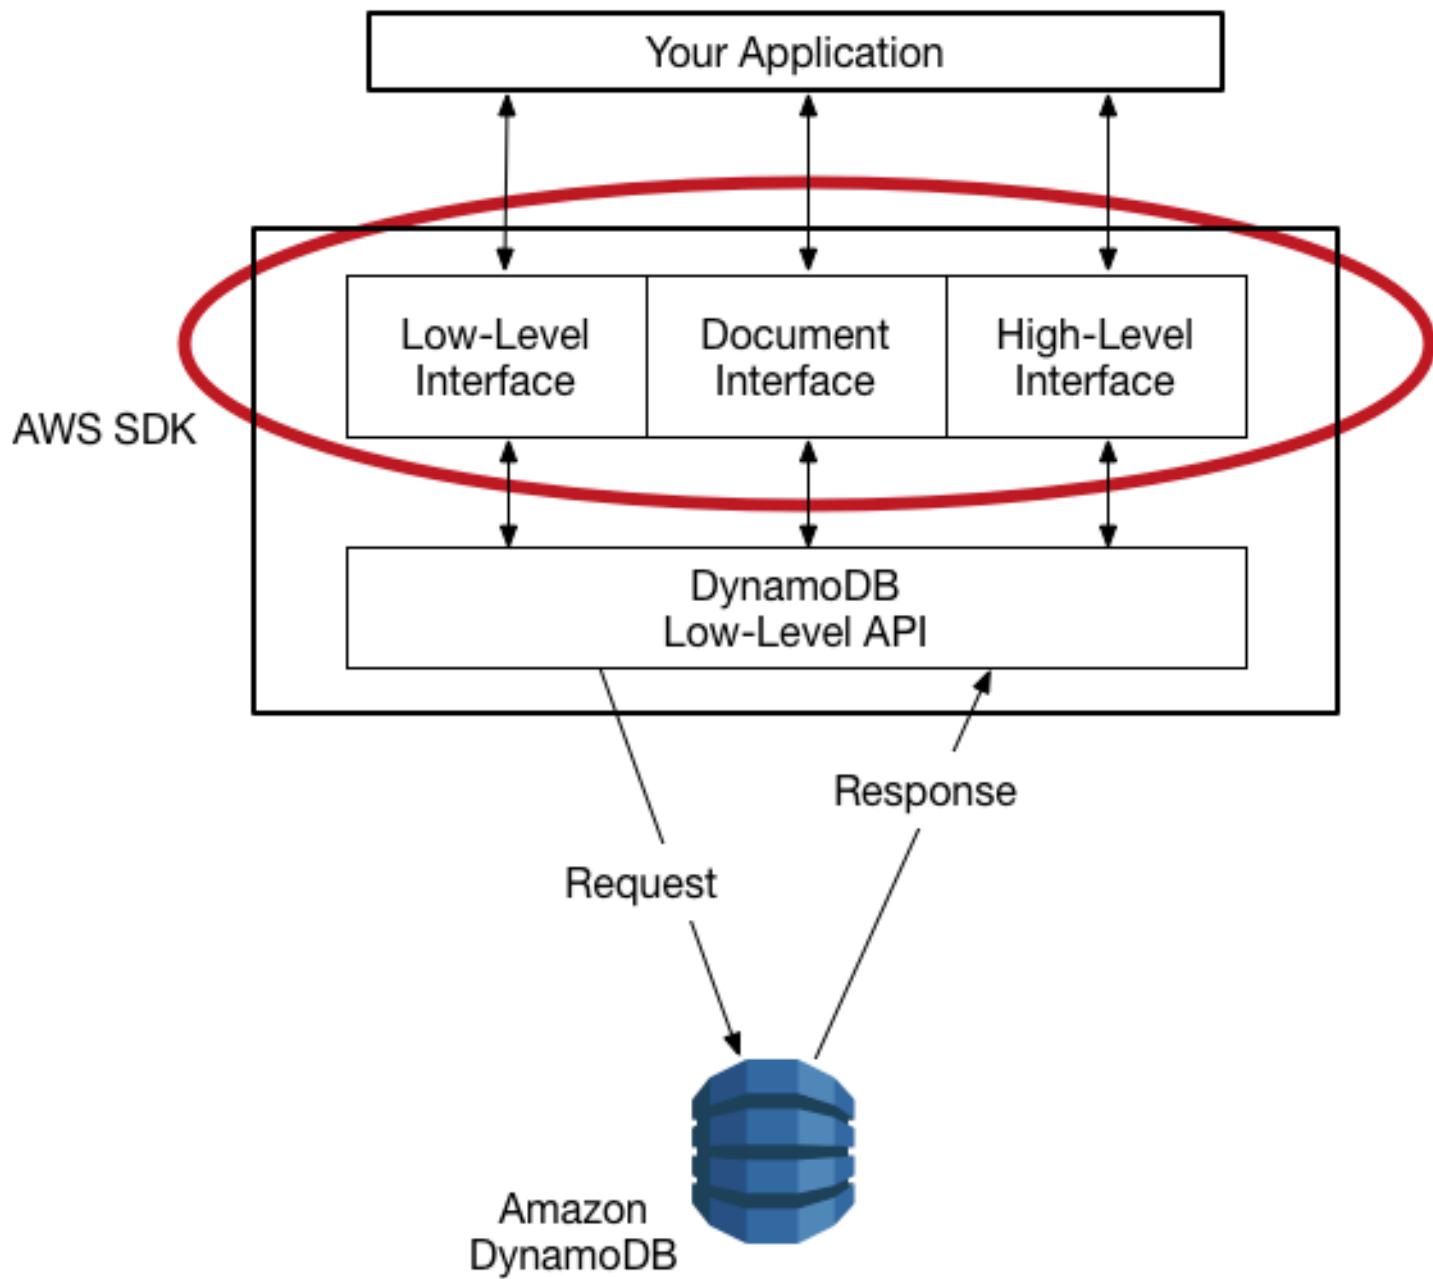

- Formatting HTTP(S) requests and serializing request parameters.
- Generating a cryptographic signature for each request.
- Forwarding requests to a DynamoDB endpoint and receiving responses from DynamoDB.
- Extracting the results from those responses.
- Implementing basic retry logic in case of errors.

You do not need to write code for any of these tasks.

 **Note**

For more information about AWS SDKs, including installation instructions and documentation, see [Tools for Amazon Web Services](#).

Programmatic interfaces

Every [AWS SDK](#) provides one or more programmatic interfaces for working with Amazon DynamoDB. These interfaces range from simple low-level DynamoDB wrappers to object-oriented persistence layers. The available interfaces vary depending on the AWS SDK and programming language that you use.

The following section highlights some of the interfaces available, using the AWS SDK for Java as an example. (Not all interfaces are available in all AWS SDKs.)

Topics

- [Low-level interfaces](#)
- [Document interfaces](#)
- [Object persistence interface](#)

Low-level interfaces

Every language-specific AWS SDK provides a low-level interface for Amazon DynamoDB, with methods that closely resemble low-level DynamoDB API requests.

In some cases, you will need to identify the data types of the attributes using [Data type descriptors](#), such as S for string or N for number.

 **Note**

A low-level interface is available in every language-specific AWS SDK.

The following Java program uses the low-level interface of the AWS SDK for Java.

```
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;
import software.amazon.awssdk.services.dynamodb.model.GetItemRequest;
import java.util.HashMap;
import java.util.Map;
import java.util.Set;

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 *
 * To get an item from an Amazon DynamoDB table using the AWS SDK for Java V2,
 * its better practice to use the
 * Enhanced Client, see the EnhancedGetItem example.
 */
```

```
/*
public class GetItem {
    public static void main(String[] args) {
        final String usage = """

            Usage:
            <tableName> <key> <keyVal>

            Where:
            tableName - The Amazon DynamoDB table from which an item is
            retrieved (for example, Music3).\s
            key - The key used in the Amazon DynamoDB table (for example,
            Artist).\s
            keyval - The key value that represents the item to get (for
            example, Famous Band).
            """;

        if (args.length != 3) {
            System.out.println(usage);
            System.exit(1);
        }

        String tableName = args[0];
        String key = args[1];
        String keyVal = args[2];
        System.out.format("Retrieving item \"%s\" from \"%s\"\n", keyVal, tableName);
        Region region = Region.US_EAST_1;
        DynamoDbClient ddb = DynamoDbClient.builder()
            .region(region)
            .build();

        getDynamoDBItem(ddb, tableName, key, keyVal);
        ddb.close();
    }

    public static void getDynamoDBItem(DynamoDbClient ddb, String tableName, String
key, String keyVal) {
        HashMap<String, AttributeValue> keyToGet = new HashMap<>();
        keyToGet.put(key, AttributeValue.builder()
            .s(keyVal)
            .build());

        GetItemRequest request = GetItemRequest.builder()
            .key(keyToGet)
```

```
.tableName(tableName)
.build();

try {
    // If there is no matching item, GetItem does not return any data.
    Map<String, AttributeValue> returnedItem = ddb.getItem(request).item();
    if (returnedItem.isEmpty())
        System.out.format("No item found with the key %s!\n", key);
    else {
        Set<String> keys = returnedItem.keySet();
        System.out.println("Amazon DynamoDB table attributes: \n");
        for (String key1 : keys) {
            System.out.format("%s: %s\n", key1,
returnedItem.get(key1).toString());
        }
    }
} catch (DynamoDbException e) {
    System.err.println(e.getMessage());
    System.exit(1);
}
}
```

Document interfaces

Many AWS SDKs provide a document interface, allowing you to perform data plane operations (create, read, update, delete) on tables and indexes. With a document interface, you do not need to specify [Data type descriptors](#). The data types are implied by the semantics of the data itself. These AWS SDKs also provide methods to easily convert JSON documents to and from native Amazon DynamoDB data types.

 **Note**

Document interfaces are available in the AWS SDKs for [Java](#), [.NET](#), [Node.js](#), and [JavaScript in the browser](#).

The following Java program uses the document interface of the AWS SDK for Java. The program creates a Table object that represents the Music table, and then asks that object to use GetItem to retrieve a song. The program then prints the year that the song was released.

The `com.amazonaws.services.dynamodbv2.document.DynamoDB` class implements the DynamoDB document interface. Note how DynamoDB acts as a wrapper around the low-level client (`AmazonDynamoDB`).

```
package com.amazonaws.codesamples.gsg;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.GetItemOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;

public class MusicDocumentDemo {

    public static void main(String[] args) {

        AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
        DynamoDB docClient = new DynamoDB(client);

        Table table = docClient.getTable("Music");
        GetItemOutcome outcome = table.getItemOutcome(
            "Artist", "No One You Know",
            "SongTitle", "Call Me Today");

        int year = outcome.getItem().getInt("Year");
        System.out.println("The song was released in " + year);

    }
}
```

Object persistence interface

Some AWS SDKs provide an object persistence interface where you do not directly perform data plane operations. Instead, you create objects that represent items in Amazon DynamoDB tables and indexes, and interact only with those objects. This allows you to write object-centric code, rather than database-centric code.

Note

Object persistence interfaces are available in the AWS SDKs for Java and .NET. For more information, see [Higher-level programming interfaces for DynamoDB](#) for DynamoDB.

```
import com.example.dynamodb.Customer;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedClient;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbTable;
import software.amazon.awssdk.enhanced.dynamodb.Key;
import software.amazon.awssdk.enhanced.dynamodb.TableSchema;
import software.amazon.awssdk.enhanced.dynamodb.model.GetItemEnhancedRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;
```

```
import com.example.dynamodb.Customer;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbEnhancedClient;
import software.amazon.awssdk.enhanced.dynamodb.DynamoDbTable;
import software.amazon.awssdk.enhanced.dynamodb.Key;
import software.amazon.awssdk.enhanced.dynamodb.TableSchema;
import software.amazon.awssdk.enhanced.dynamodb.model.GetItemEnhancedRequest;
import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.DynamoDbException;

/*
 * Before running this code example, create an Amazon DynamoDB table named Customer
 * with these columns:
 *   - id - the id of the record that is the key. Be sure one of the id values is
 `id101`
 *   - custName - the customer name
 *   - email - the email value
 *   - registrationDate - an instant value when the item was added to the table. These
 values
 *           need to be in the form of `YYYY-MM-DDTHH:mm:ssZ`, such as
2022-07-11T00:00:00Z
 *
 * Also, ensure that you have set up your development environment, including your
credentials.
*
* For information, see this documentation topic:
*
* https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
*/
public class EnhancedGetItem {
    public static void main(String[] args) {
        Region region = Region.US_EAST_1;
```

```
DynamoDbClient ddb = DynamoDbClient.builder()
    .region(region)
    .build();

DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
    .dynamoDbClient(ddb)
    .build();

getItem(enhancedClient);
ddb.close();
}

public static String getItem(DynamoDbEnhancedClient enhancedClient) {
    Customer result = null;
    try {
        DynamoDbTable<Customer> table = enhancedClient.table("Customer",
TableSchema.fromBean(Customer.class));
        Key key = Key.builder()
            .partitionValue("id101").sortValue("tred@noserver.com")
            .build();

        // Get the item by using the key.
        result = table.getItem(
            (GetItemEnhancedRequest.Builder requestBuilder) ->
requestBuilder.key(key));
        System.out.println("***** The description value is " +
result.getCustName());

    } catch (DynamoDbException e) {
        System.err.println(e.getMessage());
        System.exit(1);
    }
    return result.getCustName();
}
}
```

DynamoDB low-level API

Topics

- [Request format](#)
- [Response format](#)
- [Data type descriptors](#)

- [Numeric data](#)
- [Binary data](#)

The Amazon DynamoDB *low-level API* is the protocol-level interface for DynamoDB. At this level, every HTTP(S) request must be correctly formatted and carry a valid digital signature.

The AWS SDKs construct low-level DynamoDB API requests on your behalf and process the responses from DynamoDB. This lets you focus on your application logic, instead of low-level

details. However, you can still benefit from a basic knowledge of how the low-level DynamoDB API works.

For more information about the low-level DynamoDB API, see [Amazon DynamoDB API Reference](#).

Note

DynamoDB Streams has its own low-level API, which is separate from that of DynamoDB and is fully supported by the AWS SDKs.

For more information, see [Change data capture for DynamoDB Streams](#). For the low-level DynamoDB Streams API, see the [Amazon DynamoDB Streams API Reference](#).

The low-level DynamoDB API uses JavaScript Object Notation (JSON) as a wire protocol format. JSON presents data in a hierarchy so that both data values and data structure are conveyed simultaneously. Name-value pairs are defined in the format name : value. The data hierarchy is defined by nested brackets of name-value pairs.

DynamoDB uses JSON only as a transport protocol, not as a storage format. The AWS SDKs use JSON to send data to DynamoDB, and DynamoDB responds with JSON. DynamoDB does not store data persistently in JSON format.

Note

For more information about JSON, see [Introducing JSON](#) on the [JSON.org](#) website.

Request format

The DynamoDB low-level API accepts HTTP(S) POST requests as input. The AWS SDKs construct these requests for you.

Suppose that you have a table named Pets, with a key schema consisting of AnimalType (partition key) and Name (sort key). Both of these attributes are of type string. To retrieve an item from Pets, the AWS SDK constructs the following request.

```
POST / HTTP/1.1
Host: dynamodb.<region>.amazonaws.com;
Accept-Encoding: identity
```

```
Content-Length: <PayloadSizeBytes>
User-Agent: <UserAgentString>
Content-Type: application/x-amz-json-1.0
Authorization: AWS4-HMAC-SHA256 Credential=<Credential>, SignedHeaders=<Headers>,
Signature=<Signature>
X-Amz-Date: <Date>
X-Amz-Target: DynamoDB_20120810.GetItem

{
    "TableName": "Pets",
    "Key": {
        "AnimalType": {"S": "Dog"},
        "Name": {"S": "Fido"}
    }
}
```

Note the following about this request:

- The Authorization header contains information required for DynamoDB to authenticate the request. For more information, see [Signing AWS API requests](#) and [Signature Version 4 signing process](#) in the *Amazon Web Services General Reference*.
- The X-Amz-Target header contains the name of a DynamoDB operation: GetItem. (This is also accompanied by the low-level API version, in this case 20120810.)
- The payload (body) of the request contains the parameters for the operation, in JSON format. For the GetItem operation, the parameters are TableName and Key.

Response format

Upon receipt of the request, DynamoDB processes it and returns a response. For the request shown previously, the HTTP(S) response payload contains the results from the operation, as shown in the following example.

```
HTTP/1.1 200 OK
x-amzn-RequestId: <RequestId>
x-amz-crc32: <Checksum>
Content-Type: application/x-amz-json-1.0
Content-Length: <PayloadSizeBytes>
Date: <Date>
{
    "Item": {
```

```
"Age": {"N": "8"},  
"Colors": {  
    "L": [  
        {"S": "White"},  
        {"S": "Brown"},  
        {"S": "Black"}  
    ]  
},  
"Name": {"S": "Fido"},  
"Vaccinations": {  
    "M": {  
        "Rabies": {  
            "L": [  
                {"S": "2009-03-17"},  
                {"S": "2011-09-21"},  
                {"S": "2014-07-08"}  
            ]  
        },  
        "Distemper": {"S": "2015-10-13"}  
    }  
},  
"Breed": {"S": "Beagle"},  
"AnimalType": {"S": "Dog"}  
}  
}
```

At this point, the AWS SDK returns the response data to your application for further processing.

 **Note**

If DynamoDB can't process a request, it returns an HTTP error code and message. The AWS SDK propagates these to your application in the form of exceptions. For more information, see [Error handling with DynamoDB](#).

Data type descriptors

The low-level DynamoDB API protocol requires each attribute to be accompanied by a data type descriptor. *Data type descriptors* are tokens that tell DynamoDB how to interpret each attribute.

The examples in [Request format](#) and [Response format](#) show examples of how data type descriptors are used. The GetItem request specifies S for the Pets key schema attributes (AnimalType and

Name), which are of type **string**. The GetItem response contains a *Pets* item with attributes of type **string** (S), **number** (N), **map** (M), and **list** (L).

The following is a complete list of DynamoDB data type descriptors:

- **S** – String
- **N** – Number
- **B** – Binary
- **BOOL** – Boolean
- **NULL** – Null
- **M** – Map
- **L** – List
- **SS** – String Set
- **NS** – Number Set
- **BS** – Binary Set

 **Note**

For detailed descriptions of DynamoDB data types, see [Data types](#).

Numeric data

Different programming languages offer different levels of support for JSON. In some cases, you might decide to use a third-party library for validating and parsing JSON documents.

Some third-party libraries build upon the JSON number type, providing their own types such as `int`, `long`, or `double`. However, the native number data type in DynamoDB does not map exactly to these other data types, so these type distinctions can cause conflicts. In addition, many JSON libraries do not handle fixed-precision numeric values, and they automatically infer a double data type for digit sequences that contain a decimal point.

To solve these problems, DynamoDB provides a single numeric type with no data loss. To avoid unwanted implicit conversions to a double value, DynamoDB uses strings for the data transfer of numeric values. This approach provides flexibility for updating attribute values while maintaining proper sorting semantics, such as putting the values "01", "2", and "03" in the proper sequence.

If number precision is important to your application, you should convert numeric values to strings before you pass them to DynamoDB.

Binary data

DynamoDB supports binary attributes. However, JSON does not natively support encoding binary data. To send binary data in a request, you will need to encode it in base64 format. Upon receiving the request, DynamoDB decodes the base64 data back to binary.

The base64 encoding scheme used by DynamoDB is described at [RFC 4648](#) on the Internet Engineering Task Force (IETF) website.

Error handling with DynamoDB

This section describes runtime errors and how to handle them. It also describes error messages and codes that are specific to Amazon DynamoDB. For a list of common errors that apply to all AWS services, see [Access Management](#)

Topics

- [Error components](#)
- [Transactional errors](#)
- [Error messages and codes](#)
- [Error handling in your application](#)
- [Error retries and exponential backoff](#)
- [Batch operations and error handling](#)

Error components

When your program sends a request, DynamoDB attempts to process it. If the request is successful, DynamoDB returns an HTTP success status code (200 OK), along with the results from the requested operation.

If the request is unsuccessful, DynamoDB returns an error. Each error has three components:

- An HTTP status code (such as 400).
- An exception name (such as `ResourceNotFoundException`).
- An error message (such as `Requested resource not found: Table: tablename not found`).

The AWS SDKs take care of propagating errors to your application so that you can take appropriate action. For example, in a Java program, you can write try-catch logic to handle a `ResourceNotFoundException`.

If you are not using an AWS SDK, you need to parse the content of the low-level response from DynamoDB. The following is an example of such a response.

```
HTTP/1.1 400 Bad Request
x-amzn-RequestId: LDM6CJP8RMQ1FHKSC1RBVJFPNVV4KQNS05AEMF66Q9ASUAAJG
Content-Type: application/x-amz-json-1.0
Content-Length: 240
Date: Thu, 15 Mar 2012 23:56:23 GMT

{"__type":"com.amazonaws.dynamodb.v20120810#ResourceNotFoundException",
"message":"Requested resource not found: Table: tablename not found"}
```

Transactional errors

For information on transactional errors, please see [Transaction conflict handling in DynamoDB](#)

Error messages and codes

The following is a list of exceptions returned by DynamoDB, grouped by HTTP status code. If *OK to retry?* is *Yes*, you can submit the same request again. If *OK to retry?* is *No*, you need to fix the problem on the client side before you submit a new request.

HTTP status code 400

An HTTP 400 status code indicates a problem with your request, such as authentication failure, missing required parameters, or exceeding a table's provisioned throughput. You have to fix the issue in your application before submitting the request again.

AccessDeniedException

Message: *Access denied.*

The client did not correctly sign the request. If you are using an AWS SDK, requests are signed for you automatically; otherwise, go to the [Signature version 4 signing process](#) in the AWS *General Reference*.

OK to retry? No

ConditionalCheckFailedException

Message: *The conditional request failed.*

You specified a condition that evaluated to false. For example, you might have tried to perform a conditional update on an item, but the actual value of the attribute did not match the expected value in the condition.

OK to retry? No

IncompleteSignatureException

Message: *The request signature does not conform to AWS standards.*

The request signature did not include all of the required components. If you are using an AWS SDK, requests are signed for you automatically; otherwise, go to the [Signature Version 4 signing process](#) in the *AWS General Reference*.

OK to retry? No

ItemCollectionSizeLimitExceededException

Message: *Collection size exceeded.*

For a table with a local secondary index, a group of items with the same partition key value has exceeded the maximum size limit of 10 GB. For more information on item collections, see [Item collections in Local Secondary Indexes](#).

OK to retry? Yes

LimitExceededException

Message: *Too many operations for a given subscriber.*

There are too many concurrent control plane operations. The cumulative number of tables and indexes in the CREATING, DELETING, or UPDATING state cannot exceed 500.

OK to retry? Yes

MissingAuthenticationTokenException

Message: Request must contain a valid (registered) AWS Access Key ID.

The request did not include the required authorization header, or it was malformed. See [DynamoDB low-level API](#).

OK to retry? No

ProvisionedThroughputExceededException

Message: You exceeded your maximum allowed provisioned throughput for a table or for one or more global secondary indexes. To view performance metrics for provisioned throughput vs. consumed throughput, open the [Amazon CloudWatch console](#).

Example: Your request rate is too high. The AWS SDKs for DynamoDB automatically retry requests that receive this exception. Your request is eventually successful, unless your retry queue is too large to finish. Reduce the frequency of requests using [Error retries and exponential backoff](#).

OK to retry? Yes

RequestLimitExceeded

Message: Throughput exceeds the current throughput limit for your account. To request a limit increase, contact AWS Support at <https://aws.amazon.com/support>.

Example: Rate of on-demand requests exceeds the allowed account throughput and the table cannot be scaled further.

OK to retry? Yes

ResourceInUseException

Message: The resource which you are attempting to change is in use.

Example: You tried to re-create an existing table, or delete a table currently in the CREATING state.

OK to retry? No

ResourceNotFoundException

Message: *Requested resource not found.*

Example: The table that is being requested does not exist, or is too early in the CREATING state.

OK to retry? No

ThrottlingException

Message: *Rate of requests exceeds the allowed throughput.*

This exception is returned as an AmazonServiceException response with a THROTTLING_EXCEPTION status code. This exception might be returned if you perform [control plane](#) API operations too rapidly.

For tables using on-demand mode, this exception might be returned for any [data plane](#) API operation if your request rate is too high. To learn more about on-demand scaling, see [Peak traffic and scaling properties](#)

OK to retry? Yes

UnrecognizedClientException

Message: *The Access Key ID or security token is invalid.*

The request signature is incorrect. The most likely cause is an invalid AWS access key ID or secret key.

OK to retry? Yes

ValidationException

Message: Varies, depending upon the specific error(s) encountered

This error can occur for several reasons, such as a required parameter that is missing, a value that is out of range, or mismatched data types. The error message contains details about the specific part of the request that caused the error.

OK to retry? No

HTTP status code 5xx

An HTTP 5xx status code indicates a problem that must be resolved by AWS. This might be a transient error, in which case you can retry your request until it succeeds. Otherwise, go to the [AWS Service Health Dashboard](#) to see if there are any operational issues with the service.

For more information, see [How do I resolve HTTP 5xx errors in Amazon DynamoDB?](#)

InternalServerError (HTTP 500)

DynamoDB could not process your request.

OK to retry? Yes

Note

You might encounter internal server errors while working with items. These are expected during the lifetime of a table. Any failed requests can be retried immediately. When you receive a status code 500 on a write operation, the operation may have succeeded or failed. If the write operation is a `TransactWriteItem` request, then it is OK to retry the operation. If the write operation is a single-item write request such as `PutItem`, `UpdateItem`, or `DeleteItem`, then your application should read the state of the item before retrying the operation, and/or use [Condition expressions](#) to ensure that the item remains in a correct state after retrying regardless of whether the prior operation succeeded or failed. If idempotency is a requirement for the write operation, please use [TransactWriteItem](#), which supports idempotent requests by automatically specifying a `ClientRequestToken` to disambiguate multiple attempts to perform the same action.

ServiceUnavailable (HTTP 503)

DynamoDB is currently unavailable. (This should be a temporary state.)

OK to retry? Yes

Error handling in your application

For your application to run smoothly, you need to add logic to catch and respond to errors. Typical approaches include using try-catch blocks or if-then statements.

The AWS SDKs perform their own retries and error checking. If you encounter an error while using one of the AWS SDKs, the error code and description can help you troubleshoot it.

You should also see a Request ID in the response. The Request ID can be helpful if you need to work with AWS Support to diagnose an issue.

Error retries and exponential backoff

Numerous components on a network, such as DNS servers, switches, load balancers, and others, can generate errors anywhere in the life of a given request. The usual technique for dealing with these error responses in a networked environment is to implement retries in the client application. This technique increases the reliability of the application.

Each AWS SDK implements retry logic automatically. You can modify the retry parameters to your needs. For example, consider a Java application that requires a fail-fast strategy, with no retries allowed in case of an error. With the AWS SDK for Java, you could use the `ClientConfiguration` class and provide a `maxErrorRetry` value of `0` to turn off the retries. For more information, see the AWS SDK documentation for your programming language.

If you're not using an AWS SDK, you should retry original requests that receive server errors (5xx). However, client errors (4xx, other than a `ThrottlingException` or a `ProvisionedThroughputExceededException`) indicate that you need to revise the request itself to correct the problem before trying again.

In addition to simple retries, each AWS SDK implements an exponential backoff algorithm for better flow control. The concept behind exponential backoff is to use progressively longer waits between retries for consecutive error responses. For example, up to 50 milliseconds before the first retry, up to 100 milliseconds before the second, up to 200 milliseconds before third, and so on. However, after a minute, if the request has not succeeded, the problem might be the request size exceeding your provisioned throughput, and not the request rate. Set the maximum number of retries to stop around one minute. If the request is not successful, investigate your provisioned throughput options.

Note

The AWS SDKs implement automatic retry logic and exponential backoff.

Most exponential backoff algorithms use jitter (randomized delay) to prevent successive collisions. Because you aren't trying to avoid such collisions in these cases, you do not need to use this

random number. However, if you use concurrent clients, jitter can help your requests succeed faster. For more information, see the blog post about [Exponential backoff and jitter](#).

Batch operations and error handling

The DynamoDB low-level API supports batch operations for reads and writes. `BatchGetItem` reads items from one or more tables, and `BatchWriteItem` puts or deletes items in one or more tables. These batch operations are implemented as wrappers around other non-batch DynamoDB operations. In other words, `BatchGetItem` invokes `GetItem` once for each item in the batch. Similarly, `BatchWriteItem` invokes `DeleteItem` or `PutItem`, as appropriate, for each item in the batch.

A batch operation can tolerate the failure of individual requests in the batch. For example, consider a `BatchGetItem` request to read five items. Even if some of the underlying `GetItem` requests fail, this does not cause the entire `BatchGetItem` operation to fail. However, if all five read operations fail, then the entire `BatchGetItem` fails.

The batch operations return information about individual requests that fail so that you can diagnose the problem and retry the operation. For `BatchGetItem`, the tables and primary keys in question are returned in the `UnprocessedKeys` value of the response. For `BatchWriteItem`, similar information is returned in `UnprocessedItems`.

The most likely cause of a failed read or a failed write is *throttling*. For `BatchGetItem`, one or more of the tables in the batch request does not have enough provisioned read capacity to support the operation. For `BatchWriteItem`, one or more of the tables does not have enough provisioned write capacity.

If DynamoDB returns any unprocessed items, you should retry the batch operation on those items. However, *we strongly recommend that you use an exponential backoff algorithm*. If you retry the batch operation immediately, the underlying read or write requests can still fail due to throttling on the individual tables. If you delay the batch operation using exponential backoff, the individual requests in the batch are much more likely to succeed.

Higher-level programming interfaces for DynamoDB

The AWS SDKs provide applications with low-level interfaces for working with Amazon DynamoDB. These client-side classes and methods correspond directly to the low-level DynamoDB API. However, many developers experience a sense of disconnect, or *impedance mismatch*, when they need to map complex data types to items in a database table. With a low-level database interface,

developers must write methods for reading or writing object data to database tables, and vice versa. The amount of extra code required for each combination of object type and database table can seem overwhelming.

To simplify development, the AWS SDKs for Java and .NET provide additional interfaces with higher levels of abstraction. The higher-level interfaces for DynamoDB let you define the relationships between objects in your program and the database tables that store those objects' data. After you define this mapping, you call simple object methods such as save, load, or delete, and the underlying low-level DynamoDB operations are automatically invoked on your behalf. This allows you to write object-centric code, rather than database-centric code.

The higher-level programming interfaces for DynamoDB are available in the AWS SDKs for Java and .NET.

Java

- [Java 1.x: DynamoDBMapper](#)
- [Java 2.x: DynamoDB Enhanced Client](#)

.NET

- [.NET: Document model](#)
- [.NET: Object persistence model](#)

Java 1.x: DynamoDBMapper

The AWS SDK for Java provides a `DynamoDBMapper` class, allowing you to map your client-side classes to Amazon DynamoDB tables. To use `DynamoDBMapper`, you define the relationship between items in a DynamoDB table and their corresponding object instances in your code. The `DynamoDBMapper` class enables you to perform various create, read, update, and delete (CRUD) operations on items, and run queries and scans against tables.

Topics

- [Supported data types for DynamoDB Mapper for Java](#)
- [Java Annotations for DynamoDB](#)
- [DynamoDBMapper Class](#)
- [Optional configuration settings for DynamoDBMapper](#)

- [Optimistic locking with version number](#)
- [Mapping arbitrary data](#)
- [DynamoDBMapper Examples](#)

Note

The `DynamoDBMapper` class does not allow you to create, update, or delete tables.

To perform those tasks, use the low-level SDK for Java interface instead. For more information, see [Working with DynamoDB tables in Java](#).

The SDK for Java provides a set of annotation types so that you can map your classes to tables. For example, consider a `ProductCatalog` table that has `Id` as the partition key.

```
ProductCatalog(Id, ...)
```

You can map a class in your client application to the `ProductCatalog` table as shown in the following Java code. This code defines a plain old Java object (POJO) named `CatalogItem`, which uses annotations to map object fields to DynamoDB attribute names.

Example

```
package com.amazonaws.codesamples;

import java.util.Set;

import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBAttribute;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBIgnore;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;

@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {

    private Integer id;
    private String title;
    private String ISBN;
    private Set<String> bookAuthors;
    private String someProp;
```

```
@DynamoDBHashKey(attributeName="Id")
public Integer getId() { return id; }
public void setId(Integer id) {this.id = id; }

@dynamoDBAttribute(attributeName="Title")
public String getTitle() {return title; }
public void setTitle(String title) { this.title = title; }

@dynamoDBAttribute(attributeName="ISBN")
public String getISBN() { return ISBN; }
public void setISBN(String ISBN) { this.ISBN = ISBN; }

@dynamoDBAttribute(attributeName="Authors")
public Set<String> getBookAuthors() { return bookAuthors; }
public void setBookAuthors(Set<String> bookAuthors) { this.bookAuthors =
bookAuthors; }

@DynamoDBIgnore
public String getSomeProp() { return someProp; }
public void setSomeProp(String someProp) { this.someProp = someProp; }
}
```

In the preceding code, the `@DynamoDBTable` annotation maps the `CatalogItem` class to the `ProductCatalog` table. You can store individual class instances as items in the table. In the class definition, the `@DynamoDBHashKey` annotation maps the `Id` property to the primary key.

By default, the class properties map to the same name attributes in the table. The properties `Title` and `ISBN` map to the same name attributes in the table.

The `@DynamoDBAttribute` annotation is optional when the name of the DynamoDB attribute matches the name of the property declared in the class. When they differ, use this annotation with the `attributeName` parameter to specify which DynamoDB attribute this property corresponds to.

In the preceding example, the `@DynamoDBAttribute` annotation is added to each property to ensure that the property names match exactly with the tables created in [Creating tables and loading data for code examples in DynamoDB](#), and to be consistent with the attribute names used in other code examples in this guide.

Your class definition can have properties that don't map to any attributes in the table. You identify these properties by adding the `@DynamoDBIgnore` annotation. In the preceding example, the

The SomeProp property is marked with the @DynamoDBIgnore annotation. When you upload a CatalogItem instance to the table, your DynamoDBMapper instance does not include the SomeProp property. In addition, the mapper does not return this attribute when you retrieve an item from the table.

After you define your mapping class, you can use DynamoDBMapper methods to write an instance of that class to a corresponding item in the Catalog table. The following code example demonstrates this technique.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

DynamoDBMapper mapper = new DynamoDBMapper(client);

CatalogItem item = new CatalogItem();
item.setId(102);
item.setTitle("Book 102 Title");
item.setISBN("222-222222222");
item.setBookAuthors(new HashSet<String>(Arrays.asList("Author 1", "Author 2")));
item.setSomeProp("Test");

mapper.save(item);
```

The following code example shows how to retrieve the item and access some of its attributes.

```
CatalogItem partitionKey = new CatalogItem();

partitionKey.setId(102);
DynamoDBQueryExpression<CatalogItem> queryExpression = new
DynamoDBQueryExpression<CatalogItem>()
.withHashKeyValues(partitionKey);

List<CatalogItem> itemList = mapper.query(CatalogItem.class, queryExpression);

for (int i = 0; i < itemList.size(); i++) {
    System.out.println(itemList.get(i).getTitle());
    System.out.println(itemList.get(i).getBookAuthors());
}
```

DynamoDBMapper offers an intuitive, natural way of working with DynamoDB data within Java. It also provides several built-in features, such as optimistic locking, ACID transactions, autogenerated partition key and sort key values, and object versioning.

Supported data types for DynamoDB Mapper for Java

This section describes the supported primitive Java data types, collections, and arbitrary data types in Amazon DynamoDB.

Amazon DynamoDB supports the following primitive Java data types and primitive wrapper classes.

- `String`
- `Boolean`, `boolean`
- `Byte`, `byte`
- `Date` (as [ISO_8601](#) millisecond-precision string, shifted to UTC)
- `Calendar` (as [ISO_8601](#) millisecond-precision string, shifted to UTC)
- `Long`, `long`
- `Integer`, `int`
- `Double`, `double`
- `Float`, `float`
- `BigDecimal`
- `BigInteger`

Note

- For more information about DynamoDB naming rules and the various supported data types, see [Supported data types and naming rules in Amazon DynamoDB](#).
- Empty Binary values are supported by the DynamoDBMapper.
- Empty String values are supported by AWS SDK for Java 2.x.

In AWS SDK for Java 1.x, DynamoDBMapper supports reading of empty String attribute values, however, it will not write empty String attribute values because these attributes are dropped from the request.

DynamoDB supports the Java [Set](#), [List](#), and [Map](#) collection types. The following table summarizes how these Java types map to the DynamoDB types.

Java type	DynamoDB type
All number types	N (number type)
Strings	S (string type)
Boolean	BOOL (Boolean type), 0 or 1.
ByteBuffer	B (binary type)
Date	S (string type). The Date values are stored as ISO-8601 formatted strings.
Set collection types	SS (string set) type, NS (number set) type, or BS (binary set) type.

The `DynamoDBTypeConverter` interface lets you map your own arbitrary data types to a data type that is natively supported by DynamoDB. For more information, see [Mapping arbitrary data](#).

Java Annotations for DynamoDB

This section describes the annotations that are available for mapping your classes and properties to tables and attributes in Amazon DynamoDB.

For the corresponding Javadoc documentation, see [Annotation Types Summary](#) in the [AWS SDK for Java API Reference](#).

 **Note**

In the following annotations, only `DynamoDBTable` and the `DynamoDBHashKey` are required.

Topics

- [DynamoDBAttribute](#)
- [DynamoDBAutoGeneratedKey](#)
- [DynamoDBAutoGeneratedTimestamp](#)

- [DynamoDBDocument](#)
- [DynamoDBHashKey](#)
- [DynamoDBIgnore](#)
- [DynamoDBIndexHashKey](#)
- [DynamoDBIndexRangeKey](#)
- [DynamoDBRangeKey](#)
- [DynamoDBTable](#)
- [DynamoDBTypeConverted](#)
- [DynamoDBTyped](#)
- [DynamoDBVersionAttribute](#)

DynamoDBAttribute

Maps a property to a table attribute. By default, each class property maps to an item attribute with the same name. However, if the names are not the same, you can use this annotation to map a property to the attribute. In the following Java snippet, the `DynamoDBAttribute` maps the `BookAuthors` property to the `Authors` attribute name in the table.

```
@DynamoDBAttribute(attributeName = "Authors")
public List<String> getBookAuthors() { return BookAuthors; }
public void setBookAuthors(List<String> BookAuthors) { this.BookAuthors =
    BookAuthors; }
```

The `DynamoDBMapper` uses `Authors` as the attribute name when saving the object to the table.

DynamoDBAutoGeneratedKey

Marks a partition key or sort key property as being autogenerated. `DynamoDBMapper` generates a random [UUID](#) when saving these attributes. Only String properties can be marked as autogenerated keys.

The following example demonstrates using autogenerated keys.

```
@DynamoDBTable(tableName="AutoGeneratedKeysExample")
public class AutoGeneratedKeys {
    private String id;
```

```
private String payload;

@DynamoDBHashKey(attributeName = "Id")
@DynamoDBAutoGeneratedKey
public String getId() { return id; }
public void setId(String id) { this.id = id; }

@DynamoDBAttribute(attributeName="payload")
public String getPayload() { return this.payload; }
public void setPayload(String payload) { this.payload = payload; }

public static void saveItem() {
    AutoGeneratedKeys obj = new AutoGeneratedKeys();
    obj.setPayload("abc123");

    // id field is null at this point
    DynamoDBMapper mapper = new DynamoDBMapper(dynamoDBClient);
    mapper.save(obj);

    System.out.println("Object was saved with id " + obj.getId());
}
}
```

DynamoDBAutoGeneratedTimestamp

Automatically generates a timestamp.

```
@DynamoDBAutoGeneratedTimestamp(strategy=DynamoDBAutoGenerateStrategy.ALWAYS)
public Date getLastUpdatedDate() { return lastUpdatedDate; }
public void setLastUpdatedDate(Date lastUpdatedDate) { this.lastUpdatedDate =
lastUpdatedDate; }
```

Optionally, the auto-generation strategy can be defined by providing a strategy attribute. The default is ALWAYS.

DynamoDBDocument

Indicates that a class can be serialized as an Amazon DynamoDB document.

For example, suppose that you wanted to map a JSON document to a DynamoDB attribute of type Map (M). The following code example defines an item containing a nested attribute (Pictures) of type Map.

```
public class ProductCatalogItem {  
  
    private Integer id; //partition key  
    private Pictures pictures;  
    /* ...other attributes omitted... */  
  
    @DynamoDBHashKey(attributeName="Id")  
    public Integer getId() { return id; }  
    public void setId(Integer id) {this.id = id;}  
  
    @DynamoDBAttribute(attributeName="Pictures")  
    public Pictures getPictures() { return pictures; }  
    public void setPictures(Pictures pictures) {this.pictures = pictures;}  
  
    // Additional properties go here.  
  
    @DynamoDBDocument  
    public static class Pictures {  
        private String frontView;  
        private String rearView;  
        private String sideView;  
  
        @DynamoDBAttribute(attributeName = "FrontView")  
        public String getFrontView() { return frontView; }  
        public void setFrontView(String frontView) { this.frontView = frontView; }  
  
        @DynamoDBAttribute(attributeName = "RearView")  
        public String getRearView() { return rearView; }  
        public void setRearView(String rearView) { this.rearView = rearView; }  
  
        @DynamoDBAttribute(attributeName = "SideView")  
        public String getSideView() { return sideView; }  
        public void setSideView(String sideView) { this.sideView = sideView; }  
    }  
}
```

You could then save a new `ProductCatalog` item, with `Pictures`, as shown in the following example.

```
ProductCatalogItem item = new ProductCatalogItem();  
  
Pictures pix = new Pictures();
```

```
pix.setFrontView("http://example.com/products/123_front.jpg");
pix.setRearView("http://example.com/products/123_rear.jpg");
pix.setSideView("http://example.com/products/123_left_side.jpg");
item.setPictures(pic);

item.setId(123);

mapper.save(item);
```

The resulting ProductCatalog item would look like the following (in JSON format).

```
{
    "Id" : 123
    "Pictures" : {
        "SideView" : "http://example.com/products/123_left_side.jpg",
        "RearView" : "http://example.com/products/123_rear.jpg",
        "FrontView" : "http://example.com/products/123_front.jpg"
    }
}
```

DynamoDBHashKey

Maps a class property to the partition key of the table. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Assume that you have a table, ProductCatalog, that has Id as the primary key. The following Java code defines a CatalogItem class and maps its Id property to the primary key of the ProductCatalog table using the @DynamoDBHashKey tag.

```
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {
    private Integer Id;
    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() {
        return Id;
    }
    public void setId(Integer Id) {
        this.Id = Id;
    }
    // Additional properties go here.
}
```

DynamoDBIgnore

Indicates to the `DynamoDBMapper` instance that the associated property should be ignored. When saving data to the table, the `DynamoDBMapper` does not save this property to the table.

Applied to the getter method or the class field for a non-modeled property. If the annotation is applied directly to the class field, the corresponding getter and setter must be declared in the same class.

DynamoDBIndexHashKey

Maps a class property to the partition key of a global secondary index. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Use this annotation if you need to Query a global secondary index. You must specify the index name (`globalSecondaryIndexName`). If the name of the class property is different from the index partition key, you also must specify the name of that index attribute (`attributeName`).

DynamoDBIndexRangeKey

Maps a class property to the sort key of a global secondary index or a local secondary index. The property must be one of the scalar string, number, or binary types. The property can't be a collection type.

Use this annotation if you need to Query a local secondary index or a global secondary index and want to refine your results using the index sort key. You must specify the index name (either `globalSecondaryIndexName` or `localSecondaryIndexName`). If the name of the class property is different from the index sort key, you must also specify the name of that index attribute (`attributeName`).

DynamoDBRangeKey

Maps a class property to the sort key of the table. The property must be one of the scalar string, number, or binary types. It cannot be a collection type.

If the primary key is composite (partition key and sort key), you can use this tag to map your class field to the sort key. For example, assume that you have a `Reply` table that stores replies for forum threads. Each thread can have many replies. So the primary key of this table is both the `ThreadId` and `ReplyDateTime`. The `ThreadId` is the partition key, and `ReplyDateTime` is the sort key.

The following Java code defines a `Reply` class and maps it to the `Reply` table. It uses both the `@DynamoDBHashKey` and `@DynamoDBRangeKey` tags to identify class properties that map to the primary key.

```
@DynamoDBTable(tableName="Reply")
public class Reply {
    private Integer id;
    private String replyDateTime;

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer id) { this.id = id; }

    @DynamoDBRangeKey(attributeName="ReplyDateTime")
    public String getReplyDateTime() { return replyDateTime; }
    public void setReplyDateTime(String replyDateTime) { this.replyDateTime =
        replyDateTime; }

    // Additional properties go here.
}
```

DynamoDBTable

Identifies the target table in DynamoDB. For example, the following Java code defines a class `Developer` and maps it to the `People` table in DynamoDB.

```
@DynamoDBTable(tableName="People")
public class Developer { ... }
```

The `@DynamoDBTable` annotation can be inherited. Any new class that inherits from the `Developer` class also maps to the `People` table. For example, assume that you create a `Lead` class that inherits from the `Developer` class. Because you mapped the `Developer` class to the `People` table, the `Lead` class objects are also stored in the same table.

The `@DynamoDBTable` can also be overridden. Any new class that inherits from the `Developer` class by default maps to the same `People` table. However, you can override this default mapping. For example, if you create a class that inherits from the `Developer` class, you can explicitly map it to another table by adding the `@DynamoDBTable` annotation as shown in the following Java code example.

```
@DynamoDBTable(tableName="Managers")
```

```
public class Manager extends Developer { ...}
```

DynamoDBTypeConverted

An annotation to mark a property as using a custom type converter. Can be annotated on a user-defined annotation to pass additional properties to the `DynamoDBTypeConverter`.

The `DynamoDBTypeConverter` interface lets you map your own arbitrary data types to a data type that is natively supported by DynamoDB. For more information, see [Mapping arbitrary data](#).

DynamoDBTyped

An annotation to override the standard attribute type binding. Standard types do not require the annotation if applying the default attribute binding for that type.

DynamoDBVersionAttribute

Identifies a class property for storing an optimistic locking version number. `DynamoDBMapper` assigns a version number to this property when it saves a new item, and increments it each time you update the item. Only number scalar types are supported. For more information about data types, see [Data types](#). For more information about versioning, see [Optimistic locking with version number](#).

DynamoDBMapper Class

The `DynamoDBMapper` class is the entry point to Amazon DynamoDB. It provides access to a DynamoDB endpoint and enables you to access your data in various tables. It also enables you to perform various create, read, update, and delete (CRUD) operations on items, and run queries and scans against tables. This class provides the following methods for working with DynamoDB.

For the corresponding Javadoc documentation, see [DynamoDBMapper in the AWS SDK for Java API Reference](#).

Topics

- [save](#)
- [load](#)
- [delete](#)
- [query](#)
- [queryPage](#)

- [scan](#)
- [scanPage](#)
- [parallelScan](#)
- [batchSave](#)
- [batchLoad](#)
- [batchDelete](#)
- [batchWrite](#)
- [transactionWrite](#)
- [transactionLoad](#)
- [count](#)
- [generateCreateTableRequest](#)
- [createS3Link](#)
- [getS3ClientCache](#)

save

Saves the specified object to the table. The object that you want to save is the only required parameter for this method. You can provide optional configuration parameters using the `DynamoDBMapperConfig` object.

If an item that has the same primary key does not exist, this method creates a new item in the table. If an item that has the same primary key exists, it updates the existing item. If the partition key and sort key are of type `String` and are annotated with `@DynamoDBAutoGeneratedKey`, they are given a random universally unique identifier (UUID) if left uninitialized. Version fields that are annotated with `@DynamoDBVersionAttribute` are incremented by one. Additionally, if a version field is updated or a key generated, the object passed in is updated as a result of the operation.

By default, only attributes corresponding to mapped class properties are updated. Any additional existing attributes on an item are unaffected. However, if you specify `SaveBehavior.CLOBBER`, you can force the item to be completely overwritten.

```
DynamoDBMapperConfig config = DynamoDBMapperConfig.builder()
    .withSaveBehavior(DynamoDBMapperConfig.SaveBehavior.CLOBBER).build();

mapper.save(item, config);
```

If you have versioning enabled, the client-side and server-side item versions must match. However, the version does not need to match if the `SaveBehavior.CLOBBER` option is used. For more information about versioning, see [Optimistic locking with version number](#).

load

Retrieves an item from a table. You must provide the primary key of the item that you want to retrieve. You can provide optional configuration parameters using the `DynamoDBMapperConfig` object. For example, you can optionally request strongly consistent reads to ensure that this method retrieves only the latest item values as shown in the following Java statement.

```
DynamoDBMapperConfig config = DynamoDBMapperConfig.builder()
    .withConsistentReads(DynamoDBMapperConfig.ConsistentReads.CONSISTENT).build();

CatalogItem item = mapper.load(CatalogItem.class, item.getId(), config);
```

By default, DynamoDB returns the item that has values that are eventually consistent. For information about the eventual consistency model of DynamoDB, see [Read consistency](#).

delete

Deletes an item from the table. You must pass in an object instance of the mapped class.

If you have versioning enabled, the client-side and server-side item versions must match. However, the version does not need to match if the `SaveBehavior.CLOBBER` option is used. For more information about versioning, see [Optimistic locking with version number](#).

query

Queries a table or a secondary index. You can query a table or an index only if it has a composite primary key (partition key and sort key). This method requires you to provide a partition key value and a query filter that is applied on the sort key. A filter expression includes a condition and a value.

Assume that you have a table, `Reply`, that stores forum thread replies. Each thread subject can have zero or more replies. The primary key of the `Reply` table consists of the `Id` and `ReplyDateTime` fields, where `Id` is the partition key and `ReplyDateTime` is the sort key of the primary key.

```
Reply ( Id, ReplyDateTime, ... )
```

Assume that you created a mapping between a Reply class and the corresponding Reply table in DynamoDB. The following Java code uses DynamoDBMapper to find all replies in the past two weeks for a specific thread subject.

Example

```
String forumName = "&DDB;";
String forumSubject = "&DDB; Thread 1";
String partitionKey = forumName + "#" + forumSubject;

long twoWeeksAgoMilli = (new Date()).getTime() - (14L*24L*60L*60L*1000L);
Date twoWeeksAgo = new Date();
twoWeeksAgo.setTime(twoWeeksAgoMilli);
SimpleDateFormat df = new SimpleDateFormat("yyyy-MM-dd'T'HH:mm:ss.SSS'Z'");
String twoWeeksAgoStr = df.format(twoWeeksAgo);

Map<String,AttributeValue> eav = new HashMap<String,AttributeValue>();
eav.put(":v1", new AttributeValue().withS(partitionKey));
eav.put(":v2", new AttributeValue().withS(twoWeeksAgoStr.toString()));

DynamoDBQueryExpression<Reply> queryExpression = new DynamoDBQueryExpression<Reply>()
    .withKeyConditionExpression("Id = :v1 and ReplyDateTime > :v2")
    .withExpressionAttributeValues(eav);

List<Reply> latestReplies = mapper.query(Reply.class, queryExpression);
```

The query returns a collection of Reply objects.

By default, the query method returns a "lazy-loaded" collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, iterate over the latestReplies collection.

Note that calling the size() method on the collection will load every result in order to provide an accurate count. This can result in a lot of provisioned throughput being consumed, and on a very large table could even exhaust all the memory in your JVM.

To query an index, you must first model the index as a mapper class. Suppose that the Reply table has a global secondary index named *PostedBy-Message-Index*. The partition key for this index is PostedBy, and the sort key is Message. The class definition for an item in the index would look like the following.

```
@DynamoDBTable(tableName="Reply")
```

```
public class PostedByMessage {  
    private String postedBy;  
    private String message;  
  
    @DynamoDBIndexHashKey(globalSecondaryIndexName = "PostedBy-Message-Index",  
    attributeName = "PostedBy")  
    public String getPostedBy() { return postedBy; }  
    public void setPostedBy(String postedBy) { this.postedBy = postedBy; }  
  
    @DynamoDBIndexRangeKey(globalSecondaryIndexName = "PostedBy-Message-Index",  
    attributeName = "Message")  
    public String getMessage() { return message; }  
    public void setMessage(String message) { this.message = message; }  
  
    // Additional properties go here.  
}
```

The `@DynamoDBTable` annotation indicates that this index is associated with the `Reply` table. The `@DynamoDBIndexHashKey` annotation denotes the partition key (`PostedBy`) of the index, and `@DynamoDBIndexRangeKey` denotes the sort key (`Message`) of the index.

Now you can use `DynamoDBMapper` to query the index, retrieving a subset of messages that were posted by a particular user. You do not need to specify the index name if you do not have conflicting mappings across tables and indexes and the mappings are already made in the mapper. The mapper will infer based on the primary key and sort key. The following code queries a global secondary index. Because global secondary indexes support eventually consistent reads but not strongly consistent reads, you must specify `withConsistentRead(false)`.

```
HashMap<String,AttributeValue> eav = new HashMap<String,AttributeValue>();  
eav.put(":v1", new AttributeValue().withS("User A"));  
eav.put(":v2", new AttributeValue().withS("DynamoDB"));  
  
DynamoDBQueryExpression<PostedByMessage> queryExpression = new  
DynamoDBQueryExpression<PostedByMessage>()  
    .withIndexName("PostedBy-Message-Index")  
    .withConsistentRead(false)  
    .withKeyConditionExpression("PostedBy = :v1 and begins_with(Message, :v2)")  
    .withExpressionAttributeValues(eav);  
  
List<PostedByMessage> iList = mapper.query(PostedByMessage.class, queryExpression);
```

The query returns a collection of `PostedByMessage` objects.

queryPage

Queries a table or secondary index and returns a single page of matching results. As with the query method, you must specify a partition key value and a query filter that is applied on the sort key attribute. However, queryPage returns only the first "page" of data, that is, the amount of data that fits in 1 MB

scan

Scans an entire table or a secondary index. You can optionally specify a FilterExpression to filter the result set.

Assume that you have a table, Reply, that stores forum thread replies. Each thread subject can have zero or more replies. The primary key of the Reply table consists of the Id and ReplyDateTime fields, where Id is the partition key and ReplyDateTime is the sort key of the primary key.

```
Reply ( Id, ReplyDateTime, ... )
```

If you mapped a Java class to the Reply table, you can use the DynamoDBMapper to scan the table. For example, the following Java code scans the entire Reply table, returning only the replies for a particular year.

Example

```
HashMap<String,AttributeValue> eav = new HashMap<String,AttributeValue>();
eav.put(":v1", new AttributeValue().withS("2015"));

DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withFilterExpression("begins_with(ReplyDateTime,:v1)")
    .withExpressionAttributeValues(eav);

List<Reply> replies = mapper.scan(Reply.class, scanExpression);
```

By default, the scan method returns a "lazy-loaded" collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, iterate over the replies collection.

Note that calling the size() method on the collection will load every result in order to provide an accurate count. This can result in a lot of provisioned throughput being consumed, and on a very large table could even exhaust all the memory in your JVM.

To scan an index, you must first model the index as a mapper class. Suppose that the Reply table has a global secondary index named PostedBy-Message-Index. The partition key for this index is PostedBy, and the sort key is Message. A mapper class for this index is shown in the [query](#) section. It uses the `@DynamoDBIndexHashKey` and `@DynamoDBIndexRangeKey` annotations to specify the index partition key and sort key.

The following code example scans PostedBy-Message-Index. It does not use a scan filter, so all of the items in the index are returned to you.

```
DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withIndexName("PostedBy-Message-Index")
    .withConsistentRead(false);

List<PostedByMessage> iList = mapper.scan(PostedByMessage.class, scanExpression);
Iterator<PostedByMessage> indexItems = iList.iterator();
```

scanPage

Scans a table or secondary index and returns a single page of matching results. As with the `scan` method, you can optionally specify a `FilterExpression` to filter the result set. However, `scanPage` only returns the first "page" of data, that is, the amount of data that fits within 1 MB.

parallelScan

Performs a parallel scan of an entire table or secondary index. You specify a number of logical segments for the table, along with a scan expression to filter the results. The `parallelScan` divides the scan task among multiple workers, one for each logical segment; the workers process the data in parallel and return the results.

The following Java code example performs a parallel scan on the Product table.

```
int numberOfThreads = 4;

Map<String, AttributeValue> eav = new HashMap<String, AttributeValue>();
eav.put(":n", new AttributeValue().withN("100"));

DynamoDBScanExpression scanExpression = new DynamoDBScanExpression()
    .withFilterExpression("Price <= :n")
    .withExpressionAttributeValues(eav);
```

```
List<Product> scanResult = mapper.parallelScan(Product.class, scanExpression, numberofThreads);
```

For a Java code example illustrating the usage of `parallelScan`, see [DynamoDBMapper Query and scan operations](#).

batchSave

Saves objects to one or more tables using one or more calls to the `AmazonDynamoDB.batchWriteItem` method. This method does not provide transaction guarantees.

The following Java code saves two items (books) to the `ProductCatalog` table.

```
Book book1 = new Book();
book1.setId(901);
book1.setProductCategory("Book");
book1.setTitle("Book 901 Title");

Book book2 = new Book();
book2.setId(902);
book2.setProductCategory("Book");
book2.setTitle("Book 902 Title");

mapper.batchSave(Arrays.asList(book1, book2));
```

batchLoad

Retrieves multiple items from one or more tables using their primary keys.

The following Java code retrieves two items from two different tables.

```
ArrayList<Object> itemsToGet = new ArrayList<Object>();

ForumItem forumItem = new ForumItem();
forumItem.setForumName("Amazon DynamoDB");
itemsToGet.add(forumItem);

ThreadItem threadItem = new ThreadItem();
threadItem.setForumName("Amazon DynamoDB");
threadItem.setSubject("Amazon DynamoDB thread 1 message text");
```

```
itemsToGet.add(threadItem);

Map<String, List<Object>> items = mapper.batchLoad(itemsToGet);
```

batchDelete

Deletes objects from one or more tables using one or more calls to the `AmazonDynamoDB.batchWriteItem` method. This method does not provide transaction guarantees.

The following Java code deletes two items (books) from the `ProductCatalog` table.

```
Book book1 = mapper.load(Book.class, 901);
Book book2 = mapper.load(Book.class, 902);
mapper.batchDelete(Arrays.asList(book1, book2));
```

batchWrite

Saves objects to and deletes objects from one or more tables using one or more calls to the `AmazonDynamoDB.batchWriteItem` method. This method does not provide transaction guarantees or support versioning (conditional puts or deletes).

The following Java code writes a new item to the `Forum` table, writes a new item to the `Thread` table, and deletes an item from the `ProductCatalog` table.

```
// Create a Forum item to save
Forum forumItem = new Forum();
forumItem.setName("Test BatchWrite Forum");

// Create a Thread item to save
Thread threadItem = new Thread();
threadItem.setForumName("AmazonDynamoDB");
threadItem.setSubject("My sample question");

// Load a ProductCatalog item to delete
Book book3 = mapper.load(Book.class, 903);

List<Object> objectsToWrite = Arrays.asList(forumItem, threadItem);
List<Book> objectsToDelete = Arrays.asList(book3);

mapper.batchWrite(objectsToWrite, objectsToDelete);
```

transactionWrite

Saves objects to and deletes objects from one or more tables using one call to the `AmazonDynamoDB.transactWriteItems` method.

For a list of transaction-specific exceptions, see [TransactWriteItems errors](#).

For more information about DynamoDB transactions and the provided atomicity, consistency, isolation, and durability (ACID) guarantees see [Amazon DynamoDB Transactions](#).

 **Note**

This method does not support the following:

- [DynamoDBMapperConfig.SaveBehavior](#).

The following Java code writes a new item to each of the `Forum` and `Thread` tables, transactionally.

```
Thread s3ForumThread = new Thread();
s3ForumThread.setForumName("S3 Forum");
s3ForumThread.setSubject("Sample Subject 1");
s3ForumThread.setMessage("Sample Question 1");

Forum s3Forum = new Forum();
s3Forum.setName("S3 Forum");
s3Forum.setCategory("Amazon Web Services");
s3Forum.setThreads(1);

TransactionWriteRequest transactionWriteRequest = new TransactionWriteRequest();
transactionWriteRequest.addPut(s3Forum);
transactionWriteRequest.addPut(s3ForumThread);
mapper.transactionWrite(transactionWriteRequest);
```

transactionLoad

Loads objects from one or more tables using one call to the `AmazonDynamoDB.transactGetItems` method.

For a list of transaction-specific exceptions, see [TransactGetItems errors](#).

For more information about DynamoDB transactions and the provided atomicity, consistency, isolation, and durability (ACID) guarantees see [Amazon DynamoDB Transactions](#).

The following Java code loads one item from each of the Forum and Thread tables, transactionally.

```
Forum dynamodbForum = new Forum();
dynamodbForum.setName("DynamoDB Forum");
Thread dynamodbForumThread = new Thread();
dynamodbForumThread.setForumName("DynamoDB Forum");

TransactionLoadRequest transactionLoadRequest = new TransactionLoadRequest();
transactionLoadRequest.addLoad(dynamodbForum);
transactionLoadRequest.addLoad(dynamodbForumThread);
mapper.transactionLoad(transactionLoadRequest);
```

count

Evaluates the specified scan expression and returns the count of matching items. No item data is returned.

generateCreateTableRequest

Parses a POJO class that represents a DynamoDB table, and returns a CreateTableRequest for that table.

createS3Link

Creates a link to an object in Amazon S3. You must specify a bucket name and a key name, which uniquely identifies the object in the bucket.

To use `createS3Link`, your mapper class must define getter and setter methods. The following code example illustrates this by adding a new attribute and getter/setter methods to the `CatalogItem` class.

```
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {

    ...

    public S3Link productImage;

    ...
}
```

```
@DynamoDBAttribute(attributeName = "ProductImage")
public S3Link getProductImage() {
    return productImage;
}

public void setProductImage(S3Link productImage) {
    this.productImage = productImage;
}

...
}
```

The following Java code defines a new item to be written to the Product table. The item includes a link to a product image; the image data is uploaded to Amazon S3.

```
CatalogItem item = new CatalogItem();

item.setId(150);
item.setTitle("Book 150 Title");

String myS3Bucket = "myS3bucket";
String myS3Key = "productImages/book_150_cover.jpg";
item.setProductImage(mapper.createS3Link(myS3Bucket, myS3Key));

item.getProductImage().uploadFrom(new File("/file/path/book_150_cover.jpg"));

mapper.save(item);
```

The S3Link class provides many other methods for manipulating objects in Amazon S3. For more information, see the [Javadocs for S3Link](#).

getS3ClientCache

Returns the underlying S3ClientCache for accessing Amazon S3. An S3ClientCache is a smart Map for AmazonS3Client objects. If you have multiple clients, an S3ClientCache can help you keep the clients organized by AWS Region, and can create new Amazon S3 clients on demand.

Optional configuration settings for DynamoDBMapper

When you create an instance of DynamoDBMapper, it has certain default behaviors; you can override these defaults by using the DynamoDBMapperConfig class.

The following code snippet creates a `DynamoDBMapper` with custom settings:

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

DynamoDBMapperConfig mapperConfig = DynamoDBMapperConfig.builder()
    .withSaveBehavior(DynamoDBMapperConfig.SaveBehavior.CLOBBER)
    .withConsistentReads(DynamoDBMapperConfig.ConsistentReads.CONSTANT)
    .withTableNameOverride(null)

    .withPaginationLoadingStrategy(DynamoDBMapperConfig.PaginationLoadingStrategy.EAGER_LOADING)
    .build();

DynamoDBMapper mapper = new DynamoDBMapper(client, mapperConfig);
```

For more information, see [DynamoDBMapperConfig](#) in the [AWS SDK for Java API Reference](#).

You can use the following arguments for an instance of `DynamoDBMapperConfig`:

- A `DynamoDBMapperConfig.ConsistentReads` enumeration value:
 - `EVENTUAL`—the mapper instance uses an eventually consistent read request.
 - `CONSISTENT`—the mapper instance uses a strongly consistent read request. You can use this optional setting with load, query, or scan operations. Strongly consistent reads have implications for performance and billing; see the [DynamoDB product detail page](#) for more information.

If you do not specify a read consistency setting for your mapper instance, the default is `EVENTUAL`.

 **Note**

This value is applied in the `query`, `querypage`, `load`, and `batch load` operations of the `DynamoDBMapper`.

- A `DynamoDBMapperConfig.PaginationLoadingStrategy` enumeration value—Controls how the mapper instance processes a paginated list of data, such as the results from a `query` or `scan`:
 - `LAZY_LOADING`—the mapper instance loads data when possible, and keeps all loaded results in memory.
 - `EAGER_LOADING`—the mapper instance loads the data as soon as the list is initialized.

- **ITERATION_ONLY**—you can only use an Iterator to read from the list. During the iteration, the list will clear all the previous results before loading the next page, so that the list will keep at most one page of the loaded results in memory. This also means the list can only be iterated once. This strategy is recommended when handling large items, in order to reduce memory overhead.

If you do not specify a pagination loading strategy for your mapper instance, the default is **LAZY_LOADING**.

- A `DynamoDBMapperConfig.SaveBehavior` enumeration value - Specifies how the mapper instance should deal with attributes during save operations:
 - **UPDATE**—during a save operation, all modeled attributes are updated, and unmodeled attributes are unaffected. Primitive number types (byte, int, long) are set to 0. Object types are set to null.
 - **CL0BBER**—clears and replaces all attributes, included unmodeled ones, during a save operation. This is done by deleting the item and re-creating it. Versioned field constraints are also disregarded.

If you do not specify the save behavior for your mapper instance, the default is **UPDATE**.

 **Note**

DynamoDBMapper transactional operations do not support `DynamoDBMapperConfig.SaveBehavior` enumeration.

- A `DynamoDBMapperConfig.TableNameOverride` object—Instructs the mapper instance to ignore the table name specified by a class's `DynamoDBTable` annotation, and instead use a different table name that you supply. This is useful when partitioning your data into multiple tables at runtime.

You can override the default configuration object for `DynamoDBMapper` per operation, as needed.

Optimistic locking with version number

Optimistic locking is a strategy to ensure that the client-side item that you are updating (or deleting) is the same as the item in Amazon DynamoDB. If you use this strategy, your database writes are protected from being overwritten by the writes of others, and vice versa.

With optimistic locking, each item has an attribute that acts as a version number. If you retrieve an item from a table, the application records the version number of that item. You can update the item, but only if the version number on the server side has not changed. If there is a version mismatch, it means that someone else has modified the item before you did. The update attempt fails, because you have a stale version of the item. If this happens, try again by retrieving the item and then trying to update it. Optimistic locking prevents you from accidentally overwriting changes that were made by others. It also prevents others from accidentally overwriting your changes.

While you can implement your own optimistic locking strategy, the AWS SDK for Java provides the `@DynamoDBVersionAttribute` annotation. In the mapping class for your table, you designate one property to store the version number, and mark it using this annotation. When you save an object, the corresponding item in the DynamoDB table will have an attribute that stores the version number. The `DynamoDBMapper` assigns a version number when you first save the object, and it automatically increments the version number each time you update the item. Your update or delete requests succeed only if the client-side object version matches the corresponding version number of the item in the DynamoDB table.

`ConditionalCheckFailedException` is thrown if:

- You use optimistic locking with `@DynamoDBVersionAttribute` and the version value on the server is different from the value on the client side.
- You specify your own conditional constraints while saving data by using `DynamoDBMapper` with `DynamoDBSaveExpression` and these constraints failed.

 **Note**

- DynamoDB global tables use a “last writer wins” reconciliation between concurrent updates. If you use global tables, last writer policy wins. So in this case, the locking strategy does not work as expected.
- `DynamoDBMapper` transactional write operations do not support `@DynamoDBVersionAttribute` annotation and condition expressions on the same object. If an object within a transactional write is annotated with `@DynamoDBVersionAttribute` and also has a condition expression, then an `SdkClientException` will be thrown.

For example, the following Java code defines a `CatalogItem` class that has several properties. The `Version` property is tagged with the `@DynamoDBVersionAttribute` annotation.

Example

```
@DynamoDBTable(tableName="ProductCatalog")
public class CatalogItem {

    private Integer id;
    private String title;
    private String ISBN;
    private Set<String> bookAuthors;
    private String someProp;
    private Long version;

    @DynamoDBHashKey(attributeName="Id")
    public Integer getId() { return id; }
    public void setId(Integer Id) { this.id = Id; }

    @DynamoDBAttribute(attributeName="Title")
    public String getTitle() { return title; }
    public void setTitle(String title) { this.title = title; }

    @DynamoDBAttribute(attributeName="ISBN")
    public String getISBN() { return ISBN; }
    public void setISBN(String ISBN) { this.ISBN = ISBN; }

    @DynamoDBAttribute(attributeName = "Authors")
    public Set<String> getBookAuthors() { return bookAuthors; }
    public void setBookAuthors(Set<String> bookAuthors) { this.bookAuthors =
bookAuthors; }

    @DynamoDBIgnore
    public String getSomeProp() { return someProp; }
    public void setSomeProp(String someProp) {this.someProp = someProp; }

    @DynamoDBVersionAttribute
    public Long getVersion() { return version; }
    public void setVersion(Long version) { this.version = version; }
}
```

You can apply the `@DynamoDBVersionAttribute` annotation to nullable types provided by the primitive wrappers classes that provide a nullable type, such as `Long` and `Integer`.

Optimistic locking has the following impact on these `DynamoDBMapper` methods:

- `save` — For a new item, the `DynamoDBMapper` assigns an initial version number of 1. If you retrieve an item, update one or more of its properties, and attempt to save the changes, the `save` operation succeeds only if the version number on the client side and the server side match. The `DynamoDBMapper` increments the version number automatically.
- `delete` — The `delete` method takes an object as a parameter, and the `DynamoDBMapper` performs a version check before deleting the item. The version check can be disabled if `DynamoDBMapperConfig.SaveBehavior.CLOBBER` is specified in the request.

The internal implementation of optimistic locking within `DynamoDBMapper` uses conditional update and conditional delete support provided by DynamoDB.

- `transactionWrite` —

- `Put` — For a new item, the `DynamoDBMapper` assigns an initial version number of 1. If you retrieve an item, update one or more of its properties, and attempt to save the changes, the `put` operation succeeds only if the version number on the client side and the server side match. The `DynamoDBMapper` increments the version number automatically.
- `Update` — For a new item, the `DynamoDBMapper` assigns an initial version number of 1. If you retrieve an item, update one or more of its properties, and attempt to save the changes, the `update` operation succeeds only if the version number on the client side and the server side match. The `DynamoDBMapper` increments the version number automatically.
- `Delete` — The `DynamoDBMapper` performs a version check before deleting the item. The `delete` operation succeeds only if the version number on the client side and the server side match.
- `ConditionCheck` — The `@DynamoDBVersionAttribute` annotation is not supported for `ConditionCheck` operations. An `SdkClientException` will be thrown when a `ConditionCheck` item is annotated with `@DynamoDBVersionAttribute`.

Disabling optimistic locking

To disable optimistic locking, you can change the `DynamoDBMapperConfig.SaveBehavior` enumeration value from `UPDATE` to `CLOBBER`. You can do this by creating a `DynamoDBMapperConfig` instance that skips version checking and use this instance for all your requests. For information about `DynamoDBMapperConfig.SaveBehavior` and other optional `DynamoDBMapper` parameters, see [Optional configuration settings for `DynamoDBMapper`](#).

You can also set locking behavior for a specific operation only. For example, the following Java snippet uses the `DynamoDBMapper` to save a catalog item. It specifies `DynamoDBMapperConfig.SaveBehavior` by adding the optional `DynamoDBMapperConfig` parameter to the `save` method.

 **Note**

The `transactionWrite` method does not support `DynamoDBMapperConfig.SaveBehavior` configuration. Disabling optimistic locking for `transactionWrite` is not supported.

Example

```
DynamoDBMapper mapper = new DynamoDBMapper(client);

// Load a catalog item.
CatalogItem item = mapper.load(CatalogItem.class, 101);
item.setTitle("This is a new title for the item");
...
// Save the item.
mapper.save(item,
    new DynamoDBMapperConfig(
        DynamoDBMapperConfig.SaveBehavior.CLOBBER));
```

Mapping arbitrary data

In addition to the supported Java types (see [Supported data types for DynamoDB Mapper for Java](#)), you can use types in your application for which there is no direct mapping to the Amazon DynamoDB types. To map these types, you must provide an implementation that converts your complex type to a DynamoDB supported type and vice versa, and annotate the complex type accessor method using the `@DynamoDBTypeConverted` annotation. The converter code transforms data when objects are saved or loaded. It is also used for all operations that consume complex types. Note that when comparing data during query and scan operations, the comparisons are made against the data stored in DynamoDB.

For example, consider the following `CatalogItem` class that defines a property, `Dimension`, that is of `DimensionType`. This property stores the item dimensions as height, width, and thickness. Assume that you decide to store these item dimensions as a string (such as `8.5x11x.05`) in DynamoDB. The following example provides converter code that converts the `DimensionType` object to a string and a string to the `DimensionType`.

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

Example

```
public class DynamoDBMapperExample {  
  
    static AmazonDynamoDB client;  
  
    public static void main(String[] args) throws IOException {  
  
        // Set the AWS region you want to access.  
        Regions usWest2 = Regions.US_WEST_2;  
        client = AmazonDynamoDBClientBuilder.standard().withRegion(usWest2).build();  
  
        DimensionType dimType = new DimensionType();  
        dimType.setHeight("8.00");  
        dimType.setLength("11.0");  
        dimType.setThickness("1.0");  
  
        Book book = new Book();  
        book.setId(502);  
        book.setTitle("Book 502");  
        book.setISBN("555-5555555555");  
        book.setBookAuthors(new HashSet<String>(Arrays.asList("Author1", "Author2")));  
        book.setDimensions(dimType);  
  
        DynamoDBMapper mapper = new DynamoDBMapper(client);  
        mapper.save(book);  
  
        Book bookRetrieved = mapper.load(Book.class, 502);  
        System.out.println("Book info: " + "\n" + bookRetrieved);  
  
        bookRetrieved.getDimensions().setHeight("9.0");  
        bookRetrieved.getDimensions().setLength("12.0");  
        bookRetrieved.getDimensions().setThickness("2.0");
```

```
    mapper.save(bookRetrieved);

    bookRetrieved = mapper.load(Book.class, 502);
    System.out.println("Updated book info: " + "\n" + bookRetrieved);
}

@DynamoDBTable(tableName = "ProductCatalog")
public static class Book {
    private int id;
    private String title;
    private String ISBN;
    private Set<String> bookAuthors;
    private DimensionType dimensionType;

    // Partition key
    @DynamoDBHashKey(attributeName = "Id")
    public int getId() {
        return id;
    }

    public void setId(int id) {
        this.id = id;
    }

    @DynamoDBAttribute(attributeName = "Title")
    public String getTitle() {
        return title;
    }

    public void setTitle(String title) {
        this.title = title;
    }

    @DynamoDBAttribute(attributeName = "ISBN")
    public String getISBN() {
        return ISBN;
    }

    public void setISBN(String ISBN) {
        this.ISBN = ISBN;
    }

    @DynamoDBAttribute(attributeName = "Authors")
```

```
public Set<String> getBookAuthors() {
    return bookAuthors;
}

public void setBookAuthors(Set<String> bookAuthors) {
    this.bookAuthors = bookAuthors;
}

@DynamoDBTypeConverted(converter = DimensionTypeConverter.class)
@DynamoDBAttribute(attributeName = "Dimensions")
public DimensionType getDimensions() {
    return dimensionType;
}

@DynamoDBAttribute(attributeName = "Dimensions")
public void setDimensions(DimensionType dimensionType) {
    this.dimensionType = dimensionType;
}

@Override
public String toString() {
    return "Book [ISBN=" + ISBN + ", bookAuthors=" + bookAuthors + ",
dimensionType= "
        + dimensionType.getHeight() + " X " + dimensionType.getLength() + "
X "
        + dimensionType.getThickness()
        + ", Id=" + id + ", Title=" + title + "]";
}
}

static public class DimensionType {

    private String length;
    private String height;
    private String thickness;

    public String getLength() {
        return length;
    }

    public void setLength(String length) {
        this.length = length;
    }
}
```

```
public String getHeight() {
    return height;
}

public void setHeight(String height) {
    this.height = height;
}

public String getThickness() {
    return thickness;
}

public void setThickness(String thickness) {
    this.thickness = thickness;
}

// Converts the complex type DimensionType to a string and vice-versa.
static public class DimensionTypeConverter implements DynamoDBTypeConverter<String,
DimensionType> {

    @Override
    public String convert(DimensionType object) {
        DimensionType itemDimensions = (DimensionType) object;
        String dimension = null;
        try {

DynamoDBMapper Examples

The following Java code examples demonstrate how to perform a variety of operations with the DynamoDBMapper class. You can use these examples to perform CRUD, query, scan, batch, and transaction operations.

Topics

- [DynamoDBMapper CRUD operations](#)
- [DynamoDBMapper Query and scan operations](#)
- [DynamoDBMapper batch operations](#)
- [DynamoDBMapper Transaction operations](#)

DynamoDBMapper CRUD operations

The following Java code example declares a CatalogItem class that has Id, Title, ISBN, and Authors properties. It uses the annotations to map these properties to the ProductCatalog table in DynamoDB. The example then uses the DynamoDBMapper to save a book object, retrieve it, update it, and then delete the book item.

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

Imports

```
import java.io.IOException;
import java.util.Arrays;
import java.util.HashSet;
import java.util.Set;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBAttribute;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBHashKey;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapper;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBMapperConfig;
import com.amazonaws.services.dynamodbv2.datamodeling.DynamoDBTable;
```

Code

```
public class DynamoDBMapperCRUDExample {

    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

    public static void main(String[] args) throws IOException {
        testCRUDOperations();
        System.out.println("Example complete!");
    }

    @DynamoDBTable(tableName = "ProductCatalog")
    public static class CatalogItem {
        private Integer id;
        private String title;
        private String ISBN;
        private Set<String> bookAuthors;

        // Partition key
        @DynamoDBHashKey(attributeName = "Id")
        public Integer getId() {
            return id;
        }

        public void setId(Integer id) {
            this.id = id;
        }
    }
}
```

```
@DynamoDBAttribute(attributeName = "Title")
public String getTitle() {
    return title;
}

public void setTitle(String title) {
    this.title = title;
}

@dynamoDBAttribute(attributeName = "ISBN")
public String getISBN() {
    return ISBN;
}

public void setISBN(String ISBN) {
    this.ISBN = ISBN;
}

@dynamoDBAttribute(attributeName = "Authors")
public Set<String> getBookAuthors() {
    return bookAuthors;
}

public void setBookAuthors(Set<String> bookAuthors) {
    this.bookAuthors = bookAuthors;
}

@Override
public String toString() {
    return "Book [ISBN=" + ISBN + ", bookAuthors=" + bookAuthors + ", id=" + id
+ ", title=" + title + "]";
}

private static void testCRUDOperations() {

    CatalogItem item = new CatalogItem();
    item.setId(601);
    item.setTitle("Book 601");
    item.setISBN("611-1111111111");
    item.setBookAuthors(new HashSet<String>(Arrays.asList("Author1", "Author2")));

    // Save the item (book).
    DynamoDBMapper mapper = new DynamoDBMapper(client);
```

```
mapper.save(item);

// Retrieve the item.
CatalogItem itemRetrieved = mapper.load(CatalogItem.class, 601);
System.out.println("Item retrieved:");
System.out.println(itemRetrieved);

// Update the item.
itemRetrieved.setISBN("622-222222222");
itemRetrieved.setBookAuthors(new HashSet<String>(Arrays.asList("Author1",
"Author3")));
mapper.save(itemRetrieved);
System.out.println("Item updated:");
System.out.println(itemRetrieved);

// Retrieve the updated item.
DynamoDBMapperConfig config = DynamoDBMapperConfig.builder()
    .withConsistentReads(DynamoDBMapperConfig.ConsistentReads.CONSISTENT)
    .build();
CatalogItem updatedItem = mapper.load(CatalogItem.class, 601, config);
System.out.println("Retrieved the previously updated item:");
System.out.println(updatedItem);

// Delete the item.
mapper.delete(updatedItem);

// Try to retrieve deleted item.
CatalogItem deletedItem = mapper.load(CatalogItem.class, updatedItem.getId(),
config);
if (deletedItem == null) {
    System.out.println("Done - Sample item is deleted.");
}
}
```

DynamoDBMapper Query and scan operations

The Java example in this section defines the following classes and maps them to the tables in Amazon DynamoDB. For more information about creating sample tables, see [Creating tables and loading data for code examples in DynamoDB](#).

- The Book class maps to ProductCatalog table

- The Forum, Thread, and Reply classes map to tables of the same name.

The example then runs the following query and scan operations using a DynamoDBMapper instance.

- Get a book by Id.

The ProductCatalog table has Id as its primary key. It does not have a sort key as part of its primary key. Therefore, you cannot query the table. You can get an item using its Id value.

- Run the following queries against the Reply table.

The Reply table's primary key is composed of Id and ReplyDateTime attributes.

ReplyDateTime is a sort key. Therefore, you can query this table.

- Find replies to a forum thread posted in the last 15 days.
- Find replies to a forum thread posted in a specific date range.
- Scan the ProductCatalog table to find books whose price is less than a specified value.

For performance reasons, you should use the query operation instead of the scan operation. However, there are times you might need to scan a table. Suppose that there was a data entry error and one of the book prices was set to less than 0. This example scans the ProductCategory table to find book items (ProductCategory is book) whose price is less than 0.

- Perform a parallel scan of the ProductCatalog table to find bicycles of a specific type.

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

DynamoDBMapper batch operations

The following Java code example declares Book, Forum, Thread, and Reply classes and maps them to the Amazon DynamoDB tables using the DynamoDBMapper class.

The code illustrates the following batch write operations:

- `batchSave` to put book items in the `ProductCatalog` table.
- `batchDelete` to delete items from the `ProductCatalog` table.
- `batchWrite` to put and delete items from the `Forum` and the `Thread` tables.

For more information about the tables used in this example, see [Creating tables and loading data for code examples in DynamoDB](#). For step-by-step instructions for testing the following example, see [Java code examples](#).

DynamoDBMapper Transaction operations

The following Java code example declares a `Forum` and a `Thread` class and maps them to the DynamoDB tables using the `DynamoDBMapper` class.

The code illustrates the following transactional operations:

- `transactionWrite` to add, update, and delete multiple items from one or more tables in one transaction.
- `transactionLoad` to retrieve multiple items from one or more tables in one transaction.

    private String category;
    private int threads;

    // Partition key
    @DynamoDBHashKey(attributeName = "Name")
    public String getName() {
        return name;
    }

    public void setName(String name) {
        this.name = name;
    }

    @DynamoDBAttribute(attributeName = "Category")
    public String getCategory() {
        return category;
    }

    public void setCategory(String category) {
        this.category = category;
    }

    @DynamoDBAttribute(attributeName = "Threads")
    public int getThreads() {
        return threads;
    }

    public void setThreads(int threads) {
        this.threads = threads;
    }
}
```

Java 2.x: DynamoDB Enhanced Client

The DynamoDB enhanced client is a high-level library that is part of the AWS SDK for Java version 2 (v2). It offers a straightforward way to map client-side classes to DynamoDB tables. You define the relationships between tables and their corresponding model classes in your code. After you define those relationships, you can intuitively perform various create, read, update, or delete (CRUD) operations on tables or items in DynamoDB.

For more information on how you can use the enhanced client with DynamoDB, see [Using the DynamoDB Enhanced Client in the AWS SDK for Java 2.x](#).

.NET: Document model

The AWS SDK for .NET provides document model classes that wrap some of the low-level Amazon DynamoDB operations, further simplifying your coding. In the document model, the primary classes are `Table` and `Document`. The `Table` class provides data operation methods such as `PutItem`, `GetItem`, and `DeleteItem`. It also provides the `Query` and the `Scan` methods. The `Document` class represents a single item in a table.

The preceding document model classes are available in the `Amazon.DynamoDBv2.DocumentModel` namespace.

 **Note**

You can't use the document model classes to create, update, and delete tables. However, the document model does support most common data operations.

Topics

- [Supported data types](#)
- [Working with items in DynamoDB using the AWS SDK for .NET document model](#)
- [Example: CRUD operations using the AWS SDK for .NET document model](#)
- [Example: Batch operations using the AWS SDK for .NET document model API](#)
- [Working with tables in DynamoDB using the AWS SDK for .NET document model](#)

Supported data types

The document model supports a set of primitive .NET data types and collections data types. The model supports the following primitive data types.

- bool
- byte
- char
- DateTime
- decimal
- double
- float
- Guid
- Int16
- Int32
- Int64
- SByte
- string
- UInt16
- UInt32
- UInt64

The following table summarizes the mapping of the preceding .NET types to the DynamoDB types.

.NET primitive type	DynamoDB type
All number types	N (number type)
All string types	S (string type)
MemoryStream, byte[]	B (binary type)
bool	N (number type). 0 represents false and 1 represents true.

.NET primitive type	DynamoDB type
DateTime	S (string type). The DateTime values are stored as ISO-8601 formatted strings.
Guid	S (string type).
Collection types (List, HashSet, and array)	BS (binary set) type, SS (string set) type, and NS (number set) type

AWS SDK for .NET defines types for mapping DynamoDB's Boolean, null, list and map types to .NET document model API:

- Use `DynamoDBBool` for Boolean type.
- Use `DynamoDBNull` for null type.
- Use `DynamoDBList` for list type.
- Use `Document` for map type.

 **Note**

- Empty binary values are supported.
- Reading of empty string values is supported. Empty string attribute values are supported within attribute values of string Set type while writing to DynamoDB. Empty string attribute values of string type and empty string values contained within List or Map type are dropped from write requests

Working with items in DynamoDB using the AWS SDK for .NET document model

The following code examples demonstrate how to perform a variety of operations with the AWS SDK for .NET document model. You can use these examples to perform CRUD, batch, and transaction operations.

Topics

- [Putting an item - Table.PutItem method](#)

- [Specifying optional parameters](#)
- [Getting an item - Table.GetItem](#)
- [Deleting an item - Table.DeleteItem](#)
- [Updating an item - Table.UpdateItem](#)
- [Batch write - putting and deleting multiple items](#)

To perform data operations using the document model, you must first call the `Table.LoadTable` method, which creates an instance of the `Table` class that represents a specific table. The following C# example creates a `Table` object that represents the `ProductCatalog` table in Amazon DynamoDB.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");
```

Note

In general, you use the `LoadTable` method once at the beginning of your application because it makes a `DescribeTable` call that adds to the round trip to DynamoDB.

You can then use the `Table` object to perform various data operations. Each data operation has two types of overloads: One takes the minimum required parameters and the other takes optional, operation-specific configuration information. For example, to retrieve an item, you must provide the table's primary key value, in which case you can use the following `GetItem` overload.

Example

```
// Get the item from a table that has a primary key that is composed of only a
// partition key.
Table.GetItem(Primitive partitionKey);
// Get the item from a table whose primary key is composed of both a partition key and
// sort key.
Table.GetItem(Primitive partitionKey, Primitive sortKey);
```

You also can pass optional parameters to these methods. For example, the preceding `GetItem` returns the entire item including all its attributes. You can optionally specify a list of attributes to

retrieve. In this case, you use the following `GetItem` overload that takes in the operation-specific configuration object parameter.

Example

```
// Configuration object that specifies optional parameters.  
GetItemOperationConfig config = new GetItemOperationConfig()  
{  
    AttributesToGet = new List<string>() { "Id", "Title" },  
};  
// Pass in the configuration to the GetItem method.  
// 1. Table that has only a partition key as primary key.  
Table.GetItem(Primitive partitionKey, GetItemOperationConfig config);  
// 2. Table that has both a partition key and a sort key.  
Table.GetItem(Primitive partitionKey, Primitive sortKey, GetItemOperationConfig  
config);
```

You can use the configuration object to specify several optional parameters such as request a specific list of attributes or specify the page size (number of items per page). Each data operation method has its own configuration class. For example, you can use the `GetItemOperationConfig` class to provide options for the `GetItem` operation. You can use the `PutItemOperationConfig` class to provide optional parameters for the `PutItem` operation.

The following sections discuss each of the data operations that are supported by the `Table` class.

Putting an item - `Table.PutItem` method

The `PutItem` method uploads the input `Document` instance to the table. If an item that has a primary key that is specified in the input `Document` exists in the table, the `PutItem` operation replaces the entire existing item. The new item is identical to the `Document` object that you provided to the `PutItem` method. If your original item had any extra attributes, they are no longer present in the new item.

The following are the steps to put a new item into a table using the AWS SDK for .NET document model.

1. Run the `Table.LoadTable` method that provides the table name in which you want to put an item.
2. Create a `Document` object that has a list of attribute names and their values.
3. Run `Table.PutItem` by providing the `Document` instance as a parameter.

The following C# code example demonstrates the preceding tasks. The example uploads an item to the ProductCatalog table.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;
book["Title"] = "Book 101 Title";
book["ISBN"] = "11-11-11-11";
book["Authors"] = new List<string> { "Author 1", "Author 2" };
book["InStock"] = new DynamoDBBool(true);
book["QuantityOnHand"] = new DynamoDBNull();

table.PutItem(book);
```

In the preceding example, the Document instance creates an item that has Number, String, String Set, Boolean, and Null attributes. (Null is used to indicate that the *QuantityOnHand* for this product is unknown.) For Boolean and Null, use the constructor methods DynamoDBBool and DynamoDBNull.

In DynamoDB, the List and Map data types can contain elements composed of other data types. Here is how to map these data types to the document model API:

- List — use the DynamoDBList constructor.
- Map — use the Document constructor.

You can modify the preceding example to add a List attribute to the item. To do this, use a DynamoDBList constructor, as shown in the following code example.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;

/*other attributes omitted for brevity...*/

var relatedItems = new DynamoDBList();
```

```
relatedItems.Add(341);
relatedItems.Add(472);
relatedItems.Add(649);
book.Add("RelatedItems", relatedItems);

table.PutItem(book);
```

To add a Map attribute to the book, you define another Document. The following code example illustrates how to do this.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 101;

/*other attributes omitted for brevity...*/

var pictures = new Document();
pictures.Add("FrontView", "http://example.com/products/101_front.jpg" );
pictures.Add("RearView", "http://example.com/products/101_rear.jpg" );

book.Add("Pictures", pictures);

table.PutItem(book);
```

These examples are based on the item shown in [Specifying item attributes when using expressions](#). The document model lets you create complex nested attributes, such as the ProductReviews attribute shown in the case study.

Specifying optional parameters

You can configure optional parameters for the PutItem operation by adding the PutItemOperationConfig parameter. For a complete list of optional parameters, see [PutItem](#). The following C# code example puts an item in the ProductCatalog table. It specifies the following optional parameter:

- The ConditionalExpression parameter to make this a conditional put request. The example creates an expression that specifies the ISBN attribute must have a specific value that has to be present in the item that you are replacing.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");

var book = new Document();
book["Id"] = 555;
book["Title"] = "Book 555 Title";
book["Price"] = "25.00";
book["ISBN"] = "55-55-55-55";
book["Name"] = "Item 1 updated";
book["Authors"] = new List<string> { "Author x", "Author y" };
book["InStock"] = new DynamoDBBool(true);
book["QuantityOnHand"] = new DynamoDBNull();

// Create a condition expression for the optional conditional put operation.
Expression expr = new Expression();
expr.ExpressionStatement = "ISBN = :val";
expr.ExpressionAttributeValues[":val"] = "55-55-55-55";

PutItemOperationConfig config = new PutItemOperationConfig()
{
    // Optional parameter.
    ConditionalExpression = expr
};

table.PutItem(book, config);
```

Getting an item - Table.GetItem

The GetItem operation retrieves an item as a Document instance. You must provide the primary key of the item that you want to retrieve as shown in the following C# code example.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");
Document document = table.GetItem(101); // Primary key 101.
```

The GetItem operation returns all the attributes of the item and performs an eventually consistent read (see [Read consistency](#)) by default.

Specifying optional parameters

You can configure additional options for the `GetItem` operation by adding the `GetItemOperationConfig` parameter. For a complete list of optional parameters, see [GetItem](#). The following C# code example retrieves an item from the `ProductCatalog` table. It specifies the `GetItemOperationConfig` to provide the following optional parameters:

- The `AttributesToGet` parameter to retrieve only the specified attributes.
- The `ConsistentRead` parameter to request the latest values for all the specified attributes. To learn more about data consistency, see [Read consistency](#).

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");

GetItemOperationConfig config = new GetItemOperationConfig()
{
    AttributesToGet = new List<string>() { "Id", "Title", "Authors", "InStock",
    "QuantityOnHand" },
    ConsistentRead = true
};
Document doc = table.GetItem(101, config);
```

When you retrieve an item using the document model API, you can access individual elements within the `Document` object is returned, as shown in the following example.

Example

```
int id = doc["Id"].AsInt();
string title = doc["Title"].AsString();
List<string> authors = doc["Authors"].AsListOfString();
bool inStock = doc["InStock"].AsBoolean();
DynamoDBNull quantityOnHand = doc["QuantityOnHand"].AsDynamoDBNull();
```

For attributes that are of type `List` or `Map`, here is how to map these attributes to the document model API:

- `List` — Use the `AsDynamoDBList` method.
- `Map` — Use the `AsDocument` method.

The following code example shows how to retrieve a List (RelatedItems) and a Map (Pictures) from the Document object:

Example

```
DynamoDBList relatedItems = doc["RelatedItems"].AsDynamoDBList();  
  
Document pictures = doc["Pictures"].AsDocument();
```

Deleting an item - Table.DeleteItem

The DeleteItem operation deletes an item from a table. You can pass the item's primary key as a parameter. Or, if you've already read an item and have the corresponding Document object, you can pass it as a parameter to the DeleteItem method, as shown in the following C# code example.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");  
  
// Retrieve a book (a Document instance)  
Document document = table.GetItem(111);  
  
// 1) Delete using the Document instance.  
table.DeleteItem(document);  
  
// 2) Delete using the primary key.  
int partitionKey = 222;  
table.DeleteItem(partitionKey)
```

Specifying optional parameters

You can configure additional options for the Delete operation by adding the DeleteItemOperationConfig parameter. For a complete list of optional parameters, see [DeleteTable](#). The following C# code example specifies the two following optional parameters:

- The ConditionalExpression parameter to ensure that the book item being deleted has a specific value for the ISBN attribute.
- The ReturnValue parameter to request that the Delete method return the item that it deleted.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");
int partitionKey = 111;

Expression expr = new Expression();
expr.ExpressionStatement = "ISBN = :val";
expr.ExpressionAttributeValues[":val"] = "11-11-11-11";

// Specify optional parameters for Delete operation.
DeleteItemOperationConfig config = new DeleteItemOperationConfig
{
    ConditionalExpression = expr,
    ReturnValues = ReturnValues.AllOldAttributes // This is the only supported value
    when using the document model.
};

// Delete the book.
Document d = table.DeleteItem(partitionKey, config);
```

Updating an item - Table.UpdateItem

The `UpdateItem` operation updates an existing item if it is present. If the item that has the specified primary key is not found, the `UpdateItem` operation adds a new item.

You can use the `UpdateItem` operation to update existing attribute values, add new attributes to the existing collection, or delete attributes from the existing collection. You provide these updates by creating a `Document` instance that describes the updates that you want to perform.

The `UpdateItem` action uses the following guidelines:

- If the item does not exist, `UpdateItem` adds a new item using the primary key that is specified in the input.
- If the item exists, `UpdateItem` applies the updates as follows:
 - Replaces the existing attribute values with the values in the update.
 - If an attribute that you provide in the input does not exist, it adds a new attribute to the item.
 - If the input attribute value is null, it deletes the attributes, if it is present.

Note

This midlevel `UpdateItem` operation does not support the Add action (see [UpdateItem](#)) that is supported by the underlying DynamoDB operation.

Note

The `PutItem` operation ([Putting an item - Table.PutItem method](#)) can also perform an update. If you call `PutItem` to upload an item and the primary key exists, the `PutItem` operation replaces the entire item. If there are attributes in the existing item and those attributes are not specified on the Document that is being put, the `PutItem` operation deletes those attributes. However, `UpdateItem` only updates the specified input attributes. Any other existing attributes of that item remain unchanged.

The following are the steps to update an item using the AWS SDK for .NET document model:

1. Run the `Table.LoadTable` method by providing the name of the table in which you want to perform the update operation.
2. Create a `Document` instance by providing all the updates that you want to perform.

To delete an existing attribute, specify the attribute value as null.

3. Call the `Table.UpdateItem` method and provide the `Document` instance as an input parameter.

You must provide the primary key either in the `Document` instance or explicitly as a parameter.

The following C# code example demonstrates the preceding tasks. The code example updates an item in the Book table. The `UpdateItem` operation updates the existing `Authors` attribute, deletes the `PageCount` attribute, and adds a new `XYZ` attribute. The `Document` instance includes the primary key of the book to update.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");
```

```
var book = new Document();

// Set the attributes that you wish to update.
book["Id"] = 111; // Primary key.
// Replace the authors attribute.
book["Authors"] = new List<string> { "Author x", "Author y" };
// Add a new attribute.
book["XYZ"] = 12345;
// Delete the existing PageCount attribute.
book["PageCount"] = null;

table.Update(book);
```

Specifying optional parameters

You can configure additional options for the `UpdateItem` operation by adding the `UpdateItemOperationConfig` parameter. For a complete list of optional parameters, see [UpdateItem](#).

The following C# code example updates a book item price to 25. It specifies the two following optional parameters:

- The `ConditionalExpression` parameter that identifies the `Price` attribute with value 20 that you expect to be present.
- The `ReturnValues` parameter to request the `UpdateItem` operation to return the item that is updated.

Example

```
Table table = Table.LoadTable(client, "ProductCatalog");
string partitionKey = "111";

var book = new Document();
book["Id"] = partitionKey;
book["Price"] = 25;

Expression expr = new Expression();
expr.ExpressionStatement = "Price = :val";
expr.ExpressionAttributeValues[":val"] = "20";

UpdateItemOperationConfig config = new UpdateItemOperationConfig()
```

```
{  
    ConditionalExpression = expr,  
    ReturnValues = ReturnValues.AllOldAttributes  
};  
  
Document d1 = table.Update(book, config);
```

Batch write - putting and deleting multiple items

Batch write refers to putting and deleting multiple items in a batch. The operation enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to put or delete multiple items from a table using the AWS SDK for .NET document model API.

1. Create a `Table` object by executing the `Table.LoadTable` method by providing the name of the table in which you want to perform the batch operation.
2. Run the `createBatchWrite` method on the table instance you created in the preceding step and create a `DocumentBatchWrite` object.
3. Use the `DocumentBatchWrite` object methods to specify the documents that you want to upload or delete.
4. Call the `DocumentBatchWrite.Execute` method to run the batch operation.

When using the document model API, you can specify any number of operations in a batch. However, DynamoDB limits the number of operations in a batch and the total size of the batch in a batch operation. For more information about the specific limits, see [BatchWriteItem](#). If the document model API detects that your batch write request exceeded the number of allowed write requests, or the HTTP payload size of a batch exceeded the limit allowed by `BatchWriteItem`, it breaks the batch into several smaller batches. Additionally, if a response to a batch write returns unprocessed items, the document model API automatically sends another batch request with those unprocessed items.

The following C# code example demonstrates the preceding steps. The example uses batch write operation to perform two writes; upload a book item and delete another book item.

```
Table productCatalog = Table.LoadTable(client, "ProductCatalog");  
var batchWrite = productCatalog.CreateBatchWrite();  
  
var book1 = new Document();  
book1["Id"] = 902;
```

```
book1["Title"] = "My book1 in batch write using .NET document model";
book1["Price"] = 10;
book1["Authors"] = new List<string> { "Author 1", "Author 2", "Author 3" };
book1["InStock"] = new DynamoDBBool(true);
book1["QuantityOnHand"] = 5;

batchWrite.AddDocumentToPut(book1);
// specify delete item using overload that takes PK.
batchWrite.AddKeyToDelete(12345);

batchWrite.Execute();
```

For a working example, see [Example: Batch operations using the AWS SDK for .NET document model API](#).

You can use the `batchWrite` operation to perform put and delete operations on multiple tables. The following are the steps to put or delete multiple items from multiple tables using the AWS SDK for .NET document model.

1. You create a `DocumentBatchWrite` instance for each table in which you want to put or delete multiple items, as described in the preceding procedure.
2. Create an instance of the `MultiTableDocumentBatchWrite` and add the individual `DocumentBatchWrite` objects to it.
3. Run the `MultiTableDocumentBatchWrite.Execute` method.

The following C# code example demonstrates the preceding steps. The example uses the batch write operation to perform the following write operations:

- Put a new item in the `Forum` table item.
- Put an item in the `Thread` table and delete an item from the same table.

```
// 1. Specify item to add in the Forum table.
Table forum = Table.LoadTable(client, "Forum");
var forumBatchWrite = forum.CreateBatchWrite();

var forum1 = new Document();
forum1["Name"] = "Test BatchWrite Forum";
forum1["Threads"] = 0;
```

```
forumBatchWrite.AddDocumentToPut(forum1);

// 2a. Specify item to add in the Thread table.
Table thread = Table.LoadTable(client, "Thread");
var threadBatchWrite = thread.CreateBatchWrite();

var thread1 = new Document();
thread1["ForumName"] = "Amazon S3 forum";
thread1["Subject"] = "My sample question";
thread1["Message"] = "Message text";
thread1["KeywordTags"] = new List<string>{ "Amazon S3", "Bucket" };
threadBatchWrite.AddDocumentToPut(thread1);

// 2b. Specify item to delete from the Thread table.
threadBatchWrite.AddKeyToDelete("someForumName", "someSubject");

// 3. Create multi-table batch.
var superBatch = new MultiTableDocumentBatchWrite();
superBatch.AddBatch(forumBatchWrite);
superBatch.AddBatch(threadBatchWrite);

superBatch.Execute();
```

Example: CRUD operations using the AWS SDK for .NET document model

The following C# code example performs the following actions:

- Creates a book item in the ProductCatalog table.
- Retrieves the book item.
- Updates the book item. The code example shows a normal update that adds new attributes and updates existing attributes. It also shows a conditional update that updates the book price only if the existing price value is as specified in the code.
- Deletes the book item.

For step-by-step instructions to test the following example, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
```

```
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class MidlevelItemCRUD
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();
        private static string tableName = "ProductCatalog";
        // The sample uses the following id PK value to add book item.
        private static int sampleBookId = 555;

        static void Main(string[] args)
        {
            try
            {
                Table productCatalog = Table.LoadTable(client, tableName);
                CreateBookItem(productCatalog);
                RetrieveBook(productCatalog);
                // Couple of sample updates.
                UpdateMultipleAttributes(productCatalog);
                UpdateBookPriceConditionally(productCatalog);

                // Delete.
                DeleteBook(productCatalog);
                Console.WriteLine("To continue, press Enter");
                Console.ReadLine();
            }
            catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }
        }

        // Creates a sample book item.
        private static void CreateBookItem(Table productCatalog)
        {
            Console.WriteLine("\n*** Executing CreateBookItem() ***");
            var book = new Document();
            book["Id"] = sampleBookId;
            book["Title"] = "Book " + sampleBookId;
            book["Price"] = 19.99;
            book["ISBN"] = "111-1111111111";
        }
    }
}
```

```
book["Authors"] = new List<string> { "Author 1", "Author 2", "Author 3" };
book["PageCount"] = 500;
book["Dimensions"] = "8.5x11x.5";
book["InPublication"] = new DynamoDBBool(true);
book["InStock"] = new DynamoDBBool(false);
book["QuantityOnHand"] = 0;

productCatalog.PutItem(book);
}

private static void RetrieveBook(Table productCatalog)
{
    Console.WriteLine("\n*** Executing RetrieveBook() ***");
    // Optional configuration.
    GetItemOperationConfig config = new GetItemOperationConfig
    {
        AttributesToGet = new List<string> { "Id", "ISBN", "Title", "Authors",
"Price" },
        ConsistentRead = true
    };
    Document document = productCatalog.GetItem(sampleBookId, config);
    Console.WriteLine("RetrieveBook: Printing book retrieved...");
    PrintDocument(document);
}

private static void UpdateMultipleAttributes(Table productCatalog)
{
    Console.WriteLine("\n*** Executing UpdateMultipleAttributes() ***");
    Console.WriteLine("\nUpdating multiple attributes....");
    int partitionKey = sampleBookId;

    var book = new Document();
    book["Id"] = partitionKey;
    // List of attribute updates.
    // The following replaces the existing authors list.
    book["Authors"] = new List<string> { "Author x", "Author y" };
    book["newAttribute"] = "New Value";
    book["ISBN"] = null; // Remove it.

    // Optional parameters.
    UpdateItemOperationConfig config = new UpdateItemOperationConfig
    {
        // Get updated item in response.
        ReturnValue = ReturnValue.AllNewAttributes
```

```
};

Document updatedBook = productCatalog.UpdateItem(book, config);
Console.WriteLine("UpdateMultipleAttributes: Printing item after
updates ...");
PrintDocument(updatedBook);
}

private static void UpdateBookPriceConditionally(Table productCatalog)
{
    Console.WriteLine("\n*** Executing UpdateBookPriceConditionally() ***");

    int partitionKey = sampleBookId;

    var book = new Document();
    book["Id"] = partitionKey;
    book["Price"] = 29.99;

    // For conditional price update, creating a condition expression.
    Expression expr = new Expression();
    expr.ExpressionStatement = "Price = :val";
    expr.ExpressionAttributeValues[":val"] = 19.00;

    // Optional parameters.
    UpdateItemOperationConfig config = new UpdateItemOperationConfig
    {
        ConditionalExpression = expr,
        ReturnValues = ReturnValues.AllNewAttributes
    };
    Document updatedBook = productCatalog.UpdateItem(book, config);
    Console.WriteLine("UpdateBookPriceConditionally: Printing item whose price
was conditionally updated");
    PrintDocument(updatedBook);
}

private static void DeleteBook(Table productCatalog)
{
    Console.WriteLine("\n*** Executing DeleteBook() ***");
    // Optional configuration.
    DeleteItemOperationConfig config = new DeleteItemOperationConfig
    {
        // Return the deleted item.
        ReturnValues = ReturnValues.AllOldAttributes
    };
    Document document = productCatalog.DeleteItem(sampleBookId, config);
```

```
        Console.WriteLine("DeleteBook: Printing deleted just deleted...");  
        PrintDocument(document);  
    }  
  
    private static void PrintDocument(Document updatedDocument)  
{  
        foreach (var attribute in updatedDocument.GetAttributeNames())  
        {  
            string stringValue = null;  
            var value = updatedDocument[attribute];  
            if (value is Primitive)  
                stringValue = value.AsPrimitive().Value.ToString();  
            else if (value is PrimitiveList)  
                stringValue = string.Join(", ", (from primitive  
                                                in value.AsPrimitiveList().Entries  
                                                select primitive.Value).ToArray());  
            Console.WriteLine("{0} - {1}", attribute, stringValue);  
        }  
    }  
}
```

Example: Batch operations using the AWS SDK for .NET document model API

Topics

- [Example: Batch write using the AWS SDK for .NET document model](#)

Example: Batch write using the AWS SDK for .NET document model

The following C# code example illustrates single table and multi-table batch write operations. The example performs the following tasks:

- Illustrates a single table batch write. It adds two items to the ProductCatalog table.
- Illustrates a multi-table batch write. It adds an item to both the Forum and Thread tables and deletes an item from the Thread table.

If you followed the steps in [Creating tables and loading data for code examples in DynamoDB](#), you already have the ProductCatalog, Forum, and Thread tables created. You can also create these sample tables programmatically. For more information, see [Creating example tables and uploading](#)

[data using the AWS SDK for .NET](#). For step-by-step instructions for testing the following example, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class MidLevelBatchWriteItem
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();
        static void Main(string[] args)
        {
            try
            {
                SingleTableBatchWrite();
                MultiTableBatchWrite();
            }
            catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void SingleTableBatchWrite()
        {
            Table productCatalog = Table.LoadTable(client, "ProductCatalog");
            var batchWrite = productCatalog.CreateBatchWrite();

            var book1 = new Document();
            book1["Id"] = 902;
            book1["Title"] = "My book1 in batch write using .NET helper classes";
            book1["ISBN"] = "902-11-11111";
            book1["Price"] = 10;
            book1["ProductCategory"] = "Book";
            book1["Authors"] = new List<string> { "Author 1", "Author 2", "Author 3" };
            book1["Dimensions"] = "8.5x11x.5";
        }
    }
}
```

```
        book1["InStock"] = new DynamoDBBool(true);
        book1["QuantityOnHand"] = new DynamoDBNull(); //Quantity is unknown at this
time

        batchWrite.AddDocumentToPut(book1);
        // Specify delete item using overload that takes PK.
        batchWrite.AddKeyToDelete(12345);
        Console.WriteLine("Performing batch write in SingleTableBatchWrite()");
        batchWrite.Execute();
    }

private static void MultiTableBatchWrite()
{
    // 1. Specify item to add in the Forum table.
    Table forum = Table.LoadTable(client, "Forum");
    var forumBatchWrite = forum.CreateBatchWrite();

    var forum1 = new Document();
    forum1["Name"] = "Test BatchWrite Forum";
    forum1["Threads"] = 0;
    forumBatchWrite.AddDocumentToPut(forum1);

    // 2a. Specify item to add in the Thread table.
    Table thread = Table.LoadTable(client, "Thread");
    var threadBatchWrite = thread.CreateBatchWrite();

    var thread1 = new Document();
    thread1["ForumName"] = "S3 forum";
    thread1["Subject"] = "My sample question";
    thread1["Message"] = "Message text";
    thread1["KeywordTags"] = new List<string> { "S3", "Bucket" };
    threadBatchWrite.AddDocumentToPut(thread1);

    // 2b. Specify item to delete from the Thread table.
    threadBatchWrite.AddKeyToDelete("someForumName", "someSubject");

    // 3. Create multi-table batch.
    var superBatch = new MultiTableDocumentBatchWrite();
    superBatch.AddBatch(forumBatchWrite);
    superBatch.AddBatch(threadBatchWrite);
    Console.WriteLine("Performing batch write in MultiTableBatchWrite()");
    superBatch.Execute();
}
```

```
    }  
}
```

Working with tables in DynamoDB using the AWS SDK for .NET document model

Topics

- [Table.Query method in the AWS SDK for .NET](#)
- [Table.Scan method in the AWS SDK for .NET](#)

Table.Query method in the AWS SDK for .NET

The Query method enables you to query your tables. You can only query the tables that have a composite primary key (partition key and sort key). If your table's primary key is made of only a partition key, then the Query operation is not supported. By default, Query internally performs queries that are eventually consistent. To learn about the consistency model, see [Read consistency](#).

The Query method provides two overloads. The minimum required parameters to the Query method are a partition key value and a sort key filter. You can use the following overload to provide these minimum required parameters.

Example

```
Query(Primitive partitionKey, RangeFilter Filter);
```

For example, the following C# code queries for all forum replies that were posted in the last 15 days.

Example

```
string tableName = "Reply";  
Table table = Table.LoadTable(client, tableName);  
  
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);  
RangeFilter filter = new RangeFilter(QueryOperator.GreaterThan, twoWeeksAgoDate);  
Search search = table.Query("DynamoDB Thread 2", filter);
```

This creates a Search object. You can now call the Search.GetNextSet method iteratively to retrieve one page of results at a time, as shown in the following C# code example. The code prints the attribute values for each item that the query returns.

Example

```
List<Document> documentSet = new List<Document>();
do
{
    documentSet = search.GetNextSet();
    foreach (var document in documentSet)
        PrintDocument(document);
} while (!search.IsDone());

private static void PrintDocument(Document document)
{
    Console.WriteLine();
    foreach (var attribute in document.GetAttributeNames())
    {
        string stringValue = null;
        var value = document[attribute];
        if (value is Primitive)
            stringValue = value.AsPrimitive().Value;
        else if (value is PrimitiveList)
            stringValue = string.Join(", ", (from primitive
                                              in value.AsPrimitiveList().Entries
                                              select primitive.Value).ToArray());
        Console.WriteLine("{0} - {1}", attribute, stringValue);
    }
}
```

Specifying optional parameters

You can also specify optional parameters for `Query`, such as specifying a list of attributes to retrieve, strongly consistent reads, page size, and the number of items returned per page. For a complete list of parameters, see [Query](#). To specify optional parameters, you must use the following overload in which you provide the `QueryOperationConfig` object.

Example

```
Query(QueryOperationConfig config);
```

Assume that you want to run the query in the preceding example (retrieve forum replies posted in the last 15 days). However, assume that you want to provide optional query parameters to retrieve

only specific attributes and also request a strongly consistent read. The following C# code example constructs the request using the `QueryOperationConfig` object.

Example

```
Table table = Table.LoadTable(client, "Reply");
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
QueryOperationConfig config = new QueryOperationConfig()
{
    HashKey = "DynamoDB Thread 2", //Partition key
    AttributesToGet = new List<string>
    {
        "Subject", "ReplyDateTime", "PostedBy"
    },
    ConsistentRead = true,
    Filter = new RangeFilter(QueryOperator.GreaterThan, twoWeeksAgoDate)
};

Search search = table.Query(config);
```

Example: Query using the Table.Query method

The following C# code example uses the `Table.Query` method to run the following sample queries.

- The following queries are run against the `Reply` table.
 - Find forum thread replies that were posted in the last 15 days.

This query is run twice. In the first `Table.Query` call, the example provides only the required query parameters. In the second `Table.Query` call, you provide optional query parameters to request a strongly consistent read and a list of attributes to retrieve.

- Find forum thread replies posted during a period of time.

This query uses the `Between` query operator to find replies posted in between two dates.

- Get a product from the `ProductCatalog` table.

Because the `ProductCatalog` table has a primary key that is only a partition key, you can only get items; you cannot query the table. The example retrieves a specific product item using the item Id.

Example

```
using System;
using System.Collections.Generic;
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class MidLevelQueryAndScan
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                // Query examples.
                Table replyTable = Table.LoadTable(client, "Reply");
                string forumName = "Amazon DynamoDB";
                string threadSubject = "DynamoDB Thread 2";
                FindRepliesInLast15Days(replyTable, forumName, threadSubject);
                FindRepliesInLast15DaysWithConfig(replyTable, forumName,
threadSubject);
                FindRepliesPostedWithinTimePeriod(replyTable, forumName,
threadSubject);

                // Get Example.
                Table productCatalogTable = Table.LoadTable(client, "ProductCatalog");
                int productId = 101;
                GetProduct(productCatalogTable, productId);

                Console.WriteLine("To continue, press Enter");
                Console.ReadLine();
            }
            catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }
        }

        private static void GetProduct(Table tableName, int productId)
```

```
{  
    Console.WriteLine("**** Executing GetProduct() ****");  
    Document productDocument = tableName.GetItem(productId);  
    if (productDocument != null)  
    {  
        PrintDocument(productDocument);  
    }  
    else  
    {  
        Console.WriteLine("Error: product " + productId + " does not exist");  
    }  
  
    private static void FindRepliesInLast15Days(Table table, string forumName,  
string threadSubject)  
    {  
        string Attribute = forumName + "#" + threadSubject;  
  
        DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);  
        QueryFilter filter = new QueryFilter("Id", QueryOperator.Equal,  
partitionKey);  
        filter.AddCondition("ReplyDateTime", QueryOperator.GreaterThan,  
twoWeeksAgoDate);  
  
        // Use Query overloads that takes the minimum required query parameters.  
        Search search = table.Query(filter);  
  
        List<Document> documentSet = new List<Document>();  
        do  
        {  
            documentSet = search.GetNextSet();  
            Console.WriteLine("\nFindRepliesInLast15Days: printing .....");  
            foreach (var document in documentSet)  
                PrintDocument(document);  
        } while (!search.IsDone);  
    }  
  
    private static void FindRepliesPostedWithinTimePeriod(Table table, string  
forumName, string threadSubject)  
    {  
        DateTime startDate = DateTime.UtcNow.Subtract(new TimeSpan(21, 0, 0, 0));  
        DateTime endDate = DateTime.UtcNow.Subtract(new TimeSpan(1, 0, 0, 0));  
    }
```

```
        QueryFilter filter = new QueryFilter("Id", QueryOperator.Equal, forumName +
"#" + threadSubject);
        filter.AddCondition("ReplyDateTime", QueryOperator.Between, startDate,
endDate);

        QueryOperationConfig config = new QueryOperationConfig()
{
    Limit = 2, // 2 items/page.
    Select = SelectValues.SpecificAttributes,
    AttributesToGet = new List<string> { "Message",
                                         "ReplyDateTime",
                                         "PostedBy" },

{
    documentList = search.GetNextSet();
    Console.WriteLine("\nFindRepliesPostedWithinTimePeriod: printing
replies posted within dates: {0} and {1} ....", startDate, endDate);
    foreach (var document in documentList)
    {
        PrintDocument(document);
    }
} while (!search.IsDone());
}

private static void FindRepliesInLast15DaysWithConfig(Table table, string
forumName, string threadName)
{
    DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
    QueryFilter filter = new QueryFilter("Id", QueryOperator.Equal, forumName +
"#" + threadName);
    filter.AddCondition("ReplyDateTime", QueryOperator.GreaterThan,
twoWeeksAgoDate);
    // You are specifying optional parameters so use QueryOperationConfig.
    QueryOperationConfig config = new QueryOperationConfig()
{
    Filter = filter,
```

```
// Optional parameters.
Select = SelectValues.SpecificAttributes,
AttributesToGet = new List<string> { "Message", "ReplyDateTime",
                                         "PostedBy" },
ConsistentRead = true
};

Search search = table.Query(config);

List<Document> documentSet = new List<Document>();
do
{
    documentSet = search.GetNextSet();
    Console.WriteLine("\nFindRepliesInLast15DaysWithConfig:
printing .....");
    foreach (var document in documentSet)
        PrintDocument(document);
} while (!search.IsDone());
}

private static void PrintDocument(Document document)
{
    // count++;
    Console.WriteLine();
    foreach (var attribute in document.GetAttributeNames())
    {
        string stringValue = null;
        var value = document[attribute];
        if (value is Primitive)
            stringValue = value.AsPrimitive().Value.ToString();
        else if (value is PrimitiveList)
            stringValue = string.Join(", ", (from primitive
                                              in value.AsPrimitiveList().Entries
                                              select primitive.Value).ToArray());
        Console.WriteLine("{0} - {1}", attribute, stringValue);
    }
}
}
```

Table.Scan method in the AWS SDK for .NET

The Scan method performs a full table scan. It provides two overloads. The only parameter required by the Scan method is the scan filter, which you can provide using the following overload.

Example

```
Scan(ScanFilter filter);
```

For example, assume that you maintain a table of forum threads tracking information such as thread subject (primary), the related message, forum Id to which the thread belongs, Tags, and other information. Assume that the subject is the primary key.

Example

```
Thread(Subject, Message, ForumId, Tags, LastPostedDateTime, .... )
```

This is a simplified version of forums and threads that you see on AWS forums (see [Discussion forums](#)). The following C# code example queries all threads in a specific forum (ForumId = 101) that are tagged "sortkey". Because the ForumId is not a primary key, the example scans the table. The ScanFilter includes two conditions. The query returns all the threads that satisfy both of the conditions.

Example

```
string tableName = "Thread";
Table ThreadTable = Table.LoadTable(client, tableName);

ScanFilter scanFilter = new ScanFilter();
scanFilter.AddCondition("ForumId", ScanOperator.Equal, 101);
scanFilter.AddCondition("Tags", ScanOperator.Contains, "sortkey");

Search search = ThreadTable.Scan(scanFilter);
```

Specifying optional parameters

You also can specify optional parameters to Scan, such as a specific list of attributes to retrieve or whether to perform a strongly consistent read. To specify optional parameters, you must create a ScanOperationConfig object that includes both the required and optional parameters and use the following overload.

Example

```
Scan(ScanOperationConfig config);
```

The following C# code example runs the same preceding query (find forum threads in which the ForumId is 101 and the Tag attribute contains the "sortkey" keyword). Assume that you want to add an optional parameter to retrieve only a specific attribute list. In this case, you must create a ScanOperationConfig object by providing all the parameters, required and optional parameters, as shown in the following code example.

Example

```
string tableName = "Thread";
Table ThreadTable = Table.LoadTable(client, tableName);

ScanFilter scanFilter = new ScanFilter();
scanFilter.AddCondition("ForumId", ScanOperator.Equal, forumId);
scanFilter.AddCondition("Tags", ScanOperator.Contains, "sortkey");

ScanOperationConfig config = new ScanOperationConfig()
{
    AttributesToGet = new List<string> { "Subject", "Message" } ,
    Filter = scanFilter
};

Search search = ThreadTable.Scan(config);
```

Example: Scan using the Table.Scan method

The Scan operation performs a full table scan making it a potentially expensive operation. You should use queries instead. However, there are times when you might need to run a scan against a table. For example, you might have a data entry error in the product pricing, and you must scan the table as shown in the following C# code example. The example scans the ProductCatalog table to find products for which the price value is less than 0. The example illustrates the use of the two Table.Scan overloads.

- Table.Scan that takes the ScanFilter object as a parameter.

You can pass the ScanFilter parameter when passing in only the required parameters.

- Table.Scan that takes the ScanOperationConfig object as a parameter.

You must use the `ScanOperationConfig` parameter if you want to pass any optional parameters to the `Scan` method.

Example

```
using System;
using System.Collections.Generic;
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DocumentModel;

namespace com.amazonaws.codesamples
{
    class MidLevelScanOnly
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            Table productCatalogTable = Table.LoadTable(client, "ProductCatalog");
            // Scan example.
            FindProductsWithNegativePrice(productCatalogTable);
            FindProductsWithNegativePriceWithConfig(productCatalogTable);

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void FindProductsWithNegativePrice(Table productCatalogTable)
        {
            // Assume there is a price error. So we scan to find items priced < 0.
            ScanFilter scanFilter = new ScanFilter();
            scanFilter.AddCondition("Price", ScanOperator.LessThan, 0);

            Search search = productCatalogTable.Scan(scanFilter);

            List<Document> documentList = new List<Document>();
            do
            {
                documentList = search.GetNextSet();
                Console.WriteLine("\nFindProductsWithNegativePrice:
printing .....");
```

```
        foreach (var document in documentList)
            PrintDocument(document);
    } while (!search.IsDone);
}

private static void FindProductsWithNegativePriceWithConfig(Table
productCatalogTable)
{
    // Assume there is a price error. So we scan to find items priced < 0.
    ScanFilter scanFilter = new ScanFilter();
    scanFilter.AddCondition("Price", ScanOperator.LessThan, 0);

    ScanOperationConfig config = new ScanOperationConfig()
    {
        Filter = scanFilter,
        Select = SelectValues.SpecificAttributes,
        AttributesToGet = new List<string> { "Title", "Id" }
    };

    Search search = productCatalogTable.Scan(config);

    List<Document> documentList = new List<Document>();
    do
    {
        documentList = search.GetNextSet();
        Console.WriteLine("\nFindProductsWithNegativePriceWithConfig:
printing .....");
        foreach (var document in documentList)
            PrintDocument(document);
    } while (!search.IsDone);
}

private static void PrintDocument(Document document)
{
    // count++;
    Console.WriteLine();
    foreach (var attribute in document.GetAttributeNames())
    {
        string stringValue = null;
        var value = document[attribute];
        if (value is Primitive)
            stringValue = value.AsPrimitive().Value.ToString();
        else if (value is PrimitiveList)
            stringValue = string.Join(", ", (from primitive
```

```
        in value.AsPrimitiveList().Entries
            select primitive.Value).ToArray());
    Console.WriteLine("{0} - {1}", attribute, stringValue);
}
}
}
```

.NET: Object persistence model

Topics

- [DynamoDB attributes](#)

The AWS SDK for .NET provides an object persistence model that enables you to map your client-side classes to Amazon DynamoDB tables. Each object instance then maps to an item in the corresponding tables. To save your client-side objects to the tables, the object persistence model provides the `DynamoDBContext` class, an entry point to DynamoDB. This class provides you a connection to DynamoDB and enables you to access tables, perform various CRUD operations, and run queries.

The object persistence model provides a set of attributes to map client-side classes to tables, and properties/fields to table attributes.

Note

The object persistence model does not provide an API to create, update, or delete tables. It provides only data operations. You can use only the AWS SDK for .NET low-level API

to create, update, and delete tables. For more information, see [Working with DynamoDB tables in .NET](#).

The following example shows how the object persistence model works. It starts with the ProductCatalog table. It has Id as the primary key.

```
ProductCatalog(Id, ...)
```

Suppose that you have a Book class with Title, ISBN, and Authors properties. You can map the Book class to the ProductCatalog table by adding the attributes defined by the object persistence model, as shown in the following C# code example.

Example

```
[DynamoDBTable("ProductCatalog")]
public class Book
{
    [DynamoDBHashKey]
    public int Id { get; set; }

    public string Title { get; set; }
    public int ISBN { get; set; }

    [DynamoDBProperty("Authors")]
    public List<string> BookAuthors { get; set; }

    [DynamoDBIgnore]
    public string CoverPage { get; set; }
}
```

In the preceding example, the DynamoDBTable attribute maps the Book class to the ProductCatalog table.

The object persistence model supports both the explicit and default mapping between class properties and table attributes.

- **Explicit mapping**—To map a property to a primary key, you must use the DynamoDBHashKey and DynamoDBRangeKey object persistence model attributes. Additionally, for the nonprimary key attributes, if a property name in your class and the corresponding table attribute to which

you want to map it are not the same, you must define the mapping by explicitly adding the `DynamoDBProperty` attribute.

In the preceding example, the `Id` property maps to the primary key with the same name, and the `BookAuthors` property maps to the `Authors` attribute in the `ProductCatalog` table.

- **Default mapping**—By default, the object persistence model maps the class properties to the attributes with the same name in the table.

In the preceding example, the properties `Title` and `ISBN` map to the attributes with the same name in the `ProductCatalog` table.

You don't have to map every single class property. You identify these properties by adding the `DynamoDBIgnore` attribute. When you save a `Book` instance to the table, the `DynamoDBContext` does not include the `CoverPage` property. It also does not return this property when you retrieve the book instance.

You can map properties of .NET primitive types such as `int` and `string`. You also can map any arbitrary data types as long as you provide an appropriate converter to map the arbitrary data to one of the DynamoDB types. To learn about mapping arbitrary types, see [Mapping arbitrary data with DynamoDB using the AWS SDK for .NET object persistence model](#).

The object persistence model supports optimistic locking. During an update operation, this ensures that you have the latest copy of the item you are about to update. For more information, see [Optimistic locking using a version number with DynamoDB using the AWS SDK for .NET object persistence model](#).

DynamoDB attributes

This section describes the attributes that the object persistence model offers so that you can map your classes and properties to DynamoDB tables and attributes.

Note

In the following attributes, only `DynamoDBTable` and `DynamoDBHashKey` are required.

DynamoDBGlobalSecondaryIndexHashKey

Maps a class property to the partition key of a global secondary index. Use this attribute if you need to Query a global secondary index.

DynamoDBGlobalSecondaryIndexRangeKey

Maps a class property to the sort key of a global secondary index. Use this attribute if you need to Query a global secondary index and want to refine your results using the index sort key.

DynamoDBHashKey

Maps a class property to the partition key of the table's primary key. The primary key attributes cannot be a collection type.

The following C# code example maps the Book class to the ProductCatalog table, and the Id property to the table's primary key partition key.

```
[DynamoDBTable("ProductCatalog")]
public class Book
{
    [DynamoDBHashKey]
    public int Id { get; set; }

    // Additional properties go here.
}
```

DynamoDBIgnore

Indicates that the associated property should be ignored. If you don't want to save any of your class properties, you can add this attribute to instruct DynamoDBContext not to include this property when saving objects to the table.

DynamoDBLocalSecondaryIndexRangeKey

Maps a class property to the sort key of a local secondary index. Use this attribute if you need to Query a local secondary index and want to refine your results using the index sort key.

DynamoDBProperty

Maps a class property to a table attribute. If the class property maps to a table attribute of the same name, you don't need to specify this attribute. However, if the names are not the same, you

can use this tag to provide the mapping. In the following C# statement, the `DynamoDBProperty` maps the `BookAuthors` property to the `Authors` attribute in the table.

```
[DynamoDBProperty("Authors")]
public List<string> BookAuthors { get; set; }
```

`DynamoDBContext` uses this mapping information to create the `Authors` attribute when saving object data to the corresponding table.

DynamoDBRenamable

Specifies an alternative name for a class property. This is useful if you are writing a custom converter for mapping arbitrary data to a DynamoDB table where the name of a class property is different from a table attribute.

DynamoDBRangeKey

Maps a class property to the sort key of the table's primary key. If the table has a composite primary key (partition key and sort key), you must specify both the `DynamoDBHashKey` and `DynamoDBRangeKey` attributes in your class mapping.

For example, the sample table `Reply` has a primary key made of the `Id` partition key and `Replenishment` sort key. The following C# code example maps the `Reply` class to the `Reply` table. The class definition also indicates that two of its properties map to the primary key.

For more information about sample tables, see [Creating tables and loading data for code examples in DynamoDB](#).

```
[DynamoDBTable("Reply")]
public class Reply
{
    [DynamoDBHashKey]
    public int ThreadId { get; set; }
    [DynamoDBRangeKey]
    public string Replenishment { get; set; }

    // Additional properties go here.
}
```

DynamoDBTable

Identifies the target table in DynamoDB to which the class maps. For example, the following C# code example maps the `Developer` class to the `People` table in DynamoDB.

```
[DynamoDBTable("People")]
public class Developer { ... }
```

This attribute can be inherited or overridden.

- The `DynamoDBTable` attribute can be inherited. In the preceding example, if you add a new class, `Lead`, that inherits from the `Developer` class, it also maps to the `People` table. Both the `Developer` and `Lead` objects are stored in the `People` table.
- The `DynamoDBTable` attribute can also be overridden. In the following C# code example, the `Manager` class inherits from the `Developer` class. However, the explicit addition of the `DynamoDBTable` attribute maps the class to another table (`Managers`).

```
[DynamoDBTable("Managers")]
public class Manager : Developer { ... }
```

You can add the optional parameter, `LowerCamelCaseProperties`, to request DynamoDB to make the first letter of the property name lowercase when storing the objects to a table, as shown in the following C# example.

```
[DynamoDBTable("People", LowerCamelCaseProperties=true)]
public class Developer
{
    string DeveloperName;
    ...
}
```

When saving instances of the `Developer` class, `DynamoDBContext` saves the `DeveloperName` property as the `developerName`.

DynamoDBVersion

Identifies a class property for storing the item version number. For more information about versioning, see [Optimistic locking using a version number with DynamoDB using the AWS SDK for .NET object persistence model](#).

DynamoDBContext class

The `DynamoDBContext` class is the entry point to the Amazon DynamoDB database. It provides a connection to DynamoDB and enables you to access your data in various tables, perform various CRUD operations, and run queries. The `DynamoDBContext` class provides the following methods.

CreateMultiTableBatchGet

Creates a `MultiTableBatchGet` object, composed of multiple individual `BatchGet` objects. Each of these `BatchGet` objects can be used for retrieving items from a single DynamoDB table.

To retrieve the items from tables, use the `ExecuteBatchGet` method, passing the `MultiTableBatchGet` object as a parameter.

CreateMultiTableBatchWrite

Creates a `MultiTableBatchWrite` object, composed of multiple individual `BatchWrite` objects. Each of these `BatchWrite` objects can be used for writing or deleting items in a single DynamoDB table.

To write to tables, use the `ExecuteBatchWrite` method, passing the `MultiTableBatchWrite` object as a parameter.

CreateBatchGet

Creates a `BatchGet` object that you can use to retrieve multiple items from a table. For more information, see [Batch get: Getting multiple items](#).

createBatchWrite

Creates a `BatchWrite` object that you can use to put multiple items into a table, or to delete multiple items from a table. For more information, see [Batch write: Putting and deleting multiple items](#).

Delete

Deletes an item from the table. The method requires the primary key of the item you want to delete. You can provide either the primary key value or a client-side object containing a primary key value as a parameter to this method.

- If you specify a client-side object as a parameter and you have enabled optimistic locking, the delete succeeds only if the client-side and the server-side versions of the object match.

- If you specify only the primary key value as a parameter, the delete succeeds regardless of whether you have enabled optimistic locking or not.

 **Note**

To perform this operation in the background, use the `DeleteAsync` method instead.

Dispose

Disposes of all managed and unmanaged resources.

Executebatchget

Reads data from one or more tables, processing all of the `BatchGet` objects in a `MultiTableBatchGet`.

 **Note**

To perform this operation in the background, use the `ExecuteBatchGetAsync` method instead.

Executebatchwrite

Writes or deletes data in one or more tables, processing all of the `BatchWrite` objects in a `MultiTableBatchWrite`.

 **Note**

To perform this operation in the background, use the `ExecuteBatchWriteAsync` method instead.

FromDocument

Given an instance of a `Document`, the `FromDocument` method returns an instance of a client-side class.

This is helpful if you want to use the document model classes along with the object persistence model to perform any data operations. For more information about the document model classes provided by the AWS SDK for .NET, see [.NET: Document model](#).

Suppose that you have a Document object named doc, that contains a representation of a Forum item. (To see how to construct this object, see the description for the ToDocument method later in this topic.) You can use FromDocument to retrieve the Forum item from the Document, as shown in the following C# code example.

Example

```
forum101 = context.FromDocument<Forum>(101);
```

Note

If your Document object implements the `IEnumerable` interface, you can use the `FromDocuments` method instead. This allows you to iterate over all of the class instances in the Document.

FromQuery

Runs a Query operation, with the query parameters defined in a `QueryOperationConfig` object.

Note

To perform this operation in the background, use the `FromQueryAsync` method instead.

FromScan

Runs a Scan operation, with the scan parameters defined in a `ScanOperationConfig` object.

Note

To perform this operation in the background, use the `FromScanAsync` method instead.

Gettargetable

Retrieves the target table for the specified type. This is useful if you are writing a custom converter for mapping arbitrary data to a DynamoDB table, and you need to determine which table is associated with a custom data type.

Load

Retrieves an item from a table. The method requires only the primary key of the item you want to retrieve.

By default, DynamoDB returns the item with values that are eventually consistent. For information about the eventual consistency model, see [Read consistency](#).

Note

To perform this operation in the background, use the LoadAsync method instead.

Query

Queries a table based on query parameters you provide.

You can query a table only if it has a composite primary key (partition key and sort key). When querying, you must specify a partition key and a condition that applies to the sort key.

Suppose that you have a client-side Reply class mapped to the Reply table in DynamoDB. The following C# code example queries the Reply table to find forum thread replies posted in the past 15 days. The Reply table has a primary key that has the Id partition key and the ReplyDateTime sort key. For more information about the Reply table, see [Creating tables and loading data for code examples in DynamoDB](#).

Example

```
DynamoDBContext context = new DynamoDBContext(client);

string replyId = "DynamoDB#DynamoDB Thread 1"; //Partition key
DateTime twoWeeksAgoDate = DateTime.UtcNow.Subtract(new TimeSpan(14, 0, 0, 0)); // Date
// to compare.
IEnumerable<Reply> latestReplies = context.Query<Reply>(replyId,
    QueryOperator.GreaterThan, twoWeeksAgoDate);
```

This returns a collection of Reply objects.

The Query method returns a "lazy-loaded" `IEnumerable` collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, you need to iterate only over the `IEnumerable`.

If your table has a simple primary key (partition key), you can't use the Query method. Instead, you can use the Load method and provide the partition key to retrieve the item.

 **Note**

To perform this operation in the background, use the `QueryAsync` method instead.

Save

Saves the specified object to the table. If the primary key specified in the input object doesn't exist in the table, the method adds a new item to the table. If the primary key exists, the method updates the existing item.

If you have optimistic locking configured, the update succeeds only if the client and the server-side versions of the item match. For more information, see [Optimistic locking using a version number with DynamoDB using the AWS SDK for .NET object persistence model](#).

 **Note**

To perform this operation in the background, use the `SaveAsync` method instead.

Scan

Performs an entire table scan.

You can filter scan results by specifying a scan condition. The condition can be evaluated on any attributes in the table. Suppose that you have a client-side class `Book` mapped to the `ProductCatalog` table in DynamoDB. The following C# example scans the table and returns only the book items priced less than 0.

Example

```
IEnumerable<Book> itemsWithWrongPrice = context.Scan<Book>()
```

```
        new ScanCondition("Price", ScanOperator.LessThan, price),
        new ScanCondition("ProductCategory", ScanOperator.Equal, "Book")
    );
```

The `Scan` method returns a "lazy-loaded" `IEnumerable` collection. It initially returns only one page of results, and then makes a service call for the next page if needed. To obtain all the matching items, you only need to iterate over the `IEnumerable`.

For performance reasons, you should query your tables and avoid a table scan.

 **Note**

To perform this operation in the background, use the `ScanAsync` method instead.

ToDocument

Returns an instance of the `Document` document model class from your class instance.

This is helpful if you want to use the document model classes along with the object persistence model to perform any data operations. For more information about the document model classes provided by the AWS SDK for .NET, see [.NET: Document model](#).

Suppose that you have a client-side class mapped to the sample `Forum` table. You can then use a `DynamoDBContext` to get an item as a `Document` object from the `Forum` table, as shown in the following C# code example.

Example

```
DynamoDBContext context = new DynamoDBContext(client);

Forum forum101 = context.Load<Forum>(101); // Retrieve a forum by primary key.
Document doc = context.ToDocument<Forum>(forum101);
```

Specifying optional parameters for `DynamoDBContext`

When using the object persistence model, you can specify the following optional parameters for the `DynamoDBContext`.

- **ConsistentRead**—When retrieving data using the `Load`, `Query`, or `Scan` operations, you can add this optional parameter to request the latest values for the data.

- **IgnoreNullValues**—This parameter informs DynamoDBContext to ignore null values on attributes during a Save operation. If this parameter is false (or if it is not set), then a null value is interpreted as a directive to delete the specific attribute.
- **SkipVersionCheck**— This parameter informs DynamoDBContext not to compare versions when saving or deleting an item. For more information about versioning, see [Optimistic locking using a version number with DynamoDB using the AWS SDK for .NET object persistence model](#).
- **TableNamePrefix**— Prefixes all table names with a specific string. If this parameter is null (or if it is not set), then no prefix is used.

The following C# example creates a new DynamoDBContext by specifying two of the preceding optional parameters.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
...
DynamoDBContext context =
    new DynamoDBContext(client, new DynamoDBContextConfig { ConsistentRead = true,
    SkipVersionCheck = true});
```

DynamoDBContext includes these optional parameters with each request that you send using this context.

Instead of setting these parameters at the DynamoDBContext level, you can specify them for individual operations you run using DynamoDBContext, as shown in the following C# code example. The example loads a specific book item. The Load method of DynamoDBContext specifies the preceding optional parameters.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
...
DynamoDBContext context = new DynamoDBContext(client);
Book bookItem = context.Load<Book>(productId,new DynamoDBContextConfig{ ConsistentRead
= true, SkipVersionCheck = true });
```

In this case, DynamoDBContext includes these parameters only when sending the Get request.

Supported data types

The object persistence model supports a set of primitive .NET data types, collections, and arbitrary data types. The model supports the following primitive data types.

- `bool`
- `byte`
- `char`
- `DateTime`
- `decimal`
- `double`
- `float`
- `Int16`
- `Int32`
- `Int64`
- `SByte`
- `string`
- `UInt16`
- `UInt32`
- `UInt64`

The object persistence model also supports the .NET collection types. `DynamoDBContext` is able to convert concrete collection types and simple Plain Old CLR Objects (POCOs).

The following table summarizes the mapping of the preceding .NET types to the DynamoDB types.

.NET primitive type	DynamoDB type
All number types	N (number type)
All string types	S (string type)
<code>MemoryStream</code> , <code>byte[]</code>	B (binary type)

.NET primitive type	DynamoDB type
bool	N (number type). 0 represents false and 1 represents true.
Collection types	BS (binary set) type, SS (string set) type, and NS (number set) type
DateTime	S (string type). The DateTime values are stored as ISO-8601 formatted strings.

The object persistence model also supports arbitrary data types. However, you must provide converter code to map the complex types to the DynamoDB types.

 **Note**

- Empty binary values are supported.
- Reading of empty string values is supported. Empty string attribute values are supported within attribute values of string Set type while writing to DynamoDB. Empty string attribute values of string type and empty string values contained within List or Map type are dropped from write requests

Optimistic locking using a version number with DynamoDB using the AWS SDK for .NET object persistence model

Optimistic locking support in the object persistence model ensures that the item version for your application is the same as the item version on the server side before updating or deleting the item. Suppose that you retrieve an item for update. However, before you send your updates back, some other application updates the same item. Now your application has a stale copy of the item. Without optimistic locking, any update you perform will overwrite the update made by the other application.

The optimistic locking feature of the object persistence model provides the `DynamoDBVersion` tag that you can use to enable optimistic locking. To use this feature, you add a property to your class for storing the version number. You add the `DynamoDBVersion` attribute to the property.

When you first save the object, the `DynamoDBContext` assigns a version number and increments this value each time you update the item.

Your update or delete request succeeds only if the client-side object version matches the corresponding version number of the item on the server side. If your application has a stale copy, it must get the latest version from the server before it can update or delete that item.

The following C# code example defines a `Book` class with object persistence attributes mapping it to the `ProductCatalog` table. The `VersionNumber` property in the class decorated with the `DynamoDBVersion` attribute stores the version number value.

Example

```
[DynamoDBTable("ProductCatalog")]
public class Book
{
    [DynamoDBHashKey] //Partition key
    public int Id { get; set; }
    [DynamoDBProperty]
    public string Title { get; set; }
    [DynamoDBProperty]
    public string ISBN { get; set; }
    [DynamoDBProperty("Authors")]
    public List<string> BookAuthors { get; set; }
    [DynamoDBVersion]
    public int? VersionNumber { get; set; }
}
```

Note

You can apply the `DynamoDBVersion` attribute only to a nullable numeric primitive type (such as `int?`).

Optimistic locking has the following impact on `DynamoDBContext` operations:

- For a new item, `DynamoDBContext` assigns initial version number 0. If you retrieve an existing item, update one or more of its properties, and try to save the changes, the save operation succeeds only if the version number on the client side and the server side match. `DynamoDBContext` increments the version number. You don't need to set the version number.

- The Delete method provides overloads that can take either a primary key value or an object as parameter, as shown in the following C# code example.

Example

```
DynamoDBContext context = new DynamoDBContext(client);
...
// Load a book.
Book book = context.Load<ProductCatalog>(111);
// Do other operations.
// Delete 1 - Pass in the book object.
context.Delete<ProductCatalog>(book);

// Delete 2 - Pass in the Id (primary key)
context.Delete<ProductCatalog>(222);
```

If you provide an object as the parameter, the delete succeeds only if the object version matches the corresponding server-side item version. However, if you provide a primary key value as the parameter, DynamoDBContext is unaware of any version numbers, and it deletes the item without making the version check.

Note that the internal implementation of optimistic locking in the object persistence model code uses the conditional update and the conditional delete API actions in DynamoDB.

Disabling optimistic locking

To disable optimistic locking, you use the SkipVersionCheck configuration property. You can set this property when creating DynamoDBContext. In this case, optimistic locking is disabled for any requests that you make using the context. For more information, see [Specifying optional parameters for DynamoDBContext](#).

Instead of setting the property at the context level, you can disable optimistic locking for a specific operation, as shown in the following C# code example. The example uses the context to delete a book item. The Delete method sets the optional SkipVersionCheck property to true, disabling version checking.

Example

```
DynamoDBContext context = new DynamoDBContext(client);
// Load a book.
```

```
Book book = context.Load<ProductCatalog>(111);
...
// Delete the book.
context.Delete<Book>(book, new DynamoDBContextConfig { SkipVersionCheck = true });
```

Mapping arbitrary data with DynamoDB using the AWS SDK for .NET object persistence model

In addition to the supported .NET types (see [Supported data types](#)), you can use types in your application for which there is no direct mapping to the Amazon DynamoDB types. The object persistence model supports storing data of arbitrary types as long as you provide the converter to convert data from the arbitrary type to the DynamoDB type and vice versa. The converter code transforms data during both the saving and loading of the objects.

You can create any types on the client-side. However the data stored in the tables is one of the DynamoDB types, and during query and scan, any data comparisons made are against the data stored in DynamoDB.

The following C# code example defines a Book class with Id, Title, ISBN, and Dimension properties. The Dimension property is of the DimensionType that describes Height, Width, and Thickness properties. The example code provides the converter methods ToEntry and FromEntry to convert data between the DimensionType and the DynamoDB string types. For example, when saving a Book instance, the converter creates a book Dimension string such as "8.5x11x.05". When you retrieve a book, it converts the string to a DimensionType instance.

The example maps the Book type to the ProductCatalog table. It saves a sample Book instance, retrieves it, updates its dimensions, and saves the updated Book again.

For step-by-step instructions for testing the following example, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
```

```
{  
    class HighLevelMappingArbitraryData  
    {  
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();  
  
        static void Main(string[] args)  
        {  
            try  
            {  
                DynamoDBContext context = new DynamoDBContext(client);  
  
                // 1. Create a book.  
                DimensionType myBookDimensions = new DimensionType()  
                {  
                    Length = 8M,  
                    Height = 11M,  
                    Thickness = 0.5M  
                };  
  
                Book myBook = new Book  
                {  
                    Id = 501,  
                    Title = "AWS SDK for .NET Object Persistence Model Handling  
Arbitrary Data",  
                    ISBN = "999-9999999999",  
                    BookAuthors = new List<string> { "Author 1", "Author 2" },  
                    Dimensions = myBookDimensions  
                };  
  
                context.Save(myBook);  
  
                // 2. Retrieve the book.  
                Book bookRetrieved = context.Load<Book>(501);  
  
                // 3. Update property (book dimensions).  
                bookRetrieved.Dimensions.Height += 1;  
                bookRetrieved.Dimensions.Length += 1;  
                bookRetrieved.Dimensions.Thickness += 0.2M;  
                // Update the book.  
                context.Save(bookRetrieved);  
  
                Console.WriteLine("To continue, press Enter");  
                Console.ReadLine();  
            }  
        }  
    }  
}
```

```
        catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
        catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
        catch (Exception e) { Console.WriteLine(e.Message); }
    }
}

[DynamoDBTable("ProductCatalog")]
public class Book
{
    [DynamoDBHashKey] //Partition key
    public int Id
    {
        get; set;
    }
    [DynamoDBProperty]
    public string Title
    {
        get; set;
    }
    [DynamoDBProperty]
    public string ISBN

string.IsNullOrEmpty((string)primitive.Value))  
            throw new ArgumentOutOfRangeException();  
  
        string[] data = ((string)(primitive.Value)).Split(new string[] { " x " },  
StringSplitOptions.None);  
        if (data.Length != 3) throw new ArgumentOutOfRangeException();  
  
        DimensionType complexData = new DimensionType  
        {  
            Length = Convert.ToDecimal(data[0]),  
            Height = Convert.ToDecimal(data[1]),  
            Thickness = Convert.ToDecimal(data[2])  
        };  
    }  
}
```

```
    };
    return complexData;
}
}
```

Batch operations using the AWS SDK for .NET object persistence model

Batch write: Putting and deleting multiple items

To put or delete multiple objects from a table in a single request, do the following:

- Run the `createBatchWrite` method of the `DynamoDBContext`, and create an instance of the `BatchWrite` class.
- Specify the items that you want to put or delete.
 - To put one or more items, use either the `AddPutItem` or the `AddPutItems` method.
 - To delete one or more items, you can specify either the primary key of the item or a client-side object that maps to the item that you want to delete. Use the `AddDeleteItem`, `AddDeleteItems`, and the `AddDeleteKey` methods to specify the list of items to delete.
- Call the `BatchWrite.Execute` method to put and delete all the specified items from the table.

Note

When using the object persistence model, you can specify any number of operations in a batch. However, note that Amazon DynamoDB limits the number of operations in a batch and the total size of the batch in a batch operation. For more information about the specific limits, see [BatchWriteItem](#). If the API detects that your batch write request exceeded the allowed number of write requests or exceeded the maximum allowed HTTP payload size, it breaks the batch into several smaller batches. Additionally, if a response to a batch write returns unprocessed items, the API automatically sends another batch request with those unprocessed items.

Suppose that you defined a C# class `Book` class that maps to the `ProductCatalog` table in DynamoDB. The following C# code example uses the `BatchWrite` object to upload two items and delete one item from the `ProductCatalog` table.

Example

```
DynamoDBContext context = new DynamoDBContext(client);
var bookBatch = context.CreateBatchWrite<Book>();

// 1. Specify two books to add.
Book book1 = new Book
{
    Id = 902,
    ISBN = "902-11-11-1111",
    ProductCategory = "Book",
    Title = "My book3 in batch write"
};

Book book2 = new Book
{
    Id = 903,
    ISBN = "903-11-11-1111",
    ProductCategory = "Book",
    Title = "My book4 in batch write"
};

bookBatch.AddPutItems(new List<Book> { book1, book2 });

// 2. Specify one book to delete.
bookBatch.AddDeleteKey(111);

bookBatch.Execute();
```

To put or delete objects from multiple tables, do the following:

- Create one instance of the BatchWrite class for each type and specify the items you want to put or delete as described in the preceding section.
- Create an instance of MultiTableBatchWrite using one of the following methods:
 - Run the Combine method on one of the BatchWrite objects that you created in the preceding step.
 - Create an instance of the MultiTableBatchWrite type by providing a list of BatchWrite objects.
 - Run the CreateMultiTableBatchWrite method of DynamoDBContext and pass in your list of BatchWrite objects.

- Call the Execute method of MultiTableBatchWrite, which performs the specified put and delete operations on various tables.

Suppose that you defined Forum and Thread C# classes that map to the Forum and Thread tables in DynamoDB. Also, suppose that the Thread class has versioning enabled. Because versioning is not supported when using batch operations, you must explicitly disable versioning as shown in the following C# code example. The example uses the MultiTableBatchWrite object to perform a multi-table update.

Example

```
DynamoDBContext context = new DynamoDBContext(client);
// Create BatchWrite objects for each of the Forum and Thread classes.
var forumBatch = context.CreateBatchWrite<Forum>();

DynamoDBOperationConfig config = new DynamoDBOperationConfig();
config.SkipVersionCheck = true;
var threadBatch = context.CreateBatchWrite<Thread>(config);

// 1. New Forum item.
Forum newForum = new Forum
{
    Name = "Test BatchWrite Forum",
    Threads = 0
};
forumBatch.AddPutItem(newForum);

// 2. Specify a forum to delete by specifying its primary key.
forumBatch.AddDeleteKey("Some forum");

// 3. New Thread item.
Thread newThread = new Thread
{
    ForumName = "Amazon S3 forum",
    Subject = "My sample question",
    KeywordTags = new List<string> { "Amazon S3", "Bucket" },
    Message = "Message text"
};

threadBatch.AddPutItem(newThread);

// Now run multi-table batch write.
```

```
var superBatch = new MultiTableBatchWrite(forumBatch, threadBatch);
superBatch.Execute();
```

For a working example, see [Example: Batch write operation using the AWS SDK for .NET object persistence model](#).

Note

The DynamoDB batch API limits the number of writes in a batch and also limits the size of the batch. For more information, see [BatchWriteItem](#). When using the .NET object persistence model API, you can specify any number of operations. However, if either the number of operations in a batch or the size exceeds the limit, the .NET API breaks the batch write request into smaller batches and sends multiple batch write requests to DynamoDB.

Batch get: Getting multiple items

To retrieve multiple items from a table in a single request, do the following:

- Create an instance of the `CreateBatchGet` class.
- Specify a list of primary keys to retrieve.
- Call the `Execute` method. The response returns the items in the `Results` property.

The following C# code example retrieves three items from the `ProductCatalog` table. The items in the result are not necessarily in the same order in which you specified the primary keys.

Example

```
DynamoDBContext context = new DynamoDBContext(client);
var bookBatch = context.CreateBatchGet<ProductCatalog>();
bookBatch.AddKey(101);
bookBatch.AddKey(102);
bookBatch.AddKey(103);
bookBatch.Execute();
// Process result.
Console.WriteLine(bookBatch.Results.Count);
Book book1 = bookBatch.Results[0];
Book book2 = bookBatch.Results[1];
Book book3 = bookBatch.Results[2];
```

To retrieve objects from multiple tables, do the following:

- For each type, create an instance of the `CreateBatchGet` type and provide the primary key values you want to retrieve from each table.
- Create an instance of the `MultiTableBatchGet` class using one of the following methods:
 - Run the `Combine` method on one of the `BatchGet` objects you created in the preceding step.
 - Create an instance of the `MultiBatchGet` type by providing a list of `BatchGet` objects.
 - Run the `CreateMultiTableBatchGet` method of `DynamoDBContext` and pass in your list of `BatchGet` objects.
- Call the `Execute` method of `MultiTableBatchGet`, which returns the typed results in the individual `BatchGet` objects.

The following C# code example retrieves multiple items from the `Order` and `OrderDetail` tables using the `CreateBatchGet` method.

Example

```
var orderBatch = context.CreateBatchGet<Order>();
orderBatch.AddKey(101);
orderBatch.AddKey(102);

var orderDetailBatch = context.CreateBatchGet<OrderDetail>();
orderDetailBatch.AddKey(101, "P1");
orderDetailBatch.AddKey(101, "P2");
orderDetailBatch.AddKey(102, "P3");
orderDetailBatch.AddKey(102, "P1");

var orderAndDetailSuperBatch = orderBatch.Combine(orderDetailBatch);
orderAndDetailSuperBatch.Execute();

Console.WriteLine(orderBatch.Results.Count);
Console.WriteLine(orderDetailBatch.Results.Count);

Order order1 = orderBatch.Results[0];
Order order2 = orderBatch.Results[1];
OrderDetail orderDetail1 = orderDetailBatch.Results[0];
```

Example: CRUD operations using the AWS SDK for .NET object persistence model

The following C# code example declares a Book class with Id, Title, ISBN, and Authors properties. The example uses object persistence attributes to map these properties to the ProductCatalog table in Amazon DynamoDB. The example then uses the DynamoDBContext to illustrate typical create, read, update, and delete (CRUD) operations. The example creates a sample Book instance and saves it to the ProductCatalog table. It then retrieves the book item and updates its ISBN and Authors properties. Note that the update replaces the existing authors list. Finally, the example deletes the book item.

For more information about the ProductCatalog table used in this example, see [Creating tables and loading data for code examples in DynamoDB](#). For step-by-step instructions to test the following example, see [.NET code examples](#).

Note

The following example doesn't work with .NET core because it doesn't support synchronous methods. For more information, see [AWS asynchronous APIs for .NET](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class HighLevelItemCRUD
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                DynamoDBContext context = new DynamoDBContext(client);
                TestCRUDOperations(context);
                Console.WriteLine("To continue, press Enter");
            }
        }
    }
}
```

```
        Console.ReadLine();
    }
    catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
    catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
    catch (Exception e) { Console.WriteLine(e.Message); }
}

private static void TestCRUDOperations(DynamoDBContext context)
{
    int bookID = 1001; // Some unique value.
    Book myBook = new Book
    {
        Id = bookID,
        Title = "object persistence-AWS SDK for.NET SDK-Book 1001",
        ISBN = "111-1111111001",
        BookAuthors = new List<string> { "Author 1", "Author 2" },
    };

    // Save the book.
    context.Save(myBook);
    // Retrieve the book.
    Book bookRetrieved = context.Load<Book>(bookID);

    // Update few properties.
    bookRetrieved.ISBN = "222-2222221001";
    bookRetrieved.BookAuthors = new List<string> { " Author 1", "Author x" }; // Replace existing authors list with this.
    context.Save(bookRetrieved);

    // Retrieve the updated book. This time add the optional ConsistentRead
    parameter using DynamoDBContextConfig object.
    Book updatedBook = context.Load<Book>(bookID, new DynamoDBContextConfig
    {
        ConsistentRead = true
    });

    // Delete the book.
    context.Delete<Book>(bookID);
    // Try to retrieve deleted book. It should return null.
    Book deletedBook = context.Load<Book>(bookID, new DynamoDBContextConfig
    {
        ConsistentRead = true
    });
    if (deletedBook == null)
```

```
        Console.WriteLine("Book is deleted");
    }
}

}
```

Example: Batch write operation using the AWS SDK for .NET object persistence model

The following C# code example declares Book, Forum, Thread, and Reply classes and maps them to Amazon DynamoDB tables using the object persistence model attributes.

The example then uses the DynamoDBContext to illustrate the following batch write operations:

- `BatchWrite` object to put and delete book items from the `ProductCatalog` table.
- `MultiTableBatchWrite` object to put and delete items from the `Forum` and the `Thread` tables.

For more information about the tables used in this example, see [Creating tables and loading data for code examples in DynamoDB](#). For step-by-step instructions to test the following example, see [.NET code examples](#).

 **Note**

The following example doesn't work with .NET core because it doesn't support synchronous methods. For more information, see [AWS asynchronous APIs for .NET](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class HighLevelBatchWriteItem
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                DynamoDBContext context = new DynamoDBContext(client);
                SingleTableBatchWrite(context);
                MultiTableBatchWrite(context);
            }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void SingleTableBatchWrite(DynamoDBContext context)

Example: Query and scan in DynamoDB using the AWS SDK for .NET object persistence model

The C# example in this section defines the following classes and maps them to the tables in DynamoDB. For more information about creating the tables used in this example, see [Creating tables and loading data for code examples in DynamoDB](#).

- The Book class maps to the ProductCatalog table.
- The Forum, Thread, and Reply classes map to tables of the same name.

The example then runs the following query and scan operations using DynamoDBContext.

- Get a book by Id.

The ProductCatalog table has Id as its primary key. It does not have a sort key as part of its primary key. Therefore, you cannot query the table. You can get an item using its Id value.

- Run the following queries against the Reply table. (The Reply table's primary key is composed of Id and ReplyDateTime attributes. The ReplyDateTime is a sort key. Therefore, you can query this table.)
 - Find replies to a forum thread posted in the last 15 days.
 - Find replies to a forum thread posted in a specific date range.
- Scan the ProductCatalog table to find books whose price is less than zero.

For performance reasons, you should use a query operation instead of a scan operation.

However, there are times you might need to scan a table. Suppose that there was a data entry error and one of the book prices is set to less than 0. This example scans the ProductCategory table to find book items (the ProductCategory is book) at price of less than 0.

For instructions about creating a working sample, see [.NET code examples](#).

Note

The following example does not work with .NET core because it does not support synchronous methods. For more information, see [AWS asynchronous APIs for .NET](#).

Example

```
using System;
using System.Collections.Generic;
using System.Configuration;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class HighLevelQueryAndScan
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                DynamoDBContext context = new DynamoDBContext(client);
                // Get an item.
                GetBook(context, 101);

                // Sample forum and thread to test queries.
                string forumName = "Amazon DynamoDB";
                string threadSubject = "DynamoDB Thread 1";

Running the code examples in this Developer Guide

The AWS SDKs provide broad support for Amazon DynamoDB in the following languages:

- [Java](#)

- [JavaScript in the browser](#)
- [.NET](#)
- [Node.js](#)
- [PHP](#)
- [Python](#)
- [Ruby](#)
- [C++](#)
- [Go](#)
- [Android](#)
- [iOS](#)

To get started quickly with these languages, see [Getting started with DynamoDB and the AWS SDKs](#).

The code examples in this developer guide provide more in-depth coverage of DynamoDB operations, using the following programming languages:

- [Java code examples](#)
- [.NET code examples](#)

Before you can begin with this exercise, you need to create an AWS account, get your access key and secret key, and set up the AWS Command Line Interface (AWS CLI) on your computer. For more information, see [Setting up DynamoDB \(web service\)](#).

 **Note**

If you are using the downloadable version of DynamoDB, you need to use the AWS CLI to create the tables and sample data. You also need to specify the `--endpoint-url` parameter with each AWS CLI command. For more information, see [Setting the local endpoint](#).

Creating tables and loading data for code examples in DynamoDB

See below for the basics on creating tables in DynamoDB, loading in a sample dataset, querying the data, and updating the data.

- [Step 1: Create a table](#)
- [Step 2: Write data to a table using the console or AWS CLI](#)
- [Step 3: Read data from a table](#)
- [Step 4: Update data in a table](#)

Java code examples

Topics

- [Java: Setting your AWS credentials](#)
- [Java: Setting the AWS Region and endpoint](#)

This Developer Guide contains Java code snippets and ready-to-run programs. You can find these code examples in the following sections:

- [Working with items and attributes](#)
- [Working with tables and data in DynamoDB](#)
- [Query operations in DynamoDB](#)
- [Working with scans in DynamoDB](#)
- [Improving data access with secondary indexes](#)
- [Java 1.x: DynamoDBMapper](#)
- [Change data capture for DynamoDB Streams](#)

You can get started quickly by using Eclipse with the [AWS Toolkit for Eclipse](#). In addition to a full-featured IDE, you also get the AWS SDK for Java with automatic updates, and preconfigured templates for building AWS applications.

To run the Java code examples (using Eclipse)

1. Download and install the [Eclipse](#) IDE.

2. Download and install the [AWS Toolkit for Eclipse](#).
3. Start Eclipse, and on the **Eclipse** menu, choose **File**, **New**, and then **Other**.
4. In **Select a wizard**, choose **AWS**, choose **AWS Java Project**, and then choose **Next**.
5. In **Create an AWS Java**, do the following:
 - a. In **Project name**, enter a name for your project.
 - b. In **Select Account**, choose your credentials profile from the list.

If this is your first time using the [AWS Toolkit for Eclipse](#), choose **Configure AWS Accounts** to set up your AWS credentials.
6. Choose **Finish** to create the project.
7. From the **Eclipse** menu, choose **File**, **New**, and then **Class**.
8. In **Java Class**, enter a name for your class in **Name** (use the same name as the code example that you want to run), and then choose **Finish** to create the class.
9. Copy the code example from the documentation page into the Eclipse editor.
10. To run the code, choose **Run** on the Eclipse menu.

The SDK for Java provides thread-safe clients for working with DynamoDB. As a best practice, your applications should create one client and reuse the client between threads.

For more information, see the [AWS SDK for Java](#).

 **Note**

The code examples in this guide are intended for use with the latest version of the AWS SDK for Java.

If you are using the AWS Toolkit for Eclipse, you can configure automatic updates for the SDK for Java. To do this in Eclipse, go to **Preferences** and choose **AWS Toolkit**, **AWS SDK for Java**, **Download new SDKs automatically**.

Java: Setting your AWS credentials

The SDK for Java requires that you provide AWS credentials to your application at runtime. The code examples in this guide assume that you are using an AWS credentials file, as described in [Set up your AWS credentials](#) in the *AWS SDK for Java Developer Guide*.

The following is an example of an AWS credentials file named `~/.aws/credentials`, where the tilde character (~) represents your home directory.

```
[default]
aws_access_key_id = AWS access key ID goes here
aws_secret_access_key = Secret key goes here
```

Java: Setting the AWS Region and endpoint

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the `AmazonDynamoDB` properties.

The following code example instantiates a new `AmazonDynamoDB`.

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.regions.Regions;
...
// This client will default to US West (Oregon)
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
    .withRegion(Regions.US_WEST_2)
    .build();
```

You can use the `withRegion` method to run your code against DynamoDB in any Region where it is available. For a complete list, see [AWS regions and endpoints](#) in the *Amazon Web Services General Reference*.

If you want to run the code examples using DynamoDB locally on your computer, set the endpoint as follows.

AWS SDK V1

```
AmazonDynamoDB client =
    AmazonDynamoDBClientBuilder.standard().withEndpointConfiguration(
        new AwsClientBuilder.EndpointConfiguration("http://localhost:8000", "us-west-2"))
    .build();
```

AWS SDK V2

```
DynamoDbClient client = DynamoDbClient.builder()
    .endpointOverride(URI.create("http://localhost:8000"))
```

```
// The region is meaningless for local DynamoDb but required for client builder validation  
.region(Region.US_EAST_1)  
.credentialsProvider(StaticCredentialsProvider.create(  
AwsBasicCredentials.create("dummy-key", "dummy-secret")))  
.build();
```

.NET code examples

Topics

- [.NET: Setting your AWS credentials](#)
- [.NET: Setting the AWS Region and endpoint](#)

This guide contains .NET code snippets and ready-to-run programs. You can find these code examples in the following sections:

- [Working with items and attributes](#)
- [Working with tables and data in DynamoDB](#)
- [Query operations in DynamoDB](#)
- [Working with scans in DynamoDB](#)
- [Improving data access with secondary indexes](#)
- [.NET: Document model](#)
- [.NET: Object persistence model](#)
- [Change data capture for DynamoDB Streams](#)

You can get started quickly by using the AWS SDK for .NET with the Toolkit for Visual Studio.

To run the .NET code examples (using Visual Studio)

1. Download and install [Microsoft Visual Studio](#).
2. Download and install the [Toolkit for Visual Studio](#).
3. Start Visual Studio. Choose **File, New, Project**.
4. In **New Project**, choose **AWS Empty Project**, and then choose **OK**.
5. In **AWS Access Credentials**, choose **Use existing profile**, choose your credentials profile from the list, and then choose **OK**.

- If this is your first time using Toolkit for Visual Studio, choose **Use a new profile** to set up your AWS credentials.
6. In your Visual Studio project, choose the tab for your program's source code (**Program.cs**). Copy the code example from the documentation page into the Visual Studio editor, replacing any other code that you see in the editor.
 7. If you see error messages of the form The type or namespace name...could not be found, you need to install the AWS SDK assembly for DynamoDB as follows:
 - a. In Solution Explorer, open the context (right-click) menu for your project, and then choose **Manage NuGet Packages**.
 - b. In NuGet Package Manager, choose **Browse**.
 - c. In the search box, enter **AWSSDK.DynamoDBv2**, and wait for the search to complete.
 - d. Choose **AWSSDK.DynamoDBv2**, and then choose **Install**.
 - e. When the installation is complete, choose the **Program.cs** tab to return to your program.
 8. To run the code, choose **Start** in the Visual Studio toolbar.

The AWS SDK for .NET provides thread-safe clients for working with DynamoDB. As a best practice, your applications should create one client and reuse the client between threads.

For more information, see [AWS SDK for .NET](#).

 **Note**

The code examples in this guide are intended for use with the latest version of the AWS SDK for .NET.

.NET: Setting your AWS credentials

The AWS SDK for .NET requires that you provide AWS credentials to your application at runtime. The code examples in this guide assume that you are using the SDK Store to manage your AWS credentials file, as described in [Using the SDK store](#) in the *AWS SDK for .NET Developer Guide*.

The Toolkit for Visual Studio supports multiple sets of credentials from any number of accounts. Each set is referred to as a *profile*. Visual Studio adds entries to the project's App.config file so that your application can find the AWS credentials at runtime.

The following example shows the default App.config file that is generated when you create a new project using Toolkit for Visual Studio.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
    <appSettings>
        <add key="AWSProfileName" value="default"/>
        <add key="AWSRegion" value="us-west-2" />
    </appSettings>
</configuration>
```

At runtime, the program uses the default set of AWS credentials, as specified by the AWSProfileName entry. The AWS credentials themselves are kept in the SDK Store in encrypted form. The Toolkit for Visual Studio provides a graphical user interface for managing your credentials, all from within Visual Studio. For more information, see [Specifying credentials](#) in the [AWS Toolkit for Visual Studio User Guide](#).

 **Note**

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the AWSRegion entry in the App.config file. You can set AWSRegion to any Region where DynamoDB is available. For a complete list, see [AWS regions and endpoints](#) in the *Amazon Web Services General Reference*.

.NET: Setting the AWS Region and endpoint

By default, the code examples access DynamoDB in the US West (Oregon) Region. You can change the Region by modifying the AWSRegion entry in the App.config file. Or, you can change the Region by modifying the AmazonDynamoDBClient properties.

The following code example instantiates a new AmazonDynamoDBClient. The client is modified so that the code runs against DynamoDB in a different Region.

```
AmazonDynamoDBConfig clientConfig = new AmazonDynamoDBConfig();
// This client will access the US East 1 region.
clientConfig.RegionEndpoint = RegionEndpoint.USEast1;
AmazonDynamoDBClient client = new AmazonDynamoDBClient(clientConfig);
```

For a complete list of Regions, see [AWS regions and endpoints](#) in the *Amazon Web Services General Reference*.

If you want to run the code examples using DynamoDB locally on your computer, set the endpoint as follows.

```
AmazonDynamoDBConfig clientConfig = new AmazonDynamoDBConfig();
// Set the endpoint URL
clientConfig.ServiceURL = "http://localhost:8000";
AmazonDynamoDBClient client = new AmazonDynamoDBClient(clientConfig);
```

Programming Amazon DynamoDB with Python and Boto3

This guide provides an orientation to programmers wanting to use Amazon DynamoDB with Python. Learn about the different abstraction layers, configuration management, error handling, controlling retry policies, managing keep-alive, and more.

Topics

- [About Boto](#)
- [Using the Boto documentation](#)
- [Understanding the client and resource abstraction layers](#)
- [Using the table resource batch_writer](#)
- [Additional code examples that explore the client and resource layers](#)

- [Customizing the Config object](#)
- [Error handling](#)
- [Logging](#)
- [Event hooks](#)
- [Pagination and the Paginator](#)
- [Waiters](#)

About Boto

You can access DynamoDB from Python by using the official AWS SDK for Python, commonly referred to as **Boto3**. The name Boto (pronounced boh-toh) comes from a freshwater dolphin

native to the Amazon River. The Boto3 library is the library's third major version, first released in 2015. The Boto3 library is quite large, as it supports all AWS services, not just DynamoDB. This orientation targets only the parts of Boto3 relevant to DynamoDB.

Boto is maintained and published by AWS as open-source project hosted on GitHub. It's split into two packages: [Botocore](#) and [Boto3](#).

- **Botocore** provides the low-level functionality. In Botocore you'll find the client, session, credentials, config, and exception classes.
- **Boto3** builds on top of Botocore. It offers a higher-level, more Pythonic interface. Specifically, it exposes a DynamoDB table as a Resource and offers a simpler, more elegant interface compared to the lower-level, service-oriented client interface.

Because these projects are hosted on GitHub, you can view the source code, track open issues, or submit your own issues.

Using the Boto documentation

Get started with the Boto documentation with the following resources:

- Begin with the [Quickstart section](#) that provides a solid starting point for the package installation. Go there for instructions on getting Boto3 installed if it's not already (Boto3 is often automatically available within AWS services such as AWS Lambda).
- After that, focus on the documentation's [DynamoDB guide](#). It shows you how to perform the basic DynamoDB activities: create and delete a table, manipulate items, run batch operations, run a query, and perform a scan. Its examples use the **resource** interface. When you see `boto3.resource('dynamodb')` that indicates you're using the higher-level **resource** interface.
- After the guide, you can review the [DynamoDB reference](#). This landing page provides an exhaustive list of the classes and methods available to you. At the top, you'll see the `DynamoDB.Client` class. This provides low-level access to all the control-plane and data-plane operations. At the bottom, look at the `DynamoDB.ServiceResource` class. This is the higher-level Pythonic interface. With it you can create a table, do batch operations across tables, or obtain a `DynamoDB.ServiceResource.Table` instance for table-specific actions.

Understanding the client and resource abstraction layers

The two interfaces you'll be working with are the **client** interface and the **resource** interface.

- The low-level **client** interface provides a 1-to-1 mapping to the underlying service API. Every API offered by DynamoDB is available through the client. This means the client interface can provide complete functionality, but it's often more verbose and complex to use.
- The higher-level **resource** interface does not provide a 1-to-1 mapping of the underlying service API. However, it provides methods that make it more convenient for you to access the service such as `batch_writer`.

Here's an example of inserting an item using the client interface. Notice how all values are passed as a map with the key indicating their type ('S' for string, 'N' for number) and their value as a string. This is known as DynamoDB JSON format.

```
import boto3

dynamodb = boto3.client('dynamodb')

dynamodb.put_item(
    TableName='YourTableName',
    Item={
        'pk': {'S': 'id#1'},
        'sk': {'S': 'cart#123'},
        'name': {'S': 'SomeName'},
        'inventory': {'N': '500'},
        # ... more attributes ...
    }
)
```

Here's the same PutItem operation using the resource interface. The data typing is implicit:

```
import boto3

dynamodb = boto3.resource('dynamodb')

table = dynamodb.Table('YourTableName')

table.put_item(
    Item={
```

```
'pk': 'id#1',
'sk': 'cart#123',
'name': 'SomeName',
'inventory': 500,
# ... more attributes ...
}
)
```

If needed, you can convert between regular JSON and DynamoDB JSON using the `TypeSerializer` and `TypeDeserializer` classes provided with `boto3`:

```
def dynamo_to_python(dynamo_object: dict) -> dict:
    deserializer = TypeDeserializer()
    return {
        k: deserializer.deserialize(v)
        for k, v in dynamo_object.items()
    }

def python_to_dynamo(python_object: dict) -> dict:
    serializer = TypeSerializer()
    return {
        k: serializer.serialize(v)
        for k, v in python_object.items()
    }
```

Here is how to perform a query using the client interface. It expresses the query as a JSON construct. It uses a `KeyConditionExpression` string which requires variable substitution to handle any potential keyword conflicts:

```
import boto3

client = boto3.client('dynamodb')

# Construct the query
response = client.query(
    TableName='YourTableName',
    KeyConditionExpression='pk = :pk_val AND begins_with(sk, :sk_val)',
    FilterExpression='#name = :name_val',
    ExpressionAttributeValues={
        ':pk_val': {'S': 'id#1'},
        ':sk_val': {'S': 'cart#'}
    }
)
```

```
    ':name_val': {'S': 'SomeName'},
},
ExpressionAttributeNames={
    '#name': 'name',
}
)
```

The same query operation using the resource interface can be shortened and simplified:

```
import boto3
from boto3.dynamodb.conditions import Key, Attr

dynamodb = boto3.resource('dynamodb')
table = dynamodb.Table('YourTableName')

response = table.query(
    KeyConditionExpression=Key('pk').eq('id#1') & Key('sk').begins_with('cart#'),
    FilterExpression=Attr('name').eq('SomeName')
)
```

As a final example, imagine you want to get the approximate size of a table (which is metadata kept on the table that is updated about every 6 hours). With the client interface, you do a `describe_table()` operation and pull the answer from the JSON structure returned:

```
import boto3

dynamodb = boto3.client('dynamodb')

response = dynamodb.describe_table(TableName='YourTableName')
size = response['Table']['TableSizeBytes']
```

With the resource interface, the table performs the describe operation implicitly and presents the data directly as an attribute:

```
import boto3

dynamodb = boto3.resource('dynamodb')

table = dynamodb.Table('YourTableName')
size = table.table_size_bytes
```

Note

When considering whether to develop using the client or resource interface, be aware that new features will not be added to the resource interface per the [resource documentation](#): “The AWS Python SDK team does not intend to add new features to the resources interface in boto3. Existing interfaces will continue to operate during boto3’s lifecycle. Customers can find access to newer service features through the client interface.”

Using the table resource batch_writer

One convenience available only with the higher-level table resource is the `batch_writer`. DynamoDB supports batch write operations allowing up to 25 put or delete operations in one network request. Batching like this improves efficiency by minimizing network round trips.

With the low-level client library, you use the `client.batch_write_item()` operation to run batches. You must manually split your work into batches of 25. After each operation, you also have to request to receive a list of unprocessed items (some of the write operations may succeed while others could fail). You then have to pass those unprocessed items again into a later `batch_write_item()` operation. There's a significant amount of boilerplate code.

The [Table.batch_writer](#) method creates a context manager for writing objects in a batch. It presents an interface where it seems as if you're writing items one at a time, but internally it's buffering and sending the items in batches. It also handles unprocessed item retries implicitly.

```
dynamodb = boto3.resource('dynamodb')

table = dynamodb.Table('YourTableName')

movies = # long list of movies in {'pk': 'val', 'sk': 'val', etc} format
with table.batch_writer() as writer:
    for movie in movies:
        writer.put_item(Item=movie)
```

Additional code examples that explore the client and resource layers

You can also refer to the following code sample repositories that explore usage of the various functions, using both client and resource:

- [Official AWS single-action code examples.](#)
- [Official AWS scenario-oriented code examples.](#)
- [Community-maintained single-action code examples.](#)

Understanding how the Client and Resource objects interact with sessions and threads

The Resource object is not thread safe and should not be shared across threads or processes. Refer to the [guide on Resource](#) for more details.

The Client object, in contrast, is generally thread safe, except for specific advanced features. Refer to the [guide on Clients](#) for more details.

The Session object is not thread safe. So, each time you make a Client or Resource in a multi-threaded environment you should create a new Session first and then make the Client or Resource from the Session. Refer to the [guide on Sessions](#) for more details.

When you call the `boto3.resource()`, you're implicitly using the default Session. This is convenient for writing single-threaded code. When writing multi-threaded code, you'll want to first construct a new Session for each thread and then retrieve the resource from that Session:

```
# Explicitly create a new Session for this thread
session = boto3.Session()
dynamodb = session.resource('dynamodb')
```

Customizing the Config object

When constructing a Client or Resource object, you can pass optional named parameters to customize behavior. The parameter named `config` unlocks a variety of functionality. It's an instance of `botocore.client.Config` and the [reference documentation for Config](#) shows everything it exposes for you to control. The [guide to Configuration](#) provides a good overview.

Note

You can modify many of these behavioral settings at the Session level, within the AWS configuration file, or as environment variables.

Config for timeouts

One use of a custom config is to adjust networking behaviors:

- **connect_timeout (float or int)** – The time in seconds till a timeout exception is thrown when attempting to make a connection. The default is 60 seconds.
- **read_timeout (float or int)** – The time in seconds till a timeout exception is thrown when attempting to read from a connection. The default is 60 seconds.

Timeouts of 60 seconds are excessive for DynamoDB. It means a transient network glitch will cause a minute's delay for the client before it can try again. The following code shortens the timeouts to a second:

```
import boto3
from botocore.config import Config

my_config = Config(
    connect_timeout = 1.0,
    read_timeout = 1.0
)
dynamodb = boto3.resource('dynamodb', config=my_config)
```

For more discussion about timeouts, see [Tuning AWS Java SDK HTTP request settings for latency-aware DynamoDB applications](#). Note the Java SDK has more timeout configurations than Python.

Config for keep-alive

If you're using botocore 1.27.84 or later, you can also control **TCP Keep-Alive**:

- **tcp_keepalive (bool)** - Enables the TCP Keep-Alive socket option used when creating new connections if set to True (defaults to False). This is only available starting with botocore 1.27.84.

Setting TCP Keep-Alive to True can reduce average latencies. Here's sample code that conditionally sets TCP Keep-Alive to true when you have the right botocore version:

```
import botocore
import boto3
from botocore.config import Config
from distutils.version import LooseVersion
```

```
required_version = "1.27.84"
current_version = botocore.__version__

my_config = Config(
    connect_timeout = 0.5,
    read_timeout = 0.5
)
if LooseVersion(current_version) > LooseVersion(required_version):
    my_config = my_config.merge(Config(tcp_keepalive = True))

dynamodb = boto3.resource('dynamodb', config=my_config)
```

Note

TCP Keep-Alive is different than HTTP Keep-Alive. With TCP Keep-Alive, small packets are sent by the underlying operating system over the socket connection to keep the connection alive and immediately detect any drops. With HTTP Keep-Alive, the web connection built on the underlying socket gets reused. HTTP Keep-Alive is always enabled with boto3.

There's a limit to how long an idle connection can be kept alive. Consider sending periodic requests (say every minute) if you have an idle connection but want the next request to use an already-established connection.

Config for retries

The config also accepts a dictionary called **retries** where you can specify your desired retry behavior. Retries happen within the SDK when the SDK receives an error and the error is of a transient type. If an error is retried internally (and a retry eventually produces a successful response), there's no error seen from the calling code's perspective, just a slightly elevated latency. Here are the values you can specify:

- **max_attempts** – An integer representing the maximum number of retry attempts that will be made on a single request. For example, setting this value to 2 will result in the request being retried at most two times after the initial request. Setting this value to 0 will result in no retries ever being attempted after the initial request.
- **total_max_attempts** – An integer representing the maximum number of total attempts that will be made on a single request. This includes the initial request, so a value of 1 indicates that no requests will be retried. If **total_max_attempts** and **max_attempts** are both

provided, `total_max_attempts` takes precedence. `total_max_attempts` is preferred over `max_attempts` because it maps to the `AWS_MAX_ATTEMPTS` environment variable and the `max_attempts` config file value.

- **mode** – A string representing the type of retry mode botocore should use. Valid values are:
 - **legacy** – The default mode. Waits 50ms the first retry, then uses exponential backoff with a base factor of 2. For DynamoDB, it performs up to 10 total max attempts (unless overridden with the above).

 **Note**

With exponential backoff, the last attempt will wait almost 13 seconds.

- **standard** – Named standard because it's more consistent with other AWS SDKs. Waits a random time from 0ms to 1,000ms for the first retry. If another retry is necessary, it picks another random time from 0ms to 1,000ms and multiplies it by 2. If an additional retry is necessary, it does the same random pick multiplied by 4, and so on. Each wait is capped at 20 seconds. This mode will perform retries on more detected failure conditions than the legacy mode. For DynamoDB, it performs up to 3 total max attempts (unless overridden with the above).
- **adaptive** - An experimental retry mode that includes all the functionality of standard mode but adds automatic client-side throttling. With adaptive rate limiting, SDKs can slow down the rate at which requests are sent to better accommodate the capacity of AWS services. This is a provisional mode whose behavior might change.

An expanded definition of these retry modes can be found in the [guide to retries](#) as well as in the [Retry behavior topic in the SDK reference](#).

Here's an example that explicitly uses the legacy retry policy with a maximum of 3 total requests (2 retries):

```
import boto3
from botocore.config import Config

my_config = Config(
    connect_timeout = 1.0,
    read_timeout = 1.0,
    retries = {
        'mode': 'legacy',
```

```
'total_max_attempts': 3
}
)
dynamodb = boto3.resource('dynamodb', config=my_config)
```

Because DynamoDB is a highly-available, low-latency system, you may want to be more aggressive with the speed of retries than the built-in retry policies allow. You can implement your own retry policy by setting the max attempts to 0, catching the exceptions yourself, and retrying as appropriate from your own code instead of relying on boto3 to do implicit retries.

If you manage your own retry policy, you'll want to differentiate between throttles and errors:

- A **throttle** (indicated by a `ProvisionedThroughputExceededException` or `ThrottlingException`) indicates a healthy service that's informing you that you've exceeded your read or write capacity on a DynamoDB table or partition. Every millisecond that passes, a bit more read or write capacity is made available, so you can retry quickly (such as every 50ms) to attempt to access that newly released capacity. With throttles, you don't especially need exponential backoff because throttles are lightweight for DynamoDB to return and incur no per-request charge to you. Exponential backoff assigns longer delays to client threads that have already waited the longest, which statistically extends the p50 and p99 outward.
- An **error** (indicated by an `InternalServerError` or a `ServiceUnavailable`, among others) indicates a transient issue with the service. This can be for the whole table or possibly just the partition you're reading from or writing to. With errors, you can pause longer before retries (such as 250ms or 500ms) and use jitter to stagger the retries.

Config for max pool connections

Lastly, the config lets you control the connection pool size:

- **max_pool_connections (int)** – The maximum number of connections to keep in a connection pool. If this value is not set, the default value of 10 is used.

This option controls the maximum number of HTTP connections to keep pooled for reuse. A different pool is kept per Session. If you anticipate more than 10 threads going against clients or resources built off the same Session, you should consider raising this, so threads don't have to wait on other threads using a pooled connection.

```
import boto3
```

```
from botocore.config import Config

my_config = Config(
    max_pool_connections = 20
)

# Setup a single session holding up to 20 pooled connections
session = boto3.Session(my_config)

# Create up to 20 resources against that session for handing to threads
# Notice the single-threaded access to the Session and each Resource
resource1 = session.resource('dynamodb')
resource2 = session.resource('dynamodb')
# etc
```

Error handling

AWS service exceptions aren't all statically defined in Boto3. This is because errors and exceptions from AWS services vary widely and are subject to change. Boto3 wraps all service exceptions as a `ClientError` and exposes the details as structured JSON. For example, an error response might be structured like this:

```
{
    'Error': {
        'Code': 'SomeServiceException',
        'Message': 'Details/context around the exception or error'
    },
    'ResponseMetadata': {
        'RequestId': '1234567890ABCDEF',
        'HostId': 'host ID data will appear here as a hash',
        'HTTPStatusCode': 400,
        'HTTPHeaders': {'header metadata key/values will appear here'},
        'RetryAttempts': 0
    }
}
```

The following code catches any `ClientError` exceptions and looks at the string value of the `Code` within the `Error` to determine what action to take:

```
import botocore
import boto3
```

```
dynamodb = boto3.client('dynamodb')

try:
    response = dynamodb.put_item(...)

except botocore.exceptions.ClientError as err:
    print('Error Code: {}'.format(err.response['Error']['Code']))
    print('Error Message: {}'.format(err.response['Error']['Message']))
    print('Http Code: {}'.format(err.response['ResponseMetadata']['HTTPStatusCode']))
    print('Request ID: {}'.format(err.response['ResponseMetadata']['RequestId']))

    if err.response['Error']['Code'] in ('ProvisionedThroughputExceeded', 'ThrottlingException'):
        print("Received a throttle")
    elif err.response['Error']['Code'] == 'InternalServerError':
        print("Received a server error")
    else:
        raise err
```

Some (but not all) exception codes have been materialized as top-level classes. You can choose to handle these directly. When using the Client interface, these exceptions are dynamically populated on your client and you catch these exceptions using your client instance, like this:

```
except ddb_client.exceptions.ProvisionedThroughputExceeded:
```

When using the Resource interface, you have to use `.meta.client` to traverse from the resource to the underlying Client to access the exceptions, like this:

```
except ddb_resource.meta.client.exceptions.ProvisionedThroughputExceeded:
```

To review the list of materialized exception types, you can generate the list dynamically:

```
ddb = boto3.client("dynamodb")
print([e for e in dir(ddb.exceptions) if e.endswith('Exception') or
      e.endswith('Error')])
```

When doing a write operation with a condition expression, you can request that if the expression fails the value of the item should be returned in the error response.

```
try:
    response = table.put_item(
```

```
        Item=item,
        ConditionExpression='attribute_not_exists(pk)',
        ReturnValuesOnConditionCheckFailure='ALL_OLD'
    )
except table.meta.client.exceptions.ConditionalCheckFailedException as e:
    print('Item already exists:', e.response['Item'])
```

For further reading on error handling and exceptions:

- The [boto3 guide on error handling](#) has more information on error handling techniques.
- The [DynamoDB developer guide section on programming errors](#) lists what errors you might encounter.
- The [Common Errors section in the API reference](#).
- The documentation on each API operation lists what errors that call might generate (for example [BatchWriteItem](#)).

Logging

The boto3 library integrates with Python's built-in logging module for tracking what happens during a session. To control logging levels, you can configure the logging module:

```
import logging

logging.basicConfig(level=logging.INFO)
```

This configures the root logger to log INFO and above level messages. Logging messages which are less severe than level will be ignored. Logging levels include DEBUG, INFO, WARNING, ERROR, and CRITICAL. The default is WARNING.

Loggers in boto3 are hierarchical. The library uses a few different loggers, each corresponding to different parts of the library. You can separately control the behavior of each:

- **boto3**: The main logger for the boto3 module.
- **botocore**: The main logger for the botocore package.
- **botocore.auth**: Used for logging AWS signature creation for requests.
- **botocore.credentials**: Used for logging the process of credential fetching and refresh.
- **botocore.endpoint**: Used for logging request creation before it's sent over the network.

- **botocore.hooks**: Used for logging events triggered in the library.
- **botocore.loaders**: Used for logging when parts of AWS service models are loaded.
- **botocore.parsers**: Used for logging AWS service responses before they're parsed.
- **botocore.retryhandler**: Used for logging the processing of AWS service request retries (legacy mode).
- **botocore.retries.standard**: Used for logging the processing of AWS service request retries (standard or adaptive mode).
- **botocore.utils**: Used for logging miscellaneous activities in the library.
- **botocore.waiter**: Used for logging the functionality of waiters, which poll an AWS service until a certain state is reached.

Other libraries log as well. Internally, boto3 uses the third party urllib3 for HTTP connection handling. When latency is important, you can watch its logs to ensure your pool is being well utilized by seeing when urllib3 establishes a new connection or closes an idle one down.

- **urllib3.connectionpool**: Use for logging connection pool handling events.

The following code snippet sets most logging to INFO with DEBUG logging for endpoint and connection pool activity:

```
import logging

logging.getLogger('boto3').setLevel(logging.INFO)
logging.getLogger('botocore').setLevel(logging.INFO)
logging.getLogger('botocore.endpoint').setLevel(logging.DEBUG)
logging.getLogger('urllib3.connectionpool').setLevel(logging.DEBUG)
```

Event hooks

Botocore emits events during various parts of its execution. You can register handlers for these events so that whenever an event is emitted, your handler will be called. This lets you extend the behavior of botocore without having to modify the internals.

For instance, let's say you want to keep track of every time a PutItem operation is called on any DynamoDB table in your application. You might register on the 'provide-client-params.dynamodb.PutItem' event to catch and log every time a PutItem operation is invoked on the associated Session. Here's an example:

```
import boto3
import botocore
import logging

def log_put_params(params, **kwargs):
    if 'TableName' in params and 'Item' in params:
        logging.info(f"PutItem on table {params['TableName']}: {params['Item']}")

logging.basicConfig(level=logging.INFO)

session = boto3.Session()
event_system = session.events

# Register our interest in hooking in when the parameters are provided to PutItem
event_system.register('provide-client-params.dynamodb.PutItem', log_put_params)

# Now, every time you use this session to put an item in DynamoDB,
# it will log the table name and item data.
dynamodb = session.resource('dynamodb')
table = dynamodb.Table('YourTableName')
table.put_item(
    Item={
        'pk': '123',
        'sk': 'cart#123',
        'item_data': 'YourItemData',
        # ... more attributes ...
    }
)
```

Within the handler, you can even manipulate the params programmatically to change behavior:

```
params['TableName'] = "NewTableName"
```

For more information on events, see the [botocore documentation on events](#) and the [boto3 documentation on events](#).

Pagination and the Paginator

Some requests, such as Query and Scan, limit the size of data returned on a single request and require you to make repeated requests to pull subsequent pages.

You can control the maximum number of items to be read for each page with the `limit` parameter. For example, if you want the last 10 items, you can use `limit` to retrieve only the last 10. Note the limit is how much should be read from the table before any filtering is applied. There's no way to specify you want exactly 10 after filtering; you can only control the pre-filtered count and check client-side when you've actually retrieved 10. Regardless of the limit, every response always has a maximum size of 1 MB.

If the response includes a `LastEvaluatedKey`, it indicates the response ended because it hit a count or size limit. The key is the last key evaluated for the response. You can retrieve this `LastEvaluatedKey` and pass it to a follow-up call as `ExclusiveStartKey` to read the next chunk from that starting point. When there's no `LastEvaluatedKey` returned that, means there are no more items matching the Query or Scan.

Here's a simple example (using the Resource interface, but the Client interface has the same pattern) that reads at most 100 items per page and loops until all items have been read.

```
import boto3

dynamodb = boto3.resource('dynamodb')
table = dynamodb.Table('YourTableName')

query_params = {
    'KeyConditionExpression': Key('pk').eq('123') & Key('sk').gt(1000),
    'Limit': 100
}

while True:
    response = table.query(**query_params)

    # Process the items however you like
    for item in response['Items']:
        print(item)

    # No LastEvaluatedKey means no more items to retrieve
    if 'LastEvaluatedKey' not in response:
        break

    # If there are possibly more items, update the start key for the next page
    query_params['ExclusiveStartKey'] = response['LastEvaluatedKey']
```

For convenience, boto3 can do this for you with Paginators. However, it only works with the Client interface. Here's the code rewritten to use Paginators:

```
import boto3

dynamodb = boto3.client('dynamodb')

paginator = dynamodb.get_paginator('query')

query_params = {
    'TableName': 'YourTableName',
    'KeyConditionExpression': 'pk = :pk_val AND sk > :sk_val',
    'ExpressionAttributeValues': {
        ':pk_val': {'S': '123'},
        ':sk_val': {'N': '1000'},
    },
    'Limit': 100
}

page_iterator = paginator.paginate(**query_params)

for page in page_iterator:
    # Process the items however you like
    for item in page['Items']:
        print(item)
```

For more information, see the [Guide on Paginators](#) and the [API reference for DynamoDB.Paginator.Query](#).

 **Note**

Paginators also have their own configuration settings named `MaxItems`, `StartingToken`, and `PageSize`. For paginating with DynamoDB, you should ignore these settings.

Waiters

Waiters provide the ability to wait for something to complete before proceeding. At present, they only support waiting for a table to be created or deleted. In the background, the waiter operation does a check for you every 20 seconds up to 25 times. You could do this yourself, but using a waiter is elegant when writing automation.

This code shows how to wait for a particular table to have been created:

```
# Create a table, wait until it exists, and print its ARN
response = client.create_table(...)
waiter = client.get_waiter('table_exists')
waiter.wait(TableName='YourTableName')
print('Table created:', response['TableDescription']['TableArn'])
```

For more information, see the [Guide to Waiters](#) and [Reference on Waiters](#).

Programming Amazon DynamoDB with JavaScript

This guide provides an orientation to programmers wanting to use Amazon DynamoDB with JavaScript. Learn about the AWS SDK for JavaScript, abstraction layers available, configuring connections, handling errors, defining retry policies, managing keep-alive, and more.

About AWS SDK for JavaScript

The AWS SDK for JavaScript provides access to AWS services using either browser scripts or Node.js. This documentation focuses on the latest version of the SDK (V3). The AWS SDK for JavaScript V3

is maintained by AWS as an [open-source project hosted on GitHub](#). Issues and feature requests are public and you can access them on the issues page for the GitHub repository.

JavaScript V2 is similar to V3, but contains syntax differences. V3 is more modular, making it easier to ship smaller dependencies, and has first-class TypeScript support. We recommend using the latest version of the SDK.

Using the AWS SDK for JavaScript V3

You can add the SDK to your Node.js application using the Node Package Manager. The examples below show how to add the most common SDK packages for working with DynamoDB.

- `npm install @aws-sdk/client-dynamodb`
- `npm install @aws-sdk/lib-dynamodb`
- `npm install @aws-sdk/util-dynamodb`

Installing packages adds references to the dependency section of your package.json project file. You have the option to use the newer ECMAScript module syntax. For further details on these two approaches, see the Considerations section.

Accessing JavaScript documentation

Get started with JavaScript documentation with the following resources:

- Access the [Developer guide](#) for core JavaScript documentation. Installation instructions are located in the **Setting up** section.
- Access the [API reference](#) documentation to explore all available classes and methods.
- The SDK for JavaScript supports many AWS services other than DynamoDB. Use the following procedure to locate specific API coverage for DynamoDB:
 1. From **Services**, choose **DynamoDB and Libraries**. This documents the low-level client.
 2. Choose **lib-dynamodb**. This documents the high-level client. The two clients represent two different abstraction layers that you have the choice to use. See the section below for more information about abstraction layers.

Abstraction layers

The SDK for JavaScript V3 has a low-level client (`DynamoDBClient`) and a high-level client (`DynamoDBDocumentClient`).

Topics

- [Low-level client \(`DynamoDBClient`\)](#)
- [High-level client \(`DynamoDBDocumentClient`\)](#)

Low-level client (`DynamoDBClient`)

The low-level client provides no extra abstractions over the underlying wire protocol. It gives you full control over all aspects of communication, but because there are no abstractions, you must do things like provide item definitions using the DynamoDB JSON format.

As the example below shows, with this format data types must be stated explicitly. An `S` indicates a string value and an `N` indicates a number value. Numbers on the wire are always sent as strings tagged as number types to ensure no loss in precision. The low-level API calls have a naming pattern such as `PutItemCommand` and `GetItemCommand`.

The following example is using low-level client with Item defined using DynamoDB JSON:

```
const { DynamoDBClient, PutItemCommand } = require("@aws-sdk/client-dynamodb");

const client = new DynamoDBClient({});

async function addProduct() {
  const params = {
    TableName: "products",
    Item: {
      "id": { S: "Product01" },
      "description": { S: "Hiking Boots" },
      "category": { S: "footwear" },
      "sku": { S: "hiking-sku-01" },
      "size": { N: "9" }
    }
  };
  try {
    const data = await client.send(new PutItemCommand(params));
    console.log('result : ' + JSON.stringify(data));
  }
}
```

```
    } catch (error) {
      console.error("Error:", error);
    }
}
addProduct();
```

High-level client (**DynamoDBDocumentClient**)

The high-level DynamoDB document client offers built-in convenience features, such as eliminating the need to manually marshal data and allowing for direct reads and writes using standard JavaScript objects. The [documentation for lib-dynamodb](#) provides the list of advantages.

To instantiate the `DynamoDBDocumentClient`, construct a low-level `DynamoDBClient` and then wrap it with a `DynamoDBDocumentClient`. The function naming convention differs slightly between the two packages. For instance, the low-level uses `PutItemCommand` while the high-level uses `PutCommand`. The distinct names allow both sets of functions to coexist in the same context, allowing you to mix both in the same script.

```
const { DynamoDBClient } = require("@aws-sdk/client-dynamodb");
const { DynamoDBDocumentClient, PutCommand } = require("@aws-sdk/lib-dynamodb");

const client = new DynamoDBClient({});

const docClient = DynamoDBDocumentClient.from(client);

async function addProduct() {
  const params = {
    TableName: "products",
    Item: {
      id: "Product01",
      description: "Hiking Boots",
      category: "footwear",
      sku: "hiking-sku-01",
      size: 9,
    },
  };
}

try {
  const data = await docClient.send(new PutCommand(params));
  console.log('result : ' + JSON.stringify(data));
} catch (error) {
  console.error("Error:", error);
```

```
    }
}

addProduct();
```

The pattern of usage is consistent when you're reading items using API operations such as `GetItem`, `Query`, or `Scan`.

Using the marshall utility function

You can use the low-level client and marshall or unmarshall the data types on your own. The utility package, [util-dynamodb](#), has a `marshall()` utility function that accepts JSON and produces DynamoDB JSON, as well as an `unmarshall()` function, that does the reverse. The following example uses the low-level client with data marshalling handled by the `marshall()` call.

```
const { DynamoDBClient, PutItemCommand } = require("@aws-sdk/client-dynamodb");
const { marshall } = require("@aws-sdk/util-dynamodb");

const client = new DynamoDBClient({});

async function addProduct() {
  const params = {
    TableName: "products",
    Item: marshall({
      id: "Product01",
      description: "Hiking Boots",
      category: "footwear",
      sku: "hiking-sku-01",
      size: 9,
    }),
  };
  try {
    const data = await client.send(new PutItemCommand(params));
  } catch (error) {
    console.error("Error:", error);
  }
}
addProduct();
```

Reading items

To read a single item from DynamoDB, you use the `GetItem` API operation. Similar to the `PutItem` command, you have the choice to use either the low-level client or the high-level Document client. The example below demonstrates using the high-level Document client to retrieve an item.

```
const { DynamoDBClient } = require("@aws-sdk/client-dynamodb");
const { DynamoDBDocumentClient, GetCommand } = require("@aws-sdk/lib-dynamodb");

const client = new DynamoDBClient({});

const docClient = DynamoDBDocumentClient.from(client);

async function getProduct() {
  const params = {
    TableName: "products",
    Key: {
      id: "Product01",
    },
  };
  try {
    const data = await docClient.send(new GetCommand(params));
    console.log('result : ' + JSON.stringify(data));
  } catch (error) {
    console.error("Error:", error);
  }
}

getProduct();
```

Use the `Query` API operation to read multiple items. You can use the low-level client or the Document client. The example below uses the high-level Document client.

```
const { DynamoDBClient } = require("@aws-sdk/client-dynamodb");
const {
  DynamoDBDocumentClient,
  QueryCommand,
} = require("@aws-sdk/lib-dynamodb");

const client = new DynamoDBClient({});
```

```
const docClient = DynamoDBDocumentClient.from(client);

async function productSearch() {
  const params = {
    TableName: "products",
    IndexName: "GSI1",
    KeyConditionExpression: "#category = :category and begins_with(#sku, :sku)",
    ExpressionAttributeNames: {
      "#category": "category",
      "#sku": "sku",
    },
    ExpressionAttributeValues: {
      ":category": "footwear",
      ":sku": "hiking",
    },
  };
}

try {
  const data = await docClient.send(new QueryCommand(params));
  console.log('result : ' + JSON.stringify(data));
} catch (error) {
  console.error("Error:", error);
}
}

productSearch();
```

Conditional writes

DynamoDB write operations can specify a logical condition expression that must evaluate to true for the write to proceed. If the condition does not evaluate to true, the write operation generates an exception. The condition expression can check if the item already exists or if its attributes match certain constraints.

ConditionExpression = "version = :ver AND size(VideoClip) < :maxsize"

When the conditional expression fails, you can use `ReturnValuesOnConditionCheckFailure` to request that the error response include the item that didn't satisfy the conditions to deduce what the problem was. For more details, see [Handle conditional write errors in high concurrency scenarios with Amazon DynamoDB](#).

```
try {
```

```
const response = await client.send(new PutCommand({
    TableName: "YourTableName",
    Item: item,
    ConditionExpression: "attribute_not_exists(pk)",
    ReturnValuesOnConditionCheckFailure: "ALL_OLD"
}));
} catch (e) {
    if (e.name === 'ConditionalCheckFailedException') {
        console.log('Item already exists:', e.Item);
    } else {
        throw e;
    }
}
```

Additional code examples showing other aspects of JavaScript SDK V3 usage are available in the [JavaScript SDK V3 Documentation](#) and under the [DynamoDB-SDK-Examples GitHub repository](#).

Pagination

Topics

- [Using the paginateScan convenience method](#)

Read requests such as Scan or Query will likely return multiple items in a dataset. If you perform a Scan or Query with a Limit parameter, then once the system has read that many items, a partial response will be sent, and you'll need to paginate to retrieve additional items.

The system will only read a maximum of 1 megabyte of data per request. If you're including a Filter expression, the system will still read a megabyte, at maximum, of data from disk, but will return the items of that megabyte that match the filter. The filter operation could return 0 items for a page, but still require further pagination before the search is exhausted.

You should look for LastEvaluatedKey in the response and using it as the ExclusiveStartKey parameter in a subsequent request to continue data retrieval. This serves as a bookmark as noted in the following example.

 **Note**

The sample passes a null lastEvaluatedKey as the ExclusiveStartKey on the first iteration and this is allowed.

Example using the LastEvaluatedKey:

```
const { DynamoDBClient, ScanCommand } = require("@aws-sdk/client-dynamodb");

const client = new DynamoDBClient({});

async function paginatedScan() {
  let lastEvaluatedKey;
  let pageCount = 0;

  do {
    const params = {
      TableName: "products",
      ExclusiveStartKey: lastEvaluatedKey,
    };

    const response = await client.send(new ScanCommand(params));
    pageCount++;
    console.log(`Page ${pageCount}, Items:`, response.Items);
    lastEvaluatedKey = response.LastEvaluatedKey;
  } while (lastEvaluatedKey);
}

paginatedScan().catch((err) => {
  console.error(err);
});
```

Using the paginateScan convenience method

The SDK provides convenience methods called `paginateScan` and `paginateQuery` that do this work for you and makes the repeated requests behind the scenes. Specify the max number of items to read per request using the standard `Limit` parameter.

```
const { DynamoDBClient, paginateScan } = require("@aws-sdk/client-dynamodb");

const client = new DynamoDBClient({});

async function paginatedScanUsingPaginator() {
  const params = {
    TableName: "products",
    Limit: 100
```

```
};

const paginator = paginateScan({client}, params);

let pageCount = 0;

for await (const page of paginator) {
    pageCount++;
    console.log(`Page ${pageCount}, Items:`, page.Items);
}

paginatedScanUsingPaginator().catch((err) => {
    console.error(err);
});
```

 **Note**

Performing full table scans regularly is not a recommended access pattern unless the table is small.

Specifying configuration

Topics

- [Config for timeouts](#)
- [Config for keep-alive](#)
- [Config for retries](#)

When setting up the `DynamoDBClient`, you can specify various configuration overrides by passing a configuration object to the constructor. For example, you can specify the Region to connect to if it's not already known to the calling context or the endpoint URL to use. This is useful if you want to target a DynamoDB Local instance for development purposes.

```
const client = new DynamoDBClient({
    region: "eu-west-1",
    endpoint: "http://localhost:8000",
});
```

Config for timeouts

DynamoDB uses HTTPS for client-server communication. You can control some aspects of the HTTP layer by providing a `NodeHttpHandler` object. For example, you can adjust the key timeout values `connectionTimeout` and `requestTimeout`. The `connectionTimeout` is the maximum duration, in milliseconds, that the client will wait while trying to establish a connection before giving up.

The `requestTimeout` defines how long the client will wait for a response after a request has been sent, also in milliseconds. The defaults for both are zero, meaning the timeout is disabled and there's no limit on how long the client will wait if the response does not arrive. You should set the timeouts to something reasonable so in the event of a network issue the request will error out and a new request can be initiated. For example:

```
import { DynamoDBClient } from "@aws-sdk/client-dynamodb";
import { NodeHttpHandler } from "@smithy/node-http-handler";

const requestHandler = new NodeHttpHandler({
  connectionTimeout: 2000,
  requestTimeout: 2000,
});

const client = new DynamoDBClient({
  requestHandler
});
```

Note

The example provided uses the [Smithy](#) import. Smithy is a language for defining services and SDKs, open-source and maintained by AWS.

In addition to configuring timeout values, you can set the maximum number of sockets, which allows for an increased number of concurrent connections per origin. The developer guide includes [details on configuring the `maxSockets` parameter](#).

Config for keep-alive

When using HTTPS, the first request always takes some back-and-forth communication to establish a secure connection. HTTP Keep-Alive allows subsequent requests to reuse the already-established

connection, making the requests more efficient and lowering latency. HTTP Keep-Alive is enabled by default with JavaScript V3.

There's a limit to how long an idle connection can be kept alive. Consider sending periodic requests, maybe every minute, if you have an idle connection but want the next request to use an already-established connection.

Note

Note that in the older V2 of the SDK, keep-alive was off by default, meaning each connection would get closed immediately after use. If using V2, you can override this setting.

Config for retries

When the SDK receives an error response and the error is resumable as determined by the SDK, such as a throttling exception or a temporary service exception, it will retry again. This happens invisibly to you as the caller, except that you might notice the request took longer to succeed.

The SDK for JavaScript V3 will make 3 total requests, by default, before giving up and passing the error into the calling context. You can adjust the number and frequency of these retries.

The `DynamoDBClient` constructor accepts a `maxAttempts` setting that limits how many attempts will happen. The below example raises the value from the default of 3 to a total of 5. If you set it to 0 or 1, that indicates you don't want any automatic retries and want to handle any resumable errors yourself within your catch block.

```
const client = new DynamoDBClient({  
    maxAttempts: 5,  
});
```

You can also control the timing of the retries with a custom retry strategy. To do this, import the `util-retry` utility package and create a custom backoff function that calculates the wait time between retries based on the current retry count.

The example below says to make a maximum of 5 attempts with delays of 15, 30, 90, and 360 milliseconds should the first attempt fail. The custom backoff function,

`calculateRetryBackoff`, calculates the delays by accepting the retry attempt number (starts with 1 for the first retry) and returns how many milliseconds to wait for that request.

```
const { ConfiguredRetryStrategy } = require("@aws-sdk/util-retry");

const calculateRetryBackoff = (attempt) => {
  const backoffTimes = [15, 30, 90, 360];
  return backoffTimes[attempt - 1] || 0;
};

const client = new DynamoDBClient({
  retryStrategy: new ConfiguredRetryStrategy(
    5, // max attempts.
    calculateRetryBackoff // backoff function.
  ),
});
```

Waiters

The DynamoDB client includes two useful [waiter functions](#) that can be used when creating, modifying, or deleting tables when you want your code to wait to proceed until the table modification has finished. For example, you can deploy a table, call the `waitUntilTableExists` function, and the code will block until the table has been made **ACTIVE**. The waiter internally polls the DynamoDB service with a `describe-table` every 20 seconds.

```
import {waitUntilTableExists, waitUntilTableNotExists} from "@aws-sdk/client-dynamodb";

... <create table details>

const results = await waitUntilTableExists({client: client, maxWaitTime: 180},
  {TableName: "products"});
if (results.state == 'SUCCESS') {
  return results.reason.Table
}
console.error(` ${results.state} ${results.reason}`);
```

The `waitUntilTableExists` feature returns control only when it can perform a `describe-table` command that shows the table status **ACTIVE**. This ensures that you can use `waitUntilTableExists` to wait for the completion of creation, as well as modifications such as adding a GSI index, which may take some time to apply before the table returns to **ACTIVE** status.

Error handling

In the early examples here, we've caught all errors broadly. However, in practical applications, it's important to discern between various error types and implement more precise error handling.

DynamoDB error responses contain metadata, including the name of the error. You can catch errors then match against the possible string names of error conditions to determine how to proceed. For server-side errors, you can leverage the `instanceof` operator with the error types exported by the `@aws-sdk/client-dynamodb` package to manage error handling efficiently.

It's important to note that these errors only manifest after all retries have been exhausted. If an error is retried and is eventually followed by a successful call, from the code's perspective, there's no error just a slightly elevated latency. Retries will show up in Amazon CloudWatch charts as unsuccessful requests, such as throttle or error requests. If the client reaches the maximum retry count, it will give up and generate an exception. This is the client's way of saying it's not going to retry.

Below is a snippet to catch the error and take action based on the type of error that was returned.

```
import {  
    ResourceNotFoundException,  
    ProvisionedThroughputExceededException,  
    DynamoDBServiceException,  
} from "@aws-sdk/client-dynamodb";  
  
try {  
    await client.send(someCommand);  
} catch (e) {  
    if (e instanceof ResourceNotFoundException) {  
        // Handle ResourceNotFoundException  
    } else if (e instanceof ProvisionedThroughputExceededException) {  
        // Handle ProvisionedThroughputExceededException  
    } else if (e instanceof DynamoDBServiceException) {  
        // Handle DynamoDBServiceException  
    } else {  
        // Other errors such as those from the SDK  
        if (e.name === "TimeoutError") {  
            // Handle SDK TimeoutError.  
        } else {  
            // Handle other errors.  
        }  
    }  
}
```

```
}
```

See [the section called “Error handling”](#) for common error strings in the *DynamoDB Developer Guide*. The exact errors possible with any particular API call can be found in the documentation for that API call, such as the [Query API docs](#).

The metadata of errors include additional properties, depending on the error. For a `TimeoutError`, the metadata includes the number of attempts that were made and the `totalRetryDelay`, as shown below.

```
{
  "name": "TimeoutError",
  "$metadata": {
    "attempts": 3,
    "totalRetryDelay": 199
  }
}
```

If you manage your own retry policy, you'll want to differentiate between throttles and errors:

- A **throttle** (indicated by a `ProvisionedThroughputExceeded` or `ThrottlingException`) indicates a healthy service that's informing you that you've exceeded your read or write capacity on a DynamoDB table or partition. Every millisecond that passes, a bit more read or write capacity is made available, and so you can retry quickly, such as every 50ms, to attempt to access that newly released capacity.

With throttles you don't especially need exponential backoff because throttles are lightweight for DynamoDB to return and incur no per-request charge to you. Exponential backoff assigns longer delays to client threads that have already waited the longest, which statistically extends the p50 and p99 outward.

- An **error** (indicated by an `InternalServerError` or a `ServiceUnavailable`, among others) indicates a transient issue with the service, possibly the whole table or just the partition you're reading from or writing to. With errors, you can pause longer before retries, such as 250ms or 500ms, and use jitter to stagger the retries.

Logging

Turn on logging to get more details about what the SDK is doing. You can set a parameter on the `DynamoDBClient` as shown in the example below. More log information will appear in the console

and includes metadata such as the status code and the consumed capacity. If you run the code locally in a terminal window, the logs appear there. If you run the code in AWS Lambda, and you have Amazon CloudWatch logs set up, then the console output will be written there.

```
const client = new DynamoDBClient({  
    logger: console  
});
```

You can also hook into the internal SDK activities and perform custom logging as certain events happen. The example below uses the client's `middlewareStack` to intercept each request as it's being sent from the SDK and logs it as it's happening.

```
const client = new DynamoDBClient({});  
  
client.middlewareStack.add(  
    (next) => async (args) => {  
        console.log("Sending request from AWS SDK", { request: args.request });  
        return next(args);  
    },  
    {  
        step: "build",  
        name: "log-ddb-calls",  
    }  
);
```

The `MiddlewareStack` provides a powerful hook for observing and controlling SDK behavior. See the blog [Introducing Middleware Stack in Modular AWS SDK for JavaScript](#), for more information.

Considerations

When implementing the AWS SDK for JavaScript in your project, here are some further factors to consider.

Module systems

The SDK supports two module systems, CommonJS and ES (ECMAScript). CommonJS uses the `require` function, while ES uses the `import` keyword.

1. **Common JS** – `const { DynamoDBClient, PutItemCommand } = require("@aws-sdk/client-dynamodb");`

```
2. ES (ECMAScript – import { DynamoDBClient, PutItemCommand } from "@aws-sdk/client-dynamodb";
```

The project type dictates the module system to be used and is specified in the type section of your package.json file. The default is CommonJS. Use "type": "module" to indicate an ES project. If you have an existing Node.JS project that uses the CommonJS package format, you can still add functions with the more modern SDK V3 Import syntax by naming your function files with the .mjs extension. This will allow the code file to be treated as ES (ECMAScript).

Asynchronous operations

You'll see many code samples using callbacks and promises to handle the result of DynamoDB operations. With modern JavaScript this complexity is no longer needed and developers can take advantage of the more succinct and readable async/await syntax for asynchronous operations.

Web browser runtime

Web and mobile developers building with React or React Native can use the SDK for JavaScript in their projects. With the earlier V2 of the SDK, web developers would have to load the full SDK into the browser, referencing an SDK image hosted at <https://sdk.amazonaws.com/js/>.

With V3, it's possible to bundle just the required V3 client modules and all required JavaScript functions into a single JavaScript file using Webpack, and add it in a script tag in the <head> of your HTML pages, as explained in the [Getting started in a browser script](#) section of the SDK documentation.

DAX data plane operations

The SDK for JavaScript V3 does not at this time provide support for the Amazon DynamoDB Streams Accelerator (DAX) data plane operations. If you request DAX support, consider using the SDK for JavaScript V2 which supports DAX data plane operations.

Programming Amazon DynamoDB with AWS SDK for Java 2.x

This guide provides an orientation to programmers wanting to use Amazon DynamoDB with Java. This guide covers the different concepts, such as abstraction layers, configuration management, error handling, controlling retry policies, and managing keep-alive.

Topics

- [About AWS SDK for Java 2.x](#)

- [Getting started with AWS SDK for Java 2.x](#)

- [Data class annotations](#)

About AWS SDK for Java 2.x

You can access DynamoDB from Java using the official AWS SDK for Java. The SDK for Java has two versions: 1.x and 2.x. For 1.x the end-of-support was [announced](#) on January 12, 2024. It entered maintenance mode on July 31, 2024 and its end-of-support is due on December 31, 2025. For new development, we highly recommend that you use 2.x, which was first released in 2018. This guide exclusively targets 2.x and focuses only on the parts of the SDK relevant to DynamoDB.

You can find more information about maintenance and support for SDKs in the [AWS SDK and Tools maintenance policy](#) and [AWS SDKs and Tools version support matrix](#) topics of the [AWS SDKs and Tools Reference Guide](#).

The AWS SDK for Java 2.x is a major rewrite of the 1.x code base to support modern Java features, such as the non-blocking I/O introduced in Java 8. SDK for Java 2.x also adds support for pluggable HTTP client implementations to provide more flexibility and configurability for network connections.

A noticeable change between the SDK for Java 1.x and the SDK for Java 2.x is the use of a new package name. The Java 1.x SDK uses the `com.amazonaws` package name, while the Java 2.x SDK uses `software.amazon.awssdk`. Similarly, Maven artifacts for the Java 1.x SDK use the `com.amazonaws` groupId, while Java 2.x SDK artifacts use the `software.amazon.awssdk` groupId.

Important

The AWS SDK for Java 1.x has a DynamoDB package named com.amazonaws.dynamodbv2. The v2 in the package name doesn't indicate it's Java v2. v2 indicates that the package supports the [second version](#) of the DynamoDB low-level API instead of the [original version](#) of the low-level API.

Support for Java versions

The AWS SDK for Java 2.x provides full support for long-term support (LTS) [Java releases](#).

Getting started with AWS SDK for Java 2.x

The following tutorial shows you how to use [Apache Maven](#) for defining dependencies for the SDK for Java 2.x. This tutorial also shows you how to write the code that connects to DynamoDB for listing the available DynamoDB tables. This tutorial is based on the [Get started with the AWS SDK for Java 2.x](#). We've edited this tutorial to make calls to DynamoDB instead of Amazon S3.

Perform the following steps to complete this tutorial:

- [Step 1: Set up for this tutorial](#)
- [Step 2: Create the project](#)
- [Step 3: Write the code](#)
- [Step 4: Build and run the application](#)

Step 1: Set up for this tutorial

Before you begin this tutorial, you need the following:

- Permission to access Amazon DynamoDB.
- A Java development environment that is configured to access AWS services using single sign-on to the AWS IAM Identity Center

Use the instructions in [Setup overview](#) to get set up for this tutorial. After you have [configured your development environment with single sign-on access](#) for the Java SDK and you have an [active AWS access portal session](#), continue with [Step 2](#) of this tutorial.

Step 2: Create the project

To create the project for this tutorial, you run a Maven command that prompts you for input on how to configure the project. After all input is entered and confirmed, Maven finishes building out the project by creating a `pom.xml` file and creating stub Java files.

1. Open a terminal or command prompt window and navigate to a directory of your choice, for example, your Desktop or Home folder.
2. Enter the following command at the terminal and press Enter.

```
mvn archetype:generate \
-DarchetypeGroupId=software.amazon.awssdk \
-DarchetypeArtifactId=archetype-app-quickstart \
-DarchetypeVersion=2.22.0
```

3. Enter the value listed in the second column for each prompt.

Prompt	Value to enter
Define value for property 'service':	dynamodb
Define value for property 'httpClient' :	apache-client
Define value for property 'nativeImage' :	false
Define value for property 'credentialProvider'	identity-center
Define value for property 'groupId':	org.example
Define value for property 'artifactId':	getstarted
Define value for property 'version' 1.0-SNAPSHOT:	<Enter>

Prompt	Value to enter
Define value for property 'package' org.example:	<Enter>

4. After the last value is entered, Maven lists the choices you made. Confirm by entering *Y* or re-enter values by entering *N*.

Maven creates the project folder named `getstarted` based on the `artifactId` value that you entered. Inside the `getstarted` folder, find a `README.md` file that you can review, a `pom.xml` file, and a `src` directory.

Maven builds the following directory tree.

```
getstarted
### README.md
### pom.xml
### src
    ### main
        #   ### java
        #   #   ### org
        #   #       ### example
        #   #           ### App.java
        #   #           ### DependencyFactory.java
        #   #           ### Handler.java
        #   ### resources
        #       ### simplelogger.properties
    ### test
        ### java
            ### org
                ### example
                    ### HandlerTest.java
```

10 directories, 7 files

The following shows the contents of the `pom.xml` project file.

pom.xml

The `dependencyManagement` section contains a dependency to the AWS SDK for Java 2.x and the `dependencies` section has a dependency for Amazon DynamoDB. Specifying these dependencies

forces Maven to include the relevant jar files into your Java class path. By default, the AWS SDK doesn't include all the classes for all AWS services. For DynamoDB, you should have dependency on dynamodb artifact in case you use the low-level interface or dynamodb-enhanced if you use the high-level interface. If you don't include the relevant dependencies, your code will not compile. The project uses Java 1.8 because of the 1.8 value in the maven.compiler.source and maven.compiler.target properties.

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.org/xsd/maven-4.0.0.xsd">
    <modelVersion>4.0.0</modelVersion>

    <groupId>org.example</groupId>
    <artifactId>getstarted</artifactId>
    <version>1.0-SNAPSHOT</version>
    <packaging>jar</packaging>
    <properties>
        <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
        <maven.compiler.source>1.8</maven.compiler.source>
        <maven.compiler.target>1.8</maven.compiler.target>
        <maven.shade.plugin.version>3.2.1</maven.shade.plugin.version>
        <maven.compiler.plugin.version>3.6.1</maven.compiler.plugin.version>

            <artifactId>maven-compiler-plugin</artifactId>
            <version>${maven.compiler.plugin.version}</version>
        </plugin>
    </plugins>
</build>

</project>
```

Step 3: Write the code

The following code shows the App class created by Maven. The `main` method is the entry point into the application, which creates an instance of the `Handler` class and then calls its `sendRequest` method.

App class

```
package org.example;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class App {
    private static final Logger logger = LoggerFactory.getLogger(App.class);

    public static void main(String... args) {
        logger.info("Application starts");

        Handler handler = new Handler();
        handler.sendRequest();

        logger.info("Application ends");
    }
}
```

The DependencyFactory class created by Maven contains the dynamoDbClient factory method that builds and returns an [DynamoDbClient](#) instance. The DynamoDbClient instance uses an instance of the Apache-based HTTP client. This is because you specified apache-client when Maven prompted you for which HTTP client to use.

The DependencyFactory is shown in the following code.

DependencyFactory class

```
package org.example;

import software.amazon.awssdk.http.apache.ApacheHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

/**
 * The module containing all dependencies required by the {@link Handler}.
 */
public class DependencyFactory {

    private DependencyFactory() {}

    /**
     * @return an instance of DynamoDbClient

```

```
 */
public static DynamoDbClient dynamoDbClient() {
    return DynamoDbClient.builder()
        .httpClientBuilder(ApacheHttpClient.builder())
        .build();
}
```

The `Handler` class contains the main logic of your program. When an instance of `Handler` is created in the `App` class, the `DependencyFactory` furnishes the `DynamoDbClient` service client. Your code uses the `DynamoDbClient` instance to call the DynamoDB service.

Maven generates the following `Handler` class with a *TODO* comment. The next step in the tutorial replaces the *TODO* with code.

Handler class, Maven-generated

```
package org.example;

import software.amazon.awssdk.services.dynamodb.DynamoDbClient;

public class Handler {
    private final DynamoDbClient dynamoDbClient;

    public Handler() {
        dynamoDbClient = DependencyFactory.dynamoDbClient();
    }

    public void sendRequest() {
        // TODO: invoking the API calls using dynamoDbClient.
    }
}
```

To fill in the logic, replace the entire contents of the `Handler` class with the following code. The `sendRequest` method is filled in and the necessary imports are added.

Handler class, implemented

The following code uses the [DynamoDbClient](#) instance to retrieve a list of existing tables. If tables exist for a given account and Region, the code uses the `Logger` instance to log the names of these tables.

```
package org.example;

import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.ListTablesResponse;

public class Handler {
    private final DynamoDbClient dynamoDbClient;

    public Handler() {
        dynamoDbClient = DependencyFactory.dynamoDbClient();
    }

    public void sendRequest() {
        Logger logger = LoggerFactory.getLogger(Handler.class);

        logger.info("calling the DynamoDB API to get a list of existing tables");
        ListTablesResponse response = dynamoDbClient.listTables();

        if (!response.hasTableNames()) {
            logger.info("No existing tables found for the configured account & region");
        } else {
            response.tableNames().forEach(tableName -> logger.info("Table: " + tableName));
        }
    }
}
```

Step 4: Build and run the application

After the project is created and contains the complete `Handler` class, build and run the application.

1. Make sure that you have an active IAM Identity Center session. To do so, run the AWS Command Line Interface command `aws sts get-caller-identity` and check the response. If you don't have an active session, see [Sign in using the AWS CLI](#) for instructions.
2. Open a terminal or command prompt window and navigate to your project directory `getstarted`.

3. Use the following command to build your project:

```
mvn clean package
```

4. Use the following command to run the application.

```
mvn exec:java -Dexec.mainClass="org.example.App"
```

After you view the file, delete the object, and then delete the bucket.

Success

If your Maven project built and ran without error, then congratulations! You have successfully built your first Java application using the SDK for Java 2.x.

Cleanup

To clean up the resources you created during this tutorial, do the following:

- Delete the project folder `getstarted`.

Using the AWS SDK for Java 2.x documentation

The [AWS SDK for Java 2.x documentation](#) covers all aspects of the SDK across all AWS services. Use the following topics as your starting points:

- [Migrate from version 1.x to 2.x](#) — Includes a detailed explanation of the differences between 1.x and 2.x. This topic also contains instructions about how to use both major versions side-by-side.
- [DynamoDB guide for Java 2.x SDK](#) — Shows you how to perform basic DynamoDB operations: creating a table, manipulating items, and retrieving items. These examples use the low-level interface. Java has several interfaces, as explained in the following section: [Supported interfaces](#).

Tip

We recommend that after going through these topics in the AWS SDK for Java 2.x documentation, you bookmark the [Javadoc documentation](#). It covers all AWS services and will act as your main API reference.

Supported interfaces

The AWS SDK for Java 2.x supports the following interfaces depending on the level of abstraction you want.

Topics in this section

- [Low-level interface](#)
- [High-level interface](#)
- [Document Interface](#)
- [Comparing interfaces with a Query example](#)

Low-level interface

The low-level interface provides a one-to-one mapping to the underlying service API. Every DynamoDB API is available through this interface. This means the low-level interface can provide complete functionality, but it's often more verbose and complex to use. For example, you have to use the `.s()` functions to hold strings and the `.n()` functions to hold numbers. The following example of [PutItem](#) inserts an item using the low-level interface.

```
import org.slf4j.*;
import software.amazon.awssdk.http.crt.AwsCrtHttpClient;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.*;

import java.util.Map;

public class PutItem {

    // Create a DynamoDB client with the default settings connected to the DynamoDB
    // endpoint in the default region based on the default credentials provider chain.
    private static final DynamoDbClient DYNAMODB_CLIENT = DynamoDbClient.create();
    private static final Logger LOGGER = LoggerFactory.getLogger(PutItem.class);

    private void putItem() {
        PutItemResponse response = DYNAMODB_CLIENT.putItem(PutItemRequest.builder()
            .item(Map.of(
                "pk", AttributeValue.builder().s("123").build(),
                "sk", AttributeValue.builder().s("cart#123").build(),
                "item_data",
                AttributeValue.builder().s("YourItemData").build(),
            ))
        );
    }
}
```

```
        "inventory", AttributeValue.builder().n("500").build()
        // ... more attributes ...
    ))
    .returnConsumedCapacity(ReturnConsumedCapacity.TOTAL)
    .tableName("YourTableName")
    .build());
    LOGGER.info("PutItem call consumed [" +
response.consumedCapacity().capacityUnits() + "] Write Capacity Units (WCUs)");
}
}
```

High-level interface

The high-level interface in AWS SDK for Java 2.x is called the DynamoDB enhanced client. This interface provides a more idiomatic code authoring experience.

The enhanced client offers a way to map between client-side data classes and DynamoDB tables designed to store that data. You define the relationships between tables and their corresponding model classes in your code. Then, you can rely on the SDK to manage the data type manipulation. For more information about the enhanced client, see [DynamoDB enhanced client API](#) in the [AWS SDK for Java 2.x documentation](#).

The following example of [PutItem](#) uses the high-level interface. In this example, the `DynamoDbBean` named `YourItem` creates a `TableSchema` allowing its direct use as input for the `putItem()` call.

```
import org.slf4j.*;
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.*;
import software.amazon.awssdk.enhanced.dynamodb.model.*;
import software.amazon.awssdk.services.dynamodb.model.ReturnConsumedCapacity;

public class DynamoDbEnhancedClientPutItem {
    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =
DynamoDbEnhancedClient.builder().build();
    private static final DynamoDbTable<YourItem> DYNAMODB_TABLE =
ENHANCED_DYNAMODB_CLIENT.table("YourTableName", TableSchema.fromBean(YourItem.class));
    private static final Logger LOGGER = LoggerFactory.getLogger(PutItem.class);

    private void putItem() {
        PutItemEnhancedResponse<YourItem> response =
DYNAMODB_TABLE.putItemWithResponse(PutItemEnhancedRequest.builder(YourItem.class)
```

```
        .item(new YourItem("123", "cart#123", "YourItemData", 500))
        .returnConsumedCapacity(ReturnConsumedCapacity.TOTAL)
        .build());
    LOGGER.info("PutItem call consumed [" +
response.consumedCapacity().capacityUnits() + "] Write Capacity Unites (WCU)");
}

{@DynamoDbBean
public static class YourItem {

    public YourItem() {}

    public YourItem(String pk, String sk, String itemData, int inventory) {
        this.pk = pk;
        this.sk = sk;
        this.itemData = itemData;
        this.inventory = inventory;
    }

    private String pk;
    private String sk;
    private String itemData;

    private int inventory;

    @DynamoDbPartitionKey
    public void setPk(String pk) {
        this.pk = pk;
    }

    public String getPk() {
        return pk;
    }

    @DynamoDbSortKey
    public void setSk(String sk) {
        this.sk = sk;
    }

    public String getSk() {
        return sk;
    }

    public void setItemData(String itemData) {
```

```
        this.itemData = itemData;
    }

    public String getItemData() {
        return itemData;
    }

    public void setInventory(int inventory) {
        this.inventory = inventory;
    }

    public int getInventory() {
        return inventory;
    }
}
}
```

AWS SDK for Java 1.x has its own high-level interface, which is often referred to by its main class `DynamoDBMapper`. The AWS SDK for Java 2.x is published in a separate package (and Maven artifact) named `software.amazon.awssdk.enhanced.dynamodb`. The Java 2.x SDK is often referred to by its main class `DynamoDbEnhancedClient`.

High-level interface using immutable data classes

The mapping feature of the DynamoDB enhanced client API also works with immutable data classes. An immutable class has only getters and requires a builder class that the SDK uses to create instances of the class. Immutability in Java is a commonly used style that allows developers to create classes that are side-effect free and, therefore, more predictable in their behavior in complex multi-threaded applications. Instead of using the `@DynamoDbBean` annotation as shown in the [High-level interface example](#), immutable classes use the `@DynamoDbImmutable` annotation, which takes the builder class as its input.

The following example takes the builder class `DynamoDbEnhancedClientImmutablePutItem` as input to create a table schema. The example then provides the schema as input for the [PutItem](#) API call.

```
import org.slf4j.*;
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.model.*;
import software.amazon.awssdk.services.dynamodb.model.ReturnConsumedCapacity;
```

```
public class DynamoDbEnhancedClientImmutablePutItem {  
    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =  
DynamoDbEnhancedClient.builder().build();  
    private static final DynamoDbTable<YourImmutableItem>  
DYNAMODB_TABLE = ENHANCED_DYNAMODB_CLIENT.table("YourTableName",  
TableSchema.fromImmutableClass(YourImmutableItem.class));  
    private static final Logger LOGGER =  
LoggerFactory.getLogger(DynamoDbEnhancedClientImmutablePutItem.class);  
  
    private void putItem() {  
        PutItemEnhancedResponse<YourImmutableItem> response =  
DYNAMODB_TABLE.putItemWithResponse(PutItemEnhancedRequest.builder(YourImmutableItem.class)  
            .item(YourImmutableItem.builder()  
                .pk("123")  
                .sk("cart#123")  
                .itemData("YourItemData")  
                .inventory(500)  
                .build())  
            .returnConsumedCapacity(ReturnConsumedCapacity.TOTAL)  
            .build());  
        LOGGER.info("PutItem call consumed [" +  
response.consumedCapacity().capacityUnits() + "] Write Capacity Units (WCU)");  
    }  
}
```

The following example shows the immutable data class.

```
@DynamoDbImmutable(builder = YourImmutableItem.YourImmutableItemBuilder.class)  
class YourImmutableItem {  
    private final String pk;  
    private final String sk;  
    private final String itemData;  
    private final int inventory;  
    public YourImmutableItem(YourImmutableItemBuilder builder) {  
        this.pk = builder.pk;  
        this.sk = builder.sk;  
        this.itemData = builder.itemData;  
        this.inventory = builder.inventory;  
    }  
  
    public static YourImmutableItemBuilder builder() { return new  
YourImmutableItemBuilder(); }
```

```
@DynamoDbPartitionKey
public String getPk() {
    return pk;
}

@dynamoDbSortKey
public String getSk() {
    return sk;
}

public String getItemData() {
    return itemData;
}

public int getInventory() {
    return inventory;
}

static final class YourImmutableItemBuilder {
    private String pk;
    private String sk;
    private String itemData;
    private int inventory;

    private YourImmutableItemBuilder() {}

    public YourImmutableItemBuilder pk(String pk) { this.pk = pk; return this; }
    public YourImmutableItemBuilder sk(String sk) { this.sk = sk; return this; }
    public YourImmutableItemBuilder itemData(String itemData) { this.itemData = itemData; return this; }
    public YourImmutableItemBuilder inventory(int inventory) { this.inventory = inventory; return this; }

    public YourImmutableItem build() { return new YourImmutableItem(this); }
}
}
```

High-level interface using immutable data classes and third-party boilerplate generation libraries

The immutable data classes example mentioned in the previous section require some boilerplate code. For example, the getter and setter logic on the data classes in addition to the Builder classes. Third-party libraries, such as [Project Lombok](#), can help you generate that type of boilerplate code.

The [Use third-party libraries, such as Lombok](#) section in the AWS SDK for Java 2.x documentation introduces the concept of leveraging the Project Lombok library. Reducing most of the boilerplate code helps you limit the amount of code needed for working with immutable data classes and the AWS SDK. This further results in improved productivity and readability of your code.

The following example demonstrates how Project Lombok simplifies the code needed to use the DynamoDB enhanced client API.

```
import org.slf4j.*;
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.model.*;
import software.amazon.awssdk.services.dynamodb.model.ReturnConsumedCapacity;

public class DynamoDbEnhancedClientImmutableLombokPutItem {

    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =
DynamoDbEnhancedClient.builder().build();
    private static final DynamoDbTable<YourImmutableLombokItem>
DYNAMODB_TABLE = ENHANCED_DYNAMODB_CLIENT.table("YourTableName",
TableSchema.fromImmutableClass(YourImmutableLombokItem.class));
    private static final Logger LOGGER =
LoggerFactory.getLogger(DynamoDbEnhancedClientImmutableLombokPutItem.class);

    private void putItem() {
        PutItemEnhancedResponse<YourImmutableLombokItem> response =
DYNAMODB_TABLE.putItemWithResponse(PutItemEnhancedRequest.builder(YourImmutableLombokItem.clas
            .item(YourImmutableLombokItem.builder()
                .pk("123")
                .sk("cart#123")
                .itemData("YourItemData")
                .inventory(500)
                .build())
            .returnConsumedCapacity(ReturnConsumedCapacity.TOTAL)
            .build());
        LOGGER.info("PutItem call consumed [" +
response.consumedCapacity().capacityUnits() + "] Write Capacity Units (WCU)");
    }
}
```

The following example shows the immutable data object of the immutable data class.

```
import lombok.*;
```

```
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.*;

@Builder
@DynamoDbImmutable(builder =
    YourImmutableLombokItem.YourImmutableLombokItemBuilder.class)
@Value
public class YourImmutableLombokItem {

    @Getter(onMethod_=@DynamoDbPartitionKey)
    String pk;
    @Getter(onMethod_=@DynamoDbSortKey)
    String sk;
    String itemData;
    int inventory;
}
```

The `YourImmutableLombokItem` class uses the following annotations provided by Project Lombok and the AWS SDK:

- [@Builder](#) — Produces complex builder APIs for data classes provided by Project Lombok.
- [@DynamoDbImmutable](#) — Identifies the `DynamoDbImmutable` class as a DynamoDB mappable entity annotation provided by the AWS SDK.
- [@Value](#) — The immutable variant of `@Data`; all fields are made private and final by default, and setters are not generated. This annotation is provided by Project Lombok.

Document Interface

The Document interface avoids the need to specify data type descriptors. The data types are implied by the semantics of the data itself. If you're familiar with the AWS SDK for Java 1.x Document interface, the Document interface in AWS SDK for Java 2.x offers a similar but redesigned interface.

The following [Document interface example](#) shows the `PutItem` call expressed using the Document interface. The example also uses `EnhancedDocument`. To execute commands against a DynamoDB table using the enhanced document API, you must first associate the table with your document table schema to create a `DynamoDBTable` resource object. The Document table schema builder requires the primary index key and attribute converter providers.

You can use `AttributeConverterProvider.defaultProvider()` to convert document attributes of default types. You can change the overall default behavior with a custom

AttributeConverterProvider implementation. You can also change the converter for a single attribute. The [AWS SDK documentation](#) provides more details and examples about how to use custom converters. Their primary use is for attributes of your domain classes that don't have a default converter available. Using a custom converter, you can provide the SDK with the needed information to write or read to DynamoDB.

```
import org.slf4j.*;
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.document EnhancedDocument;
import software.amazon.awssdk.enhanced.dynamodb.model.*;
import software.amazon.awssdk.services.dynamodb.model.ReturnConsumedCapacity;

public class DynamoDbEnhancedDocumentClientPutItem {
    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =
DynamoDbEnhancedClient.builder().build();
    private static final DynamoDbTable<EnhancedDocument> DYNAMODB_TABLE =
        ENHANCED_DYNAMODB_CLIENT.table("YourTableName",
TableSchema.documentSchemaBuilder()

.addIndexPartitionKey(TableMetadata.primaryIndexName(),"pk", AttributeValueType.S)
        .addIndexSortKey(TableMetadata.primaryIndexName(), "sk",
AttributeValueType.S)

.attributeConverterProviders(AttributeConverterProvider.defaultProvider())
        .build());

    private static final Logger LOGGER =
LoggerFactory.getLogger(DynamoDbEnhancedDocumentClientPutItem.class);

    private void putItem() {
        PutItemEnhancedResponse<EnhancedDocument> response =
DYNAMODB_TABLE.putItemWithResponse(
            PutItemEnhancedRequest.builder(EnhancedDocument.class)
                .item(
                    EnhancedDocument.builder()

.attributeConverterProviders(AttributeConverterProvider.defaultProvider())
                .putString("pk", "123")
                .putString("sk", "cart#123")
                .putString("item_data", "YourItemData")
                .putNumber("inventory", 500)
                .build())
        .returnConsumedCapacity(ReturnConsumedCapacity.TOTAL)
```

```
        .build());
    LOGGER.info("PutItem call consumed [" +
response.consumedCapacity().capacityUnits() + "] Write Capacity Units (WCUs)");
}
}
```

Using the following utility methods you can convert JSON documents to and from the native Amazon DynamoDB data types:

- [EnhancedDocument.fromJson\(String json\)](#)—Creates a new EnhancedDocument instance from a JSON string.
- [EnhancedDocument.toJson\(\)](#)—Creates a JSON string representation of the document which allows you to use it in your application like any other JSON object.

Comparing interfaces with a Query example

This section shows the same [Query](#) call expressed using the various interfaces. These queries use a couple of attributes to fine tune the query results:

- You must specify the partition key completely because DynamoDB will target to one specific partition key value.
- The sort key has a key condition expression using `begins_with` so that only cart items are targeted with this query.
- We limit the query to return maximum of 100 item by using `limit()`.
- We set the `scanIndexForward` to false. The results are returned in order of UTF-8 bytes, which usually means the cart item with the lowest number is returned first. By setting the `scanIndexForward` to false we reverse the order and the cart item with the highest number is returned first.
- We apply a filter to remove any result that does not match the criteria. The data being filtered consumes read capacity whether or not the item matches the filter.

Example Query using low-level interface

The following example queries a table named `YourTableName` using a `keyConditionExpression`, which limits the query to a specific partition key value and sort key value that begin with a specific prefix value. These key conditions limit the amount of data read

from DynamoDB. Finally, the query applies a filter on the data retrieved from DynamoDB using a `filterExpression`.

```
import org.slf4j.*;
import software.amazon.awssdk.services.dynamodb.DynamoDbClient;
import software.amazon.awssdk.services.dynamodb.model.*;

import java.util.Map;

public class Query {

    // Create a DynamoDB client with the default settings connected to the DynamoDB
    // endpoint in the default region based on the default credentials provider chain.
    private static final DynamoDbClient DYNAMODB_CLIENT =
DynamoDbClient.builder().build();
    private static final Logger LOGGER = LoggerFactory.getLogger(Query.class);

    private static void query() {
        QueryResponse response = DYNAMODB_CLIENT.query(QueryRequest.builder()
            .expressionAttributeNames(Map.of("#name", "name"))
            .expressionAttributeValues(Map.of(
                ":pk_val", AttributeValue.fromS("id#1"),
                ":sk_val", AttributeValue.fromS("cart#"),
                ":name_val", AttributeValue.fromS("SomeName")))
            .filterExpression("#name = :name_val")
            .keyConditionExpression("pk = :pk_val AND begins_with(sk, :sk_val)")
            .limit(100)
            .scanIndexForward(false)
            .tableName("YourTableName")
            .build());

        LOGGER.info("nr of items: " + response.count());
        LOGGER.info("First item pk: " + response.items().get(0).get("pk"));
        LOGGER.info("First item sk: " + response.items().get(0).get("sk"));
    }
}
```

Example Query using Document interface

The following example queries a table named `YourTableName` using document interface.

```
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
```

```
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.document EnhancedDocument;
import software.amazon.awssdk.enhanced.dynamodb.model.*;

import java.util.Map;

public class DynamoDbEnhancedDocumentClientQuery {

    // Create a DynamoDB client with the default settings connected to the DynamoDB
    // endpoint in the default region based on the default credentials provider chain.
    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =
DynamoDbEnhancedClient.builder().build();
    private static final DynamoDbTable<EnhancedDocument> DYNAMODB_TABLE =
        ENHANCED_DYNAMODB_CLIENT.table("YourTableName",
TableSchema.documentSchemaBuilder()
        .addIndexPartitionKey(TableMetadata.primaryIndexName(),"pk",
AttributeValueType.S)
        .addIndexSortKey(TableMetadata.primaryIndexName(), "sk",
AttributeValueType.S)

.attributeConverterProviders(AttributeConverterProvider.defaultProvider())
        .build());
    private static final Logger LOGGER =
LoggerFactory.getLogger(DynamoDbEnhancedDocumentClientQuery.class);

    private void query() {
        PageIterable<EnhancedDocument> response =
DYNAMODB_TABLE.query(QueryEnhancedRequest.builder()
        .filterExpression(Expression.builder()
            .expression("#name = :name_val")
            .expressionNames(Map.of("#name", "name"))
            .expressionValues(Map.of(":name_val",
AttributeValue.fromS("SomeName"))))
        .build())
        .limit(100)
        .queryConditional(QueryConditional.sortBeginsWith(Key.builder()
            .partitionValue("id#1")
            .sortValue("cart#")
            .build())))
        .scanIndexForward(false)
        .build());

        LOGGER.info("nr of items: " + response.items().stream().count());
    }
}
```

```
        LOGGER.info("First item pk: " +
response.items().iterator().next().getString("pk"));
        LOGGER.info("First item sk: " +
response.items().iterator().next().getString("sk"));

    }
}
```

Example Query using high-level interface

The following example queries a table named `YourTableName` using the DynamoDB enhanced client API.

```
import org.slf4j.*;
import software.amazon.awssdk.enhanced.dynamodb.*;
import software.amazon.awssdk.enhanced.dynamodb.mapper.annotations.*;
import software.amazon.awssdk.enhanced.dynamodb.model.*;
import software.amazon.awssdk.services.dynamodb.model.AttributeValue;

import java.util.Map;

public class DynamoDbEnhancedClientQuery {

    private static final DynamoDbEnhancedClient ENHANCED_DYNAMODB_CLIENT =
DynamoDbEnhancedClient.builder().build();
    private static final DynamoDbTable<YourItem> DYNAMODB_TABLE =
ENHANCED_DYNAMODB_CLIENT.table("YourTableName",
TableSchema.fromBean(DynamoDbEnhancedClientQuery.YourItem.class));
    private static final Logger LOGGER =
LoggerFactory.getLogger(DynamoDbEnhancedClientQuery.class);

    private void query() {
        PageIterable<YourItem> response =
DYNAMODB_TABLE.query(QueryEnhancedRequest.builder()
            .filterExpression(Expression.builder()
                .expression("#name = :name_val")
                .expressionNames(Map.of("#name", "name"))
                .expressionValues(Map.of(":name_val",
AttributeValue.fromString("SomeName"))))
            .build())
            .limit(100)
            .queryConditional(QueryConditional.sortBeginsWith(Key.builder()
                .partitionValue("id#1")
                .build())))
            .build());
    }
}
```

```
        .sortValue("cart#")
        .build()))
.scanIndexForward(false)
.build());
```

```
LOGGER.info("nr of items: " + response.items().stream().count());
LOGGER.info("First item pk: " + response.items().iterator().next().getPk());
LOGGER.info("First item sk: " + response.items().iterator().next().getSk());
}
```

```
@DynamoDbBean
public static class YourItem {

    public YourItem() {}

    public YourItem(String pk, String sk, String name) {
        this.pk = pk;
        this.sk = sk;
        this.name = name;
    }

    private String pk;
    private String sk;
    private String name;

    @DynamoDbPartitionKey
    public void setPk(String pk) {
        this.pk = pk;
    }

    public String getPk() {
        return pk;
    }

    @DynamoDbSortKey
    public void setSk(String sk) {
        this.sk = sk;
    }

    public String getSk() {
        return sk;
    }

    public void setName(String name) {
```

```
        this.name = name;
    }

    public String getName() {
        return name;
    }
}

}
```

High-level interface using immutable data classes

When you perform a Query with the high-level immutable data classes, the code is the same as the high-level interface example except for the construction of the entity class YourItem or YourImmutableItem. For more information, see the [PutItem](#) example.

High-level interface using immutable data classes and third-party boilerplate generation libraries

When you perform a Query with the high-level immutable data classes, the code is the same as the high-level interface example except for the construction of the entity class YourItem or YourImmutableLombokItem. For more information, see the [PutItem](#) example.

Additional code examples

You can also refer to the following code sample repositories that provide additional examples to use DynamoDB with SDK for Java 2.x:

- [Official AWS single-action code examples](#)
- [Community-maintained single-action code examples](#)
- [Official AWS scenario-oriented code examples](#)

Synchronous and asynchronous programming

The AWS SDK for Java 2.x provides both *synchronous* and *asynchronous* clients for AWS services, such as DynamoDB.

The `DynamoDbClient` and `DynamoDbEnhancedClient` classes provide synchronous methods that block your thread's execution until the client receives a response from the service. This client is the most straightforward way of interacting with DynamoDB if you have no need for asynchronous operations.

The `DynamoDbAsyncClient` and `DynamoDbEnhancedAsyncClient` classes provide asynchronous methods that return immediately, and give control back to the calling thread without waiting for a response. The non-blocking client has an advantage that it allows for high concurrency across a few threads, which provides efficient handling of I/O requests with minimal compute resources. This improves throughput and responsiveness.

The AWS SDK for Java 2.x uses the native support for non-blocking I/O. The AWS SDK for Java 1.x had to simulate non-blocking I/O.

The synchronous methods return before a response is available, so you need a way to get the response when it's ready. The asynchronous methods in the AWS SDK for Java return a [CompletableFuture](#) object that contains the results of the asynchronous operation in the future. When you call `get()` or `join()` on these `CompletableFuture` objects, your code will block till the result is available. If you make this call at the same time as making the request, it's similar behavior to a plain synchronous call.

The AWS SDK documentation for [asynchronous programming](#) provides more details about how to leverage this asynchronous style.

HTTP clients

For supporting every client, there exists an HTTP client that handles communication with the AWS services. You can plug in alternative HTTP clients, choosing one that has the characteristics that best fit your application. Some are more lightweight; some have more configuration options.

Some HTTP clients support only synchronous use, while others support only asynchronous use. The AWS SDK documentation provides a [flowchart](#) that helps you select the optimal HTTP client for your workload.

The following list presents some of the possible HTTP clients:

Topics

- [Apache-based HTTP client](#)
- [URLConnection-based HTTP client](#)
- [Netty-based HTTP client](#)
- [AWS CRT-based HTTP client](#)

Apache-based HTTP client

[ApacheHttpClient](#) supports synchronous service clients and is the default HTTP client for synchronous use. For information about configuring the ApacheHttpClient, see [Configure the Apache-based HTTP client](#) in the AWS SDK for Java 2.x documentation.

URLConnection-based HTTP client

The [URLConnectionHttpClient](#) is another option for synchronous clients. It loads more quickly than the Apache-based HTTP client, but has fewer features. For information about configuring the [URLConnectionHttpClient](#), see [Configure the URLConnection-based HTTP client](#).

Netty-based HTTP client

[NettyNioAsyncHttpClient](#) supports async clients and is the default choice for async use. For information about configuring the [NettyNioAsyncHttpClient](#), see [Configure the Netty-based HTTP client](#).

AWS CRT-based HTTP client

The newer [AwsCrtHttpClient](#) and [AwsCrtAsyncHttpClient](#) from the AWS Common Runtime (CRT) libraries is another option that supports both synchronous and asynchronous clients.

Compared to other HTTP clients, AWS CRT offers:

- Faster SDK startup time
- Smaller memory footprint
- Reduced latency time
- Connection health management
- DNS load balancing

For information about configuring [AwsCrtHttpClient](#) and [AwsCrtAsyncHttpClient](#), see [Configure the AWS CRT-based HTTP clients](#).

AWS CRT-based HTTP client isn't the default because that would break backward compatibility for existing applications. However, for DynamoDB we recommend that you use the AWS CRT-based HTTP client for both sync and async uses.

For an introduction about the AWS CRT-based HTTP client, see [Announcing availability of the AWS CRT HTTP Client in the AWS SDK for Java 2.x](#).

Configuring an HTTP client

When configuring a client, you can provide various configuration options, including:

- Setting timeouts for different aspects of API calls
- Controlling if TCP Keep-Alive is enabled
- Controlling the retry policy when encountering errors
- Specifying execution attributes that [Execution interceptor](#) instances can modify. Execution interceptors can write code that intercept the execution of your API requests and responses. This enables you to perform tasks, such as publish metrics and modify requests in-flight.
- Adding or manipulating HTTP headers
- Enabling the tracking of [client-side performance metrics](#). Using this feature helps you to collect metrics about the service clients in your application and analyze the output in Amazon CloudWatch.
- Specifying an alternate executor service to be used for scheduling tasks, such as async retry attempts and timeout tasks

You control the configuration by providing a [ClientOverrideConfiguration](#) object to the service client `Builder` class. You'll see this in some code examples in the following sections.

The `ClientOverrideConfiguration` provides standard configuration choices. The different pluggable HTTP clients have implementation-specific configuration possibilities as well. Each of these clients also maintains its own documentation:

- [Apache-based HTTP client](#)
- [URLConnection-based HTTP client](#)
- [Netty-based HTTP client](#)
- [AWS CRT-based HTTP clients](#)

Topics in this section

- [Timeout configuration](#)
- [RetryMode](#)
- [DefaultsMode](#)
- [Keep-Alive configuration](#)

Timeout configuration

You can adjust the client configuration to control various timeouts related to the service calls. DynamoDB provides lower latencies compared to other AWS services. Therefore, you might want to adjust these properties to lower timeout values so you can fail fast if there's a networking issue.

You can customize the latency related behavior using `ClientOverrideConfiguration` on the DynamoDB client or by changing detailed configuration options on the underlying HTTP client implementation.

You can configure the following impactful properties using `ClientOverrideConfiguration`:

- `apiCallAttemptTimeout`—The amount of time to wait for a single attempt for an HTTP request to complete before giving up and timing out.
- `apiCallTimeout`—The amount of time to allow the client to complete the execution of an API call. This includes the request handler execution that consists of all the HTTP requests including retries.

The AWS SDK for Java 2.x provides [default values](#) for some timeout options, such as connection timeout and socket timeouts. The SDK doesn't provide default values for API call timeouts or individual API call attempt timeouts. If these timeouts aren't set in the `ClientOverrideConfiguration`, the SDK will use the socket timeout value instead for the overall API call timeout. The socket timeout has a default value of 30 seconds.

RetryMode

Another configuration related to the timeout configuration that you should consider is the `RetryMode` configuration object. This configuration object contains a collection of retry behaviors.

The SDK for Java 2.x supports the following retry modes:

- `legacy` — The default retry mode if you don't explicitly change it. This retry mode is specific to the Java SDK and characterized by:
 - Up to three retries, or more for services, such as DynamoDB which has up to 8 retries.
- `standard` — Named standard because it's more consistent with other AWS SDKs. This mode waits for a random amount of time ranging from 0ms to 1,000ms for the first retry. If another retry is necessary, it picks another random time from 0ms to 1,000ms and multiplies it by two. If an additional retry is necessary, it does the same random pick multiplied by 4, and so on. Each wait is capped at 20 seconds. This mode will perform retries on more detected failure conditions

than the legacy mode. For DynamoDB, it performs up to three total max attempts unless you overridde with [numRetries](#).

- adaptive — Builds on standard mode and dynamically limits the rate of AWS requests to maximize success rate. This may done be at the expense of request latency. We do not recommend adaptive retry mode when predictable latency is important.

You can find an expanded definition of these retry modes in the [Retry behavior](#) topic in the *AWS SDKs and Tools Reference Guide*.

Retry policies

All RetryMode configurations have a [RetryPolicy](#), which is built based on one or more [RetryCondition](#) configurations. The [TokenBucketRetryCondition](#) is especially important to the retry behaviour of the DynamoDB SDK client implementation. This condition limits the number of retries made by the SDK using a token bucket algorithm. Depending on the selected retry mode, throttling exceptions may or may not subtract tokens from the TokenBucket.

When a client encounters a retryable error, such as a throttling exception or a temporary server error, the SDK will automatically retry the request. You can control how many times and how quickly these retries happen.

When configuring a client, you can provide a [RetryPolicy](#) that supports the following parameters:

- numRetries—The maximum number of retries that should be applied before a request is considered to be failed. Default value is 8 regardless of the retry mode you use.

Warning

Make sure that you change this default value after due consideration.

- backoffStrategy—The [BackoffStrategy](#) to apply to the retries, with [FullJitterBackoffStrategy](#) being the default strategy. This strategy performs an exponential delay between additional retries based on the current number of retries, a base delay, and a maximum backoff time. It then adds jitter to provide a bit of randomness. The base delay used in the exponential delay is 25 ms regardless of the retry mode.
- retryCondition—The [RetryCondition](#) determines whether a request should be retried at all. By default it will retry a specific set of HTTP status codes and exceptions that it believes are retryable. For most situations, the default configuration should be sufficient.

The following code provides an alternative retry policy. It specifies to allow a total of five retries (six total requests). The first retry should come after approximately a 100ms delay, with each additional retry doubling that time exponentially, up to a maximum of one second delay.

```
DynamoDbClient client = DynamoDbClient.builder()
    .overrideConfiguration(ClientOverrideConfiguration.builder()
        .retryPolicy(RetryPolicy.builder()
            .backoffStrategy(FullJitterBackoffStrategy.builder()
                .baseDelay(Duration.ofMillis(100))
                .maxBackoffTime(Duration.ofSeconds(1))
                .build())
            .numRetries(5)
            .build())
        .build())
    .build();
```

DefaultsMode

The timeout properties not managed by `ClientOverrideConfiguration` and the `RetryMode` are typically not configured explicitly. Instead, their configuration is set implicitly by specifying a `DefaultsMode`.

Support for `DefaultsMode` was introduced in AWS SDK for Java 2.x (version 2.17.102 or later) to provide a set of default values for common configurable settings, such as HTTP communication settings, retry behavior, service Regional endpoint settings, and, potentially, any SDK-related configuration. When you use this feature, you can get new configuration defaults tailored to common usage scenarios.

The default modes are standardized across all of the AWS SDKs. The SDK for Java 2.x supports the following default modes:

- `legacy` — Provides default settings that vary by SDK and existed before `DefaultsMode` was established.
- `standard` — Provides default non-optimized settings for most scenarios.
- `in-region` — Builds on the standard mode and includes settings tailored for applications that call AWS services from within the same AWS Region.
- `cross-region` — Builds on the standard mode and includes settings with high timeouts for applications that call AWS services in a different AWS Region.

- **mobile** — Builds on the standard mode and includes settings with high timeouts tailored for mobile applications with higher latencies.
- **auto** — Builds on the standard mode and includes experimental features. The SDK attempts to discover the runtime environment to determine the appropriate settings automatically. The auto-detection is heuristics-based and does not provide 100% accuracy. If the runtime environment can't be determined, standard mode is used. The auto-detection might query [Instance metadata and user data](#), which might introduce latency. If startup latency is critical to your application, we recommend choosing an explicit `DefaultsMode` instead.

You can configure the defaults mode in the following ways:

- Directly on a client through `AwsClientBuilder.Builder#defaultsMode(DefaultsMode)`.
- On a configuration profile through the `defaults_mode` profile file property.
- Globally through the `aws.defaultsMode` system property.
- Globally through the `AWS_DEFAULTS_MODE` environment variable.

 **Note**

For any mode other than legacy, the vended default values might change as best practices evolve. Therefore, we encourage you to perform testing when upgrading the SDK if you are using a mode other than legacy.

The [Smart configuration defaults](#) in the *AWS SDKs and Tools Reference Guide* provides a list of configuration properties and their default values in the different default modes.

You choose the defaults mode value based on your application's characteristics and the AWS service your application interacts with.

These values are configured with a broad selection of AWS services in mind. For a typical DynamoDB deployment where both your DynamoDB table(s) and application are deployed in one Region, the `in-region` defaults mode is most relevant among the standard default modes.

Example DynamoDB SDK client configuration tuned for low-latency calls

The following example adjusts the timeouts to lower values for an expected low-latency DynamoDB call.

```
DynamoDbAsyncClient asyncClient = DynamoDbAsyncClient.builder()
    .defaultsMode(DefaultsMode.IN_REGION)
    .httpClientBuilder(AwsCrtAsyncHttpClient.builder())
    .overrideConfiguration(ClientOverrideConfiguration.builder()
        .apiCallTimeout(Duration.ofSeconds(3))
        .apiCallAttemptTimeout(Duration.ofMillis(500)))
    .build())
.build();
```

The individual HTTP client implementation may provide you with even more granular control over the timeout and connection usage behavior. For example, in case of the AWS CRT-based client, you can enable `ConnectionHealthConfiguration` which allows the AWS CRT-based client to actively monitor the health of the used connections. For more details, see the [documentation](#) for AWS SDK for Java 2.x.

Keep-Alive configuration

Enabling keep-alive can reduce latencies by reusing connections. There are two different kinds of keep-alive: HTTP Keep-Alive and TCP Keep-Alive.

- HTTP Keep-Alive attempts to maintain the HTTPS connection between the client and server so later requests can reuse that connection. This skips the heavyweight HTTPS authentication on later requests. HTTP Keep-Alive is enabled by default on all clients.
- TCP Keep-Alive requests the underlying operating system to send small packets over the socket connection to provide extra assurance the socket is kept alive and to immediately detect any drops. This ensures a later request won't spend time trying to use a dropped socket. TCP Keep-Alive is disabled by default on all clients. You may want to enable it. The following code examples show how to do this with each HTTP client. When enabled for all non-CRT based HTTP clients, the actual Keep-Alive mechanism is dependent on the operating system. Therefore, you must configure additional TCP Keep-Alive values, such as timeout and number of packets, through the operating system. You can do this using `sysctl` on a Linux or Mac machine, or Registry values on a Windows machine.

Example to enable TCP Keep-Alive on an Apache-based HTTP client

```
DynamoDbClient client = DynamoDbClient.builder()
    .httpClientBuilder(ApacheHttpClient.builder().tcpKeepAlive(true))
    .build();
```

URLConnection-based HTTP client

Any synchronous client using the URLConnection-based HTTP client [HttpURLConnection](#) doesn't have a [mechanism](#) to enable keep-alive.

Example to enable TCP Keep-Alive on a Netty-based HTTP client

```
DynamoDbAsyncClient client = DynamoDbAsyncClient.builder()
    .httpClientBuilder(NettyNioAsyncHttpClient.builder().tcpKeepAlive(true))
    .build();
```

Example to enable TCP Keep-Alive on an AWS CRT-based HTTP client

With the AWS CRT-based HTTP client, you can enable TCP keep-alive and control the duration.

```
DynamoDbClient client = DynamoDbClient.builder()
    .httpClientBuilder(AwsCrtHttpClient.builder())
    .tcpKeepAliveConfiguration(TcpKeepAliveConfiguration.builder()
        .keepAliveInterval(Duration.ofSeconds(50))
        .keepAliveTimeout(Duration.ofSeconds(5))
        .build()))
    .build();
```

When using the asynchronous DynamoDB client, you can enable TCP Keep-Alive as shown in the following code.

```
DynamoDbAsyncClient client = DynamoDbAsyncClient.builder()
    .httpClientBuilder(AwsCrtAsyncHttpClient.builder())
    .tcpKeepAliveConfiguration(TcpKeepAliveConfiguration.builder()
        .keepAliveInterval(Duration.ofSeconds(50))
        .keepAliveTimeout(Duration.ofSeconds(5))
        .build()))
    .build();
```

Error handling

When it comes to exception handling, the AWS SDK for Java 2.x uses runtime (unchecked) exceptions.

The base exception, covering all SDK exceptions, is [SdkServiceException](#), which extends from the Java unchecked RuntimeException. If you catch this, you'll catch all exceptions thrown by the SDK.

SdkServiceException has a subclass called [AwsServiceException](#). This subclass indicates any issue in communication with the AWS service. It has a subclass called [DynamoDbException](#), which indicates an issue in communication with DynamoDB. If you catch this, you'll catch all exceptions related to DynamoDB but no other SDK exceptions.

There are more specific [exception types](#) under DynamoDbException. Some of these exception types apply to control-plane operations such as [TableAlreadyExistsException](#). Others apply to data-plane operations. The following is an example of a common data-plane exception:

- [ConditionalCheckFailedException](#)—You specified a condition in the request that evaluated to false. For example, you might have tried to perform a conditional update on an item, but the actual value of the attribute did not match the expected value in the condition. A request that fails in this manner will not be retried.

Other situations don't have a specific exception defined. For example, when your requests get throttled the specific ProvisionedThroughputExceededException might get thrown, while in other cases the more generic DynamoDbException is thrown. In either case you can determine if the exception was caused by throttling by checking if `isThrottlingException()` returns true.

Depending on your application needs, you can catch all AwsServiceException or DynamoDbException instances. But often you need different behavior in different situations. The logic to deal with a condition check failure will be different compared to dealing with throttling. Define which exceptional paths you want to deal with and make sure to test the alternative paths. This helps you make sure you're able to deal with all relevant scenarios.

The [Error handling with DynamoDB](#) lists some common errors you might encounter. You can also refer to [Common Errors](#) to see a list of common errors. For a particular API call, you can also find the exact errors possible along with its documentation, such as the [Query API](#). For information about handling exceptions, see [Exception handling for the AWS SDK for Java 2.x](#).

AWS request ID

Each request includes a Request ID which can be useful to pull if you're working with AWS Support to diagnose an issue. Each exception derived from SdkServiceException has a method [requestId\(\)](#) available to retrieve the request ID.

Logging

Using the logging provided by the SDK can be useful both for catching any important messages from the client libraries and for more in-depth debugging purposes. Loggers are hierarchical and the SDK uses `software.amazon.awssdk` as its root logger. The level may be configured with one of TRACE, DEBUG, INFO, WARN, ERROR, ALL, or OFF. The configured level will apply to that logger and down into the logger hierarchy.

The AWS SDK for Java 2.x leverages the Simple Logging Façade for Java (SLF4J) for its logging, which acts as an abstraction layer around other loggers. This enables you to plug in the logger that you prefer. For instructions about plugging in loggers, see the [SLF4J user manual](#).

Each logger has a particular behavior. The Log4j 2.x logger by default creates a `ConsoleAppender` which appends log events to `System.out` and defaults to the `ERROR` log level.

The `SimpleLogger` logger included in SLF4J outputs by default to `System.err` and defaults to the `INFO` log level.

We recommend that you set the level to `WARN` for `software.amazon.awssdk` for any production deployments to catch any important messages from the SDK's client libraries while limiting the output quantity.

If SLF4J can't find a supported logger on the class path (no SLF4J binding), SLF4J will default to a [no operation implementation](#). This implementation results in logging messages to `System.err` explaining that SLF4J could not find a logger implementation on the classpath. To prevent this situation, you need to add a logger implementation. To do this, you can add a dependency in your Apache Maven `pom.xml` on artifacts, such as `org.slf4j.slf4j-simple` or `org.apache.logging.log4j.log4j-slf4j2-imp`.

The documentation for AWS SDK for Java 2.x explains how to configure the logging in the SDK including adding logging dependencies to your application configuration. For information, see [Logging with the SDK for Java 2.x](#).

The following configuration in the `Log4j2.xml` file shows how to adjust the logging behavior if you're using the Apache Log4j 2 logger. This configuration sets the root logger level to `WARN`. This log level will be inherited by all loggers in the hierarchy including the `software.amazon.awssdk` logger.

By default, the output will go to `System.out`. In the following example, we still override the default output Log4j appender to apply a tailored Log4j `PatternLayout`.

Example of Log4j2.xml configuration file

The following configuration will log messages at the ERROR and WARN levels to the console for all logger hierarchies.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="WARN">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
  </Loggers>
</Configuration>
```

AWS request ID logging

You can find RequestIds within exceptions when something goes wrong. However, if you want the RequestIds for requests that aren't generating exceptions, you can use logging.

Request IDs are outputted at DEBUG level by the `software.amazon.awssdk.request` logger. The following example extends the previous [configuration example](#) to keep the root logger level at ERROR, the `software.amazon.awssdk` at level WARN, and the `software.amazon.awssdk.request` at level DEBUG. Setting these levels helps to catch the Request IDs and other request related details, such as the endpoint and status code.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="ConsoleAppender" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{YYYY-MM-dd HH:mm:ss} [%t] %-5p %c:%L - %m%n" />
    </Console>
  </Appenders>

  <Loggers>
    <Root level="ERROR">
      <AppenderRef ref="ConsoleAppender"/>
    </Root>
    <Logger name="software.amazon.awssdk" level="WARN" />
  </Loggers>
</Configuration>
```

```
<Logger name="software.amazon.awssdk.request" level="DEBUG" />
</Loggers>
</Configuration>
```

Here is an example of the log output:

```
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Sending Request:
DefaultSdkHttpFullRequest(httpMethod=POST, protocol=https, host=dynamodb.us-
east-1.amazonaws.com, encodedPath=/, headers=[amz-sdk-invocation-id, Content-Length,
Content-Type, User-Agent, X-Amz-Target], queryParameters[])
2022-09-23 16:02:08 [main] DEBUG software.amazon.awssdk.request:85 - Received
successful response: 200, Request ID:
QS9DUMME2NHEDH8TGT9N5V530JVV4KQNS05AEMVJF66Q9ASUAAJG, Extended Request ID: not
available
```

Pagination

Some requests, such as [Query](#) and [Scan](#), limit the size of data returned on a single request and require you make repeated requests to pull subsequent pages.

You can control the maximum number of items to be read for each page with the `Limit` parameter. For example, you can use the `Limit` parameter to retrieve only the last 10 items. This limit is how many items should be read from the table before any filtering is applied. There's no way to specify you want exactly 10 after filtering. You can only control the pre-filtered count and check client-side when you've actually retrieved 10 items. Regardless of the limit, every response always has a maximum size of 1 MB.

In the API response a `LastEvaluatedKey` might be included, which indicates that the response ended because it hit a count limit or a size limit. This key is the last key evaluated for that response. Interacting directly with the API you can retrieve this `LastEvaluatedKey` and pass it to a follow-up call as `ExclusiveStartKey` to read the next chunk from that starting point. If no `LastEvaluatedKey` is returned, it means that there're no more items matching the `Query` or `Scan` API call.

The following example uses the low-level interface to limit the items to 100 based on the `keyConditionExpression` parameter.

```
QueryRequest.Builder queryRequestBuilder = QueryRequest.builder()
    .expressionAttributeValues(Map.of(
```

```
        ":pk_val", AttributeValue.fromS("123"),
        ":sk_val", AttributeValue.fromN("1000")))
    .keyConditionExpression("pk = :pk_val AND sk > :sk_val")
    .limit(100)
    .tableName(TABLE_NAME);

while (true) {
    QueryResponse queryResponse = DYNAMODB_CLIENT.query(queryRequestBuilder.build());

    queryResponse.items().forEach(item -> {
        LOGGER.info("item PK: [" + item.get("pk") + "] and SK: [" + item.get("sk") +
    "']");
    });

    if (!queryResponse.hasLastEvaluatedKey()) {
        break;
    }
    queryRequestBuilder.exclusiveStartKey(queryResponse.lastEvaluatedKey());
}
```

The AWS SDK for Java 2.x can simplify this interaction with DynamoDB by providing auto-pagination methods that make multiple service calls to get the next pages of results for you automatically. This simplifies your code, but does take away some control on resource usage that you would keep by reading pages manually.

By using the `Iterable` methods available in the DynamoDB client such as [QueryPaginator](#) and [ScanPaginator](#), the SDK takes care of the pagination. The return type of these methods is a custom iterable that you can use to iterate through all the pages. The SDK will internally handle service calls for you. Using the Java Stream API, you could handle the result of `QueryPaginator` as shown in the following example.

```
QueryPublisher queryPublisher =
    DYNAMODB_CLIENT.queryPaginator(QueryRequest.builder()
        .expressionAttributeValues(Map.of(
            ":pk_val", AttributeValue.fromS("123"),
            ":sk_val", AttributeValue.fromN("1000")))
        .keyConditionExpression("pk = :pk_val AND sk > :sk_val")
        .limit(100)
        .tableName("YourTableName")
        .build()));

queryPublisher.items().subscribe(item ->
```

```
System.out.println(item.get("itemData"))).join();
```

Data class annotations

The Java SDK provides several annotations which you can put on your data class' attributes that will influence how the SDK interacts with them. By adding the annotation, you can have an attribute behave as an implicit atomic counter, maintain an auto-generated timestamp value, or track an item version number. For more information, see [Data class annotations](#).

Working with tables, items, queries, scans, and indexes

This section provides details about working with tables, items, queries, and more in Amazon DynamoDB.

- [Working with DynamoDB tables in Java](#)
- [Working with DynamoDB tables in .NET](#)

Basic operations on DynamoDB tables

Similar to other database systems, Amazon DynamoDB stores data in tables. You can manage your tables using a few basic operations.

Topics

- [Creating a table](#)
- [Describing a table](#)
- [Updating a table](#)
- [Deleting a table](#)
- [Using deletion protection](#)
- [Listing table names](#)
- [Describing provisioned throughput quotas](#)

Creating a table

Use the `CreateTable` operation to create a table in Amazon DynamoDB. To create the table, you must provide the following information:

- **Table name.** The name must conform to the DynamoDB naming rules, and must be unique for the current AWS account and Region. For example, you could create a `People` table in US East (N. Virginia) and another `People` table in Europe (Ireland). However, these two tables would be entirely different from each other. For more information, see [Supported data types and naming rules in Amazon DynamoDB](#).
- **Primary key.** The primary key can consist of one attribute (partition key) or two attributes (partition key and sort key). You need to provide the attribute names, data types, and the role of

each attribute: HASH (for a partition key) and RANGE (for a sort key). For more information, see [Primary key](#).

- **Throughput settings (for provisioned tables).** If using provisioned mode, you must specify the initial read and write throughput settings for the table. You can modify these settings later, or enable DynamoDB auto scaling to manage the settings for you. For more information, see [Managing settings on DynamoDB provisioned capacity tables](#) and [Managing throughput capacity automatically with DynamoDB auto scaling](#).

Example 1: Create a provisioned table

The following AWS CLI example shows how to create a table (Music). The primary key consists of Artist (partition key) and SongTitle (sort key), each of which has a data type of String. The maximum throughput for this table is 10 read capacity units and 5 write capacity units.

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5
```

The CreateTable operation returns metadata for the table, as shown following.

```
{
    "TableDescription": {
        "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music",
        "AttributeDefinitions": [
            {
                "AttributeName": "Artist",
                "AttributeType": "S"
            },
            {
                "AttributeName": "SongTitle",
                "AttributeType": "S"
            }
        ],
        "KeySchema": [
            {
                "AttributeName": "Artist",
                "KeyType": "HASH"
            },
            {
                "AttributeName": "SongTitle",
                "KeyType": "RANGE"
            }
        ],
        "ProvisionedThroughput": {
            "ReadCapacityUnits": 10,
            "WriteCapacityUnits": 5
        }
    }
}
```

```
"ProvisionedThroughput": {  
    "NumberOfDecreasesToday": 0,  
    "WriteCapacityUnits": 5,  
    "ReadCapacityUnits": 10  
},  
"TableSizeBytes": 0,  
"TableName": "Music",  
"TableStatus": "CREATING",  
"TableId": "12345678-0123-4567-a123-abcdefghijkl",  
"KeySchema": [  
    {  
        "KeyType": "HASH",  
        "AttributeName": "Artist"  
    },  
    {  
        "KeyType": "RANGE",  
        "AttributeName": "SongTitle"  
    }  
],  
"ItemCount": 0,  
"CreationDateTime": 1542397215.37  
}  
}
```

The TableStatus element indicates the current state of the table (CREATING). It might take a while to create the table, depending on the values you specify for ReadCapacityUnits and WriteCapacityUnits. Larger values for these require DynamoDB to allocate more resources for the table.

Example 2: Create an on-demand table

To create the same table Music using on-demand mode.

```
aws dynamodb create-table \  
    --table-name Music \  
    --attribute-definitions \  
        AttributeName=Artist,AttributeType=S \  
        AttributeName=SongTitle,AttributeType=S \  
    --key-schema \  
        AttributeName=Artist,KeyType=HASH \  
        AttributeName=SongTitle,KeyType=RANGE \  
    --billing-mode=PAY_PER_REQUEST
```

The `CreateTable` operation returns metadata for the table, as shown following.

```
{  
    "TableDescription": {  
        "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music",  
        "AttributeDefinitions": [  
            {  
                "AttributeName": "Artist",  
                "AttributeType": "S"  
            },  
            {  
                "AttributeName": "SongTitle",  
                "AttributeType": "S"  
            }  
        ],  
        "ProvisionedThroughput": {  
            "NumberOfDecreasesToday": 0,  
            "WriteCapacityUnits": 0,  
            "ReadCapacityUnits": 0  
        },  
        "TableSizeBytes": 0,  
        "TableName": "Music",  
        "BillingModeSummary": {  
            "BillingMode": "PAY_PER_REQUEST"  
        },  
        "TableStatus": "CREATING",  
        "TableId": "12345678-0123-4567-a123-abcdefghijkl",  
        "KeySchema": [  
            {  
                "KeyType": "HASH",  
                "AttributeName": "Artist"  
            },  
            {  
                "KeyType": "RANGE",  
                "AttributeName": "SongTitle"  
            }  
        ],  
        "ItemCount": 0,  
        "CreationDateTime": 1542397468.348  
    }  
}
```

⚠️ Important

When calling `DescribeTable` on an on-demand table, read capacity units and write capacity units are set to 0.

Example 3: Create a table using the DynamoDB standard-infrequent access table class

To create the same Music table using the DynamoDB Standard-Infrequent Access table class.

```
aws dynamodb create-table \
    --table-name Music \
    --attribute-definitions \
        AttributeName=Artist,AttributeType=S \
        AttributeName=SongTitle,AttributeType=S \
    --key-schema \
        AttributeName=Artist,KeyType=HASH \
        AttributeName=SongTitle,KeyType=RANGE \
    --provisioned-throughput \
        ReadCapacityUnits=10,WriteCapacityUnits=5 \
    --table-class STANDARD_INFREQUENT_ACCESS
```

The `CreateTable` operation returns metadata for the table, as shown following.

```
{
  "TableDescription": {
    "TableArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music",
    "AttributeDefinitions": [
      {
        "AttributeName": "Artist",
        "AttributeType": "S"
      },
      {
        "AttributeName": "SongTitle",
        "AttributeType": "S"
      }
    ],
    "ProvisionedThroughput": {
      "NumberOfDecreasesToday": 0,
      "WriteCapacityUnits": 5,
      "ReadCapacityUnits": 10
    },
  }
}
```

```
"TableClassSummary": {  
    "LastUpdateDateTime": 1542397215.37,  
    "TableClass": "STANDARD_INFREQUENT_ACCESS"  
},  
"TableSizeBytes": 0,  
"TableName": "Music",  
"TableStatus": "CREATING",  
"TableId": "12345678-0123-4567-a123-abcdefghijkl",  
"KeySchema": [  
    {  
        "KeyType": "HASH",  
        "AttributeName": "Artist"  
    },  
    {  
        "KeyType": "RANGE",  
        "AttributeName": "SongTitle"  
    }  
],  
"ItemCount": 0,  
"CreationDateTime": 1542397215.37  
}  
}
```

Describing a table

To view details about a table, use the `DescribeTable` operation. You must provide the table name. The output from `DescribeTable` is in the same format as that from `CreateTable`. It includes the timestamp when the table was created, its key schema, its provisioned throughput settings, its estimated size, and any secondary indexes that are present.

Important

When calling `DescribeTable` on an on-demand table, read capacity units and write capacity units are set to 0.

Example

```
aws dynamodb describe-table --table-name Music
```

The table is ready for use when the `TableStatus` has changed from `CREATING` to `ACTIVE`.

Note

If you issue a `DescribeTable` request immediately after a `CreateTable` request, DynamoDB might return an error (`ResourceNotFoundException`). This is because `DescribeTable` uses an eventually consistent query, and the metadata for your table might not be available at that moment. Wait for a few seconds, and then try the `DescribeTable` request again.

For billing purposes, your DynamoDB storage costs include a per-item overhead of 100 bytes. (For more information, go to [DynamoDB Pricing](#).) This extra 100 bytes per item is not used in capacity unit calculations or by the `DescribeTable` operation.

Updating a table

The `UpdateTable` operation allows you to do one of the following:

- Modify a table's provisioned throughput settings (for provisioned mode tables).
- Change the table's read/write capacity mode.
- Manipulate global secondary indexes on the table (see [Using Global Secondary Indexes in DynamoDB](#)).
- Enable or disable DynamoDB Streams on the table (see [Change data capture for DynamoDB Streams](#)).

Example

The following AWS CLI example shows how to modify a table's provisioned throughput settings.

```
aws dynamodb update-table --table-name Music \
    --provisioned-throughput ReadCapacityUnits=20,WriteCapacityUnits=10
```

Note

When you issue an `UpdateTable` request, the status of the table changes from `AVAILABLE` to `UPDATING`. The table remains fully available for use while it is `UPDATING`. When this process is completed, the table status changes from `UPDATING` to `AVAILABLE`.

Example

The following AWS CLI example shows how to modify a table's read/write capacity mode to on-demand mode.

```
aws dynamodb update-table --table-name Music \
    --billing-mode PAY_PER_REQUEST
```

Deleting a table

You can remove an unused table with the `DeleteTable` operation. Deleting a table is an unrecoverable operation.

Example

The following AWS CLI example shows how to delete a table.

```
aws dynamodb delete-table --table-name Music
```

When you issue a `DeleteTable` request, the table's status changes from ACTIVE to DELETING. It might take a while to delete the table, depending on the resources it uses (such as the data stored in the table, and any streams or indexes on the table).

When the `DeleteTable` operation concludes, the table no longer exists in DynamoDB.

Using deletion protection

You can protect a table from accidental deletion with the deletion protection property. Enabling this property for tables helps ensure that tables do not get accidentally deleted during regular table management operations by your administrators. This will help prevent disruption to your normal business operations.

The table owner or an authorized administrator controls the deletion protection property for each table. The deletion protection property for every table is off by default. This includes global replicas, and tables restored from backups. When deletion protection is disabled for a table, the table can be deleted by any users authorized by an Identity and Access Management (IAM) policy. When deletion protection is enabled for a table, it cannot be deleted by anyone.

To change this setting, go to the table's **Additional settings**, navigate to the **Deletion Protection** panel and select **Enable delete protection**.

The deletion protection property is supported by the DynamoDB console, API, CLI/SDK and AWS CloudFormation. The `CreateTable` API supports the deletion protection property at table creation time, and the `UpdateTable` API supports changing the deletion protection property for existing tables.

 **Note**

- If an AWS account is deleted, all of that account's data including tables are still deleted within 90 days.
- If DynamoDB loses access to a customer managed key that was used to encrypt a table, it will still archive the table. Archiving involves making a backup of the table and deleting the original.

Listing table names

The `ListTables` operation returns the names of the DynamoDB tables for the current AWS account and Region.

Example

The following AWS CLI example shows how to list the DynamoDB table names.

```
aws dynamodb list-tables
```

Describing provisioned throughput quotas

The `DescribeLimits` operation returns the current read and write capacity quotas for the current AWS account and Region.

Example

The following AWS CLI example shows how to describe the current provisioned throughput quotas.

```
aws dynamodb describe-limits
```

The output shows the upper quotas of read and write capacity units for the current AWS account and Region.

For more information about these quotas, and how to request quota increases, see [Throughput default quotas](#).

Considerations when changing read/write Capacity Mode

You can switch between read/write capacity modes once every 24 hours. The only exception to this is if you switch a provisioned mode table to on-demand mode: you can switch back to provisioned mode in the same 24-hour period. Consider the following when updating your read/write capacity mode in Amazon DynamoDB.

Managing capacity

When you update a table from provisioned to on-demand mode, you don't need to specify how much read and write throughput you expect your application to perform.

Consider the following when you update a table from on-demand to provisioned mode:

- If you're using the AWS CLI or AWS SDK, choose the right provisioned capacity settings of your table and global secondary indexes by using Amazon CloudWatch to look at your historical consumption (`ConsumedWriteCapacityUnits` and `ConsumedReadCapacityUnits` metrics) to determine the new throughput settings.

 **Note**

If you're switching a global table to provisioned mode, look at the maximum consumption across all your regional replicas for base tables and global secondary indexes when determining the new throughput settings.

- If you are switching from on-demand mode back to provisioned mode, make sure to set the initial provisioned units high enough to handle your table or index capacity during the transition.

Managing auto scaling

When you update a table from provisioned to on-demand mode:

- If you're using the console, all of your auto scaling settings (if any) will be deleted.
- If you're using the AWS CLI or AWS SDK, all of your auto scaling settings will be preserved. These settings can be applied when you update your table to provisioned billing mode again.
- If the table is a global table, auto scaling settings are not preserved.

When you update a table from on-demand to provisioned mode:

- If you're using the console, DynamoDB recommends enabling auto scaling with the following defaults:
 - Target utilization: 70%
 - Minimum provisioned capacity: 5 units
 - Maximum provisioned capacity: The Region maximum
- If you're using the AWS CLI or SDK, your previous auto scaling settings (if any) are preserved.
- If the table is a global table, any previous auto scaling settings will be overwritten with the recommended defaults.

Considerations when choosing a table class

DynamoDB offers two table classes designed to help you optimize for cost. The DynamoDB Standard table class is the default, and is recommended for the vast majority of workloads. The DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class is optimized for tables where storage is the dominant cost. For example, tables that store infrequently accessed data, such as application logs, old social media posts, e-commerce order history, and past gaming achievements, are good candidates for the Standard-IA table class.

Every DynamoDB table is associated with a table class. All secondary indexes associated with the table use the same table class. You can set your table class when creating your table (DynamoDB Standard by default) and update the table class of an existing table using the AWS Management Console, AWS CLI, or AWS SDK. DynamoDB also supports managing your table class using AWS CloudFormation for single-region tables (tables that are not global tables). Each table class offers different pricing for data storage as well as read and write requests. When choosing a table class for your table, keep the following in mind:

- The DynamoDB Standard table class offers lower throughput costs than DynamoDB Standard-IA and is the most cost-effective option for tables where throughput is the dominant cost.
- The DynamoDB Standard-IA table class offers lower storage costs than DynamoDB Standard, and is the most cost-effective option for tables where storage is the dominant cost. When storage exceeds 50% of the throughput (reads and writes) cost of a table using the DynamoDB Standard table class, the DynamoDB Standard-IA table class can help you reduce your total table cost.
- DynamoDB Standard-IA tables offer the same performance, durability, and availability as DynamoDB Standard tables.

- Switching between the DynamoDB Standard and DynamoDB Standard-IA table classes does not require changing your application code. You use the same DynamoDB APIs and service endpoints regardless of the table class your tables use.
- DynamoDB Standard-IA tables are compatible with all existing DynamoDB features such as auto scaling, on-demand mode, time-to-live (TTL), on-demand backups, point-in-time recovery (PITR), and global secondary indexes.

The most cost-effective table class for your table depends on your table's expected storage and throughput usage patterns. You can look at your table's historical storage and throughput cost and usage with AWS Cost and Usage Reports and the AWS Cost Explorer. Use this historical data to determine the most cost-effective table class for your table. To learn more about using AWS Cost and Usage Reports and the AWS Cost Explorer, see the [AWS Billing and Cost Management Documentation](#). See [Amazon DynamoDB Pricing](#) for details about table class pricing.

 **Note**

A table class update is a background process. You can still access your table normally during a table class update. The time to update your table class depends on your table traffic, storage size, and other related variables. No more than two table class updates on your table are allowed in a 30-day trailing period.

Managing settings on DynamoDB provisioned capacity tables

When you create a new provisioned table in Amazon DynamoDB, you must specify its *provisioned throughput capacity*. This is the amount of read and write activity that the table can support. DynamoDB uses this information to reserve sufficient system resources to meet your throughput requirements.

 **Note**

You can create an on-demand mode table instead so that you don't have to manage any capacity settings for servers, storage, or throughput. DynamoDB instantly accommodates your workloads as they ramp up or down to any previously reached traffic level. If a workload's traffic level hits a new peak, DynamoDB adapts rapidly to accommodate the workload. For more information, see [On-demand mode](#).

You can optionally allow DynamoDB auto scaling to manage your table's throughput capacity. However, you still must provide initial settings for read and write capacity when you create the table. DynamoDB auto scaling uses these initial settings as a starting point, and then adjusts them dynamically in response to your application's requirements. For more information, see [Managing throughput capacity automatically with DynamoDB auto scaling](#).

As your application data and access requirements change, you might need to adjust your table's throughput settings. If you're using DynamoDB auto scaling, the throughput settings are automatically adjusted in response to actual workloads. You can also use the `UpdateTable` operation to manually adjust your table's throughput capacity. You might decide to do this if you need to bulk-load data from an existing data store into your new DynamoDB table. You could create the table with a large write throughput setting and then reduce this setting after the bulk data load is complete.

You specify throughput requirements in terms of *capacity units*—the amount of data your application needs to read or write per second. You can modify these settings later, if needed, or enable DynamoDB auto scaling to modify them automatically.

Read capacity units

A *read capacity unit* represents one strongly consistent read per second, or two eventually consistent reads per second, for an item up to 4 KB in size.

Note

To learn more about DynamoDB read consistency models, see [Read consistency](#).

For example, suppose that you create a table with 10 provisioned read capacity units. This allows you to perform 10 strongly consistent reads per second, or 20 eventually consistent reads per second, for items up to 4 KB.

Reading an item larger than 4 KB consumes more read capacity units. For example, a strongly consistent read of an item that is 8 KB ($4\text{ KB} \times 2$) consumes 2 read capacity units. An eventually consistent read on that same item consumes only 1 read capacity unit.

Item sizes for reads are rounded up to the next 4 KB multiple. For example, reading a 3,500-byte item consumes the same throughput as reading a 4 KB item.

Capacity unit consumption for reads

The following describes how DynamoDB read operations consume read capacity units:

- **GetItem**—Reads a single item from a table. To determine the number of capacity units that GetItem will consume, take the item size and round it up to the next 4 KB boundary. If you specified a strongly consistent read, this is the number of capacity units required. For an eventually consistent read (the default), divide this number by two.

For example, if you read an item that is 3.5 KB, DynamoDB rounds the item size to 4 KB. If you read an item of 10 KB, DynamoDB rounds the item size to 12 KB.

- **BatchGetItem**—Reads up to 100 items, from one or more tables. DynamoDB processes each item in the batch as an individual GetItem request, so DynamoDB first rounds up the size of each item to the next 4 KB boundary, and then calculates the total size. The result is not necessarily the same as the total size of all the items. For example, if BatchGetItem reads a 1.5 KB item and a 6.5 KB item, DynamoDB calculates the size as 12 KB ($4\text{ KB} + 8\text{ KB}$), not 8 KB ($1.5\text{ KB} + 6.5\text{ KB}$).
- **Query**—Reads multiple items that have the same partition key value. All items returned are treated as a single read operation, where DynamoDB computes the total size of all items and then rounds up to the next 4 KB boundary. For example, suppose your query returns 10 items whose combined size is 40.8 KB. DynamoDB rounds the item size for the operation to 44 KB. If a query returns 1500 items of 64 bytes each, the cumulative size is 96 KB.
- **Scan**—Reads all items in a table. DynamoDB considers the size of the data that is evaluated, not the size of the data returned by the scan.

If you perform a read operation on an item that does not exist, DynamoDB still consumes provisioned read throughput: A strongly consistent read request consumes one read capacity unit, while an eventually consistent read request consumes 0.5 of a read capacity unit.

For any operation that returns items, you can request a subset of attributes to retrieve. However, doing so has no impact on the item size calculations. In addition, Query and Scan can return item counts instead of attribute values. Getting the count of items uses the same quantity of read capacity units and is subject to the same item size calculations. This is because DynamoDB has to read each item in order to increment the count.

Read operations and read consistency

The preceding calculations assume strongly consistent read requests. For an eventually consistent read request, the operation consumes only half the capacity units. For an eventually consistent read, if the total item size is 80 KB, the operation consumes only 10 capacity units.

Write capacity units

A *write capacity unit* represents one write per second, for an item up to 1 KB in size.

For example, suppose that you create a table with 10 write capacity units. This allows you to perform 10 writes per second, for items up to 1 KB in size per second.

Item sizes for writes are rounded up to the next 1 KB multiple. For example, writing a 500-byte item consumes the same throughput as writing a 1 KB item.

Capacity unit consumption for writes

The following describes how DynamoDB write operations consume write capacity units:

- `PutItem`—Writes a single item to a table. If an item with the same primary key exists in the table, the operation replaces the item. For calculating provisioned throughput consumption, the item size that matters is the larger of the two.
- `UpdateItem`—Modifies a single item in the table. DynamoDB considers the size of the item as it appears before and after the update. The provisioned throughput consumed reflects the larger of these item sizes. Even if you update just a subset of the item's attributes, `UpdateItem` will still consume the full amount of provisioned throughput (the larger of the "before" and "after" item sizes).
- `DeleteItem`—Removes a single item from a table. The provisioned throughput consumption is based on the size of the deleted item.

- **BatchWriteItem**—Writes up to 25 items to one or more tables. DynamoDB processes each item in the batch as an individual PutItem or DeleteItem request (updates are not supported). So DynamoDB first rounds up the size of each item to the next 1 KB boundary, and then calculates the total size. The result is not necessarily the same as the total size of all the items. For example, if BatchWriteItem writes a 500-byte item and a 3.5 KB item, DynamoDB calculates the size as 5 KB (1 KB + 4 KB), not 4 KB (500 bytes + 3.5 KB).

For PutItem, UpdateItem, and DeleteItem operations, DynamoDB rounds the item size up to the next 1 KB. For example, if you put or delete an item of 1.6 KB, DynamoDB rounds the item size up to 2 KB.

PutItem, UpdateItem, and DeleteItem allow *conditional writes*, where you specify an expression that must evaluate to true in order for the operation to succeed. If the expression evaluates to false, DynamoDB still consumes write capacity units from the table. The amount consumed is dependent on the size of the item (whether it's an existing item in the table or a new one you are attempting to create or update). For example, if an existing item is 300kb and the new item you are trying to create or update is 310kb, the write capacity units consumed will be the 310kb item.

Request throttling and burst capacity

If your application performs reads or writes at a higher rate than your table can support, DynamoDB begins to *throttle* those requests. When DynamoDB throttles a read or write, it returns a ProvisionedThroughputExceededException to the caller. The application can then take appropriate action, such as waiting for a short interval before retrying the request.

Note

We recommend that you use the AWS SDKs for software development. The AWS SDKs provide built-in support for retrying throttled requests; you do not need to write this logic yourself. For more information, see [Error retries and exponential backoff](#).

The DynamoDB console displays Amazon CloudWatch metrics for your tables, so you can monitor throttled read requests and write requests. If you encounter excessive throttling, you should consider increasing your table's provisioned throughput settings.

In some cases, DynamoDB uses *burst capacity* to accommodate reads or writes in excess of your table's throughput settings. With burst capacity, unexpected read or write requests can succeed where they otherwise would be throttled. For more information, see [Using burst capacity effectively](#).

Request throttling and adaptive capacity

DynamoDB automatically distributes your data across partitions, which are stored on multiple servers in the AWS Cloud (For more information, see [Partitions and data distribution](#)). It's not always possible to distribute read and write activity evenly all the time. When data access is imbalanced, a "hot" partition can receive such a higher volume of read and write traffic compared to other partitions. Adaptive capacity works by automatically increasing throughput capacity for partitions that receive more traffic. For more information, see [Understanding DynamoDB adaptive capacity](#).

Choosing initial throughput settings

Every application has different requirements for reading and writing from a database. When you are determining the initial throughput settings for a DynamoDB table, take the following inputs into consideration:

- **Item sizes.** Some items are small enough that they can be read or written using a single capacity unit. Larger items require multiple capacity units. By estimating the sizes of the items that will be in your table, you can specify accurate settings for your table's provisioned throughput.
- **Expected read and write request rates.** In addition to item size, you should estimate the number of reads and writes you need to perform per second.
- **Read consistency requirements.** Read capacity units are based on strongly consistent read operations, which consume twice as many database resources as eventually consistent reads. You should determine whether your application requires strongly consistent reads, or whether it can relax this requirement and perform eventually consistent reads instead. (Read operations in DynamoDB are eventually consistent, by default. You can request strongly consistent reads for these operations if necessary.)

For example, suppose that you want to read 80 items per second from a table. The items are 3 KB in size, and you want strongly consistent reads. For this scenario, each read requires one provisioned read capacity unit. To determine this number, you divide the item size of the operation by 4 KB, and then round up to the nearest whole number, as in this example:

- $3 \text{ KB} / 4 \text{ KB} = 0.75$, or **1** read capacity unit

For this scenario, you have to set the table's provisioned read throughput to 80 read capacity units:

- 1 read capacity unit per item \times 80 reads per second = **80** read capacity units

Now suppose that you want to write 100 items per second to your table, and that the items are 512 bytes in size. For this scenario, each write requires one provisioned write capacity unit. To determine this number, you divide the item size of the operation by 1 KB, and then round up to the nearest whole number:

- $512 \text{ bytes} / 1 \text{ KB} = 0.5$, or **1**

For this scenario, you would want to set the table's provisioned write throughput to 100 write capacity units:

- 1 write capacity unit per item \times 100 writes per second = **100** write capacity units

 **Note**

For recommendations on provisioned throughput and related topics, see [Best practices for designing and using partition keys effectively](#).

Modifying throughput settings

If you have enabled DynamoDB auto scaling for a table, then its throughput capacity is dynamically adjusted in response to actual usage. No manual intervention is required.

You can modify your table's provisioned throughput settings using the AWS Management Console or the `UpdateTable` operation. For more information about throughput increases and decreases per day, see [Service, account, and table quotas in Amazon DynamoDB](#).

Troubleshooting throttling issues

For troubleshooting issues that appear to be related to throttling, an important first is to confirm if the throttling is coming from DynamoDB or from the application.

Following are some common scenarios, and possible steps to help resolve them.

The DynamoDB table appears to have enough provisioned capacity, but requests are being throttled.

This can occur when the throughput is below the average per minute, but throughput exceeds the amount available per second. DynamoDB only reports minute level metrics to CloudWatch, which are then calculated as the sum for one minute and averaged. But DynamoDB itself applies rate limits per second. So if too much of that throughput occurs within a small portion of that minute, such as few seconds or less, then requests for the rest of that minute can be throttled. For example, if we have provisioned 60 WCU on a table then it can do 3600 writes in 1 minute. But if all 3600 WCU requests hit in the same second, then the rest of that minute will be throttled.

One way to resolve this scenario can be to add some jitters and exponential back off to the API calls. For more information see this post about [backoff and jitter](#).

Autoscaling is enabled, but tables are still being throttled.

This can occur during sudden spikes in traffic. Auto scaling can be triggered when two data points breach the configured target utilization value within a one-minute span. Therefore, auto scaling can take place because the consumed capacity is above target utilization for two consistent minutes. But if the spikes are more than a minute apart, auto scaling might not be triggered. Similarly, a scale down event can be triggered when 15 consecutive data points are lower than the target utilization. In either case, after auto scaling is triggered an [UpdateTable](#) call is invoked. It can then take several minutes to update the provisioned capacity for the table or the index. During this period, any requests that exceed the previous provisioned capacity of the tables will be throttled.

In summary, Autoscaling requires consecutive data points where the target utilization value is being breached to scale up a DynamoDB table. For this reason Autoscaling is not recommended as a solution for dealing with spiked workloads. Please refer to the [Autoscaling documentation](#) for more information.

Tables are in "On-Demand" capacity mode but are still being throttled.

For On-Demand tables, DynamoDB automatically allocates more capacity as your traffic volume increases. As long as the access is distributed evenly across partitions, and the table does not exceed double its previous peak traffic, the overall table will not be throttled. However, throttling can still occur if the throughput exceeds double the previous peak within the same 30 minutes. Please refer to [OnDemand scaling](#) for further information.

A hot key may be causing throttling issues.

In DynamoDB, a partition key that does not have high cardinality can result in many requests which target just a few partitions. If a resulting "hot partition" goes past the per partition limits of 3000 RCU or 1000 WCU per second, this can result in throttling. The diagnostic tool CloudWatch Contributor Insights, can help debug this, by providing CCI graphs for each table's item access patterns. You can continuously monitor your DynamoDB tables' most frequently accessed keys and other traffic trends. To find out more about CloudWatch Contributor Insights see [CCI](#). For specific information on choosing the right hot key see [Choosing the right hot key](#).

Using CloudWatch metrics to investigate throttling

Below are some DynamoDB metrics to monitor during throttling events, to help locate which operations are creating throttled requests and identify root issues.

1. ThrottledRequests

- One throttled request can contain multiple throttled events, so events can be more relevant to examine.

For example, when you update an item in a table with GSIs there are multiple events - a write to the table, and a write to each index. Even if one or more of these events are throttled, there will only be one ThrottledRequest.

2. ReadThrottleEvents

- Watch for requests that exceed the provisioned RCU for a table or GSI.

3. WriteThrottleEvents

- Watch for requests that exceed the provisioned WCU for a table or GSI.

4. OnlineIndexConsumedWriteCapacity

- Pay attention to the number of WCU consumed when adding a new GSI to a table. Note that ConsumedWriteCapacityUnits for a GSI does not include the WCU consumed during index creation.
- If you have set the WCU for a GSI too low, then incoming write activity during the backfill phase might be throttled.

5. OnlineIndexThrottleEvents

- Review the number of write throttle events that occur when adding a new GSI to a table.
- If you find that the WCU is set too low and is being throttled, you can update the WCU value for a GSI even during backfill.

6. Provisioned Read/Write

- View how many provisioned read or write capacity units were consumed over the specified time period, for a table or a specified global secondary index.
- Note that the TableName dimension returns ProvisionedReadCapacityUnits for the table only by default. To view the numer of provisioned read or write capacity units for a global secondary index, you must specify both TableName and GlobalSecondaryIndexName.

7. Consumed Read/Write

- View how many read or write capacity units were consumed over the specified time period.

For more information on DynamoDB CloudWatch Metrics, see [Metrics and Dimensions](#).

DynamoDB Item sizes and formats

DynamoDB tables are schemaless, except for the primary key, so the items in a table can all have different attributes, sizes, and data types.

The total size of an item is the sum of the lengths of its attribute names and values, plus any applicable overhead as described below. You can use the following guidelines to estimate attribute sizes:

- Strings are Unicode with UTF-8 binary encoding. The size of a string is *(number of UTF-8-encoded bytes of attribute name) + (number of UTF-8-encoded bytes)*.
- Numbers are variable length, with up to 38 significant digits. Leading and trailing zeroes are trimmed. The size of a number is approximately *(number of UTF-8-encoded bytes of attribute name) + (1 byte per two significant digits) + (1 byte)*.
- A binary value must be encoded in base64 format before it can be sent to DynamoDB, but the value's raw byte length is used for calculating size. The size of a binary attribute is *(number of UTF-8-encoded bytes of attribute name) + (number of raw bytes)*.

- The size of a null attribute or a Boolean attribute is *(number of UTF-8-encoded bytes of attribute name) + (1 byte)*.
- An attribute of type List or Map requires 3 bytes of overhead, regardless of its contents. The size of a List or Map is *(number of UTF-8-encoded bytes of attribute name) + sum (size of nested elements) + (3 bytes)*. The size of an empty List or Map is *(number of UTF-8-encoded bytes of attribute name) + (3 bytes)*.
- Each List or Map element also requires 1 byte of overhead.

 **Note**

We recommend that you choose shorter attribute names rather than long ones. This helps you reduce the amount of storage required, but also can lower the amount of RCU/WCUs you use.

For storage billing purposes, each item includes a per-item storage overhead that depends on the features you have enabled.

- All items in DynamoDB require 100 bytes of storage overhead for indexing.
- Some DynamoDB features (global tables, transactions, change data capture for Kinesis Data Streams with DynamoDB) require additional storage overhead to account for system-created attributes resulting from enabling those features. For example, global tables requires an additional 48 bytes of storage overhead.

Managing throughput capacity automatically with DynamoDB auto scaling

Many database workloads are cyclical in nature, while others are difficult to predict in advance. For one example, consider a social networking app where most of the users are active during daytime hours. The database must be able to handle the daytime activity, but there's no need for the same levels of throughput at night. For another example, consider a new mobile gaming app that is experiencing unexpectedly rapid adoption. If the game becomes too popular it could exceed the available database resources, resulting in slow performance and unhappy customers. These kinds of workloads often require manual intervention to scale database resources up or down in response to varying usage levels.

Amazon DynamoDB auto scaling uses the AWS Application Auto Scaling service to dynamically adjust provisioned throughput capacity on your behalf, in response to actual traffic patterns. This enables a table or a global secondary index to increase its provisioned read and write capacity to handle sudden increases in traffic, without throttling. When the workload decreases, Application Auto Scaling decreases the throughput so that you don't pay for unused provisioned capacity.

Note

If you use the AWS Management Console to create a table or a global secondary index, DynamoDB auto scaling is enabled by default. You can modify your auto scaling settings at any time. For more information, see [Using the AWS Management Console with DynamoDB auto scaling](#).

When you delete a table or global table replica then any associated scalable targets, scaling policies, or CloudWatch alarms are not automatically deleted with it.

With Application Auto Scaling, you create a *scaling policy* for a table or a global secondary index. The scaling policy specifies whether you want to scale read capacity or write capacity (or both), and the minimum and maximum provisioned capacity unit settings for the table or index.

The scaling policy also contains a *target utilization*—the percentage of consumed provisioned throughput at a point in time. Application Auto Scaling uses a *target tracking* algorithm to adjust the provisioned throughput of the table (or index) upward or downward in response to actual workloads, so that the actual capacity utilization remains at or near your target utilization.

Auto scaling can be triggered when two data points breach the configured target utilization value within a one-minute span. Therefore, auto scaling can take place because the consumed capacity is above target utilization for two consistent minutes. But if the spikes are more than a minute apart, auto scaling might not be triggered. Similarly, a scale down event can be triggered when 15 consecutive data points are lower than the target utilization. In either case, after auto scaling is triggered an [UpdateTable](#) call is invoked. It can then take several minutes to update the provisioned capacity for the table or the index. During this period, any requests that exceed the previous provisioned capacity of the tables will be throttled.

Important

You can't adjust the number of data points to breach to trigger the underlying alarm (though the current number could change in the future).

You can set the auto scaling target utilization values between 20 and 90 percent for your read and write capacity.

Note

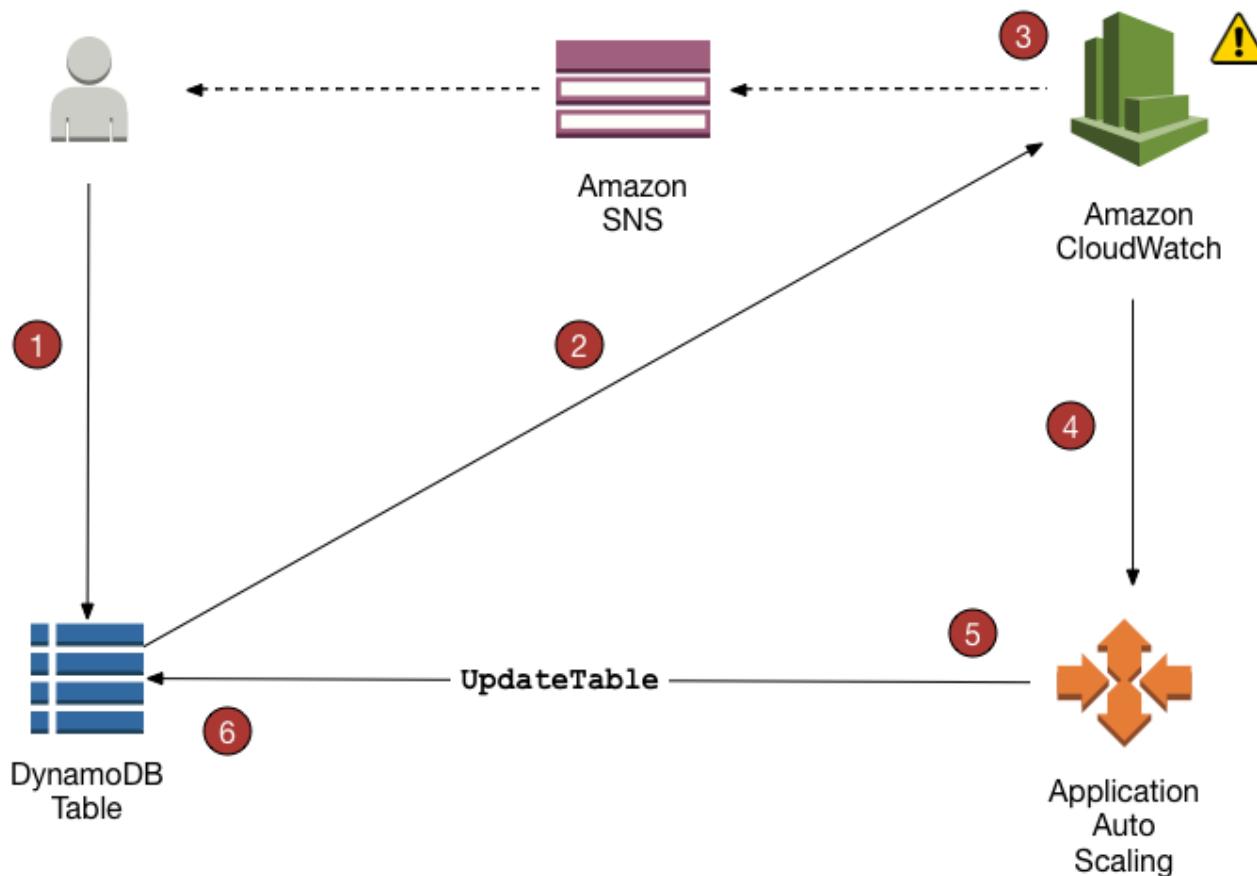

In addition to tables, DynamoDB auto scaling also supports global secondary indexes. Every global secondary index has its own provisioned throughput capacity, separate from that of its base table. When you create a scaling policy for a global secondary index, Application Auto Scaling adjusts the provisioned throughput settings for the index to ensure that its actual utilization stays at or near your desired utilization ratio.

How DynamoDB auto scaling works

Note

To get started quickly with DynamoDB auto scaling, see [Using the AWS Management Console with DynamoDB auto scaling](#).

The following diagram provides a high-level overview of how DynamoDB auto scaling manages throughput capacity for a table.

The following steps summarize the auto scaling process as shown in the previous diagram:

1. You create an Application Auto Scaling policy for your DynamoDB table.
2. DynamoDB publishes consumed capacity metrics to Amazon CloudWatch.
3. If the table's consumed capacity exceeds your target utilization (or falls below the target) for a specific length of time, Amazon CloudWatch triggers an alarm. You can view the alarm on the console and receive notifications using Amazon Simple Notification Service (Amazon SNS).
4. The CloudWatch alarm invokes Application Auto Scaling to evaluate your scaling policy.
5. Application Auto Scaling issues an **UpdateTable** request to adjust your table's provisioned throughput.
6. DynamoDB processes the **UpdateTable** request, dynamically increasing (or decreasing) the table's provisioned throughput capacity so that it approaches your target utilization.

To understand how DynamoDB auto scaling works, suppose that you have a table named `ProductCatalog`. The table is bulk-loaded with data infrequently, so it doesn't incur very much

write activity. However, it does experience a high degree of read activity, which varies over time. By monitoring the Amazon CloudWatch metrics for ProductCatalog, you determine that the table requires 1,200 read capacity units (to avoid DynamoDB throttling read requests when activity is at its peak). You also determine that ProductCatalog requires 150 read capacity units at a minimum, when read traffic is at its lowest point. For more information about preventing throttling, see [Troubleshooting throttling issues in Amazon DynamoDB](#).

Within the range of 150 to 1,200 read capacity units, you decide that a target utilization of 70 percent would be appropriate for the ProductCatalog table. *Target utilization* is the ratio of consumed capacity units to provisioned capacity units, expressed as a percentage. Application Auto Scaling uses its target tracking algorithm to ensure that the provisioned read capacity of ProductCatalog is adjusted as required so that utilization remains at or near 70 percent.

Note

DynamoDB auto scaling modifies provisioned throughput settings only when the actual workload stays elevated or depressed for a sustained period of several minutes. The Application Auto Scaling target tracking algorithm seeks to keep the target utilization at or near your chosen value over the long term.

Sudden, short-duration spikes of activity are accommodated by the table's built-in burst capacity. For more information, see [Using burst capacity effectively](#).

To enable DynamoDB auto scaling for the ProductCatalog table, you create a scaling policy. This policy specifies the following:

- The table or global secondary index that you want to manage
- Which capacity type to manage (read capacity or write capacity)
- The upper and lower boundaries for the provisioned throughput settings
- Your target utilization

When you create a scaling policy, Application Auto Scaling creates a pair of Amazon CloudWatch alarms on your behalf. Each pair represents the upper and lower boundaries for your provisioned throughput settings. These CloudWatch alarms are triggered when the table's actual utilization deviates from your target utilization for a sustained period of time.

When one of the CloudWatch alarms is triggered, Amazon SNS sends you a notification (if you have enabled it). The CloudWatch alarm then invokes Application Auto Scaling, which in turn notifies DynamoDB to adjust the ProductCatalog table's provisioned capacity upward or downward as appropriate.

During a scaling event, AWS Config is charged per configuration item recorded. When a scaling event occurs, four CloudWatch alarms are created for each read and write auto-scaling event: ProvisionedCapacity alarms: ProvisionedCapacityLow, ProvisionedCapacityHigh and ConsumedCapacity alarms: AlarmHigh, AlarmLow. This results in a total of eight alarms. Therefore, AWS Config records eight configuration items for every scaling event.

 **Note**

You can also schedule your DynamoDB scaling so it happens at certain times. Learn the basic steps [here](#).

Usage notes

Before you begin using DynamoDB auto scaling, you should be aware of the following:

- DynamoDB auto scaling can increase read capacity or write capacity as often as necessary, in accordance with your auto scaling policy. All DynamoDB quotas remain in effect, as described in [Service, account, and table quotas in Amazon DynamoDB](#).
- DynamoDB auto scaling doesn't prevent you from manually modifying provisioned throughput settings. These manual adjustments don't affect any existing CloudWatch alarms that are related to DynamoDB auto scaling.
- If you enable DynamoDB auto scaling for a table that has one or more global secondary indexes, we highly recommend that you also apply auto scaling uniformly to those indexes. This will help ensure better performance for table writes and reads, and help avoid throttling. You can enable auto scaling by selecting **Apply same settings to global secondary indexes** in the AWS Management Console. For more information, see [Enabling DynamoDB auto scaling on existing tables](#).
- When you delete a table or global table replica, any associated scalable targets, scaling policies or CloudWatch alarms are not automatically deleted with it.

- When creating a GSI for an existing table, auto scaling is not enabled for the GSI. You will have to manually manage the capacity while the GSI is being built. Once the backfill on the GSI completes and it reaches active status, auto scaling will operate as normal.

Using the AWS Management Console with DynamoDB auto scaling

When you use the AWS Management Console to create a new table, Amazon DynamoDB auto scaling is enabled for that table by default. You can also use the console to enable auto scaling for existing tables, modify auto scaling settings, or disable auto scaling.

Note

For more advanced features like setting scale-in and scale-out cooldown times, use the AWS Command Line Interface (AWS CLI) to manage DynamoDB auto scaling. For more information, see [Using the AWS CLI to manage DynamoDB auto scaling](#).

Topics

- [Before you begin: Granting user permissions for DynamoDB auto scaling](#)
- [Creating a new table with auto scaling enabled](#)
- [Enabling DynamoDB auto scaling on existing tables](#)
- [Viewing auto scaling activities on the console](#)
- [Modifying or disabling DynamoDB auto scaling settings](#)

Before you begin: Granting user permissions for DynamoDB auto scaling

In AWS Identity and Access Management (IAM), the AWS managed policy `DynamoDBFullAccess` provides the required permissions for using the DynamoDB console. However, for DynamoDB auto scaling, users require additional permissions.

Important

To delete an auto scaling-enabled table, `application-autoscaling:*` permissions are required. The AWS managed policy `DynamoDBFullAccess` includes such permissions.

To set up a user for DynamoDB console access and DynamoDB auto scaling, create a role and add the **AmazonDynamoDBFullAccess** policy to that role. Then assign the role to a user.

Creating a new table with auto scaling enabled

Note

DynamoDB auto scaling requires the presence of a service-linked role (`AWSServiceRoleForApplicationAutoScaling_DynamoDBTable`) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see [Service-linked roles for Application Auto Scaling](#) in the *Application Auto Scaling User Guide*.

To create a new table with auto scaling enabled

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. Choose **Create table**.
3. On the **Create table** page, enter a **Table name** and primary key.
4. If **Default settings** is selected, the table will be created with auto scaling enabled.

Otherwise, for custom settings:

- a. Select **Customize settings**.
- b. In the **Read/write capacity settings** section, select **Provisioned** capacity mode and set **Auto scaling to On** for **Read capacity**, **Write capacity**, or both. For each of these, set your desired scaling policy for the table and, optionally, all global secondary indexes of the table.
 - **Minimum capacity units** – Enter your lower boundary for the auto scaling range.
 - **Maximum capacity units** – Enter your upper boundary for the auto scaling range.
 - **Target utilization** – Enter your target utilization percentage for the table.

Note

If you create a global secondary index for the new table, the index's capacity at time of creation will be the same as your base table's capacity. You can change the index's capacity in the table's settings after you create the table.

- When the settings are as you want them, choose **Create table**. Your table is created with the auto scaling parameters.

Enabling DynamoDB auto scaling on existing tables

Note

DynamoDB auto scaling requires the presence of a service-linked role (`AWSServiceRoleForApplicationAutoScaling_DynamoDBTable`) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see [Service-linked roles for Application Auto Scaling](#).

To enable DynamoDB auto scaling for an existing table

- Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
- In the navigation pane on the left side of the console, choose **Tables**.
- Choose the table that you want to work with and choose the **Additional settings** tab.
- In the **Read/write capacity** section, choose **Edit**.
- In the **Capacity mode** section, choose **Provisioned**.
- In the **Table capacity** section, set **Auto scaling** to **On** for **Read capacity**, **Write capacity**, or both. For each of these, set your desired scaling policy for the table and, optionally, all global secondary indexes of the table.
 - Minimum capacity units** – Enter your lower boundary for the auto scaling range.
 - Maximum capacity units** – Enter your upper boundary for the auto scaling range.
 - Target utilization** – Enter your target utilization percentage for the table.

- **Use the same capacity read/write capacity settings for all global secondary indexes –** Choose whether global secondary indexes should use the same auto scaling policy as the base table.

 **Note**

For best performance, we recommend that you enable **Use the same read/write capacity settings for all global secondary indexes**. This option allows DynamoDB auto scaling to uniformly scale all the global secondary indexes on the base table. This includes existing global secondary indexes, and any others that you create for this table in the future.

With this option enabled, you can't set a scaling policy on an individual global secondary index.

7. When the settings are as you want them, choose **Save**.

Viewing auto scaling activities on the console

As your application drives read and write traffic to your table, DynamoDB auto scaling dynamically modifies the table's throughput settings. Amazon CloudWatch keeps track of provisioned and consumed capacity, throttled events, latency, and other metrics for all of your DynamoDB tables and secondary indexes.

To view these metrics in the DynamoDB console, choose the table that you want to work with and choose the **Monitor** tab. To create a customizable view of table metrics, select **View all in CloudWatch**.

For more information about CloudWatch monitoring in DynamoDB, see [Monitoring with Amazon CloudWatch](#).

Modifying or disabling DynamoDB auto scaling settings

You can use the AWS Management Console to modify your DynamoDB auto scaling settings. To do this, go to the **Additional settings** tab for your table, and choose **Edit** in the **Read/write capacity** section. For more information about these settings, see [Enabling DynamoDB auto scaling on existing tables](#).

Using the AWS CLI to manage DynamoDB auto scaling

Instead of using the AWS Management Console, you can use the AWS Command Line Interface (AWS CLI) to manage Amazon DynamoDB auto scaling. The tutorial in this section demonstrates how to install and configure the AWS CLI for managing DynamoDB auto scaling. In this tutorial, you do the following:

- Create a DynamoDB table named TestTable. The initial throughput settings are 5 read capacity units and 5 write capacity units.
- Create an Application Auto Scaling policy for TestTable. The policy seeks to maintain a 50 percent target ratio between consumed write capacity and provisioned write capacity. The range for this metric is between 5 and 10 write capacity units. (Application Auto Scaling is not allowed to adjust the throughput beyond this range.)
- Run a Python program to drive write traffic to TestTable. When the target ratio exceeds 50 percent for a sustained period of time, Application Auto Scaling notifies DynamoDB to adjust the throughput of TestTable upward to maintain the 50 percent target utilization.
- Verify that DynamoDB has successfully adjusted the provisioned write capacity for TestTable.

 **Note**

You can also schedule your DynamoDB scaling so it happens at certain times. Learn the basic steps [here](#).

Topics

- [Before you begin](#)
- [Step 1: Create a DynamoDB table](#)
- [Step 2: Register a scalable target](#)
- [Step 3: Create a scaling policy](#)
- [Step 4: Drive write traffic to TestTable](#)
- [Step 5: View Application Auto Scaling actions](#)
- [\(Optional\) Step 6: Clean up](#)

Before you begin

Complete the following tasks before starting the tutorial.

Install the AWS CLI

If you haven't already done so, you must install and configure the AWS CLI. To do this, follow these instructions in the *AWS Command Line Interface User Guide*:

- [Installing the AWS CLI](#)
- [Configuring the AWS CLI](#)

Install Python

Part of this tutorial requires you to run a Python program (see [Step 4: Drive write traffic to TestTable](#)). If you don't already have it installed, you can [download Python](#).

Step 1: Create a DynamoDB table

In this step, you use the AWS CLI to create TestTable. The primary key consists of pk (partition key) and sk (sort key). Both of these attributes are of type Number. The initial throughput settings are 5 read capacity units and 5 write capacity units.

1. Use the following AWS CLI command to create the table.

```
aws dynamodb create-table \
    --table-name TestTable \
    --attribute-definitions \
        AttributeName=pk,AttributeType=N \
        AttributeName=sk,AttributeType=N \
    --key-schema \
        AttributeName=pk,KeyType=HASH \
        AttributeName=sk,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5
```

2. To check the status of the table, use the following command.

```
aws dynamodb describe-table \
    --table-name TestTable \
    --query "Table.[TableName,TableStatus,ProvisionedThroughput]"
```

The table is ready for use when its status is ACTIVE.

Step 2: Register a scalable target

Next you register the table's write capacity as a scalable target with Application Auto Scaling. This allows Application Auto Scaling to adjust the provisioned write capacity for *TestTable*, but only within the range of 5–10 capacity units.

Note

DynamoDB auto scaling requires the presence of a service linked role (`AWSServiceRoleForApplicationAutoScaling_DynamoDBTable`) that performs auto scaling actions on your behalf. This role is created automatically for you. For more information, see [Service-linked roles for Application Auto Scaling](#) in the *Application Auto Scaling User Guide*.

1. Enter the following command to register the scalable target.

```
aws application-autoscaling register-scalable-target \  
  --service-namespace dynamodb \  
  --resource-id "table/TestTable" \  
  --scalable-dimension "dynamodb:table:WriteCapacityUnits" \  
  --min-capacity 5 \  
  --max-capacity 10
```

2. To verify the registration, use the following command.

```
aws application-autoscaling describe-scalable-targets \  
  --service-namespace dynamodb \  
  --resource-id "table/TestTable"
```

Note

You can also register a scalable target against a global secondary index. For example, for a global secondary index ("test-index"), the resource ID and scalable dimension arguments are updated appropriately.

```
aws application-autoscaling register-scalable-target \  
  --service-namespace dynamodb \  
  --resource-id "table/TestTable/index/test-index" \  
  --scalable-dimension "dynamodb:index:WriteCapacityUnits" \  
  --min-capacity 5 \  
  --max-capacity 10
```

```
--min-capacity 5 \
--max-capacity 10
```

Step 3: Create a scaling policy

In this step, you create a scaling policy for `TestTable`. The policy defines the details under which Application Auto Scaling can adjust your table's provisioned throughput, and what actions to take when it does so. You associate this policy with the scalable target that you defined in the previous step (write capacity units for the `TestTable` table).

The policy contains the following elements:

- **PredefinedMetricSpecification**—The metric that Application Auto Scaling is allowed to adjust. For DynamoDB, the following values are valid values for `PredefinedMetricType`:
 - `DynamoDBReadCapacityUtilization`
 - `DynamoDBWriteCapacityUtilization`
- **ScaleOutCooldown**—The minimum amount of time (in seconds) between each Application Auto Scaling event that increases provisioned throughput. This parameter allows Application Auto Scaling to continuously, but not aggressively, increase the throughput in response to real-world workloads. The default setting for `ScaleOutCooldown` is 0.
- **ScaleInCooldown**—The minimum amount of time (in seconds) between each Application Auto Scaling event that decreases provisioned throughput. This parameter allows Application Auto Scaling to decrease the throughput gradually and predictably. The default setting for `ScaleInCooldown` is 0.
- **TargetValue**—Application Auto Scaling ensures that the ratio of consumed capacity to provisioned capacity stays at or near this value. You define `TargetValue` as a percentage.

Note

To further understand how `TargetValue` works, suppose that you have a table with a provisioned throughput setting of 200 write capacity units. You decide to create a scaling policy for this table, with a `TargetValue` of 70 percent.

Now suppose that you begin driving write traffic to the table so that the actual write throughput is 150 capacity units. The consumed-to-provisioned ratio is now $(150 / 200)$, or 75 percent. This ratio exceeds your target, so Application Auto Scaling increases the

provisioned write capacity to 215 so that the ratio is (150 / 215), or 69.77 percent—as close to your TargetValue as possible, but not exceeding it.

For TestTable, you set TargetValue to 50 percent. Application Auto Scaling adjusts the table's provisioned throughput within the range of 5–10 capacity units (see [Step 2: Register a scalable target](#)) so that the consumed-to-provisioned ratio remains at or near 50 percent. You set the values for ScaleOutCooldown and ScaleInCooldown to 60 seconds.

1. Create a file named scaling-policy.json with the following contents.

```
{  
    "PredefinedMetricSpecification": {  
        "PredefinedMetricType": "DynamoDBWriteCapacityUtilization"  
    },  
    "ScaleOutCooldown": 60,  
    "ScaleInCooldown": 60,  
    "TargetValue": 50.0  
}
```

2. Use the following AWS CLI command to create the policy.

```
aws application-autoscaling put-scaling-policy \  
    --service-namespace dynamodb \  
    --resource-id "table/TestTable" \  
    --scalable-dimension "dynamodb:table:WriteCapacityUnits" \  
    --policy-name "MyScalingPolicy" \  
    --policy-type "TargetTrackingScaling" \  
    --target-tracking-scaling-policy-configuration file://scaling-policy.json
```

3. In the output, note that Application Auto Scaling has created two Amazon CloudWatch alarms—one each for the upper and lower boundary of the scaling target range.
4. Use the following AWS CLI command to view more details about the scaling policy.

```
aws application-autoscaling describe-scaling-policies \  
    --service-namespace dynamodb \  
    --resource-id "table/TestTable" \  
    --policy-name "MyScalingPolicy"
```

5. In the output, verify that the policy settings match your specifications from [Step 2: Register a scalable target](#) and [Step 3: Create a scaling policy](#).

Step 4: Drive write traffic to TestTable

Now you can test your scaling policy by writing data to TestTable. To do this, you run a Python program.

1. Create a file named bulk-load-test-table.py with the following contents.

```
import boto3
dynamodb = boto3.resource('dynamodb')

table = dynamodb.Table("TestTable")

filler = "x" * 100000

i = 0
while (i < 10):
    j = 0
    while (j < 10):
        print (i, j)

        table.put_item(
            Item={
                'pk':i,
                'sk':j,
                'filler':{'S':filler}
            }
        )
        j += 1
    i += 1
```

2. Enter the following command to run the program.

```
python bulk-load-test-table.py
```

The provisioned write capacity for TestTable is very low (5 write capacity units), so the program stalls occasionally due to write throttling. This is expected behavior.

Let the program continue running while you move on to the next step.

Step 5: View Application Auto Scaling actions

In this step, you view the Application Auto Scaling actions that are initiated on your behalf. You also verify that Application Auto Scaling has updated the provisioned write capacity for TestTable.

1. Enter the following command to view the Application Auto Scaling actions.

```
aws application-autoscaling describe-scaling-activities \
--service-namespace dynamodb
```

Rerun this command occasionally, while the Python program is running. (It takes several minutes before your scaling policy is invoked.) You should eventually see the following output.

```
...
{
    "ScalableDimension": "dynamodb:table:WriteCapacityUnits",
    "Description": "Setting write capacity units to 10.",
    "ResourceId": "table/TestTable",
    "ActivityId": "0cc6fb03-2a7c-4b51-b67f-217224c6b656",
    "StartTime": 1489088210.175,
    "ServiceNamespace": "dynamodb",
    "EndTime": 1489088246.85,
    "Cause": "monitor alarm AutoScaling-table/TestTable-
AlarmHigh-1bb3c8db-1b97-4353-baf1-4def76f4e1b9 in state ALARM triggered policy
MyScalingPolicy",
    "StatusMessage": "Successfully set write capacity units to 10. Change
successfully fulfilled by dynamodb.",
    "StatusCode": "Successful"
},
```

This indicates that Application Auto Scaling has issued an UpdateTable request to DynamoDB.

2. Enter the following command to verify that DynamoDB increased the table's write capacity.

```
aws dynamodb describe-table \
--table-name TestTable \
--query "Table.[TableName,TableStatus,ProvisionedThroughput]"
```

The WriteCapacityUnits should have been scaled from 5 to 10.

(Optional) Step 6: Clean up

In this tutorial, you created several resources. You can delete these resources if you no longer need them.

1. Delete the scaling policy for TestTable.

```
aws application-autoscaling delete-scaling-policy \
--service-namespace dynamodb \
--resource-id "table/TestTable" \
--scalable-dimension "dynamodb:table:WriteCapacityUnits" \
--policy-name "MyScalingPolicy"
```

2. Deregister the scalable target.

```
aws application-autoscaling deregister-scaling-target \
--service-namespace dynamodb \
--resource-id "table/TestTable" \
--scalable-dimension "dynamodb:table:WriteCapacityUnits"
```

3. Delete the TestTable table.

```
aws dynamodb delete-table --table-name TestTable
```

Using the AWS SDK to configure auto scaling on Amazon DynamoDB tables

In addition to using the AWS Management Console and the AWS Command Line Interface (AWS CLI), you can write applications that interact with Amazon DynamoDB auto scaling. This section contains two Java programs that you can use to test this functionality:

- `EnableDynamoDBAutoscaling.java`
- `DisableDynamoDBAutoscaling.java`

Enabling Application Auto Scaling for a table

The following program shows an example of setting up an auto scaling policy for a DynamoDB table (TestTable). It proceeds as follows:

- The program registers write capacity units as a scalable target for TestTable. The range for this metric is between 5 and 10 write capacity units.
- After the scalable target is created, the program builds a target tracking configuration. The policy seeks to maintain a 50 percent target ratio between consumed write capacity and provisioned write capacity.
- The program then creates the scaling policy, based on the target tracking configuration.

 **Note**

When you manually remove a table or global table replica, you do not automatically remove any associated scalable targets, scaling policies, or CloudWatch alarms.

The program requires that you provide an Amazon Resource Name (ARN) for a valid Application Auto Scaling service linked role. (For example: arn:aws:iam::122517410325:role/AWSServiceRoleForApplicationAutoScaling_DynamoDBTable.) In the following program, replace SERVICE_ROLE_ARN_Goes_Here with the actual ARN.

```
package com.amazonaws.codesamples.autoscaling;

import com.amazonaws.services.applicationautoscaling.AWSApplicationAutoScalingClient;
import
com.amazonaws.services.applicationautoscaling.AWSApplicationAutoScalingClientBuilder;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalableTargetsRequest;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalableTargetsResult;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalingPoliciesRequest;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalingPoliciesResult;
import com.amazonaws.services.applicationautoscaling.model.MetricType;
import com.amazonaws.services.applicationautoscaling.model.PolicyType;
import
com.amazonaws.services.applicationautoscaling.model.PredefinedMetricSpecification;
```

```
import com.amazonaws.services.applicationautoscaling.model.PutScalingPolicyRequest;
import
com.amazonaws.services.applicationautoscaling.model.RegisterScalableTargetRequest;
import com.amazonaws.services.applicationautoscaling.model.ScalableDimension;
import com.amazonaws.services.applicationautoscaling.model.ServiceNamespace;
import
com.amazonaws.services.applicationautoscaling.model.TargetTrackingScalingPolicyConfiguration;

public class EnableDynamoDBAutoscaling {

    static AWSApplicationAutoScalingClient aaClient = (AWSApplicationAutoScalingClient)
AWSApplicationAutoScalingClientBuilder
    .standard().build();

    public static void main(String args[]) {

        ServiceNamespace ns = ServiceNamespace.Dynamodb;
        ScalableDimension tableWCUs = ScalableDimension.DynamodbTableWriteCapacityUnits;
        String resourceID = "table/TestTable";

        // Define the scalable target
        RegisterScalableTargetRequest rstRequest = new RegisterScalableTargetRequest()
            .withServiceNamespace(ns)
            .withResourceId(resourceID)
            .withScalableDimension(tableWCUs)
            .withMinCapacity(5)
            .withMaxCapacity(10)
            .withRoleARN("SERVICE_ROLE_ARN_Goes_Here");

        try {
            aaClient.registerScalableTarget(rstRequest);
        } catch (Exception e) {
            System.err.println("Unable to register scalable target: ");
            System.err.println(e.getMessage());
        }

        // Verify that the target was created
        DescribeScalableTargetsRequest dscRequest = new DescribeScalableTargetsRequest()
            .withServiceNamespace(ns)
            .withScalableDimension(tableWCUs)
            .withResourceIds(resourceID);
        try {
            DescribeScalableTargetsResult dsaResult =
aaClient.describeScalableTargets(dscRequest);
```

```
System.out.println("DescribeScalableTargets result: ");
System.out.println(dsaResult);
System.out.println();
} catch (Exception e) {
    System.err.println("Unable to describe scalable target: ");
    System.err.println(e.getMessage());
}

System.out.println();

// Configure a scaling policy
TargetTrackingScalingPolicyConfiguration targetTrackingScalingPolicyConfiguration =
new TargetTrackingScalingPolicyConfiguration()
    .withPredefinedMetricSpecification(
        new PredefinedMetricSpecification()
            .withPredefinedMetricType(MetricType.DynamoDBWriteCapacityUtilization))
    .withTargetValue(50.0)
    .withScaleInCooldown(60)
    .withScaleOutCooldown(60);

// Create the scaling policy, based on your configuration
PutScalingPolicyRequest pspRequest = new PutScalingPolicyRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceId(resourceID)
    .withPolicyName("MyScalingPolicy")
    .withPolicyType(PolicyType.TargetTrackingScaling)

    .withTargetTrackingScalingPolicyConfiguration(targetTrackingScalingPolicyConfiguration);

try {
    aaClient.putScalingPolicy(pspRequest);
} catch (Exception e) {
    System.err.println("Unable to put scaling policy: ");
    System.err.println(e.getMessage());
}

// Verify that the scaling policy was created
DescribeScalingPoliciesRequest dspRequest = new DescribeScalingPoliciesRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceId(resourceID);

try {
```

```
    DescribeScalingPoliciesResult dspResult =
aaClient.describeScalingPolicies(dspRequest);
System.out.println("DescribeScalingPolicies result: ");
System.out.println(dspResult);
} catch (Exception e) {
e.printStackTrace();
System.err.println("Unable to describe scaling policy: ");
System.err.println(e.getMessage());
}

}

}
```

Disabling Application Auto Scaling for a table

The following program reverses the previous process. It removes the auto scaling policy and then deregisters the scalable target.

```
package com.amazonaws.codesamples.autoscaling;

import com.amazonaws.services.applicationautoscaling.AWSApplicationAutoScalingClient;
import com.amazonaws.services.applicationautoscaling.model.DeleteScalingPolicyRequest;
import
com.amazonaws.services.applicationautoscaling.model.DeregisterScalableTargetRequest;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalableTargetsRequest;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalableTargetsResult;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalingPoliciesRequest;
import
com.amazonaws.services.applicationautoscaling.model.DescribeScalingPoliciesResult;
import com.amazonaws.services.applicationautoscaling.model.ScalableDimension;
import com.amazonaws.services.applicationautoscaling.model.ServiceNamespace;

public class DisableDynamoDBAutoscaling {

static AWSApplicationAutoScalingClient aaClient = new
AWSApplicationAutoScalingClient();

public static void main(String args[]) {
```

```
ServiceNamespace ns = ServiceNamespace.Dynamodb;
ScalableDimension tableWCUs = ScalableDimension.DynamodbTableWriteCapacityUnits;
String resourceId = "table/TestTable";

// Delete the scaling policy
DeleteScalingPolicyRequest delSPRequest = new DeleteScalingPolicyRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceId(resourceId)
    .withPolicyName("MyScalingPolicy");

try {
    aaClient.deleteScalingPolicy(delSPRequest);
} catch (Exception e) {
    System.err.println("Unable to delete scaling policy: ");
    System.err.println(e.getMessage());
}

// Verify that the scaling policy was deleted
DescribeScalingPoliciesRequest descSPRequest = new DescribeScalingPoliciesRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceId(resourceId);

try {
    DescribeScalingPoliciesResult dspResult =
    aaClient.describeScalingPolicies(descSPRequest);
    System.out.println("DescribeScalingPolicies result: ");
    System.out.println(dspResult);
} catch (Exception e) {
    e.printStackTrace();
    System.err.println("Unable to describe scaling policy: ");
    System.err.println(e.getMessage());
}

System.out.println();

// Remove the scalable target
DeregisterScalableTargetRequest delSTRequest = new DeregisterScalableTargetRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceId(resourceId);
```

```
try {
    aaClient.deregisterScalableTarget(delSTRequest);
} catch (Exception e) {
    System.err.println("Unable to deregister scalable target: ");
    System.err.println(e.getMessage());
}

// Verify that the scalable target was removed
DescribeScalableTargetsRequest dscRequest = new DescribeScalableTargetsRequest()
    .withServiceNamespace(ns)
    .withScalableDimension(tableWCUs)
    .withResourceIds(resourceID);

try {
    DescribeScalableTargetsResult dsaResult =
aaClient.describeScalableTargets(dscRequest);
    System.out.println("DescribeScalableTargets result: ");
    System.out.println(dsaResult);
    System.out.println();
} catch (Exception e) {
    System.err.println("Unable to describe scalable target: ");
    System.err.println(e.getMessage());
}

}

}
```

Adding tags and labels to resources

You can label Amazon DynamoDB resources using *tags*. Tags let you categorize your resources in different ways, for example, by purpose, owner, environment, or other criteria. Tags can help you do the following:

- Quickly identify a resource based on the tags that you assigned to it.
- See AWS bills broken down by tags.

Note

Any local secondary indexes (LSI) and global secondary indexes (GSI) related to tagged tables are labeled with the same tags automatically. Currently, DynamoDB Streams usage cannot be tagged.

Tagging is supported by AWS services like Amazon EC2, Amazon S3, DynamoDB, and more. Efficient tagging can provide cost insights by enabling you to create reports across services that carry a specific tag.

To get started with tagging, do the following:

1. Understand [Tagging restrictions in DynamoDB](#).
2. Create tags by using [Tagging resources in DynamoDB](#).
3. Use [Cost allocation reports](#) to track your AWS costs per active tag.

Finally, it is good practice to follow optimal tagging strategies. For information, see [AWS tagging strategies](#).

Tagging restrictions in DynamoDB

Each tag consists of a key and a value, both of which you define. The following restrictions apply:

- Each DynamoDB table can have only one tag with the same key. If you try to add an existing tag (same key), the existing tag value is updated to the new value.
- Tag keys and values are case sensitive.
- The maximum key length is 128 Unicode characters.
- The maximum value length is 256 Unicode characters.
- The allowed characters are letters, white space, and numbers, plus the following special characters: + - = . _ : /
- The maximum number of tags per resource is 50.
- AWS-assigned tag names and values are automatically assigned the aws: prefix, which you can't assign. AWS-assigned tag names don't count toward the tag limit of 50. User-assigned tag names have the prefix user: in the cost allocation report.

- You can't backdate the application of a tag.

Tagging resources in DynamoDB

You can use the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI) to add, list, edit, or delete tags. You can then activate these user-defined tags so that they appear on the AWS Billing and Cost Management console for cost allocation tracking. For more information, see [Cost allocation reports](#).

For bulk editing, you can also use Tag Editor on the AWS Management Console. For more information, see [Working with Tag Editor](#).

To use the DynamoDB API instead, see the following operations in the [Amazon DynamoDB API Reference](#):

- [TagResource](#)
- [UntagResource](#)
- [ListTagsOfResource](#)

Topics

- [Setting permissions to filter by tags](#)
- [Adding tags to new or existing tables \(AWS Management Console\)](#)
- [Adding tags to new or existing tables \(AWS CLI\)](#)

Setting permissions to filter by tags

To use tags to filter your table list in the DynamoDB console, make sure your user's policies include access to the following operations:

- `tag:GetTagKeys`
- `tag:GetTagValues`

You can access these operations by attaching a new IAM policy to your user by following the steps below.

1. Go to the [IAM console](#) with an Admin user.

2. Select "Policies" in the left navigation menu.
3. Select "Create policy."
4. Paste the following policy into the JSON editor.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "tag:GetTagKeys",  
                "tag:GetTagValues"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

5. Complete the wizard and assign a name to the policy (for example, TagKeysAndValuesReadAccess).
6. Select "Users" in the left navigation menu.
7. From the list, select the user you normally use to access the DynamoDB console.
8. Select "Add permissions."
9. Select "Attach existing policies directly."
10. From the list, select the policy you created previously.
11. Complete the wizard.

Adding tags to new or existing tables (AWS Management Console)

You can use the DynamoDB console to add tags to new tables when you create them, or to add, edit, or delete tags for existing tables.

To tag resources on creation (console)

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, choose **Tables**, and then choose **Create table**.

3. On the **Create DynamoDB table** page, provide a name and primary key. In the **Tags** section, choose **Add new tag** and enter the tags that you want to use.

For information about tag structure, see [Tagging restrictions in DynamoDB](#).

For more information about creating tables, see [Basic operations on DynamoDB tables](#).

To tag existing resources (console)

Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.

1. In the navigation pane, choose **Tables**.
2. Choose a table in the list, and then choose the **Additional settings** tab. You can add, edit, or delete your tags in the **Tags** section at the bottom of the page.

Adding tags to new or existing tables (AWS CLI)

The following examples show how to use the AWS CLI to specify tags when you create tables and indexes, and to tag existing resources.

To tag resources on creation (AWS CLI)

- The following example creates a new `Movies` table and adds the `Owner` tag with a value of `blueTeam`:

```
aws dynamodb create-table \
  --table-name Movies \
  --attribute-definitions AttributeName=Title,AttributeType=S \
  --key-schema AttributeName=Title,KeyType=HASH \
  --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
  --tags Key=Owner,Value=blueTeam
```

To tag existing resources (AWS CLI)

- The following example adds the `Owner` tag with a value of `blueTeam` for the `Movies` table:

```
aws dynamodb tag-resource \
  --resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/Movies \
  --tags Key=Owner,Value=blueTeam
```

To list all tags for a table (AWS CLI)

- The following example lists all the tags that are associated with the Movies table:

```
aws dynamodb list-tags-of-resource \
--resource-arn arn:aws:dynamodb:us-east-1:123456789012:table/Movies
```

Cost allocation reports

AWS uses tags to organize resource costs on your cost allocation report. AWS provides two types of cost allocation tags:

- An AWS-generated tag. AWS defines, creates, and applies this tag for you.
- User-defined tags. You define, create, and apply these tags.

You must activate both types of tags separately before they can appear in Cost Explorer or on a cost allocation report.

To activate AWS-generated tags:

- Sign in to the AWS Management Console and open the Billing and Cost Management console at <https://console.aws.amazon.com/billing/home#/>.
- In the navigation pane, choose **Cost Allocation Tags**.
- Under **AWS-Generated Cost Allocation Tags**, choose **Activate**.

To activate user-defined tags:

- Sign in to the AWS Management Console and open the Billing and Cost Management console at <https://console.aws.amazon.com/billing/home#/>.
- In the navigation pane, choose **Cost Allocation Tags**.
- Under **User-Defined Cost Allocation Tags**, choose **Activate**.

After you create and activate tags, AWS generates a cost allocation report with your usage and costs grouped by your active tags. The cost allocation report includes all of your AWS costs for each billing period. The report includes both tagged and untagged resources, so that you can clearly organize the charges for resources.

Note

Currently, any data transferred out from DynamoDB won't be broken down by tags on cost allocation reports.

For more information, see [Using cost allocation tags](#).

Working with DynamoDB tables in Java

You can use the AWS SDK for Java to create, update, and delete Amazon DynamoDB tables, list all the tables in your account, or get information about a specific table.

Topics

- [Creating a table](#)
- [Updating a table](#)
- [Deleting a table](#)
- [Listing tables](#)
- [Example: Create, update, delete, and list tables using the AWS SDK for Java document API](#)

Creating a table

To create a table, you must provide the table name, its primary key, and the provisioned throughput values. The following code snippet creates an example table that uses a numeric type attribute ID as its primary key.

To create a table using the AWS SDK for Java API

1. Create an instance of the DynamoDB class.
2. Instantiate a `CreateTableRequest` to provide the request information.

You must provide the table name, attribute definitions, key schema, and provisioned throughput values.

3. Run the `createTable` method by providing the request object as a parameter.

The following code example demonstrates the preceding steps.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

List<AttributeDefinition> attributeDefinitions= new ArrayList<AttributeDefinition>();
attributeDefinitions.add(new
    AttributeDefinition().withAttributeName("Id").withAttributeType("N"));

List<KeySchemaElement> keySchema = new ArrayList<KeySchemaElement>();
keySchema.add(new
    KeySchemaElement().withAttributeName("Id").withKeyType(KeyType.HASH));

CreateTableRequest request = new CreateTableRequest()
    .withTableName(tableName)
    .withKeySchema(keySchema)
    .withAttributeDefinitions(attributeDefinitions)
    .withProvisionedThroughput(new ProvisionedThroughput()
        .withReadCapacityUnits(5L)
        .withWriteCapacityUnits(6L)));

Table table = dynamoDB.createTable(request);

table.waitForActive();
```

The table is not ready for use until DynamoDB creates it and sets its status to *ACTIVE*. The `createTable` request returns a `Table` object that you can use to obtain more information about the table.

Example

```
TableDescription tableDescription =
    dynamoDB.getTable(tableName).describe();

System.out.printf("%s: %s \t ReadCapacityUnits: %d \t WriteCapacityUnits: %d",
    tableDescription.getTableStatus(),
    tableDescription.getTableName(),
    tableDescription.getProvisionedThroughput().getReadCapacityUnits(),
    tableDescription.getProvisionedThroughput().getWriteCapacityUnits());
```

You can call the `describe` method of the client to get table information at any time.

Example

```
TableDescription tableDescription = dynamoDB.getTable(tableName).describe();
```

Updating a table

You can update only the provisioned throughput values of an existing table. Depending on your application requirements, you might need to update these values.

Note

For more information about throughput increases and decreases per day, see [Service, account, and table quotas in Amazon DynamoDB](#).

To update a table using the AWS SDK for Java API

1. Create an instance of the Table class.
2. Create an instance of the ProvisionedThroughput class to provide the new throughput values.
3. Run the updateTable method by providing the ProvisionedThroughput instance as a parameter.

The following code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

ProvisionedThroughput provisionedThroughput = new ProvisionedThroughput()
    .withReadCapacityUnits(15L)
    .withWriteCapacityUnits(12L);

table.updateTable(provisionedThroughput);

table.waitForActive();
```

Deleting a table

To delete a table using the AWS SDK for Java API

1. Create an instance of the Table class.
2. Create an instance of the DeleteTableRequest class and provide the table name that you want to delete.
3. Run the deleteTable method by providing the Table instance as a parameter.

The following code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

table.delete();

table.waitForDelete();
```

Listing tables

To list tables in your account, create an instance of DynamoDB and run the `listTables` method. The [ListTables](#) operation requires no parameters.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

TableCollection<ListTablesResult> tables = dynamoDB.listTables();
Iterator<Table> iterator = tables.iterator();

while (iterator.hasNext()) {
    Table table = iterator.next();
    System.out.println(table.getTableName());
}
```

Example: Create, update, delete, and list tables using the AWS SDK for Java document API

The following code example uses the AWS SDK for Java Document API to create, update, and delete an Amazon DynamoDB table (ExampleTable). As part of the table update, it increases the provisioned throughput values. The example also lists all the tables in your account and gets the description of a specific table. For step-by-step instructions to run the following example, see [Java code examples](#).

```
package com.amazonaws.codesamples.document;

import java.util.ArrayList;
import java.util.Iterator;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.TableCollection;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.CreateTableRequest;
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.ListTablesResult;
import com.amazonaws.services.dynamodbv2.model.ProvisionedThroughput;
import com.amazonaws.services.dynamodbv2.model.TableDescription;

public class DocumentAPITableExample {

    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
    static DynamoDB dynamoDB = new DynamoDB(client);

    static String tableName = "ExampleTable";

    public static void main(String[] args) throws Exception {

        createExampleTable();
        listMyTables();
        getTableInformation();
        updateExampleTable();
    }
}
```

```
        deleteExampleTable();
    }

    static void createExampleTable() {

        try {

            List<AttributeDefinition> attributeDefinitions = new
ArrayList<AttributeDefinition>();
            attributeDefinitions.add(new
AttributeDefinition().withAttributeName("Id").withAttributeType("N"));

            List<KeySchemaElement> keySchema = new ArrayList<KeySchemaElement>();
            keySchema.add(new
KeySchemaElement().withAttributeName("Id").withKeyType(KeyType.HASH)); // Partition

            // key

            CreateTableRequest request = new
CreateTableRequest().withTableName(tableName).withKeySchema(keySchema)

.withAttributeDefinitions(attributeDefinitions).withProvisionedThroughput(
            new
ProvisionedThroughput().withReadCapacityUnits(5L).withWriteCapacityUnits(6L));

            System.out.println("Issuing CreateTable request for " + tableName);
            Table table = dynamoDB.createTable(request);

            System.out.println("Waiting for " + tableName + " to be created...this may
take a while...");
            table.waitForActive();

            getTableInformation();

        } catch (Exception e) {
            System.err.println("CreateTable request failed for " + tableName);
            System.err.println(e.getMessage());
        }
    }

    static void listMyTables() {

        TableCollection<ListTablesResult> tables = dynamoDB.listTables();
```

```
Iterator<Table> iterator = tables.iterator();

System.out.println("Listing table names");

while (iterator.hasNext()) {
    Table table = iterator.next();
    System.out.println(table.getTableName());
}

static void getTableInformation() {

    System.out.println("Describing " + tableName);

    TableDescription tableDescription = dynamoDB.getTable(tableName).describe();
    System.out.format(

    Table table = dynamoDB.getTable(tableName);
    System.out.println("Modifying provisioned throughput for " + tableName);

    try {
        table.updateTable(new
ProvisionedThroughput().withReadCapacityUnits(6L).withWriteCapacityUnits(7L));

        table.waitForActive();
    } catch (Exception e) {
        System.err.println("UpdateTable request failed for " + tableName);
        System.err.println(e.getMessage());
    }
}

static void deleteExampleTable() {

    Table table = dynamoDB.getTable(tableName);
    try {
```

```
        System.out.println("Issuing DeleteTable request for " + tableName);
        table.delete();

        System.out.println("Waiting for " + tableName + " to be deleted...this may
take a while...");

        table.waitForDelete();
    } catch (Exception e) {
        System.err.println("DeleteTable request failed for " + tableName);
        System.err.println(e.getMessage());
    }
}

}
```

Working with DynamoDB tables in .NET

You can use the AWS SDK for .NET to create, update, and delete tables, list all the tables in your account, or get information about a specific table.

The following are the common steps for Amazon DynamoDB table operations using the AWS SDK for .NET.

1. Create an instance of the `AmazonDynamoDBClient` class (the client).
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.

For example, create a `CreateTableRequest` object to create a table and `UpdateTableRequest` object to update an existing table.

3. Run the appropriate method provided by the client that you created in the preceding step.

 **Note**

The examples in this section don't work with .NET core because it doesn't support synchronous methods. For more information, see [AWS asynchronous APIs for .NET](#).

Topics

- [Creating a table](#)
- [Updating a table](#)
- [Deleting a table](#)
- [Listing tables](#)
- [Example: Create, update, delete, and list tables using the AWS SDK for .NET low-level API](#)

Creating a table

To create a table, you must provide the table name, its primary key, and the provisioned throughput values.

To create a table using the AWS SDK for .NET low-level API

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.

You must provide the table name, primary key, and the provisioned throughput values.
3. Run the `AmazonDynamoDBClient.CreateTable` method by providing the request object as a parameter.

The following C# example demonstrates the preceding steps. The sample creates a table (`ProductCatalog`) that uses `Id` as the primary key and set of provisioned throughput values. Depending on your application requirements, you can update the provisioned throughput values by using the `UpdateTable` API.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new CreateTableRequest
{
    TableName = tableName,
    AttributeDefinitions = new List<AttributeDefinition>()
    {
        new AttributeDefinition
        {
            AttributeName = "Id",
            AttributeType = "N"
        }
    }
}
```

```
},
KeySchema = new List<KeySchemaElement>()
{
    new KeySchemaElement
    {
        AttributeName = "Id",
        KeyType = "HASH" //Partition key
    }
},
ProvisionedThroughput = new ProvisionedThroughput
{
    ReadCapacityUnits = 10,
    WriteCapacityUnits = 5
}
};

var response = client.CreateTable(request);
```

You must wait until DynamoDB creates the table and sets its status to ACTIVE. The `CreateTable` response includes the `TableDescription` property that provides the necessary table information.

Example

```
var result = response.CreateTableResult;
var tableDescription = result.TableDescription;
Console.WriteLine("{1}: {0} \t ReadCapacityUnits: {2} \t WriteCapacityUnits: {3}",
    tableDescription.TableStatus,
    tableDescription.TableName,
    tableDescription.ProvisionedThroughput.ReadCapacityUnits,
    tableDescription.ProvisionedThroughput.WriteCapacityUnits);

string status = tableDescription.TableStatus;
Console.WriteLine(tableName + " - " + status);
```

You can also call the `DescribeTable` method of the client to get table information at any time.

Example

```
var res = client.DescribeTable(new DescribeTableRequest{TableName = "ProductCatalog"});
```

Updating a table

You can update only the provisioned throughput values of an existing table. Depending on your application requirements, you might need to update these values.

Note

You can increase throughput capacity as often as needed, and decrease it within certain constraints. For more information about throughput increases and decreases per day, see [Service, account, and table quotas in Amazon DynamoDB](#).

To update a table using the AWS SDK for .NET low-level API

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `UpdateTableRequest` class to provide the request information.

You must provide the table name and the new provisioned throughput values.

3. Run the `AmazonDynamoDBClient.UpdateTable` method by providing the request object as a parameter.

The following C# example demonstrates the preceding steps.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ExampleTable";

var request = new UpdateTableRequest()
{
    TableName = tableName,
    ProvisionedThroughput = new ProvisionedThroughput()
    {
        // Provide new values.
        ReadCapacityUnits = 20,
        WriteCapacityUnits = 10
    }
};
var response = client.UpdateTable(request);
```

Deleting a table

Follow these steps to delete a table using the .NET low-level API.

To delete a table using the AWS SDK for .NET low-level API

1. Create an instance of the AmazonDynamoDBClient class.
2. Create an instance of the DeleteTableRequest class, and provide the table name that you want to delete.
3. Run the AmazonDynamoDBClient.DeleteTable method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ExampleTable";

var request = new DeleteTableRequest{ TableName = tableName };
var response = client.DeleteTable(request);
```

Listing tables

To list tables in your account using the AWS SDK for .NET low-level API, create an instance of the AmazonDynamoDBClient and run the `ListTables` method.

The [ListTables](#) operation requires no parameters. However, you can specify optional parameters. For example, you can set the `Limit` parameter if you want to use paging to limit the number of table names per page. This requires you to create a `ListTablesRequest` object and provide optional parameters as shown in the following C# example. Along with the page size, the request sets the `ExclusiveStartTableName` parameter. Initially, `ExclusiveStartTableName` is null. However, after fetching the first page of results, to retrieve the next page of results, you must set this parameter value to the `LastEvaluatedTableName` property of the current result.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

// Initial value for the first page of table names.
```

```
string lastEvaluatedTableName = null;
do
{
    // Create a request object to specify optional parameters.
    var request = new ListTablesRequest
    {
        Limit = 10, // Page size.
        ExclusiveStartTableName = lastEvaluatedTableName
    };

    var response = client.ListTables(request);
    ListTablesResult result = response.ListTablesResult;
    foreach (string name in result.TableNames)
        Console.WriteLine(name);

    lastEvaluatedTableName = result.LastEvaluatedTableName;

} while (lastEvaluatedTableName != null);
```

Example: Create, update, delete, and list tables using the AWS SDK for .NET low-level API

The following C# example creates, updates, and deletes a table (ExampleTable). It also lists all the tables in your account and gets the description of a specific table. The table update increases the provisioned throughput values. For step-by-step instructions to test the following example, see [.NET code examples](#).

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class LowLevelTableExample
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();
        private static string tableName = "ExampleTable";

        static void Main(string[] args)
        {
```

```
try
{
    CreateExampleTable();
    ListMyTables();
    GetTableInformation();
    UpdateExampleTable();

    DeleteExampleTable();

    Console.WriteLine("To continue, press Enter");
    Console.ReadLine();
}
catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
catch (Exception e) { Console.WriteLine(e.Message); }
}

private static void CreateExampleTable()
{
    Console.WriteLine("\n*** Creating table ***");
    var request = new CreateTableRequest
    {
        AttributeDefinitions = new List<AttributeDefinition>()
    {
        new AttributeDefinition
        {
            AttributeName = "Id",
            AttributeType = "N"
        },
        new AttributeDefinition
        {
            AttributeName = "ReplyDateTime",
            AttributeType = "N"
        }
    },
    KeySchema = new List<KeySchemaElement>
    {
        new KeySchemaElement
        {
            AttributeName = "Id",
            KeyType = "HASH" //Partition key
        },
        new KeySchemaElement
        {

```

```
        AttributeName = "ReplyDateTime",
        KeyType = "RANGE" //Sort key
    }
},
ProvisionedThroughput = new ProvisionedThroughput
{
    ReadCapacityUnits = 5,
    WriteCapacityUnits = 6
},
TableName = tableName
};

var response = client.CreateTable(request);

var tableDescription = response.TableDescription;
Console.WriteLine("{1}: {0} \t ReadsPerSec: {2} \t WritesPerSec: {3}",
    tableDescription.TableStatus,
    tableDescription.TableName,
    tableDescription.ProvisionedThroughput.ReadCapacityUnits,
    tableDescription.ProvisionedThroughput.WriteCapacityUnits);

string status = tableDescription.TableStatus;
Console.WriteLine(tableName + " - " + status);

WaitUntilTableReady(tableName);
}

private static void ListMyTables()
{
    Console.WriteLine("\n*** listing tables ***");
    string lastTableNameEvaluated = null;
    do
    {
        var request = new ListTablesRequest
        {
            Limit = 2,
            ExclusiveStartTableName = lastTableNameEvaluated
        };

        var response = client.ListTables(request);
        foreach (string name in response.TableNames)
            Console.WriteLine(name);

        lastTableNameEvaluated = response.LastEvaluatedTableName;
```

```
        } while (lastTableNameEvaluated != null);
    }

private static void GetTableInformation()
{
    Console.WriteLine("\n*** Retrieving table information ***");
    var request = new DescribeTableRequest
    {
        TableName = tableName
    };

    var response = client.DescribeTable(request);

    TableDescription description = response.Table;
    Console.WriteLine("Name: {0}", description.TableName);
    Console.WriteLine("# of items: {0}", description.ItemCount);
    Console.WriteLine("Provision Throughput (reads/sec): {0}",
                      description.ProvisionedThroughput.ReadCapacityUnits);
    Console.WriteLine("Provision Throughput (writes/sec): {0}",
                      description.ProvisionedThroughput.WriteCapacityUnits);
}

private static void UpdateExampleTable()
{
    Console.WriteLine("\n*** Updating table ***");
    var request = new UpdateTableRequest()
    {
        TableName = tableName,
        ProvisionedThroughput = new ProvisionedThroughput()
        {
            ReadCapacityUnits = 6,
            WriteCapacityUnits = 7
        }
    };

    var response = client.UpdateTable(request);

    WaitUntilTableReady(tableName);
}

private static void DeleteExampleTable()
{
    Console.WriteLine("\n*** Deleting table ***");
    var request = new DeleteTableRequest
```

```
        {
            TableName = tableName
        };

        var response = client.DeleteTable(request);

        Console.WriteLine("Table is being deleted...");
    }

private static void WaitUntilTableReady(string tableName)
{
    string status = null;
    // Let us wait until table is created. Call DescribeTable.
    do
    {
        System.Threading.Thread.Sleep(5000); // Wait 5 seconds.
        try
        {
            var res = client.DescribeTable(new DescribeTableRequest
            {
                TableName = tableName
            });

            Console.WriteLine("Table name: {0}, status: {1}",
                res.Table.TableName,
                res.Table.TableStatus);
            status = res.Table.TableStatus;
        }
        catch (ResourceNotFoundException)
        {
            // DescribeTable is eventually consistent. So you might
            // get resource not found. So we handle the potential exception.
        }
    } while (status != "ACTIVE");
}
```

Global tables - multi-Region replication for DynamoDB

Amazon DynamoDB *global tables* are a fully managed, multi-Region, and multi-active database option that delivers fast and localized read and write performance for massively scaled global applications.

Global tables provide a fully managed solution for deploying a multi-Region, multi-active database, without having to build and maintain your own replication solution. You can specify the AWS Regions where you want the tables to be available and DynamoDB will propagate ongoing data changes to all of them.

Specific benefits for using global tables include:

- Replicating your DynamoDB tables automatically across your choice of AWS Regions
- Eliminating the difficult work of replicating data between Regions and resolving update conflicts, so you can focus on your application's business logic.
- Helping your applications stay highly available even in the unlikely event of isolation or degradation of an entire Region.

DynamoDB global tables are ideal for massively scaled applications with globally dispersed users. In such an environment, users expect very fast application performance. Global tables provide automatic multi-active replication to AWS Regions worldwide. They enable you to deliver low-latency data access to your users no matter where they are located.

The following video will give you an introductory look at global tables.

You can set up global tables in the AWS Management Console or AWS CLI. Global tables use existing DynamoDB APIs, so no application changes are required. You pay only for the resources provisioned with no upfront costs or commitments.

Replicate data seamlessly across Regions with global tables

Suppose you have a large customer base spread across three geographic areas—the US East Coast, the US West Coast, and Western Europe. These customers can update their profile information using your application. To satisfy this use case, you need to create three identical DynamoDB tables named `CustomerProfiles`, in three different AWS Regions where the customers are located. These three tables would be entirely separate from each other—changes to the data in one table would not be reflected in the others. Without a managed replication solution, you would have to write code to replicate the data changes. However, doing this would be a time-consuming and labor-intensive effort.

Instead of writing your own code, you could create a global table consisting of your three Region-specific `CustomerProfiles` tables. DynamoDB would then automatically replicate data changes among those tables so that changes to `CustomerProfiles` data in one Region would seamlessly propagate to the other Regions. In addition, if one of the AWS Regions were to become temporarily unavailable, your customers could still access the same `CustomerProfiles` data in the other Regions.

Note

- Region support for global tables [Global tables version 2017.11.29 \(Legacy\)](#) is limited to US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Europe (Ireland), Europe (London), Europe (Frankfurt), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Asia Pacific (Seoul).
- Transactional operations provide atomicity, consistency, isolation, and durability (ACID) guarantees only within the region where the write is made originally. Transactions are not supported across regions in global tables. For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) regions and perform a `TransactWriteItems` operation in the US East (N. Virginia) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated.

Changes will only be replicated to other regions once they have been committed in the source region.

- If you [disable an AWS Region](#), DynamoDB will remove this replica from the replication group, 20 hours after detecting the AWS Region as inaccessible. The replica will not be deleted and replication will stop from and to this region.
- You must wait 24 hours from the time you add a read replica to successfully delete a source table. If you attempt to delete a table during the first 24 hours after adding a read replica, you will receive an error message stating: "Replica cannot be deleted because it has acted as a source region for new replicas being added in the table in the last 24 hours".
- There is no performance impact on source regions when adding new replicas.
- When you change the read and write capacity of a replica, the new write capacity is reflected to other synchronized replicas but the new read capacity is not.

For information about the AWS Region availability and pricing, see [Amazon DynamoDB Pricing](#).

Provide security and access for your global tables with AWS KMS

- You can perform AWS KMS operations on your global tables by using the `AWSServiceRoleForDynamoDBReplication` service-linked role against the [customer managed key](#) or the [AWS managed key](#) used to encrypt the replica.
- If the customer managed key used to encrypt a replica is inaccessible, DynamoDB will remove this replica from the replication group. The replica will not be deleted and replication will stop from and to this region, 20 hours after detecting the KMS key as inaccessible.
- If you want to disable your [customer managed key](#) that is used to encrypt a replica table, you must do so only if the key is no longer used to encrypt a replica table. After issuing a command to delete a replica table, you must wait for the delete operation to complete and for the global table to become Active before disabling the key. Not doing so could result in partial data replication from and to the replica table.
- If you want to modify or delete your IAM role policy for the replica table, you must do so when the replica table is in the Active state. If you don't do this, creating, updating, or deleting the replica table could fail.

- Global tables are created with deletion protection disabled by default. Even when deletion protection is enabled for a global table, any replicas of that table will start with deletion protection disabled by default.
- While deletion protection is disabled for a table, it can be accidentally deleted. While deletion protection is enabled for a table, no one can delete it.
- Changing the deletion protection setting for one replica table will not update other replicas in the group.

 **Note**

Customer managed keys are not supported in [Global tables version 2017.11.29 \(Legacy\)](#).

If you want to use a customer managed key in a DynamoDB Global Table, you need to upgrade the table to [Global Tables version 2019.11.21 \(Current\)](#) and then enable it.

Global tables: How it works

The following sections describe the concepts and behavior of global tables in Amazon DynamoDB.

Global table concepts

A *global table* is a collection of one or more replica tables, all owned by a single AWS account.

A *replica table* (or *replica*, for short) is a single DynamoDB table that functions as a part of a global table. Each replica stores the same set of data items. Any given global table can only have one replica table per AWS Region. For more information about how to get started with global tables, see [Tutorial: Creating a global table](#).

When you create a DynamoDB global table, it consists of multiple replica tables (one per Region) that DynamoDB treats as a single unit. Every replica has the same table name and the same primary key schema. When an application writes data to a replica table in one Region, DynamoDB propagates the write to the other replica tables in the other AWS Regions automatically.

You can add replica tables to the global table so that it can be available in additional Regions.

With Version 2019.11.21 (Current), when you create a Global Secondary Index in one Region it is automatically replicated to the other Region(s) as well as automatically backfilled.

Common tasks

Common tasks for global tables work as follows.

You can delete a global table's replica table the same as a regular table. This will stop replication to that Region and delete the table copy kept in that Region. You cannot sever the replication and have copies of the table exist as independent entities. You can instead copy the global table to a local table in that Region, and then delete the global replica for that Region.

 **Note**

You won't be able to delete a source table until at least 24 hours after it's used to initiate a new Region. If you try to delete it too soon you will receive an error.

Conflicts can arise if applications update the same item in different Regions at about the same time. To help ensure eventual consistency, DynamoDB global tables use a "last writer wins" method to reconcile between concurrent updates. All the replicas will agree on the latest update and converge toward a state in which they all have identical data.

 **Note**

There are several ways to avoid conflicts, including:

- Only allowing writes to the table in one Region.
- Routing user traffic to different Regions according to your write policies, to ensure there are no conflicts.
- Avoiding the use of non-idempotent updates such as `Bookmark = Bookmark + 1`, in favor of static updates such as `Bookmark=25`.
- Keep in mind that when you need to route writes or reads to one Region, it's up to your application to ensure that flow is enforced.

Monitoring global tables

You can use CloudWatch to observe the metric `ReplicationLatency`. This tracks the elapsed time between when an item is written to a replica table, and when that item appears in another replica in the global table. It's expressed in milliseconds and is emitted for every source-Region

and destination-Region pair. This metric is kept at the source Region. This is the only CloudWatch metric provided by Global Tables v2.

The replication latency you will experience depends on the distance between your chosen AWS Regions, as well as other variables. If your original table was in the US West (N. California) (us-west-1) Region, a replica in a closer Region, such as the US West (Oregon) (us-west-2) Region, would have lower replication latency compared to a replica in a region which is much further away, such as the Africa (Cape Town) (af-south-1) Region. It is common to see 0.5 to 2.5 seconds of replication latency for AWS Regions within a hectometer from one another.

Note

Replication latency does not effect API latency. If you've a client and table in Region A and you add a global tables replica in Region B, the client and table in Region A will have the same latency as before adding Region B. If you call the [PutItem](#) API operation in Region B, it will eventually be available to read in Region A after a delay of approximately the ReplicationLatency statistic available in Amazon CloudWatch. Before it is replicated, you'd receive an empty response and after it's replicated, you'd receive the item; both calls would have approximately the same API latency.

Time To Live (TTL)

You can use Time To Live (TTL) to specify an attribute name whose value indicates the time of expiration for the item. This value is given as a number in seconds since the start of the Unix epoch. After that time DynamoDB can delete the item without incurring write costs.

With global tables you configure TTL in one Region, and that setting is auto replicated to the other Region(s). When an item is deleted via a TTL rule, that work is performed without consuming Write Units on the source table - but the target table(s) will incur Replicated Write Unit costs.

Be aware that if the source and target table have very low Provisioned write capacity, this may cause throttling as the TTL deletes require write capacity.

Streams and transactions with global tables

Each global table produces an independent stream based on all its writes, regardless of the origination point for those writes. You can choose to consume this DynamoDB stream in one Region or in all Regions independently.

If you want processed local writes but not replicated writes, you can add your own region attribute to each item. Then you can use a Lambda event filter to invoke only the Lambda for writes in the local Region.

Transactional operations provide ACID (Atomicity, Consistency, Isolation, and Durability) guarantees ONLY within the Region where the write is made originally. Transactions are not supported across Regions in global tables.

For example, if you have a global table with replicas in the US East (Ohio) and US West (Oregon) Regions and perform a `TransactWriteItems` operation in the US East (Ohio) Region, you may observe partially completed transactions in US West (Oregon) Region as changes are replicated. Changes will only be replicated to other Regions once they have been committed in the source Region.

 **Note**

- Global tables “write around” DynamoDB Accelerator by updating DynamoDB directly. As a result DAX will not be aware it is holding stale data. The DAX cache will only be refreshed when the cache’s TTL expires.
- Tags on global tables do not automatically propagate.

Read and write throughput

Global tables manage read and write throughput in the following ways.

- The write capacity must be the same on all table instances across Regions.
- With Version 2019.11.21 (Current), if the table is set to support autoscaling or is in on-demand mode then the write capacity is automatically kept in sync. This means that a write capacity change to one table replicates to the others.
- Read capacity can differ between Regions because reads may not be equal. When adding a global replica to a table, the capacity of the source Region is propagated. After creation you can adjust the read capacity for one replica, and this new setting is not transferred to the other side.

Consistency and conflict resolution

Any changes made to any item in any replica table are replicated to all the other replicas within the same global table. In a global table, a newly written item is usually propagated to all replica tables within a second.

With a global table, each replica table stores the same set of data items. DynamoDB does not support partial replication of only some of the items.

An application can read and write data to any replica table. If your application only uses eventually consistent reads and only issues reads against one AWS Region, it will work without any modification. However, if your application requires strongly consistent reads, it must perform all of its strongly consistent reads and writes in the same Region. DynamoDB does not support strongly consistent reads across Regions. Therefore, if you write to one Region and read from another Region, the read response might include stale data that doesn't reflect the results of recently completed writes in the other Region.

If applications update the same item in different Regions at about the same time, conflicts can arise. To help ensure eventual consistency, DynamoDB global tables use a *last writer wins* reconciliation between concurrent updates, in which DynamoDB makes a best effort to determine the last writer. This is performed at the item level. With this conflict resolution mechanism, all the replicas will agree on the latest update and converge toward a state in which they all have identical data.

Availability and durability

If a single AWS Region becomes isolated or degraded, your application can redirect to a different Region and perform reads and writes against a different replica table. You can apply custom business logic to determine when to redirect requests to other Regions.

If a Region becomes isolated or degraded, DynamoDB keeps track of any writes that have been performed but have not yet been propagated to all of the replica tables. When the Region comes back online, DynamoDB resumes propagating any pending writes from that Region to the replica tables in other Regions. It also resumes propagating writes from other replica tables to the Region that is now back online.

Best practices and requirements for managing global tables

Using Amazon DynamoDB global tables, you can replicate your table data across AWS Regions. It is important that the replica tables and secondary indexes in your global table have identical write capacity settings to ensure proper replication of data.

For future clarity, it can be useful not to put the Region in the name for any table that might someday be turned into a global table.

Warning

The table name for each global table must be unique within your AWS account.

Global tables version

To determine the version of the global table that you're using, see [Determining the global table version you are using](#).

Requirements for Managing Capacity

A global table must have throughput capacity configured one of two ways:

1. On-demand capacity mode, measured in replicated write request units (rWRUs)
2. Provisioned capacity mode with auto scaling, measured in replicated write capacity units (rWCUs)

Using provisioned capacity mode with auto scaling or on-demand capacity mode helps ensure a global table has sufficient capacity to perform replicated writes to all regions of the global table.

Note

Switching from one table capacity mode to the other capacity mode in any Region switches the mode for all replicas.

Deploying global tables

In AWS CloudFormation, each global table is controlled by a single stack in a single Region. This is regardless of the number of replicas. When you deploy your template, CloudFormation will create/update all replicas as part of a single stack operation. For this reason, you should not deploy the same AWS::DynamoDB::GlobalTable resource in multiple Regions. Doing so is unsupported and will result in errors.

If you deploy your application template in multiple Regions, you can use conditions to create the resource in only one Region. Alternatively, you can choose to define your AWS::DynamoDB::GlobalTable resources in a stack separate from your application stack and make sure it is only deployed to a single Region. For more information see [Global tables in CloudFormation](#)

A DynamoDB table is referred to by AWS::DynamoDB::Table, and a global table is AWS::DynamoDB::GlobalTable. As far as CloudFormation is concerned, this essentially makes them two different resources. As a result, one approach is to create all tables that might ever be global by using the GlobalTable construct. You can then keep them as standalone tables to start, and add them later to Regions if needed.

If you have a regular table and you want to convert it while using CloudFormation, a recommended method is to:

1. Set the deletion policy to retain.
2. Remove the table from the stack.
3. Convert the table to a Global Table in the console.
4. Import the global table as a new resource to the stack.

 **Note**

Cross-account replication is not supported at this time.

Using global tables to help handle a potential Region outage

Have or be able to quickly create independent copies of your execution stack in alternative Regions, each accessing its local DynamoDB endpoint.

Use Route53 or AWS Global Accelerator to route to the nearest healthy Region. Alternately, have the client aware of the multiple endpoints it might use.

Use health checks in each Region that will be able to determine reliably if there's any issue with the stack, including if DynamoDB is degraded. For example, don't just ping that the DynamoDB endpoint is up. Actually do a call that ensures a full successful database flow.

If the health check fail, traffic can route to other Regions (by updating the DNS entry with Route53, by having Global Accelerator route differently, or by having the client choose a different endpoint). Global tables have a good RPO (recovery point objective) because the data is continuously syncing and a good RTO (recovery time objective) because both Regions always keep a table ready for both read and write traffic.

For further information on health checks see [Health check types](#).

 **Note**

DynamoDB is a core service on which other services frequently build their control plane operations, so it's unlikely you'll encounter a scenario where DynamoDB has degraded service in a Region while other services are unimpacted.

Backing up global tables

When backing up global tables, a backup of tables in one Region should be sufficient and backing up all tables in all Regions shouldn't be required. If the purpose is to be able to recover erroneously deleted or modified data, then PITR in one Region should suffice. Similarly, when preserving a snapshot for historic purposes such as regulatory requirements then backing up in one Region should suffice. The backed up data can be replicated to multiple Regions via AWS Backup.

Replicas and calculating write units

For planning, you should take the number of writes that one Region will perform and add that to the number of writes happening for each other Region. This is critical as every write that is performed in one Region must also be performed in every replica Region. If you do not have enough capacity to handle all of the writes, capacity exceptions will occur. In addition, inter-regional replication wait times will rise.

For example, suppose that you expect 5 writes per second to your replica table in Ohio, 10 writes per second to your replica table in N. Virginia, and 5 writes per second to your replica table in

Ireland. In this case, you should expect to consume 20 rWCUs or rWRUs in each Region: Ohio, N. Virginia, and Ireland. In other words, you should expect to consume 60 rWCUs total across all three Regions.

For details about provisioned capacity with auto scaling and DynamoDB, see [Managing throughput capacity automatically with DynamoDB auto scaling](#).

Note

If a table is running in provisioned capacity mode with auto scaling, the provisioned write capacity is allowed to float within those autoscaling settings for each Region.

Tutorial: Creating a global table

This section describes how to create a global table using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Topics

- [Creating a global table \(console\)](#)
- [Creating a global table \(AWS CLI\)](#)
- [Creating a global table \(Java\)](#)

Creating a global table (console)

Follow these steps to create a global table using the console. The following example creates a global table with replica tables in United States and Europe.

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/home>. For this example, choose the US East (Ohio) Region.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose **Create Table**.
 - a. For **Table name**, enter **Music**.
 - b. For **Partition key** enter **Artist**. For **Sort key** enter **SongTitle**. (**Artist** and **SongTitle** should both be strings.)

To create the table, choose **Create table**. This table serves as the first replica table in a new global table. It is the prototype for other replica tables that you add later.

4. Choose the **Global Tables** tab, and then choose **Create replica**.
5. From the **Available replication Regions** dropdown, choose **US West (Oregon)**.

The console checks to ensure that a table with the same name doesn't exist in the selected Region. If a table with the same name does exist, you must delete the existing table before you can create a new replica table in that Region.

6. Choose **Create Replica**. This starts the table creation process in US West (Oregon);

The **Global Table** tab for the selected table (and for any other replica tables) shows that the table has been replicated in multiple Regions.

7. Now add another Region so that your global table is replicated and synchronized across the United States and Europe. To do this, repeat step 5, but this time, specify **Europe (Frankfurt)** instead of **US West (Oregon)**.
8. You should still be using the AWS Management Console in the US East (Ohio) Region. Select **Items** in the left navigation menu, select the **Music** table, then choose **Create Item**.
 - a. For **Artist**, enter **item_1**.
 - b. For **SongTitle**, enter **Song Value 1**.
 - c. To write the item, choose **Create item**.
9. After a short time, the item is replicated across all three Regions of your global table. To verify this, in the console, on the Region selector in the upper-right corner, choose **Europe (Frankfurt)**. The Music table in Europe (Frankfurt) should contain the new item.
10. Repeat step 9 and choose **US West (Oregon)** to verify replication in that region.

Creating a global table (AWS CLI)

Follow these steps to create a global table `Music` using the AWS CLI. The following example creates a global table, with replica tables in the United States and in Europe.

1. Create a new table (`Music`) in US East (Ohio), with DynamoDB Streams enabled (`NEW_AND_OLD_IMAGES`).

```
aws dynamodb create-table \
```

```
--table-name Music \
--attribute-definitions \
    AttributeName=Artist,AttributeType=S \
    AttributeName=SongTitle,AttributeType=S \
--key-schema \
    AttributeName=Artist,KeyType=HASH \
    AttributeName=SongTitle,KeyType=RANGE \
--billing-mode PAY_PER_REQUEST \
--stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES \
--region us-east-2
```

2. Create an identical Music table in US East (N. Virginia).

```
aws dynamodb update-table --table-name Music --cli-input-json \
'{
  "ReplicaUpdates": [
    {
      "Create": {
        "RegionName": "us-east-1"
      }
    }
  ]
}' \
--region=us-east-2
```

3. Repeat step 2 to create a table in Europe (Ireland) (eu-west-1).

4. You can view the list of replicas created using describe-table.

```
aws dynamodb describe-table --table-name Music --region us-east-2
```

5. To verify that replication is working, add a new item to the Music table in US East (Ohio).

```
aws dynamodb put-item \
--table-name Music \
--item '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region us-east-2
```

6. Wait for a few seconds, and then check to see whether the item has been successfully replicated to US East (N. Virginia) and Europe (Ireland).

```
aws dynamodb get-item \
```

```
--table-name Music \
--key '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region us-east-1
```

```
aws dynamodb get-item \
--table-name Music \
--key '{"Artist": {"S":"item_1"}, "SongTitle": {"S":"Song Value 1"}}' \
--region eu-west-1
```

7. Delete the replica table in Europe (Ireland) Region.

```
aws dynamodb update-table --table-name Music --cli-input-json \
'{
  "ReplicaUpdates": [
    {
      "Delete": {
        "RegionName": "eu-west-1"
      }
    }
  ]
}'
```

Creating a global table (Java)

The following java code sample, create a Music table in Europe (Ireland) region then creates a replica in Asia Pacific (Seoul) region.

```
package com.amazonaws.codesamples.gtv2
import java.util.logging.Logger;
import com.amazonaws.auth.profile.ProfileCredentialsProvider;
import com.amazonaws.regions.Regions;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.model.AmazonDynamoDBException;
import com.amazonaws.services.dynamodbv2.model.AttributeDefinition;
import com.amazonaws.services.dynamodbv2.model.BillingMode;
import com.amazonaws.services.dynamodbv2.model.CreateReplicationGroupMemberAction;
import com.amazonaws.services.dynamodbv2.model.CreateTableRequest;
import com.amazonaws.services.dynamodbv2.model.DescribeTableRequest;
import com.amazonaws.services.dynamodbv2.model.GlobalSecondaryIndex;
```

```
import com.amazonaws.services.dynamodbv2.model.KeySchemaElement;
import com.amazonaws.services.dynamodbv2.model.KeyType;
import com.amazonaws.services.dynamodbv2.model.Projection;
import com.amazonaws.services.dynamodbv2.model.ProjectionType;
import com.amazonaws.services.dynamodbv2.model.ProvisionedThroughput;
import com.amazonaws.services.dynamodbv2.model.ProvisionedThroughputOverride;
import com.amazonaws.services.dynamodbv2.model.ReplicaGlobalSecondaryIndex;
import com.amazonaws.services.dynamodbv2.model.ReplicationGroupUpdate;
import com.amazonaws.services.dynamodbv2.model.ScalarAttributeType;
import com.amazonaws.services.dynamodbv2.model.StreamSpecification;
import com.amazonaws.services.dynamodbv2.model.StreamViewType;
import com.amazonaws.services.dynamodbv2.model.UpdateTableRequest;
import com.amazonaws.waiters.WaiterParameters;

public class App
{
    private final static Logger LOGGER = Logger.getLogger(Logger.GLOBAL_LOGGER_NAME);

    public static void main( String[] args )
    {

        String tableName = "Music";
        String indexName = "index1";

        Regions calledRegion = Regions.EU_WEST_1;
        Regions destRegion = Regions.AP_NORTHEAST_2;

        AmazonDynamoDB ddbClient = AmazonDynamoDBClientBuilder.standard()
            .withCredentials(new ProfileCredentialsProvider("default"))
            .withRegion(calledRegion)
            .build();

        LOGGER.info("Creating a regional table - TableName: " + tableName +",
        IndexName: " + indexName + " ....");
        ddbClient.createTable(new CreateTableRequest()
            .withTableName(tableName)
            .withAttributeDefinitions(
                new AttributeDefinition()

            .withAttributeName("Artist").withAttributeType(ScalarAttributeType.S),
            new AttributeDefinition())
    }
```

```
.withAttributeName("SongTitle").withAttributeType(ScalarAttributeType.S))
    .withKeySchema(
        new
KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH),
        new
KeySchemaElement().withAttributeName("SongTitle").withKeyType(KeyType.RANGE))
    .withBillingMode(BillingMode.PAY_PER_REQUEST)
    .withGlobalSecondaryIndexes(new GlobalSecondaryIndex()
        .withIndexName(indexName)
        .withKeySchema(new KeySchemaElement()
            .withAttributeName("SongTitle")
            .withKeyType(KeyType.HASH)))
    .withProjection(new
Projection().withProjectionType(ProjectionType.ALL)))
    .withStreamSpecification(new StreamSpecification()
        .withStreamEnabled(true)
        .withStreamViewType(StreamViewType.NEW_AND_OLD_IMAGES)));

    LOGGER.info("Waiting for ACTIVE table status ....");
    ddbClient.waiters().tableExists().run(new WaiterParameters<>(new
DescribeTableRequest(tableName)));

    LOGGER.info("Testing parameters for adding a new Replica in " + destRegion +
" ....");

    CreateReplicationGroupMemberAction createReplicaAction = new
CreateReplicationGroupMemberAction()
    .withRegionName(destRegion.getName())
    .withGlobalSecondaryIndexes(new ReplicaGlobalSecondaryIndex()
        .withIndexName(indexName)
        .withProvisionedThroughputOverride(new
ProvisionedThroughputOverride()
            .withReadCapacityUnits(15L))));

    ddbClient.updateTable(new UpdateTableRequest()
        .withTableName(tableName)
        .withReplicaUpdates(new ReplicationGroupUpdate()
            .withCreate(createReplicaAction.withKMSMasterKeyId(null))));
```

```
    }  
}
```

Monitoring global tables

You can use Amazon CloudWatch to monitor the behavior and performance of a global table. Amazon DynamoDB publishes `ReplicationLatency` metric for each replica in the global table.

- **ReplicationLatency**—The elapsed time between when an item is written to a replica table, and when that item appears in another replica in the global table. `ReplicationLatency` is expressed in milliseconds and is emitted for every source- and destination-Region pair.

During normal operation, `ReplicationLatency` should be fairly constant. An elevated value for `ReplicationLatency` could indicate that updates from one replica are not propagating to other replica tables in a timely manner. Over time, this could result in other replica tables *falling behind* because they no longer receive updates consistently. In this case, you should verify that the read capacity units (RCUs) and write capacity units (WCUs) are identical for each of the replica tables. In addition, when choosing WCU settings, follow the recommendations in [Global tables version](#).

`ReplicationLatency` can increase if an AWS Region becomes degraded and you have a replica table in that Region. In this case, you can temporarily redirect your application's read and write activity to a different AWS Region.

For more information, see [DynamoDB Metrics and dimensions](#).

Using IAM with global tables

When you create a global table for the first time, Amazon DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role is named [AWSServiceRoleForDynamoDBReplication](#), and it allows DynamoDB to manage cross-Region replication for global tables on your behalf. Don't delete this service-linked role. If you do, all of your global tables will no longer function.

For more information about service-linked roles, see [Using service-linked roles in the IAM User Guide](#).

To create replica tables in DynamoDB, you must have the following permissions in the source region.

- dynamodb:UpdateTable

To create replica tables in DynamoDB, you must have the following permissions in destination regions.

- dynamodb CreateTable
- dynamodb CreateTableReplica
- dynamodb Scan
- dynamodb Query
- dynamodb UpdateItem
- dynamodb PutItem
- dynamodb GetItem
- dynamodb DeleteItem
- dynamodb BatchWriteItem

To delete replica tables in DynamoDB, you must have the following permissions in the destination regions.

- dynamodb DeleteTable
- dynamodb DeleteTableReplica

To update replica auto scaling policy through `UpdateTableReplicaAutoScaling`, you must have the following permissions in all Regions where table replicas exist

- application-autoscaling>DeleteScalingPolicy
- application-autoscaling>DeleteScheduledAction
- application-autoscaling>DeregisterScalableTarget
- application-autoscaling>DescribeScalableTargets
- application-autoscaling>DescribeScalingActivities
- application-autoscaling>DescribeScalingPolicies

- application-autoscaling:DescribeScheduledActions
- application-autoscaling:PutScalingPolicy
- application-autoscaling:PutScheduledAction
- application-autoscaling:RegisterScalableTarget

To use UpdateTimeToLive you must have permission for dynamodb:UpdateTimeToLive in all Regions where table replicas exist.

Example: Add replica

The following IAM policy grants permissions to allow you to add replicas to a global table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:CreateTable",  
                "dynamodb:DescribeTable",  
                "dynamodb:UpdateTable",  
                "dynamodb:CreateTableReplica",  
                "iam:CreateServiceLinkedRole"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

Example: Update AutoScaling policy

The following IAM policy grants permissions to allow you to update replica auto scaling policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "application-autoscaling:DescribeScheduledActions",  
                "application-autoscaling:PutScalingPolicy",  
                "application-autoscaling:PutScheduledAction",  
                "application-autoscaling:RegisterScalableTarget"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

```
        "Action": [
            "application-autoscaling:RegisterScalableTarget",
            "application-autoscaling>DeleteScheduledAction",
            "application-autoscaling:DescribeScalableTargets",
            "application-autoscaling:DescribeScalingActivities",
            "application-autoscaling:DescribeScalingPolicies",
            "application-autoscaling:PutScalingPolicy",
            "application-autoscaling:DescribeScheduledActions",
            "application-autoscaling:DeleteScalingPolicy",
            "application-autoscaling:PutScheduledAction",
            "application-autoscaling:DeregisterScalableTarget"
        ],
        "Resource": "*"
    }
]
}
```

Example: Allow replica creations for a specific table name and regions

The following IAM policy grants permissions to allow table and replica creation for `Customers` table with replicas in three Regions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "dynamodb>CreateTable",
                "dynamodb>DescribeTable",
                "dynamodb>UpdateTable"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-east-1:123456789012:table/Customers",
                "arn:aws:dynamodb:us-west-1:123456789012:table/Customers",
                "arn:aws:dynamodb:eu-east-2:123456789012:table/Customers"
            ]
        }
    ]
}
```

Determining the global table version you are using

There are two versions of DynamoDB global tables available: [Global Tables version 2019.11.21 \(Current\)](#) and [Global tables version 2017.11.29 \(Legacy\)](#). We recommend using [Global Tables version 2019.11.21 \(Current\)](#). It is more efficient and consumes less write capacity than [Global tables version 2017.11.29 \(Legacy\)](#). The advantages of the current version include:

- The source and target tables are maintained together and kept aligned automatically for throughput, TTL settings, auto scaling settings, and other useful attributes.
- Global secondary indexes are also kept aligned.
- You can dynamically add new replica tables from a table populated with data
- The metadata attributes required to control replication are hidden which helps prevent writing of them which would cause issues with replication.
- The current version supports more Regions than the legacy version, and lets you add or remove Regions to an existing table while the legacy version does not.
- [Global Tables version 2019.11.21 \(Current\)](#) is more efficient and consumes less write capacity than [Global tables version 2017.11.29 \(Legacy\)](#), and therefore is more cost effective. In specifics:
 - Inserting a new item in one Region and then replicating to other Regions requires 2 rWCUs per region for Version 2017.11.29 (Legacy), but only 1 for Version 2019.11.21 (Current).
 - Updating an item requires 2 rWCUs in the source Region and 1 then rWCUs per destination Region in Version 2017.11.29 (Legacy), but only 1 rWCUs per source or destination in Version 2019.11.21 (Current).
 - Deleting an item requires 1 rWCUs in the source Region and then 2 rWCUs per destination Region in Version 2017.11.29 (Legacy), but only 1 rWCUs per source or destination in Version 2019.11.21 (Current).

For more information see [Amazon DynamoDB Pricing](#).

Determining the version through the CLI

To find out which version of global tables you are using through the AWS CLI, check `DescribeTable` and `DescribeGlobalTable`. `DescribeTable` will show the table version if it is Version 2019.11.21 (Current), and the `DescribeGlobalTable` property will show the table version if it is Version 2017.11.29 (Legacy).

Determining the version through the console

Finding the version through the console

To find out which version of global tables you are using through the console, do the following:

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/home>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the table you want to use.
4. Choose the **Global Tables** tab.
5. The **Global table version** displays the version of global tables in use:

 You are using global tables version 2019.11.21. If you need to use version 2017.11.29 instead, choose "Create version 2017.11.29 replica." You can create a version 2017.11.29 replica only if you have an empty table.

[Create a version 2017.11.29 replica.](#)

To upgrade from global tables Version 2017.11.29 (Legacy) to Version 2019.11.21 (Current), follow these steps [here](#). The overall upgrade process will work without disrupting live tables, and should finish in less than an hour. For more information, see [Updating to Version 2019.11.21 \(Current\)](#)

Note

- If the **Global table version** message does not appear in the console, that means there is another table in a different Region with the same name. In this case, the current table can't be made into a global table. Either the current table must be copied to a new table with a unique name, or all other tables with the same name must be removed.
- If you are using [Global Tables version 2019.11.21 \(Current\)](#) of global tables and you also use the [Time to Live](#) feature, DynamoDB replicates TTL deletes to all replica tables. The initial TTL delete does not consume write capacity in the region in which the TTL expiry occurs. However, the replicated TTL delete to the replica table(s) consumes a replicated write capacity unit when using provisioned capacity, or replicated write when using on-demand capacity mode, in each of the replica regions and applicable charges will apply.

- In [Global Tables version 2019.11.21 \(Current\)](#), when a TTL delete occurs it is replicated to all replica regions. These replicated writes do not contain type or principalID properties. This can make it difficult to distinguish a TTL delete from a user delete in the replicated tables.

Upgrading global tables to Current (2019.11.21) version from Legacy(2017.11.29) version

There are two versions of DynamoDB global tables available: [Global Tables version 2019.11.21 \(Current\)](#) and [Global tables version 2017.11.29 \(Legacy\)](#). Customers should use version 2019.11.21 (Current) when possible, as it provides greater flexibility, higher efficiency and consumes less write capacity than 2017.11.29 (Legacy). To determine which version you're using, see [Determining the global table version you are using](#).

This section describes how to upgrade your global tables to *Version 2019.11.21 (Current)* using the DynamoDB console. Upgrading from Version 2017.11.29 (Legacy) to Version 2019.11.21 (Current) is a one-time action and you cannot reverse it. Currently, you can upgrade global tables using the console only.

Topics

- [Differences in behavior between Legacy and Current versions](#)
- [Upgrade prerequisites](#)
- [Required permissions for global tables upgrade](#)
- [What to expect during the upgrade](#)
- [DynamoDB Streams behavior before, during, and after upgrade](#)
- [Upgrading to Version 2019.11.21 \(Current\)](#)

Differences in behavior between Legacy and Current versions

The following list describes the differences in behavior between the Legacy and Current versions of global tables.

- Version 2019.11.21 (Current) consumes less write capacity for several DynamoDB operations compared to Version 2017.11.29 (Legacy), and therefore, is more cost-effective for most customers. The differences for these DynamoDB operations are as follows:
 - Invoking [PutItem](#) for a 1KB item in a Region and replicating to other Regions requires 2 rWRUs per region for 2017.11.29 (Legacy), but only 1 rWRU for 2019.11.21 (Current).
 - Invoking [UpdateItem](#) for a 1KB item requires 2 rWRUs in the source Region and 1 rWRU per destination Region for 2017.11.29 (Legacy), but only 1 rWRU for both source and destination Regions for 2019.11.21 (Current).
 - Invoking [DeleteItem](#) for a 1KB item requires 1 rWRU in the source Region and 2 rWRUs per destination Region for 2017.11.29 (Legacy), but only 1 rWRU for both source or destination Region for 2019.11.21 (Current).

The following table shows the rWRU consumption for 2017.11.29 (Legacy) and 2019.11.21 (Current) tables.

rWRU consumption of 2017.11.29 (Legacy) and 2019.11.21 (Current) tables for a 1KB item in two Regions

Operation	2017.11.29 (Legacy)	2019.11.21 (Current)	Savings
PutItem	4 rWRUs	2 rWRUs	50%
UpdateItem	3 rWRUs	2 rWRUs	33%
DeleteItem	3 rWRUs	2 rWRUs	33%

- Version 2017.11.29 (Legacy) is available in only 11 AWS Regions. However, Version 2019.11.21 (Current) is available in all the AWS Regions.
- You create Version 2017.11.29 (Legacy) global tables by first creating a set of empty Regional tables, then invoking the [CreateGlobalTable](#) API to form the global table. You create Version 2019.11.21 (Current) global tables by invoking the [UpdateTable](#) API to add a replica to an existing Regional table.
- Version 2017.11.29 (Legacy) requires you to empty all replicas in the table before adding a replica in a new Region (including during creation). Version 2019.11.21 (Current) supports you to add and remove replicas to Regions on a table that already contains data.
- Version 2017.11.29 (Legacy) uses the following dedicated set of control plane APIs for managing replicas:

- [CreateGlobalTable](#)
- [DescribeGlobalTable](#)
- [DescribeGlobalTableSettings](#)
- [ListGlobalTables](#)
- [UpdateGlobalTable](#)
- [UpdateGlobalTableSettings](#)

Version 2019.11.21 (Current) uses the [DescribeTable](#) and [UpdateTable](#) APIs to manage replicas.

- Version 2017.11.29 (Legacy) publishes two DynamoDB Streams records for each write. Version 2019.11.21 (Current) only publishes one DynamoDB Streams record for each write.
- Version 2017.11.29 (Legacy) populates and updates the aws:rep:deleting, aws:rep:updateregion, and aws:rep:updatetime attributes. Version 2019.11.21 (Current) does not populate or update these attributes.
- Version 2017.11.29 (Legacy) does not synchronize [Time to Live \(TTL\)](#) settings across replicas. Version 2019.11.21 (Current) synchronizes TTL settings across replicas.
- Version 2017.11.29 (Legacy) does not replicate TTL deletes to other replicas. Version 2019.11.21 (Current) replicates TTL deletes to all replicas.
- Version 2017.11.29 (Legacy) does not synchronize [auto scaling](#) settings across replicas. Version 2019.11.21 (Current) synchronizes auto scaling settings across replicas.
- Version 2017.11.29 (Legacy) does not synchronize [global secondary index \(GSI\)](#) settings across replicas. Version 2019.11.21 (Current) synchronizes GSI settings across replicas.
- Version 2017.11.29 (Legacy) does not synchronize [encryption at rest](#) settings across replicas. Version 2019.11.21 (Current) synchronizes encryption at rest settings across replicas.
- Version 2017.11.29 (Legacy) publishes the PendingReplicationCount metric. Version 2019.11.21 (Current) does not publish this metric.

Upgrade prerequisites

Before you start upgrading to Version 2019.11.21 (Current) global tables, you must fulfill the following prerequisites:

- [Time to Live \(TTL\)](#) settings on replicas are consistent across Regions.
- [Global secondary index \(GSI\)](#) definitions on replicas are consistent across Regions.
- [Encryption at rest](#) settings on replicas are consistent across Regions.

- DynamoDB auto scaling is enabled for WCUs for all replicas, or [on-demand](#) capacity mode is enabled for all replicas.
- Applications don't require the presence of the `aws:rep:deleting`, `aws:rep:updateregion`, and `aws:rep:updatetime` attributes in table items.

Required permissions for global tables upgrade

To upgrade to Version 2019.11.21 (Current), you must have

`dynamodb:UpdateGlobalTableVersion` permissions in all Regions with replicas. These permissions are required in addition to the permissions needed for accessing the DynamoDB console and viewing tables.

The following IAM policy grants permissions to upgrade any global table to Version 2019.11.21 (Current).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "dynamodb:UpdateGlobalTableVersion",  
            "Resource": "*"  
        }  
    ]  
}
```

The following IAM policy grants permissions to upgrade only the Music global table with replicas in two Regions to Version 2019.11.21 (Current).

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "dynamodb:UpdateGlobalTableVersion",  
            "Resource": [  
                "arn:aws:dynamodb::123456789012:global-table/Music",  
                "arn:aws:dynamodb:ap-southeast-1:123456789012:table/Music",  
                "arn:aws:dynamodb:us-east-2:123456789012:table/Music"  
            ]  
        }  
    ]  
}
```

```
    ]  
}
```

What to expect during the upgrade

- All global table replicas will continue to process read and write traffic while upgrading.
- The upgrade process requires between a few minutes to several hours depending on the table size and number of replicas.
- During the upgrade process, the value of [TableStatus](#) will change from ACTIVE to UPDATING. You can view the status of the table by invoking the [DescribeTable](#) API, or with the **Tables** view in the [DynamoDB console](#).
- Auto scaling will not adjust the provisioned capacity settings for a global table while the table is being upgraded. We strongly recommend that you set the table to [on-demand](#) capacity mode during the upgrade.
- If you choose to use [provisioned](#) capacity mode with auto scaling during the upgrade, you must increase the minimum read and write throughput on your policies to accommodate any expected increases in traffic to avoid throttling during the upgrade.
- When the upgrade process is complete, your table status will change to ACTIVE.

DynamoDB Streams behavior before, during, and after upgrade

Operation	Replica Region	Behavior before upgrade	Behavior during upgrade	Behavior after upgrade
Put or Update	Source	Timestamp population happens using UpdateItem .	Timestamp population happens using PutItem .	No customer visible timestamp is generated.

Upgrading to Version 2019.11.21 (Current)

Perform the following steps to upgrade your version of DynamoDB global tables using the AWS Management Console.

To upgrade global tables to Version 2019.11.21 (Current)

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/home>.
2. In the navigation pane on the left side of the console, choose **Tables**, and then select the global table that you want to upgrade to Version 2019.11.21 (Current).
3. Choose the **Global Tables** tab.
4. Choose **Update version**.

5. Read and agree to the new requirements, and then choose **Update version**.

6. After the upgrade process is complete, the global tables version that appears on the console changes to **2019.11.21**.

Working with read and write operations

You can perform read and write operations with either the DynamoDB API or PartiQL for DynamoDB. These operations will allow you to interact with the items in your table to perform basic create, read, update, and delete (CRUD) functionality.

The following sections go more in depth on this topic.

Topics

- [DynamoDB API](#)
- [PartiQL - a SQL-compatible query language for Amazon DynamoDB](#)

DynamoDB API

Topics

- [Working with items and attributes](#)
- [Item collections - how to model one-to-many relationships in DynamoDB](#)
- [Working with scans in DynamoDB](#)

Working with items and attributes

In Amazon DynamoDB, an *item* is a collection of attributes. Each attribute has a name and a value. An attribute value can be a scalar, a set, or a document type. For more information, see [Amazon DynamoDB: How it works](#).

DynamoDB provides four operations for basic create, read, update, and delete (CRUD) functionality. All these operations are atomic.

- PutItem — Create an item.
- GetItem — Read an item.
- UpdateItem — Update an item.
- DeleteItem — Delete an item.

Each of these operations requires that you specify the primary key of the item that you want to work with. For example, to read an item using `GetItem`, you must specify the partition key and sort key (if applicable) for that item.

In addition to the four basic CRUD operations, DynamoDB also provides the following:

- `BatchGetItem` — Read up to 100 items from one or more tables.
- `BatchWriteItem` — Create or delete up to 25 items in one or more tables.

These batch operations combine multiple CRUD operations into a single request. In addition, the batch operations read and write items in parallel to minimize response latencies.

This section describes how to use these operations and includes related topics, such as conditional updates and atomic counters. This section also includes example code that uses the AWS SDKs.

Topics

- [Reading an item](#)
- [Writing an item](#)
- [Return values](#)
- [Batch operations](#)
- [Atomic counters](#)
- [Conditional writes](#)
- [Using expressions in DynamoDB](#)
- [Time to Live \(TTL\)](#)
- [Working with items: Java](#)
- [Working with items: .NET](#)

Reading an item

To read an item from a DynamoDB table, use the `GetItem` operation. You must provide the name of the table, along with the primary key of the item you want.

Example

The following AWS CLI example shows how to read an item from the `ProductCatalog` table.

```
aws dynamodb get-item \
```

```
--table-name ProductCatalog \
--key '{"Id":{"N":"1"}}'
```

Note

With `GetItem`, you must specify the *entire* primary key, not just part of it. For example, if a table has a composite primary key (partition key and sort key), you must supply a value for the partition key and a value for the sort key.

A `GetItem` request performs an eventually consistent read by default. You can use the `ConsistentRead` parameter to request a strongly consistent read instead. (This consumes additional read capacity units, but it returns the most up-to-date version of the item.)

`GetItem` returns all of the item's attributes. You can use a *projection expression* to return only some of the attributes. For more information, see [Projection expressions](#).

To return the number of read capacity units consumed by `GetItem`, set the `ReturnConsumedCapacity` parameter to `TOTAL`.

Example

The following AWS Command Line Interface (AWS CLI) example shows some of the optional `GetItem` parameters.

```
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"1"}}' \
  --consistent-read \
  --projection-expression "Description, Price, RelatedItems" \
  --return-consumed-capacity TOTAL
```

Writing an item

To create, update, or delete an item in a DynamoDB table, use one of the following operations:

- `PutItem`
- `UpdateItem`
- `DeleteItem`

For each of these operations, you must specify the entire primary key, not just part of it. For example, if a table has a composite primary key (partition key and sort key), you must provide a value for the partition key and a value for the sort key.

To return the number of write capacity units consumed by any of these operations, set the `ReturnConsumedCapacity` parameter to one of the following:

- `TOTAL` — Returns the total number of write capacity units consumed.
- `INDEXES` — Returns the total number of write capacity units consumed, with subtotals for the table and any secondary indexes that were affected by the operation.
- `NONE` — No write capacity details are returned. (This is the default.)

PutItem

`PutItem` creates a new item. If an item with the same key already exists in the table, it is replaced with the new item.

Example

Write a new item to the `Thread` table. The primary key for `Thread` consists of `ForumName` (partition key) and `Subject` (sort key).

```
aws dynamodb put-item \
  --table-name Thread \
  --item file://item.json
```

The arguments for `--item` are stored in the `item.json` file.

```
{
  "ForumName": {"S": "Amazon DynamoDB"},
  "Subject": {"S": "New discussion thread"},
  "Message": {"S": "First post in this thread"},
  "LastPostedBy": {"S": "fred@example.com"},
  "LastPostDateTime": {"S": "201603190422"}
}
```

UpdateItem

If an item with the specified key does not exist, `UpdateItem` creates a new item. Otherwise, it modifies an existing item's attributes.

You use an *update expression* to specify the attributes that you want to modify and their new values. For more information, see [Update expressions](#).

Within the update expression, you use expression attribute values as placeholders for the actual values. For more information, see [Expression attribute values](#).

Example

Modify various attributes in the Thread item. The optional `ReturnValues` parameter shows the item as it appears after the update. For more information, see [Return values](#).

```
aws dynamodb update-item \  
  --table-name Thread \  
  --key file://key.json \  
  --update-expression "SET Answered = :zero, Replies = :zero, LastPostedBy  
= :lastpostedby" \  
  --expression-attribute-values file://expression-attribute-values.json \  
  --return-values ALL_NEW
```

The arguments for `--key` are stored in the `key.json` file.

```
{  
    "ForumName": {"S": "Amazon DynamoDB"},  
    "Subject": {"S": "New discussion thread"}  
}
```

The arguments for `--expression-attribute-values` are stored in the `expression-attribute-values.json` file.

```
{  
    ":zero": {"N": "0"},  
    ":lastpostedby": {"S": "barney@example.com"}  
}
```

DeleteItem

`DeleteItem` deletes the item with the specified key.

Example

The following AWS CLI example shows how to delete the Thread item.

```
aws dynamodb delete-item \
    --table-name Thread \
    --key file://key.json
```

Return values

In some cases, you might want DynamoDB to return certain attribute values as they appeared before or after you modified them. The PutItem, UpdateItem, and DeleteItem operations have a `ReturnValues` parameter that you can use to return the attribute values before or after they are modified.

The default value for `ReturnValues` is `NONE`, meaning that DynamoDB does not return any information about attributes that were modified.

The following are the other valid settings for `ReturnValues`, organized by DynamoDB API operation.

PutItem

- `ReturnValues: ALL_OLD`
 - If you overwrite an existing item, `ALL_OLD` returns the entire item as it appeared before the overwrite.
 - If you write a nonexistent item, `ALL_OLD` has no effect.

UpdateItem

The most common usage for `UpdateItem` is to update an existing item. However, `UpdateItem` actually performs an *upsert*, meaning that it automatically creates the item if it doesn't already exist.

- `ReturnValues: ALL_OLD`
 - If you update an existing item, `ALL_OLD` returns the entire item as it appeared before the update.
 - If you update a nonexistent item (upsert), `ALL_OLD` has no effect.
- `ReturnValues: ALL_NEW`
 - If you update an existing item, `ALL_NEW` returns the entire item as it appeared after the update.

- If you update a nonexistent item (upsert), ALL_NEW returns the entire item.
- ReturnValues: UPDATED_OLD
 - If you update an existing item, UPDATED_OLD returns only the updated attributes, as they appeared before the update.
 - If you update a nonexistent item (upsert), UPDATED_OLD has no effect.
- ReturnValues: UPDATED_NEW
 - If you update an existing item, UPDATED_NEW returns only the affected attributes, as they appeared after the update.
 - If you update a nonexistent item (upsert), UPDATED_NEW returns only the updated attributes, as they appear after the update.

DeleteItem

- ReturnValues: ALL_OLD
 - If you delete an existing item, ALL_OLD returns the entire item as it appeared before you deleted it.
 - If you delete a nonexistent item, ALL_OLD doesn't return any data.

Batch operations

For applications that need to read or write multiple items, DynamoDB provides the BatchGetItem and BatchWriteItem operations. Using these operations can reduce the number of network round trips from your application to DynamoDB. In addition, DynamoDB performs the individual read or write operations in parallel. Your applications benefit from this parallelism without having to manage concurrency or threading.

The batch operations are essentially wrappers around multiple read or write requests. For example, if a BatchGetItem request contains five items, DynamoDB performs five GetItem operations on your behalf. Similarly, if a BatchWriteItem request contains two put requests and four delete requests, DynamoDB performs two PutItem and four DeleteItem requests.

In general, a batch operation does not fail unless *all* the requests in the batch fail. For example, suppose that you perform a BatchGetItem operation, but one of the individual GetItem requests in the batch fails. In this case, BatchGetItem returns the keys and data from the GetItem request that failed. The other GetItem requests in the batch are not affected.

BatchGetItem

A single BatchGetItem operation can contain up to 100 individual GetItem requests and can retrieve up to 16 MB of data. In addition, a BatchGetItem operation can retrieve items from multiple tables.

Example

Retrieve two items from the Thread table, using a projection expression to return only some of the attributes.

```
aws dynamodb batch-get-item \
--request-items file://request-items.json
```

The arguments for --request-items are stored in the request-items.json file.

```
{
    "Thread": {
        "Keys": [
            {
                "ForumName": {"S": "Amazon DynamoDB"},
                "Subject": {"S": "DynamoDB Thread 1"}
            },
            {
                "ForumName": {"S": "Amazon S3"},
                "Subject": {"S": "S3 Thread 1"}
            }
        ],
        "ProjectionExpression": "ForumName, Subject, LastPostedDateTime, Replies"
    }
}
```

BatchWriteItem

The BatchWriteItem operation can contain up to 25 individual PutItem and DeleteItem requests and can write up to 16 MB of data. (The maximum size of an individual item is 400 KB.) In addition, a BatchWriteItem operation can put or delete items in multiple tables.

Note

BatchWriteItem does not support UpdateItem requests.

Example

Write two items to the ProductCatalog table.

```
aws dynamodb batch-write-item \
--request-items file://request-items.json
```

The arguments for `--request-items` are stored in the `request-items.json` file.

```
{
    "ProductCatalog": [
        {
            "PutRequest": {
                "Item": {
                    "Id": { "N": "601" },
                    "Description": { "S": "Snowboard" },
                    "QuantityOnHand": { "N": "5" },
                    "Price": { "N": "100" }
                }
            }
        },
        {
            "PutRequest": {
                "Item": {
                    "Id": { "N": "602" },
                    "Description": { "S": "Snow shovel" }
                }
            }
        }
    ]
}
```

Atomic counters

You can use the `UpdateItem` operation to implement an *atomic counter*—a numeric attribute that is incremented, unconditionally, without interfering with other write requests. (All write requests are applied in the order in which they were received.) With an atomic counter, the updates are not idempotent. In other words, the numeric value increments or decrements each time you call `UpdateItem`. If the increment value used to update the atomic counter is positive, then it can cause overcounting. If the increment value is negative, then it can cause undercounting.

You might use an atomic counter to track the number of visitors to a website. In this case, your application would increment a numeric value, regardless of its current value. If an `UpdateItem` operation fails, the application could simply retry the operation. This would risk updating the counter twice, but you could probably tolerate a slight overcounting or undercounting of website visitors.

An atomic counter would not be appropriate where overcounting or undercounting can't be tolerated (for example, in a banking application). In this case, it is safer to use a conditional update instead of an atomic counter.

For more information, see [Incrementing and decrementing numeric attributes](#).

Example

The following AWS CLI example increments the `Price` of a product by 5. For this example, the item was known to exist before the counter is updated. Because `UpdateItem` is not idempotent, the `Price` increases every time you run this code.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id": { "N": "601" }}' \  
  --update-expression "SET Price = Price + :incr" \  
  --expression-attribute-values '{":incr":{"N":"5"}}' \  
  --return-values UPDATED_NEW
```

Conditional writes

By default, the DynamoDB write operations (`PutItem`, `UpdateItem`, `DeleteItem`) are *unconditional*: Each operation overwrites an existing item that has the specified primary key.

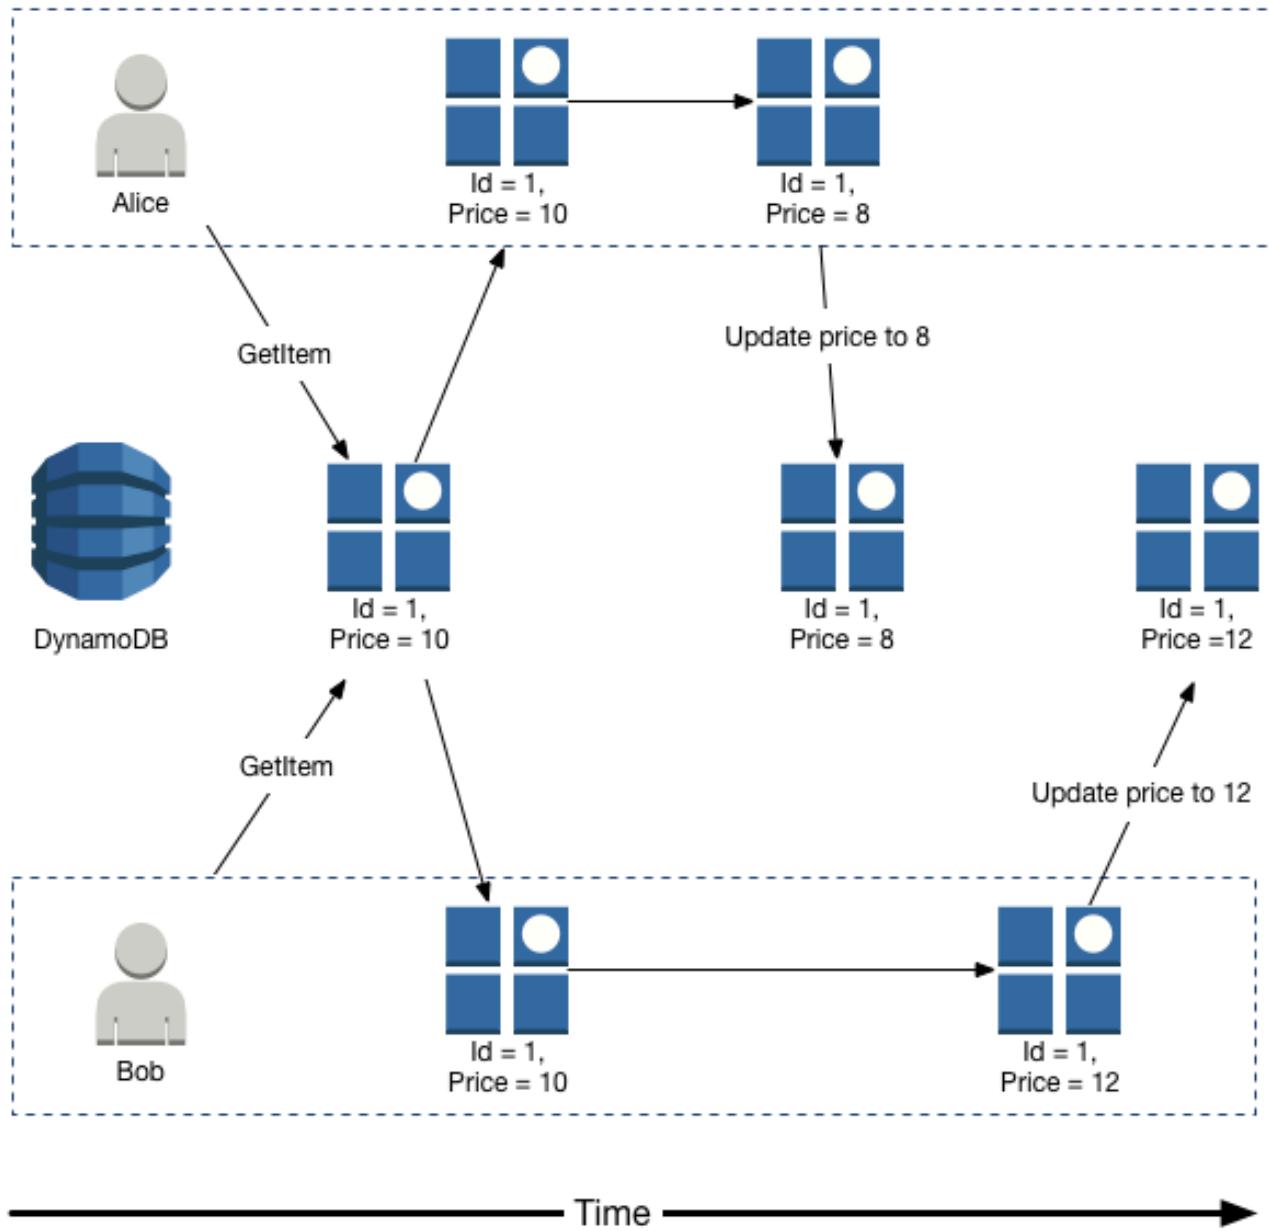

DynamoDB optionally supports conditional writes for these operations. A conditional write succeeds only if the item attributes meet one or more expected conditions. Otherwise, it returns an error.

Conditional writes check their conditions against the most recently updated version of the item. Note that if the item did not previously exist or if the most recent successful operation against that item was a delete, then the conditional write will find no previous item.

Conditional writes are helpful in many situations. For example, you might want a `PutItem` operation to succeed only if there is not already an item with the same primary key. Or you could

prevent an `UpdateItem` operation from modifying an item if one of its attributes has a certain value.

Conditional writes are helpful in cases where multiple users attempt to modify the same item. Consider the following diagram, in which two users (Alice and Bob) are working with the same item from a DynamoDB table.

Suppose that Alice uses the AWS CLI to update the Price attribute to 8.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"1"}}' \  
  --update-expression "SET Price = :newval" \  
  --expression-attribute-values file://expression-attribute-values.json
```

The arguments for `--expression-attribute-values` are stored in the file `expression-attribute-values.json`:

```
{  
  ":newval":{"N":"8"}  
}
```

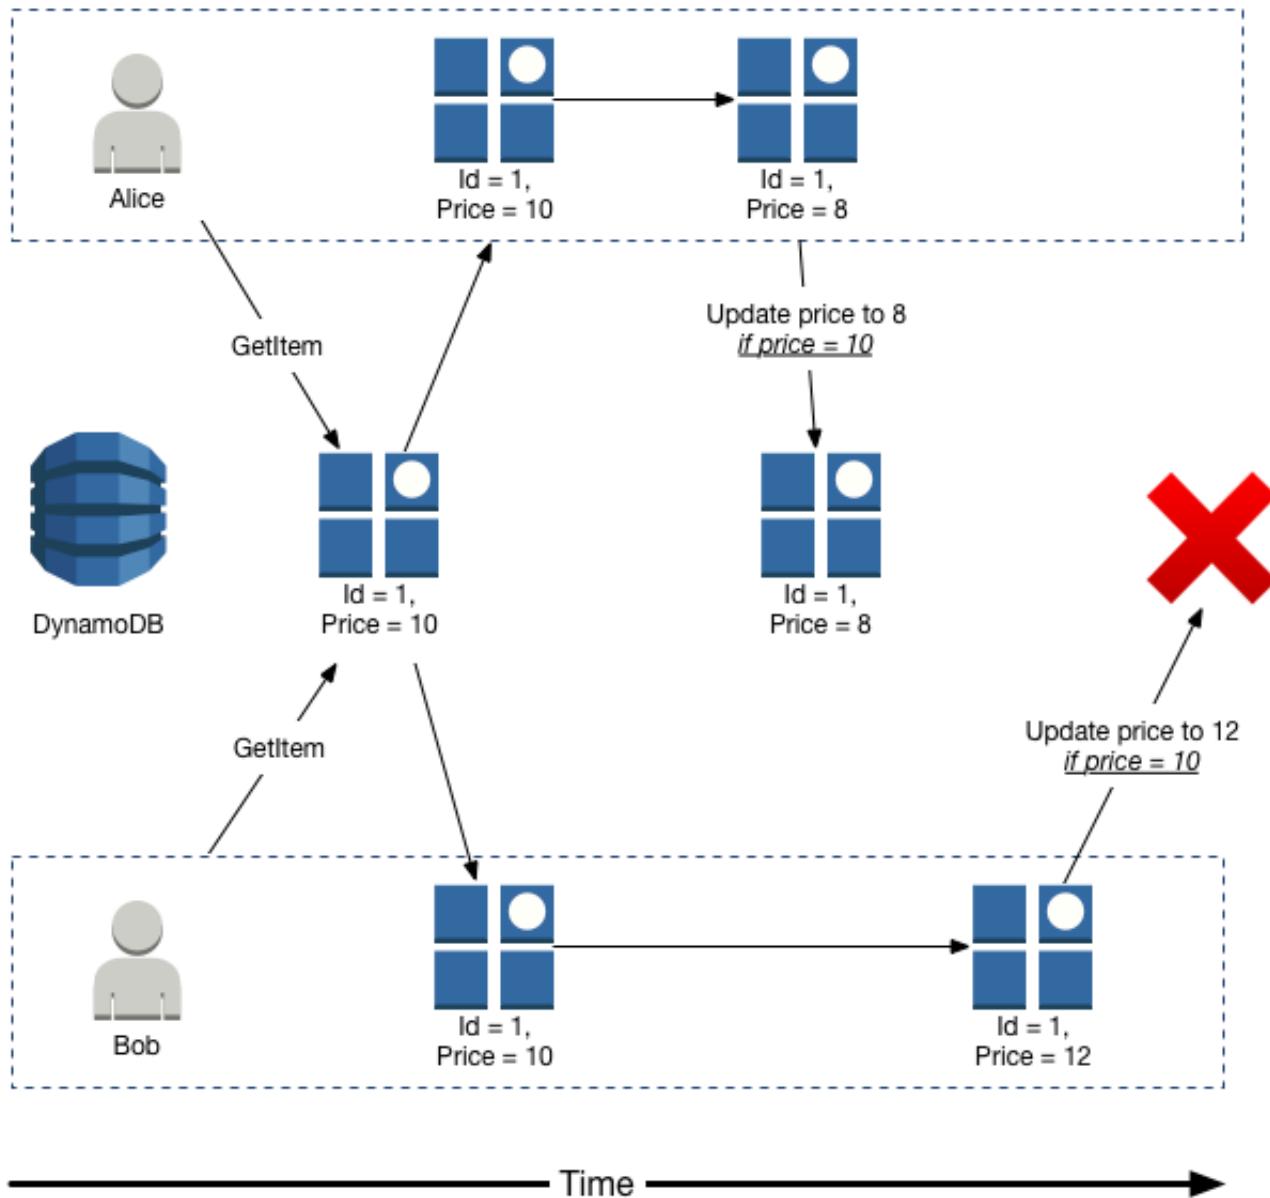

Now suppose that Bob issues a similar `UpdateItem` request later, but changes the Price to 12. For Bob, the `--expression-attribute-values` parameter looks like the following.

```
{  
  ":newval":{"N":"12"}  
}
```

Bob's request succeeds, but Alice's earlier update is lost.

To request a conditional `PutItem`, `DeleteItem`, or `UpdateItem`, you specify a condition expression. A *condition expression* is a string containing attribute names, conditional operators, and built-in functions. The entire expression must evaluate to true. Otherwise, the operation fails.

Now consider the following diagram, showing how conditional writes would prevent Alice's update from being overwritten.

Alice first tries to update Price to 8, but only if the current Price is 10.

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"1"}}' \
--update-expression "SET Price = :newval" \
--condition-expression "Price = :currval" \
```

```
--expression-attribute-values file://expression-attribute-values.json
```

The arguments for `--expression-attribute-values` are stored in the `expression-attribute-values.json` file.

```
{  
    ":newval": {"N": "8"},  
    ":currval": {"N": "10"}  
}
```

Alice's update succeeds because the condition evaluates to true.

Next, Bob attempts to update the Price to 12, but only if the current Price is 10. For Bob, the `--expression-attribute-values` parameter looks like the following.

```
{  
    ":newval": {"N": "12"},  
    ":currval": {"N": "10"}  
}
```

Because Alice has previously changed the Price to 8, the condition expression evaluates to false, and Bob's update fails.

For more information, see [Condition expressions](#).

Conditional write idempotence

Conditional writes can be *idempotent* if the conditional check is on the same attribute that is being updated. This means that DynamoDB performs a given write request only if certain attribute values in the item match what you expect them to be at the time of the request.

For example, suppose that you issue an `UpdateItem` request to increase the Price of an item by 3, but only if the Price is currently 20. After you send the request, but before you get the results back, a network error occurs, and you don't know whether the request was successful. Because this conditional write is idempotent, you can retry the same `UpdateItem` request, and DynamoDB updates the item only if the Price is currently 20.

Capacity units consumed by conditional writes

If a `ConditionExpression` evaluates to false during a conditional write, DynamoDB still consumes write capacity from the table. The amount consumed is dependent on the size of the

existing item (or a minimum of 1). For example, if an existing item is 300kb and the new item you are trying to create or update is 310kb, the write capacity units consumed will be the 300 if the condition fails, and 310 if the condition succeeds. If this is a new item (no existing item), then the write capacity units consumed will be 1 if the condition fails and 310 if the condition succeeds.

 **Note**

Write operations consume *write* capacity units only. They never consume *read* capacity units.

A failed conditional write returns a `ConditionalCheckFailedException`. When this occurs, you don't receive any information in the response about the write capacity that was consumed. However, you can view the `ConsumedWriteCapacityUnits` metric for the table in Amazon CloudWatch. For more information, see [DynamoDB metrics](#) in [Logging and monitoring in DynamoDB](#).

To return the number of write capacity units consumed during a conditional write, you use the `ReturnConsumedCapacity` parameter:

- `TOTAL` — Returns the total number of write capacity units consumed.
- `INDEXES` — Returns the total number of write capacity units consumed, with subtotals for the table and any secondary indexes that were affected by the operation.
- `NONE` — No write capacity details are returned. (This is the default.)

 **Note**

Unlike a global secondary index, a local secondary index shares its provisioned throughput capacity with its table. Read and write activity on a local secondary index consumes provisioned throughput capacity from the table.

Using expressions in DynamoDB

In Amazon DynamoDB, you use *expressions* to denote the attributes that you want to read from an item. You also use expressions when writing an item to indicate any conditions that must be met

(also known as a conditional update), and to indicate how the attributes are to be updated. This section describes the basic expression grammar and the available kinds of expressions.

Note

For backward compatibility, DynamoDB also supports conditional parameters that do not use expressions. For more information, see [Legacy conditional parameters](#).

New applications should use expressions rather than the legacy parameters.

Specifying item attributes when using expressions

This section describes how to refer to item attributes in an expression in Amazon DynamoDB. You can work with any attribute, even if it is deeply nested within multiple lists and maps.

Topics

- [Top-level attributes](#)
- [Nested attributes](#)
- [Document paths](#)

A Sample Item: ProductCatalog

The following is a representation of an item in the ProductCatalog table. (This table is described in [Example tables and data](#).)

```
{  
  "Id": 123,
```

```
"Title": "Bicycle 123",
"Description": "123 description",
"BicycleType": "Hybrid",
"Brand": "Brand-Company C",
"Price": 500,
"Color": ["Red", "Black"],
"ProductCategory": "Bicycle",
"InStock": true,
"QuantityOnHand": null,
"RelatedItems": [
    341,
    472,
    649
],
"Pictures": {
    "FrontView": "http://example.com/products/123_front.jpg",
    "RearView": "http://example.com/products/123_rear.jpg",
    "SideView": "http://example.com/products/123_left_side.jpg"
},
"ProductReviews": {
    "FiveStar": [
        "Excellent! Can't recommend it highly enough! Buy it!",
        "Do yourself a favor and buy this."
    ],
    "OneStar": [
        "Terrible product! Do not buy this."
    ]
},
"Comment": "This product sells out quickly during the summer",
"Safety.Warning": "Always wear a helmet"
}
```

Note the following:

- The partition key value (**Id**) is 123. There is no sort key.
- Most of the attributes have scalar data types, such as **String**, **Number**, **Boolean**, and **Null**.
- One attribute (**Color**) is a **String Set**.
- The following attributes are document data types:
 - A list of **RelatedItems**. Each element is an **Id** for a related product.
 - A map of **Pictures**. Each element is a short description of a picture, along with a URL for the corresponding image file.

- A map of `ProductReviews`. Each element represents a rating and a list of reviews corresponding to that rating. Initially, this map is populated with five-star and one-star reviews.

Top-level attributes

An attribute is said to be *top level* if it is not embedded within another attribute. For the `ProductCatalog` item, the top-level attributes are as follows:

- `Id`
- `Title`
- `Description`
- `BicycleType`
- `Brand`
- `Price`
- `Color`
- `ProductCategory`
- `InStock`
- `QuantityOnHand`
- `RelatedItems`
- `Pictures`
- `ProductReviews`
- `Comment`
- `Safety.Warning`

All of these top-level attributes are scalars, except for `Color` (list), `RelatedItems` (list), `Pictures` (map), and `ProductReviews` (map).

Nested attributes

An attribute is said to be *nested* if it is embedded within another attribute. To access a nested attribute, you use *dereference operators*:

- `[n]` — for list elements

- . (dot) — for map elements

Accessing list elements

The dereference operator for a list element is `[N]`, where n is the element number. List elements are zero-based, so `[0]` represents the first element in the list, `[1]` represents the second, and so on. Here are some examples:

- `MyList[0]`
- `AnotherList[12]`
- `ThisList[5][11]`

The element `ThisList[5]` is itself a nested list. Therefore, `ThisList[5][11]` refers to the 12th element in that list.

The number within the square brackets must be a non-negative integer. Therefore, the following expressions are not valid:

- `MyList[-1]`
- `MyList[0.4]`

Accessing map elements

The dereference operator for a map element is `.` (a dot). Use a dot as a separator between elements in a map:

- `MyMap.nestedField`
- `MyMap.nestedField.deeplyNestedField`

Document paths

In an expression, you use a *document path* to tell DynamoDB where to find an attribute. For a top-level attribute, the document path is simply the attribute name. For a nested attribute, you construct the document path using dereference operators.

The following are some examples of document paths. (Refer to the item shown in [Specifying item attributes when using expressions](#).)

- A top-level scalar attribute.

Description

- A top-level list attribute. (This returns the entire list, not just some of the elements.)

RelatedItems

- The third element from the RelatedItems list. (Remember that list elements are zero-based.)

RelatedItems[2]

- The front-view picture of the product.

Pictures.FrontView

- All of the five-star reviews.

ProductReviews.FiveStar

- The first of the five-star reviews.

ProductReviews.FiveStar[0]

Note

The maximum depth for a document path is 32. Therefore, the number of dereferences operators in a path cannot exceed this limit.

You can use any attribute name in a document path as long as they meet these requirements:

- The attribute name must begin with a pound sign (#)
- The first character is a-z or A-Z and or 0-9
- The second character (if present) is a-z, A-Z

Note

If an attribute name does not meet this requirement, you must define an expression attribute name as a placeholder.

For more information, see [Expression attribute names in DynamoDB](#).

Projection expressions

To read data from a table, you use operations such as GetItem, Query, or Scan. Amazon DynamoDB returns all the item attributes by default. To get only some, rather than all of the attributes, use a projection expression.

A *projection expression* is a string that identifies the attributes that you want. To retrieve a single attribute, specify its name. For multiple attributes, the names must be comma-separated.

The following are some examples of projection expressions, based on the ProductCatalog item from [Specifying item attributes when using expressions](#):

- A single top-level attribute.

Title

- Three top-level attributes. DynamoDB retrieves the entire Color set.

Title, Price, Color

- Four top-level attributes. DynamoDB returns the entire contents of RelatedItems and ProductReviews.

Title, Description, RelatedItems, ProductReviews

DynamoDB has a list of reserved words and special characters. You can use any attribute name in a projection expression, provided that the first character is a-z or A-Z and the second character (if present) is a-z, A-Z, or 0-9. If an attribute name doesn't meet this requirement, you must define an expression attribute name as a placeholder. For a complete list, see [Reserved words in DynamoDB](#). Also, the following characters have special meaning in DynamoDB: # (hash) and : (colon).

Although DynamoDB allows you to use these reserved words and special characters for names, we recommend that you avoid doing so because you have to define placeholder variables whenever you use these names in an expression. For more information, see [Expression attribute names in DynamoDB](#).

The following AWS CLI example shows how to use a projection expression with a GetItem operation. This projection expression retrieves a top-level scalar attribute

(Description), the first element in a list (RelatedItems[0]), and a list nested within a map (ProductReviews.FiveStar).

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key file://key.json \
--projection-expression "Description, RelatedItems[0], ProductReviews.FiveStar"
```

The following JSON would be returned for this example.

```
{
  "Item": {
    "Description": {
      "S": "123 description"
    },
    "ProductReviews": {
      "M": {
        "FiveStar": {
          "L": [
            {
              "S": "Excellent! Can't recommend it highly enough! Buy it!"
            },
            {
              "S": "Do yourself a favor and buy this."
            }
          ]
        }
      }
    },
    "RelatedItems": {
      "L": [
        {
          "N": "341"
        }
      ]
    }
  }
}
```

The arguments for --key are stored in the key.json file.

```
{
```

```
"Id": { "N": "123" }  
}
```

For programming language-specific code examples, see [Getting started with DynamoDB and the AWS SDKs](#).

Expression attribute names in DynamoDB

An *expression attribute name* is a placeholder that you use in an Amazon DynamoDB expression as an alternative to an actual attribute name. An expression attribute name must begin with a pound sign (#), and be followed by one or more alphanumeric characters and the underscore (_) character.

This section describes several situations in which you must use expression attribute names.

Note

The examples in this section use the AWS Command Line Interface (AWS CLI). For programming language-specific code examples, see [Getting started with DynamoDB and the AWS SDKs](#).

Topics

- [Reserved words](#)
- [Attribute names containing special characters](#)
- [Nested attributes](#)
- [Repeating attribute names](#)

Reserved words

Sometimes you might need to write an expression containing an attribute name that conflicts with a DynamoDB reserved word. (For a complete list of reserved words, see [Reserved words in DynamoDB](#).)

For example, the following AWS CLI example would fail because COMMENT is a reserved word.

```
aws dynamodb get-item \  
  --table-name ProductCatalog \  
  --key-value { "id": "123" }
```

```
--key '{"Id":{"N":"123"}}' \
--projection-expression "Comment"
```

To work around this, you can replace `Comment` with an expression attribute name such as `#c`. The `#` (pound sign) is required and indicates that this is a placeholder for an attribute name. The AWS CLI example would now look like the following.

```
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"123"}}' \
  --projection-expression "#c" \
  --expression-attribute-names '{"#c":"Comment"}'
```

Note

If an attribute name begins with a number, contains a space or contains a reserved word, you *must* use an expression attribute name to replace that attribute's name in the expression.

Attribute names containing special characters

In an expression, a dot (".") is interpreted as a separator character in a document path. However, DynamoDB also allows you to use a dot character and other special characters, such as a hyphen ("-") as part of an attribute name. This can be ambiguous in some cases. To illustrate, suppose that you wanted to retrieve the `Safety.Warning` attribute from a `ProductCatalog` item (see [Specifying item attributes when using expressions](#)).

Suppose that you wanted to access `Safety.Warning` using a projection expression.

```
aws dynamodb get-item \
  --table-name ProductCatalog \
  --key '{"Id":{"N":"123"}}' \
  --projection-expression "Safety.Warning"
```

DynamoDB would return an empty result, rather than the expected string ("Always wear a helmet"). This is because DynamoDB interprets a dot in an expression as a document path separator. In this case, you must define an expression attribute name (such as `#sw`) as a substitute for `Safety.Warning`. You could then use the following projection expression.

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "#sw" \
--expression-attribute-names '{"#sw":"Safety.Warning"}'
```

DynamoDB would then return the correct result.

 **Note**

If an attribute name contains a dot (".") or a hyphen ("-"), you *must* use an expression attribute name to replace that attribute's name in the expression.

Nested attributes

Suppose that you wanted to access the nested attribute `ProductReviews.OneStar`, using the following projection expression.

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "ProductReviews.OneStar"
```

The result would contain all of the one-star product reviews, which is expected.

But what if you decided to use an expression attribute name instead? For example, what would happen if you were to define `#pr1star` as a substitute for `ProductReviews.OneStar`?

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "#pr1star" \
--expression-attribute-names '{"#pr1star":"ProductReviews.OneStar"}'
```

DynamoDB would return an empty result instead of the expected map of one-star reviews. This is because DynamoDB interprets a dot in an expression attribute name as a character within an attribute's name. When DynamoDB evaluates the expression attribute name `#pr1star`, it determines that `ProductReviews.OneStar` refers to a scalar attribute—which is not what was intended.

The correct approach would be to define an expression attribute name for each element in the document path:

- `#pr` – `ProductReviews`
- `#1star` – `OneStar`

You could then use `#pr.#1star` for the projection expression.

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "#pr.#1star" \
--expression-attribute-names '{"#pr":"ProductReviews", "#1star": "OneStar"}'
```

DynamoDB would then return the correct result.

Repeating attribute names

Expression attribute names are helpful when you need to refer to the same attribute name repeatedly. For example, consider the following expression for retrieving some of the reviews from a `ProductCatalog` item.

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "ProductReviews.FiveStar, ProductReviews.ThreeStar,
ProductReviews.OneStar"
```

To make this more concise, you can replace `ProductReviews` with an expression attribute name such as `#pr`. The revised expression would now look like the following.

- `#pr.FiveStar, #pr.ThreeStar, #pr.OneStar`

```
aws dynamodb get-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"123"}}' \
--projection-expression "#pr.FiveStar, #pr.ThreeStar, #pr.OneStar" \
--expression-attribute-names '{"#pr":"ProductReviews"}'
```

If you define an expression attribute name, you must use it consistently throughout the entire expression. Also, you cannot omit the # symbol.

Expression attribute values

If you need to compare an attribute with a value, define an expression attribute value as a placeholder. *Expression attribute values* in Amazon DynamoDB are substitutes for the actual values that you want to compare—values that you might not know until runtime. An expression attribute value must begin with a colon (:) and be followed by one or more alphanumeric characters.

For example, suppose that you wanted to return all of the ProductCatalog items that are available in Black and cost 500 or less. You could use a Scan operation with a filter expression, as in this AWS Command Line Interface (AWS CLI) example.

```
aws dynamodb scan \
--table-name ProductCatalog \
--filter-expression "contains(Color, :c) and Price <= :p" \
--expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  ":c": { "S": "Black" },
  ":p": { "N": "500" }
}
```

Note

A Scan operation reads every item in a table. So you should avoid using Scan with large tables.

The filter expression is applied to the Scan results, and items that don't match the filter expression are discarded.

If you define an expression attribute value, you must use it consistently throughout the entire expression. Also, you can't omit the : symbol.

Expression attribute values are used with key condition expressions, condition expressions, update expressions, and filter expressions.

Note

For programming language-specific code examples, see [Getting started with DynamoDB and the AWS SDKs.](#)

Condition expressions

To manipulate data in an Amazon DynamoDB table, you use the PutItem, UpdateItem, and DeleteItem operations. (You can also use BatchWriteItem to perform multiple PutItem or DeleteItem operations in a single call.)

For these data manipulation operations, you can specify a *condition expression* to determine which items should be modified. If the condition expression evaluates to true, the operation succeeds; otherwise, the operation fails.

The PutItem, UpdateItem, and DeleteItem operations have a ReturnValues parameter you can use to return attribute values as they appeared before or after you modified them. For more information, see [ReturnValue](#).

The following are some AWS Command Line Interface (AWS CLI) examples of using condition expressions. These examples are based on the ProductCatalog table, which was introduced in [Specifying item attributes when using expressions](#). The partition key for this table is Id; there is no sort key. The following PutItem operation creates a sample ProductCatalog item that the examples refer to.

```
aws dynamodb put-item \
  --table-name ProductCatalog \
  --item file://item.json
```

The arguments for --item are stored in the item.json file. (For simplicity, only a few item attributes are used.)

```
{
  "Id": {"N": "456" },
  "ProductCategory": {"S": "Sporting Goods" },
  "Price": {"N": "650" }
}
```

Topics

- [Conditional put](#)
- [Conditional deletes](#)
- [Conditional updates](#)
- [Conditional expression examples](#)
- [Comparison operator and function reference](#)

Conditional put

The PutItem operation overwrites an item with the same primary key (if it exists). If you want to avoid this, use a condition expression. This allows the write to proceed only if the item in question does not already have the same primary key.

The following example uses `attribute_not_exists()` to check whether the primary key exists in the table before attempting the write operation.

Note

If your primary key consists of both a partition key(pk) and a sort key(sk), the parameter will check whether `attribute_not_exists(pk)` AND `attribute_not_exists(sk)` evaluate to true or false before attempting the write operation.

```
aws dynamodb put-item \  
  --table-name ProductCatalog \  
  --item file://item.json \  
  --condition-expression "attribute_not_exists(Id)"
```

If the condition expression evaluates to false, DynamoDB returns the following error message: The conditional request failed.

Note

For more information about `attribute_not_exists` and other functions, see [Comparison operator and function reference](#).

Conditional deletes

To perform a conditional delete, you use a `DeleteItem` operation with a condition expression. The condition expression must evaluate to true in order for the operation to succeed; otherwise, the operation fails.

Consider the item from [Condition expressions](#).

```
{  
    "Id": {  
        "N": "456"  
    },  
    "Price": {  
        "N": "650"  
    },  
    "ProductCategory": {  
        "S": "Sporting Goods"  
    }  
}
```

Suppose that you wanted to delete the item, but only under the following conditions:

- The `ProductCategory` is either "Sporting Goods" or "Gardening Supplies."
- The `Price` is between 500 and 600.

The following example tries to delete the item.

```
aws dynamodb delete-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"456"}}' \  
  --condition-expression "(ProductCategory IN (:cat1, :cat2)) and (Price between :lo  
  and :hi)" \  
  --expression-attribute-values file://values.json
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{  
    ":cat1": {"S": "Sporting Goods"},  
    ":cat2": {"S": "Gardening Supplies"},  
    ":lo": {"N": "500"},  
    ":hi": {"N": "600"}}
```

```
}
```

Note

In the condition expression, the : (colon character) indicates an *expression attribute value*—a placeholder for an actual value. For more information, see [Expression attribute values](#). For more information about IN, AND, and other keywords, see [Comparison operator and function reference](#).

In this example, the ProductCategory comparison evaluates to true, but the Price comparison evaluates to false. This causes the condition expression to evaluate to false and the DeleteItem operation to fail.

Conditional updates

To perform a conditional update, you use an UpdateItem operation with a condition expression. The condition expression must evaluate to true in order for the operation to succeed; otherwise, the operation fails.

Note

UpdateItem also supports *update expressions*, where you specify the modifications you want to make to an item. For more information, see [Update expressions](#).

Suppose that you started with the item shown in [Condition expressions](#).

```
{
    "Id": { "N": "456" },
    "Price": { "N": "650" },
    "ProductCategory": { "S": "Sporting Goods" }
}
```

The following example performs an UpdateItem operation. It tries to reduce the Price of a product by 75—but the condition expression prevents the update if the current Price is less than or equal to 500.

```
aws dynamodb update-item \
```

```
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--update-expression "SET Price = Price - :discount" \
--condition-expression "Price > :limit" \
--expression-attribute-values file://values.json
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{
  ":discount": { "N": "75" },
  ":limit": {"N": "500"}
}
```

If the starting Price is 650, the `UpdateItem` operation reduces the Price to 575. If you run the `UpdateItem` operation again, the Price is reduced to 500. If you run it a third time, the condition expression evaluates to false, and the update fails.

Note

In the condition expression, the `:` (colon character) indicates an *expression attribute value*—a placeholder for an actual value. For more information, see [Expression attribute values](#). For more information about `>` and other operators, see [Comparison operator and function reference](#).

Conditional expression examples

For more information about the functions used in the following examples, see [Comparison operator and function reference](#). If you want to know more about how to specify different attribute types in an expression, see [Specifying item attributes when using expressions](#).

Checking for attributes in an item

You can check for the existence (or nonexistence) of any attribute. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses `attribute_not_exists` to delete a product only if it does not have a `Price` attribute.

```
aws dynamodb delete-item \
```

```
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--condition-expression "attribute_not_exists(Price)"
```

DynamoDB also provides an `attribute_exists` function. The following example deletes a product only if it has received poor reviews.

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--condition-expression "attribute_exists(ProductReviews.OneStar)"
```

Checking for attribute type

You can check the data type of an attribute value by using the `attribute_type` function. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses `attribute_type` to delete a product only if it has a `Color` attribute of type String Set.

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--condition-expression "attribute_type(Color, :v_sub)" \
--expression-attribute-values file://expression-attribute-values.json
```

The arguments for `--expression-attribute-values` are stored in the `expression-attribute-values.json` file.

```
{
  ":v_sub": {"S": "SS"}
}
```

Checking string starting value

You can check if a String attribute value begins with a particular substring by using the `begins_with` function. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses `begins_with` to delete a product only if the `FrontView` element of the `Pictures` map starts with a specific value.

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--condition-expression "begins_with(Pictures.FrontView, :v_sub)" \
--expression-attribute-values file://expression-attribute-values.json
```

The arguments for --expression-attribute-values are stored in the expression-attribute-values.json file.

```
{  
  ":v_sub":{"S":"http://"}  
}
```

Checking for an element in a set

You can check for an element in a set or look for a substring within a string by using the contains function. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses contains to delete a product only if the Color String Set has an element with a specific value.

```
aws dynamodb delete-item \
--table-name ProductCatalog \
--key '{"Id": {"N": "456"}}' \
--condition-expression "contains(Color, :v_sub)" \
--expression-attribute-values file://expression-attribute-values.json
```

The arguments for --expression-attribute-values are stored in the expression-attribute-values.json file.

```
{  
  ":v_sub":{"S":"Red"}  
}
```

Checking the size of an attribute value

You can check for the size of an attribute value by using the size function. If the condition expression evaluates to true, the operation succeeds; otherwise, it fails.

The following example uses size to delete a product only if the size of the VideoClip Binary attribute is greater than 64000 bytes.

```
aws dynamodb delete-item \
    --table-name ProductCatalog \
    --key '{"Id": {"N": "456"}}' \
    --condition-expression "size(VideoClip) > :v_sub" \
    --expression-attribute-values file://expression-attribute-values.json
```

The arguments for `--expression-attribute-values` are stored in the `expression-attribute-values.json` file.

```
{
  ":v_sub":{"N":"64000"}
}
```

Comparison operator and function reference

This section covers the built-in functions and keywords for writing filter expressions and condition expressions in Amazon DynamoDB. For more detailed information on functions and programming with DynamoDB, see [Programming with DynamoDB and the AWS SDKs](#) and the [DynamoDB API Reference](#).

Topics

- [Syntax for filter and condition expressions](#)
- [Making comparisons](#)
- [Functions](#)
- [Logical evaluations](#)
- [Parentheses](#)
- [Precedence in conditions](#)

Syntax for filter and condition expressions

In the following syntax summary, an *operand* can be the following:

- A top-level attribute name, such as `Id`, `Title`, `Description`, or `ProductCategory`
- A document path that references a nested attribute

```
condition-expression ::=  
  operand comparator operand
```

```
| operand BETWEEN operand AND operand
| operand IN ( operand (',', operand (, ...)))
| function
| condition AND condition
| condition OR condition
| NOT condition
| ( condition )

comparator ::=
=
|
| <>
| <
| <=
| >
| >=>

function ::=
attribute_exists (path)
| attribute_not_exists (path)
| attribute_type (path, type)
| begins_with (path, substr)
| contains (path, operand)
| size (path)
```

Making comparisons

Use these comparators to compare an operand against a range of values or an enumerated list of values:

- *a* = *b* – True if *a* is equal to *b*.
- *a* <*>* *b* – True if *a* is not equal to *b*.
- *a* < *b* – True if *a* is less than *b*.
- *a* <= *b* – True if *a* is less than or equal to *b*.
- *a* > *b* – True if *a* is greater than *b*.
- *a* >= *b* – True if *a* is greater than or equal to *b*.

Use the BETWEEN and IN keywords to compare an operand against a range of values or an enumerated list of values:

- *a* BETWEEN *b* AND *c* – True if *a* is greater than or equal to *b*, and less than or equal to *c*.

- **a IN (b, c, d)** – True if **a** is equal to any value in the list—for example, any of **b**, **c**, or **d**. The list can contain up to 100 values, separated by commas.

Functions

Use the following functions to determine whether an attribute exists in an item, or to evaluate the value of an attribute. These function names are case sensitive. For a nested attribute, you must provide its full document path.

Function	Description
<code>attribute_exists (path)</code>	<p>True if the item contains the attribute specified by path.</p> <p>Example: Check whether an item in the Product table has a side view picture.</p> <ul style="list-style-type: none">• <code>attribute_exists (#Picture s.#SideView)</code>
<code>attribute_not_exists (path)</code>	<p>True if the attribute specified by path does not exist in the item.</p> <p>Example: Check whether an item has a Manufacturer attribute.</p> <ul style="list-style-type: none">• <code>attribute_not_exists (Manufacturer)</code>
<code>attribute_type (path, type)</code>	<p>True if the attribute at the specified path is of a particular data type. The type parameter must be one of the following:</p> <ul style="list-style-type: none">• S – String• SS – String set•

Function	Description
	<p>N – Number</p> <ul style="list-style-type: none">• NS – Number set• B – Binary• BS – Binary set• BOOL – Boolean• NULL – Null• L – List• M – Map
	<p>You must use an expression attribute value for the type parameter.</p> <p>Example: Check whether the <code>Quantity0nHand</code> attribute is of type List. In this example, <code>:v_sub</code> is a placeholder for the string L.</p> <ul style="list-style-type: none">• <code>attribute_type (ProductReviews.FiveStar, :v_sub)</code>
	<p>You must use an expression attribute value for the type parameter.</p>

Function	Description
<code>begins_with (<i>path</i>, <i>substr</i>)</code>	<p>True if the attribute specified by path begins with a particular substring.</p> <p>Example: Check whether the first few characters of the front view picture URL are <code>http://</code>.</p> <ul style="list-style-type: none">• <code>begins_with (Pictures.FrontView, :v_sub)</code> <p>The expression attribute value <code>:v_sub</code> is a placeholder for <code>http://</code>.</p>

Function	Description
<code>contains (path, operand)</code>	<p>True if the attribute specified by path is one of the following:</p> <ul style="list-style-type: none">• A String that contains a particular substring.• A Set that contains a particular element within the set.• A List that contains a particular element within the list. <p>If the attribute specified by path is a String, the operand must be a String. If the attribute specified by path is a Set, the operand must be the set's element type.</p> <p>The path and the operand must be distinct. That is, <code>contains (a, a)</code> returns an error.</p> <p>Example: Check whether the Brand attribute contains the substring Company.</p> <ul style="list-style-type: none">• <code>contains (Brand, :v_sub)</code> <p>The expression attribute value <code>:v_sub</code> is a placeholder for Company.</p> <p>Example: Check whether the product is available in red.</p> <ul style="list-style-type: none">• <code>contains (Color, :v_sub)</code>

Function	Description
	The expression attribute value :v_sub is a placeholder for Red.

Function	Description
<code>size (path)</code>	<p>Returns a number that represents an attribute's size. The following are valid data types for use with <code>size</code>.</p> <p>If the attribute is of type <code>String</code>, <code>size</code> returns the length of the string.</p> <p>Example: Check whether the string <code>Brand</code> is less than or equal to 20 characters. The expression attribute value <code>:v_sub</code> is a placeholder for 20.</p> <ul style="list-style-type: none">• <code>size (Brand) <= :v_sub</code>
	<p>If the attribute is of type <code>Binary</code>, <code>size</code> returns the number of bytes in the attribute value.</p> <p>Example: Suppose that the <code>ProductCatalog</code> item has a binary attribute named <code>VideoClip</code> that contains a short video of the product in use. The following expression checks whether <code>VideoClip</code> exceeds 64,000 bytes. The expression attribute value <code>:v_sub</code> is a placeholder for 64000.</p> <ul style="list-style-type: none">• <code>size(VideoClip) > :v_sub</code> <p>If the attribute is a <code>Set</code> data type, <code>size</code> returns the number of elements in the set.</p>

Function	Description
	<p>Example: Check whether the product is available in more than one color. The expression attribute value <code>:v_sub</code> is a placeholder for 1.</p> <ul style="list-style-type: none"> <li data-bbox="833 445 1274 508">• <code>size (Color) < :v_sub</code>
	<p>If the attribute is of type List or Map, <code>size</code> returns the number of child elements.</p> <p>Example: Check whether the number of OneStar reviews has exceeded a certain threshold. The expression attribute value <code>:v_sub</code> is a placeholder for 3.</p> <ul style="list-style-type: none"> <li data-bbox="833 994 1400 1100">• <code>size(ProductReviews.OneStar) > :v_sub</code>

Logical evaluations

Use the AND, OR, and NOT keywords to perform logical evaluations. In the following list, *a* and *b* represent conditions to be evaluated.

- *a* AND *b* – True if *a* and *b* are both true.
- *a* OR *b* – True if either *a* or *b* (or both) are true.
- NOT *a* – True if *a* is false. False if *a* is true.

The following is a code example of AND in an operation.

```
dynamodb-local (*)> select * from exprtest where a > 3 and a < 5;
```

Parentheses

Use parentheses to change the precedence of a logical evaluation. For example, suppose that conditions *a* and *b* are true, and that condition *c* is false. The following expression evaluates to true:

- *a* OR *b* AND *c*

However, if you enclose a condition in parentheses, it is evaluated first. For example, the following evaluates to false:

- (*a* OR *b*) AND *c*

 **Note**

You can nest parentheses in an expression. The innermost ones are evaluated first.

The following is a code example with parentheses in a logical evaluation.

```
dynamodb-local (*)> select * from exprtest where attribute_type(b, string)  
or ( a = 5 and c = "coffee");
```

Precedence in conditions

DynamoDB evaluates conditions from left to right using the following precedence rules:

- = <> < <= > >=
- IN
- BETWEEN
- attribute_exists attribute_not_exists begins_with contains
- Parentheses
- NOT
- AND
- OR

Update expressions

The `UpdateItem` operation updates an existing item, or adds a new item to the table if it does not already exist. You must provide the key of the item that you want to update. You must also provide an update expression, indicating the attributes that you want to modify and the values that you want to assign to them.

An *update expression* specifies how `UpdateItem` will modify the attributes of an item—for example, setting a scalar value or removing elements from a list or a map.

The following is a syntax summary for update expressions.

```
update-expression ::=  
  [ SET action [, action] ... ]  
  [ REMOVE action [, action] ... ]  
  [ ADD action [, action] ... ]  
  [ DELETE action [, action] ... ]
```

An update expression consists of one or more clauses. Each clause begins with a `SET`, `REMOVE`, `ADD`, or `DELETE` keyword. You can include any of these clauses in an update expression, in any order. However, each action keyword can appear only once.

Within each clause, there are one or more actions separated by commas. Each action represents a data modification.

The examples in this section are based on the `ProductCatalog` item shown in [Projection expressions](#).

The topics below cover some different use cases for the `SET` action.

Topics

- [SET — modifying or adding item attributes](#)
- [REMOVE — deleting attributes from an item](#)
- [ADD — updating numbers and sets](#)
- [DELETE — removing elements from a set](#)
- [Using multiple update expressions](#)

SET — modifying or adding item attributes

Use the SET action in an update expression to add one or more attributes to an item. If any of these attributes already exists, they are overwritten by the new values.

You can also use SET to add or subtract from an attribute that is of type Number. To perform multiple SET actions, separate them with commas.

In the following syntax summary:

- The *path* element is the document path to the item.
- An *operand* element can be either a document path to an item or a function.

```
set-action ::=  
    path = value  
  
value ::=  
    operand  
    | operand '+' operand  
    | operand '-' operand  
  
operand ::=  
    path | function
```

The following PutItem operation creates a sample item that the examples refer to.

```
aws dynamodb put-item \  
  --table-name ProductCatalog \  
  --item file://item.json
```

The arguments for --item are stored in the `item.json` file. (For simplicity, only a few item attributes are used.)

```
{  
    "Id": {"N": "789"},  
    "ProductCategory": {"S": "Home Improvement"},  
    "Price": {"N": "52"},  
    "InStock": {"BOOL": true},  
    "Brand": {"S": "Acme"}  
}
```

Topics

- [Modifying attributes](#)
- [Adding lists and maps](#)
- [Adding elements to a list](#)
- [Adding nested map attributes](#)
- [Incrementing and decrementing numeric attributes](#)
- [Appending elements to a list](#)
- [Preventing overwrites of an existing attribute](#)

Modifying attributes

Example

Update the ProductCategory and Price attributes.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "SET ProductCategory = :c, Price = :p" \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{  
  ":c": { "S": "Hardware" },  
  ":p": { "N": "60" }  
}
```

Note

In the `UpdateItem` operation, `--return-values ALL_NEW` causes DynamoDB to return the item as it appears after the update.

Adding lists and maps

Example

Add a new list and a new map.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "SET RelatedItems = :ri, ProductReviews = :pr" \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{  
  ":ri": {  
    "L": [  
      { "S": "Hammer" }  
    ]  
  },  
  ":pr": {  
    "M": {  
      "FiveStar": {  
        "L": [  
          { "S": "Best product ever!" }  
        ]  
      }  
    }  
  }  
}
```

Adding elements to a list

Example

Add a new attribute to the `RelatedItems` list. (Remember that list elements are zero-based, so `[0]` represents the first element in the list, `[1]` represents the second, and so on.)

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "SET RelatedItems[1] = :ri" \  
  --expression-attribute-values file://values.json \  
  --return-values ALL_NEW
```

```
--expression-attribute-values file://values.json \
--return-values ALL_NEW
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  ":ri": { "S": "Nails" }
}
```

Note

When you use SET to update a list element, the contents of that element are replaced with the new data that you specify. If the element doesn't already exist, SET appends the new element at the end of the list.

If you add multiple elements in a single SET operation, the elements are sorted in order by element number.

Adding nested map attributes

Example

Add some nested map attributes.

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "SET #pr.#5star[1] = :r5, #pr.#3star = :r3" \
--expression-attribute-names file://names.json \
--expression-attribute-values file://values.json \
--return-values ALL_NEW
```

The arguments for --expression-attribute-names are stored in the names.json file.

```
{
  "#pr": "ProductReviews",
  "#5star": "FiveStar",
  "#3star": "ThreeStar"
}
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{  
    ":r5": { "S": "Very happy with my purchase" },  
    ":r3": {  
        "L": [  
            { "S": "Just OK - not that great" }  
        ]  
    }  
}
```

Incrementing and decrementing numeric attributes

You can add to or subtract from an existing numeric attribute. To do this, use the + (plus) and - (minus) operators.

Example

Decrease the Price of an item.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "SET Price = Price - :p" \  
  --expression-attribute-values '{":p": {"N":"15"}}' \  
  --return-values ALL_NEW
```

To increase the Price, you would use the + operator in the update expression.

Appending elements to a list

You can add elements to the end of a list. To do this, use SET with the `list_append` function. (The function name is case sensitive.) The `list_append` function is specific to the SET action and can only be used in an update expression. The syntax is as follows.

- `list_append (list1, list2)`

The function takes two lists as input and appends all elements from `list2` to `list1`.

Example

In [Adding elements to a list](#), you create the `RelatedItems` list and populate it with two elements: Hammer and Nails. Now you append two more elements to the end of `RelatedItems`.

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "SET #ri = list_append(#ri, :vals)" \
--expression-attribute-names '{"#ri": "RelatedItems"}' \
--expression-attribute-values file://values.json \
--return-values ALL_NEW
```

The arguments for `--expression-attribute-values` are stored in the `values.json` file.

```
{
  ":vals": {
    "L": [
      { "S": "Screwdriver" },
      {"S": "Hacksaw" }
    ]
  }
}
```

Finally, you append one more element to the *beginning* of `RelatedItems`. To do this, swap the order of the `list_append` elements. (Remember that `list_append` takes two lists as input and appends the second list to the first.)

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "SET #ri = list_append(:vals, #ri)" \
--expression-attribute-names '{"#ri": "RelatedItems"}' \
--expression-attribute-values '{":vals": {"L": [ { "S": "Chisel" } ]}}' \
--return-values ALL_NEW
```

The resulting `RelatedItems` attribute now contains five elements, in the following order: Chisel, Hammer, Nails, Screwdriver, Hacksaw.

Preventing overwrites of an existing attribute

If you want to avoid overwriting an existing attribute, you can use `SET` with the `if_not_exists` function. (The function name is case sensitive.) The `if_not_exists` function is specific to the `SET` action and can only be used in an update expression. The syntax is as follows.

- `if_not_exists (path, value)`

If the item does not contain an attribute at the specified *path*, `if_not_exists` evaluates to *value*; otherwise, it evaluates to *path*.

Example

Set the Price of an item, but only if the item does not already have a Price attribute. (If Price already exists, nothing happens.)

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "SET Price = if_not_exists(Price, :p)" \  
  --expression-attribute-values '{":p": {"N": "100"}}' \  
  --return-values ALL_NEW
```

REMOVE — deleting attributes from an item

Use the REMOVE action in an update expression to remove one or more attributes from an item in Amazon DynamoDB. To perform multiple REMOVE actions, separate them with commas.

The following is a syntax summary for REMOVE in an update expression. The only operand is the document path for the attribute that you want to remove.

```
remove-action ::=  
  path
```

Example

Remove some attributes from an item. (If the attributes don't exist, nothing happens.)

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "REMOVE Brand, InStock, QuantityOnHand" \  
  --return-values ALL_NEW
```

Removing elements from a list

You can use REMOVE to delete individual elements from a list.

Example

In [Appending elements to a list](#), you modify a list attribute (`RelatedItems`) so that it contained five elements:

- [0]—Chisel
- [1]—Hammer
- [2]—Nails
- [3]—Screwdriver
- [4]—Hacksaw

The following AWS Command Line Interface (AWS CLI) example deletes Hammer and Nails from the list.

```
aws dynamodb update-item \  
  --table-name ProductCatalog \  
  --key '{"Id":{"N":"789"}}' \  
  --update-expression "REMOVE RelatedItems[1], RelatedItems[2]" \  
  --return-values ALL_NEW
```

After Hammer and Nails are removed, the remaining elements are shifted. The list now contains the following:

- [0]—Chisel
- [1]—Screwdriver
- [2]—Hacksaw

ADD — updating numbers and sets

Note

In general, we recommend using SET rather than ADD.

Use the ADD action in an update expression to add a new attribute and its values to an item.

If the attribute already exists, the behavior of ADD depends on the attribute's data type:

- If the attribute is a number, and the value you are adding is also a number, the value is mathematically added to the existing attribute. (If the value is a negative number, it is subtracted from the existing attribute.)
- If the attribute is a set, and the value you are adding is also a set, the value is appended to the existing set.

 **Note**

The ADD action supports only number and set data types.

To perform multiple ADD actions, separate them with commas.

In the following syntax summary:

- The *path* element is the document path to an attribute. The attribute must be either a Number or a set data type.
- The *value* element is a number that you want to add to the attribute (for Number data types), or a set to append to the attribute (for set types).

```
add-action ::=  
    path value
```

The topics below cover some different use cases for the ADD action.

Topics

- [Adding a number](#)
- [Adding elements to a set](#)

Adding a number

Assume that the QuantityOnHand attribute does not exist. The following AWS CLI example sets QuantityOnHand to 5.

```
aws dynamodb update-item \  
    --table-name ProductCatalog \  
    --key '{"Id":{"N":"789"}}' \  
    --attribute-value-list '{  
        "QuantityOnHand": {"N": "5"}  
    }'
```

```
--update-expression "ADD QuantityOnHand :q" \
--expression-attribute-values '{":q": {"N": "5"}}' \
--return-values ALL_NEW
```

Now that `QuantityOnHand` exists, you can rerun the example to increment `QuantityOnHand` by 5 each time.

Adding elements to a set

Assume that the `Color` attribute does not exist. The following AWS CLI example sets `Color` to a string set with two elements.

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "ADD Color :c" \
--expression-attribute-values '{":c": {"SS":["Orange", "Purple"]}}' \
--return-values ALL_NEW
```

Now that `Color` exists, you can add more elements to it.

```
aws dynamodb update-item \
--table-name ProductCatalog \
--key '{"Id":{"N":"789"}}' \
--update-expression "ADD Color :c" \
--expression-attribute-values '{":c": {"SS":["Yellow", "Green", "Blue"]}}' \
--return-values ALL_NEW
```

DELETE — removing elements from a set

Important

The `DELETE` action supports only Set data types.

Use the `DELETE` action in an update expression to remove one or more elements from a set. To perform multiple `DELETE` actions, separate them with commas.

In the following syntax summary:

- The `path` element is the document path to an attribute. The attribute must be a set data type.

- The **subset** is one or more elements that you want to delete from **path**. You must specify **subset** as a set type.

```
delete-action ::=  
    path subset
```

Example

In [Adding elements to a set](#), you create the Color string set. This example removes some of the elements from that set.

```
aws dynamodb update-item \  
    --table-name ProductCatalog \  
    --key '{"Id":{"N":"789"}}' \  
    --update-expression "DELETE Color :p" \  
    --expression-attribute-values '{":p": {"SS": ["Yellow", "Purple"]}}' \  
    --return-values ALL_NEW
```

Using multiple update expressions

You can use multiple update expressions in a single statement.

Example

If you want to modify an attribute's value and completely remove another attribute, you could use a SET and a REMOVE action in a single statement. This operation would reduce the Price value to 15 while also removing the InStock attribute from the item.

```
aws dynamodb update-item \  
    --table-name ProductCatalog \  
    --key '{"Id":{"N":"789"}}' \  
    --update-expression "SET Price = Price - :p REMOVE InStock" \  
    --expression-attribute-values '{":p": {"N":"15"}}' \  
    --return-values ALL_NEW
```

Example

If you want to add to a list while also changing another attribute's value, you could use two SET actions in a single statement. This operation would add "Nails" to the RelatedItems list attribute and also set the Price value to 21.

```
aws dynamodb update-item \
    --table-name ProductCatalog \
    --key '{"Id":{"N":"789"}}' \
    --update-expression "SET RelatedItems[1] = :newValue, Price = :newPrice" \
    --expression-attribute-values '{":newValue": {"S":"Nails"}, ":newPrice": \
    {"N":"21"} }' \
    --return-values ALL_NEW
```

Time to Live (TTL)

Time To Live (TTL) for DynamoDB is a cost-effective method for deleting items that are no longer relevant. TTL allows you to define a per-item expiration timestamp that indicates when an item is no longer needed. DynamoDB automatically deletes expired items within a few days of their expiration time, without consuming write throughput.

To use TTL, first enable it on a table and then define a specific attribute to store the TTL expiration timestamp. The timestamp must be stored in [Unix epoch time format](#) at the seconds granularity. Each time an item is created or updated, you can compute the expiration time and save it in the TTL attribute.

Items with valid, expired TTL attributes may be deleted by the system at any time, typically within a few days of their expiration. You can still update the expired items that are pending deletion, including changing or removing their TTL attributes. While updating an expired item, we recommended that you use a condition expression to make sure the item has not been subsequently deleted. Use filter expressions to remove expired items from [Scan](#) and [Query](#) results.

Deleted items work similarly to those deleted through typical delete operations. Once deleted, items go into DynamoDB Streams as service deletions instead of user deletes, and are removed from local secondary indexes and global secondary indexes just like other delete operations.

If you are using [Global Tables version 2019.11.21 \(Current\)](#) of global tables and you also use the TTL feature, DynamoDB replicates TTL deletes to all replica tables. The initial TTL delete does not consume Write Capacity Units (WCUs) in the region in which the TTL expiry occurs. However, the replicated TTL delete to the replica table(s) consumes a replicated Write Capacity Unit when using provisioned capacity, or Replicated Write Unit when using on-demand capacity mode, in each of the replica regions and applicable charges will apply.

For more information about TTL, see these topics:

Topics

- [Enabling time to live \(TTL\)](#)
- [Computing time to live \(TTL\)](#)
- [Working with expired items](#)

Enabling time to live (TTL)

TTL can be enabled in the Amazon DynamoDB Console, the AWS Command Line Interface (AWS CLI), or using the [Amazon DynamoDB API Reference](#) with any of the supposed AWS SDKs. It takes approximately one hour for TTL to be enabled across all partitions.

Enable DynamoDB TTL using the AWS console

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. Choose **Tables**, and then choose the table that you want to modify.
3. In the **Additional settings** tab, in the **Time to Live (TTL)** section, choose **Turn on** to enable TTL.

The screenshot shows the AWS Management Console interface for Amazon DynamoDB. The top navigation bar includes links for Overview, Indexes, Monitor, Global tables, Backups, Exports and streams, and Additional settings. The Additional settings tab is currently selected. Below the tabs, there are several sections: **Read/write capacity** (with an Edit button), **Auto scaling activities (0)** (with a Find events search bar and a C refresh button), and **Time to Live (TTL)**. The **Time to Live (TTL)** section contains a sub-section titled "Automatically delete expired items from a table." It features a "Run preview" button and a "Turn on" button, which is highlighted with a red rectangle. Other options in this section include "TTL status" (set to Off) and "Capacity unit" (set to 1). A note at the bottom of the TTL section states: "There are no auto scaling activities for the table or its global secondary indexes."

4. When enabling TTL on a table, DynamoDB requires you to identify a specific attribute name that the service will look for when determining if an item is eligible for expiration. The TTL attribute name, shown below, is case sensitive and must match the attribute defined in your read and write operations. A mismatch will cause expired items to go undeleted. Renaming the TTL attribute requires you to disable TTL and then reenable it with the new attribute going forward. TTL will continue to process deletions for approximately 30 minutes once it is disabled. TTL must be reconfigured on restored tables.

The screenshot shows the 'Turn on Time to Live (TTL)' configuration page. At the top, the navigation path is: DynamoDB > Tables > Music > Turn on Time to Live (TTL). The main section is titled 'TTL settings' and contains a 'TTL attribute name' field where 'expireAt' is entered. Below this, a note says 'Between 1 and 255 characters.' In the 'Preview' section, there's a 'Simulated date and time' field with an epoch time value of 1694640532, showing a timestamp of September 13, 2023, 15:28:52 (UTC-06:00), and a 'Run preview' button. A note at the bottom left states: 'Activating TTL can take up to one hour to be applied across all partitions. You will not be able to make additional TTL changes until this update is complete.' At the bottom right are 'Cancel' and 'Turn on TTL' buttons.

5. (Optional) You can perform a test by simulating the date and time of the expiration and matching a few items. This provides you with a sample list of items and confirms that there are items containing the TTL attribute name provided along with the expiration time.

Turn on Time to Live (TTL) Info

TTL settings

TTL attribute name

The name of the attribute that will be stored in the TTL timestamp.

Between 1 and 255 characters.

Preview

Confirm that your TTL attribute and values are working properly by specifying a date and time, and reviewing a sample of the items that will be deleted by then. Note that preview may show only some of the relevant items.

Simulated date and time

Specify the date and time to simulate which items would be expired.

December 11, 2023, 16:58:01 (UTC-07:00)

Items to be deleted (32)

artist	album	createdAt	expireAt (TTL)
f91897e5-0...	72499653-...	1694559481	1702339081
7d38838f-e...	64b6999b-...	1694559479	1702339079
6734d779-...	52d667bd-...	1694559481	1702339081
4553fb30-...	bb2cc547-e...	1694559481	1702339081
ea7c0eeb-5...	840b3c7b-...	1694559478	1702339078

After TTL is enabled, the TTL attribute is marked **TTL** when you view items on the DynamoDB console. You can view the date and time that an item expires by hovering your pointer over the attribute.

Items returned (100)

Enable DynamoDB TTL using the API

Python

You can enable TTL with code, using the [UpdateTimeToLive](#) operation.

```
import boto3

def enable_ttl(table_name, ttl_attribute_name):
    """
    Enables TTL on DynamoDB table for a given attribute name
        on success, returns a status code of 200
        on error, throws an exception

    :param table_name: Name of the DynamoDB table
    :param ttl_attribute_name: The name of the TTL attribute being provided to the
        table.
    """
    try:
        dynamodb = boto3.client('dynamodb')

        # Enable TTL on an existing DynamoDB table
        response = dynamodb.update_time_to_live(
            TableName=table_name,
            TimeToLiveSpecification={
                'Enabled': True,
                'AttributeName': ttl_attribute_name
            }
        )
    
```

```
# In the returned response, check for a successful status code.  
if response['ResponseMetadata']['HTTPStatusCode'] == 200:  
    print("TTL has been enabled successfully.")  
else:  
    print(f"Failed to enable TTL, status code {response['ResponseMetadata']['HTTPStatusCode']}")  
except Exception as ex:  
    print("Couldn't enable TTL in table %s. Here's why: %s" % (table_name, ex))  
    raise  
  
# your values  
enable_ttl('your-table-name', 'expirationDate')
```

You can confirm TTL is enabled by using the [DescribeTimeToLive](#) operation, which describes the TTL status on a table. The TimeToLive status is either ENABLED or DISABLED.

```
# create a DynamoDB client  
dynamodb = boto3.client('dynamodb')  
  
# set the table name  
table_name = 'YourTable'  
  
# describe TTL  
response = dynamodb.describe_time_to_live(TableName=table_name)
```

Javascript

You can enable TTL with code, using the [UpdateTimeToLiveCommand](#) operation.

```
import { DynamoDBClient, UpdateTimeToLiveCommand } from "@aws-sdk/client-dynamodb";  
  
const enableTTL = async (tableName, ttlAttribute) => {  
  
    const client = new DynamoDBClient({});  
  
    const params = {  
        TableName: tableName,  
        TimeToLiveSpecification: {  
            Enabled: true,  
            AttributeName: ttlAttribute  
        }  
    };
```

```
try {
    const response = await client.send(new UpdateTimeToLiveCommand(params));
    if (response.$metadata.httpStatusCode === 200) {
        console.log(`TTL enabled successfully for table ${tableName}, using
attribute name ${ttlAttribute}.`);
    } else {
        console.log(`Failed to enable TTL for table ${tableName}, response
object: ${response}`);
    }
    return response;
} catch (e) {
    console.error(`Error enabling TTL: ${e}`);
    throw e;
}
};

// call with your own values
enableTTL('ExampleTable', 'exampleTtlAttribute');
```

Enable Time to Live using the AWS CLI

1. Enable TTL on the TTLExample table.

```
aws dynamodb update-time-to-live --table-name TTLExample --time-to-live-
specification "Enabled=true, AttributeName=ttl"
```

2. Describe TTL on the TTLExample table.

```
aws dynamodb describe-time-to-live --table-name TTLExample
{
    "TimeToLiveDescription": {
        "AttributeName": "ttl",
        "TimeToLiveStatus": "ENABLED"
    }
}
```

3. Add an item to the TTLExample table with the Time to Live attribute set using the BASH shell and the AWS CLI.

```
EXP=`date -d '+5 days' +%s`
```

```
aws dynamodb put-item --table-name "TTLExample" --item '{"id": {"N": "1"}, "ttl": {"N": "'$EXP'"}}'
```

This example starts with the current date and adds 5 days to it to create an expiration time. Then, it converts the expiration time to epoch time format to finally add an item to the "TTLExample" table.

 **Note**

One way to set expiration values for Time to Live is to calculate the number of seconds to add to the expiration time. For example, 5 days is 432,000 seconds. However, it is often preferable to start with a date and work from there.

It is fairly simple to get the current time in epoch time format, as in the following examples.

- Linux Terminal: `date +%s`
- Python: `import time; int(time.time())`
- Java: `System.currentTimeMillis() / 1000L`
- JavaScript: `Math.floor(Date.now() / 1000)`

Enable DynamoDB TTL using AWS CloudFormation

1. Enable TTL on the TTLExample table.

```
aws dynamodb update-time-to-live --table-name TTLExample --time-to-live-specification "Enabled=true, AttributeName=ttl"
```

2. Describe TTL on the TTLExample table.

```
aws dynamodb describe-time-to-live --table-name TTLExample
{
    "TimeToLiveDescription": {
        "AttributeName": "ttl",
        "TimeToLiveStatus": "ENABLED"
    }
}
```

3. Add an item to the TTLExample table with the Time to Live attribute set using the BASH shell and the AWS CLI.

```
EXP=`date -d '+5 days' +%s`  
aws dynamodb put-item --table-name "TTLExample" --item '{"id": {"N": "1"}, "ttl": {"N": "'$EXP'"}}'
```

This example starts with the current date and adds 5 days to it to create an expiration time. Then, it converts the expiration time to epoch time format to finally add an item to the "TTLExample" table.

 **Note**

One way to set expiration values for Time to Live is to calculate the number of seconds to add to the expiration time. For example, 5 days is 432,000 seconds. However, it is often preferable to start with a date and work from there.

It is fairly simple to get the current time in epoch time format, as in the following examples.

- Linux Terminal: `date +%s`
- Python: `import time; int(time.time())`
- Java: `System.currentTimeMillis() / 1000L`
- JavaScript: `Math.floor(Date.now() / 1000)`

Computing time to live (TTL)

A common way to implement TTL is to set an expiration time for items based on when they were created or last updated. This can be done by adding time to the `createdAt` and `updatedAt` timestamps. For example, the TTL for newly created items can be set to `createdAt + 90 days`. When the item is updated the TTL can be recalculated to `updatedAt + 90 days`.

The computed expiration time must be in epoch format, in seconds. To be considered for expiry and deletion, the TTL cannot be more than five years in the past. If you use any other format, the TTL processes ignore the item. If you set the expiration date to sometime in the future when you want the item to expire, the item will be expired after that time. For example, say that you set the

expiration date to 1724241326 (which is Monday, August 21st, 2024 11:55:26 (GMT)). The item will be expired after the specified time.

Topics

- [Create an item and set the Time to Live](#)
- [Update an item and refresh the Time to Live](#)

Create an item and set the Time to Live

The following example demonstrates how to calculate the expiration time when creating a new item, using `expireAt` as the TTL attribute name. An assignment statement obtains the current time as a variable. In the example, the expiration time is calculated as 90 days from the current time. The time is then converted to epoch format and saved as an integer data type in the TTL attribute.

Python

```
import boto3
from datetime import datetime, timedelta

def create_dynamodb_item(table_name, region, primary_key, sort_key):
    """
    Creates a DynamoDB item with an attached expiry attribute.

    :param table_name: Table name for the boto3 resource to target when creating an item
    :param region: string representing the AWS region. Example: `us-east-1`
    :param primary_key: one attribute known as the partition key.
    :param sort_key: Also known as a range attribute.
    :return: Void (nothing)
    """

    try:
        dynamodb = boto3.resource('dynamodb', region_name=region)
        table = dynamodb.Table(table_name)

        # Get the current time in epoch second format
        current_time = int(datetime.now().timestamp())

        # Calculate the expiration time (90 days from now) in epoch second format
        expiration_time = int((datetime.now() + timedelta(days=90)).timestamp())
    
```

```
item = {
    'primaryKey': primary_key,
    'sortKey': sort_key,
    'createdAt': current_time,
    'expiredAt': expiration_time
}

table.put_item(Item=item)

print("Item created successfully.")
except Exception as e:
    print(f"Error creating item: {e}")
    raise

# Use your own values
create_dynamodb_item('your-table-name', 'us-west-2', 'your-partition-key-value',
    'your-sort-key-value')
```

Javascript

In this request we add logic to compute the expiration time of the newly created item:

```
import { DynamoDBClient, PutItemCommand } from "@aws-sdk/client-dynamodb";

function createDynamoDBItem(table_name, region, partition_key, sort_key) {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    // Get the current time in epoch second format
    const current_time = Math.floor(new Date().getTime() / 1000);

    // Calculate the expireAt time (90 days from now) in epoch second format
    const expire_at = Math.floor((new Date().getTime() + 90 * 24 * 60 * 60 * 1000) / 1000);

    // Create DynamoDB item
    const item = {
        'partitionKey': {'S': partition_key},
        'sortKey': {'S': sort_key},
        'createdAt': {'N': current_time.toString()},
        'expiredAt': {'N': (current_time + 90 * 24 * 60 * 60 * 1000).toString()}
    };

    const command = new PutItemCommand({
        TableName: table_name,
        Item: item
    });

    client.send(command);
}
```

```
'expireAt': {'N': expire_at.toString()}

};

const putItemCommand = new PutItemCommand({
    TableName: table_name,
    Item: item,
    ProvisionedThroughput: {
        ReadCapacityUnits: 1,
        WriteCapacityUnits: 1,
    },
});

client.send(putItemCommand, function(err, data) {
    if (err) {
        console.log("Exception encountered when creating item %s, here's what
happened: ", data, ex);
        throw err;
    } else {
        console.log("Item created successfully: %s.", data);
        return data;
    }
});
});

// use your own values
createDynamoDBItem('your-table-name', 'us-east-1', 'your-partition-key-value',
'your-sort-key-value');
```

Update an item and refresh the Time to Live

This example is a continuation of the one from the [previous section](#). The expiration time can be recomputed if the item is updated. The following example recomputes the `expireAt` timestamp to be 90 days from the current time.

Python

```
import boto3
from datetime import datetime, timedelta

def update_dynamodb_item(table_name, region, primary_key, sort_key):
    """
```

```
Update an existing DynamoDB item with a TTL.  
:param table_name: Name of the DynamoDB table  
:param region: AWS Region of the table - example `us-east-1`  
:param primary_key: one attribute known as the partition key.  
:param sort_key: Also known as a range attribute.  
:return: Void (nothing)  
"""  
  
try:  
    # Create the DynamoDB resource.  
    dynamodb = boto3.resource('dynamodb', region_name=region)  
    table = dynamodb.Table(table_name)  
  
    # Get the current time in epoch second format  
    current_time = int(datetime.now().timestamp())  
  
    # Calculate the expireAt time (90 days from now) in epoch second format  
    expire_at = int((datetime.now() + timedelta(days=90)).timestamp())  
  
    table.update_item(  
        Key={  
            'partitionKey': primary_key,  
            'sortKey': sort_key  
        },  
        UpdateExpression="set updatedAt=:c, expireAt=:e",  
        ExpressionAttributeValues={  
            ':c': current_time,  
            ':e': expire_at  
        },  
    )  
  
    print("Item updated successfully.")  
except Exception as e:  
    print(f"Error updating item: {e}")  
  
# Replace with your own values  
update_dynamodb_item('your-table-name', 'us-west-2', 'your-partition-key-value',  
    'your-sort-key-value')
```

The output from the update operation shows that, while the `createdAt` time is unchanged, the `updatedAt` and `expireAt` times have been updated. The `expireAt` time is now set to 90 days from the time of the last update, which is Thursday, October 19, 2023 at 1:27:15 PM.

partition_key	createdAt	updatedAt	expireAt	attribute_1	attribute_2
some_value	2023-07-1 7 14:11:05. 322323	2023-07-1 9 13:27:15. 213423	1697722035	new_value	some_value

Javascript

```

import { DynamoDBClient, UpdateItemCommand } from "@aws-sdk/client-dynamodb";
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

async function updateDynamoDBItem(tableName, region, partitionKey, sortKey) {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);
    const expireAt = Math.floor((Date.now() + 90 * 24 * 60 * 60 * 1000) /
1000); //is there a better way to do this?

    const params = {
        TableName: tableName,
        Key: marshall({
            partitionKey: partitionKey,
            sortKey: sortKey
        }),
        UpdateExpression: "SET updatedAt = :c, expireAt = :e",
        ExpressionAttributeValues: marshall({
            ":c": currentTime,
            ":e": expireAt
        }),
    };
}

try {
    const data = await client.send(new UpdateItemCommand(params));
    const responseData = unmarshall(data.Attributes);
    console.log("Item updated successfully: %s", responseData);
    return responseData;
} catch (err) {
}

```

```
        console.error("Error updating item:", err);
        throw err;
    }

//enter your values here
updateDynamoDBItem('your-table-name', 'us-east-1', 'your-partition-key-value',
    'your-sort-key-value');
```

The TTL examples discussed in this introduction demonstrate a method to ensure only recently updated items are kept in a table. Updated items have their lifespan extended, whereas items not updated post-creation expire and are deleted at no cost, reducing storage and maintaining clean tables.

Working with expired items

Expired items that are pending deletion can be filtered from read and write operations. This is useful in scenarios when expired data is no longer valid and should not be used. If they are not filtered, they'll continue to show in read and write operations until they are deleted by the background process.

Note

These items still count towards storage and read costs until they are deleted.

TTL deletions can be identified in DynamoDB Streams, but only in the Region where the deletion occurred. TTL deletions that are replicated to global table regions are not identifiable in DynamoDB streams in the regions the deletion is replicated to.

Filter expired items from read operations

For read operations such as [Scan](#) and [Query](#), a filter expression can filter out expired items that are pending deletion. As shown in the code snippet below, the filter expression can filter out items where the TTL time is equal to or less than the current time. This is done with an assignment statement that obtains the current time as a variable (now), which is converted to int for epoch time format.

Python

```
import boto3
from datetime import datetime

def query_dynamodb_items(table_name, partition_key):
    """
    :param table_name: Name of the DynamoDB table
    :param partition_key:
    :return:
    """
    try:
        # Initialize a DynamoDB resource
        dynamodb = boto3.resource('dynamodb',
                                  region_name='us-east-1')

        # Specify your table
        table = dynamodb.Table(table_name)

        # Get the current time in epoch format
        current_time = int(datetime.now().timestamp())

        # Perform the query operation with a filter expression to exclude expired
        items
        # response = table.query(
        #
        KeyConditionExpression=boto3.dynamodb.conditions.Key('partitionKey').eq(partition_key),
        #
        FilterExpression=boto3.dynamodb.conditions.Attr('expireAt').gt(current_time)
        #
        response = table.query(
            KeyConditionExpression=dynamodb.conditions.Key('partitionKey').eq(partition_key),
            FilterExpression=dynamodb.conditions.Attr('expireAt').gt(current_time)
        )

        # Print the items that are not expired
        for item in response['Items']:
            print(item)

    except Exception as e:
        print(f"Error querying items: {e}")
```

```
# Call the function with your values
query_dynamodb_items('Music', 'your-partition-key-value')
```

The output from the update operation shows that, while the `createdAt` time is unchanged, the `updatedAt` and `expireAt` times have been updated. The `expireAt` time is now set to 90 days from the time of the last update, which is Thursday, October 19, 2023 at 1:27:15 PM.

partition_key	createdAt	updatedAt	expireAt	attribute_1	attribute_2
some_value	2023-07-1 7 14:11:05. 322323	2023-07-1 9 13:27:15. 213423	1697722035	new_value	some_value

Javascript

```
import { DynamoDBClient, QueryCommand } from "@aws-sdk/client-dynamodb";
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

async function queryDynamoDBItems(tableName, region, primaryKey) {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);

    const params = {
        TableName: tableName,
        KeyConditionExpression: "#pk = :pk",
        FilterExpression: "#ea > :ea",
        ExpressionAttributeNames: {
            "#pk": "primaryKey",
            "#ea": "expireAt"
        },
        ExpressionAttributeValues: marshall({
            ":pk": primaryKey,
            ":ea": currentTime
        })
    };

    const result = await client.send(new QueryCommand(params));
    return result.Items;
}
```

```
        })
    };

    try {
        const { Items } = await client.send(new QueryCommand(params));
        Items.forEach(item => {
            console.log(unmarshall(item))
        });
        return Items;
    } catch (err) {
        console.error(`Error querying items: ${err}`);
        throw err;
    }
}

//enter your own values here
queryDynamoDBItems('your-table-name', 'your-partition-key-value');
```

Conditionally write to expired items

A condition expression can be used to avoid writes against expired items. The code snippet below is a conditional update that checks whether the expiration time is greater than the current time. If true, the write operation will continue.

Python

```
import boto3
from datetime import datetime, timedelta
from botocore.exceptions import ClientError

def update_dynamodb_item(table_name, region, primary_key, sort_key, ttl_attribute):
    """
    Updates an existing record in a DynamoDB table with a new or updated TTL
    attribute.

    :param table_name: Name of the DynamoDB table
    :param region: AWS Region of the table - example `us-east-1`
    :param primary_key: one attribute known as the partition key.
    :param sort_key: Also known as a range attribute.
    :param ttl_attribute: name of the TTL attribute in the target DynamoDB table
    :return:
    """

    dynamodb = boto3.client('dynamodb', region_name=region)
```

```
"""
try:
    dynamodb = boto3.resource('dynamodb', region_name=region)
    table = dynamodb.Table(table_name)

    # Generate updated TTL in epoch second format
    updated_expiration_time = int((datetime.now() +
timedelta(days=90)).timestamp())

    # Define the update expression for adding/updating a new attribute
    update_expression = "SET newAttribute = :val1"

    # Define the condition expression for checking if 'ttlExpirationDate' is not
    # expired
    condition_expression = "ttlExpirationDate > :val2"

    # Define the expression attribute values
    expression_attribute_values = {
        ':val1': ttl_attribute,
        ':val2': updated_expiration_time
    }

    response = table.update_item(
        Key={
            'primaryKey': primary_key,
            'sortKey': sort_key
        },
        UpdateExpression=update_expression,
        ConditionExpression=condition_expression,
        ExpressionAttributeValues=expression_attribute_values
    )

    print("Item updated successfully.")
    return response['ResponseMetadata']['HTTPStatusCode'] # Ideally a 200 OK
except ClientError as e:
    if e.response['Error']['Code'] == "ConditionalCheckFailedException":
        print("Condition check failed: Item's 'ttlExpirationDate' is expired.")
    else:
        print(f"Error updating item: {e}")
except Exception as e:
    print(f"Error updating item: {e}")

# replace with your values
```

```
update_dynamodb_item('your-table-name', 'us-east-1', 'your-partition-key-value',
    'your-sort-key-value',
        'your-ttl-attribute-value')
```

The output from the update operation shows that, while the `createdAt` time is unchanged, the `updatedAt` and `expireAt` times have been updated. The `expireAt` time is now set to 90 days from the time of the last update, which is Thursday, October 19, 2023 at 1:27:15 PM.

partition_key	createdAt	updatedAt	expireAt	attribute_1	attribute_2
some_value	2023-07-1 7 14:11:05. 322323	2023-07-1 9 13:27:15. 213423	1697722035	new_value	some_value

Javascript

```
import { DynamoDBClient, UpdateItemCommand } from "@aws-sdk/client-dynamodb";
import { marshall, unmarshall } from "@aws-sdk/util-dynamodb";

// Example function to update an item in a DynamoDB table.
// The function should take the table name, region, partition key, sort key, and
// new attribute as arguments.
// The function should use the DynamoDB client to update the item.
// The function should return the updated item.
// The function should handle errors and exceptions.
const updateDynamoDBItem = async (tableName, region, partitionKey, sortKey,
    newAttribute) => {
    const client = new DynamoDBClient({
        region: region,
        endpoint: `https://dynamodb.${region}.amazonaws.com`
    });

    const currentTime = Math.floor(Date.now() / 1000);

    const params = {
        TableName: tableName,
        Key: marshall({
            artist: partitionKey,
```

```
        album: sortKey
    },
    UpdateExpression: "SET newAttribute = :newAttribute",
    ConditionExpression: "expireAt > :expiration",
    ExpressionAttributeValues: marshall({
        ':newAttribute': newAttribute,
        ':expiration': currentTime
    }),
    ReturnValues: "ALL_NEW"
};

try {
    const response = await client.send(new UpdateItemCommand(params));
    const responseData = unmarshall(response.Attributes);
    console.log("Item updated successfully: ", responseData);
    return responseData;
} catch (error) {
    if (error.name === "ConditionalCheckFailedException") {
        console.log("Condition check failed: Item's 'expireAt' is expired.");
    } else {
        console.error("Error updating item: ", error);
    }
    throw error;
}
};

// Enter your values here
updateDynamoDBItem('your-table-name', 'us-east-1', 'your-partition-key-value', 'your-
sort-key-value', 'your-new-attribute-value');
```

Identifying deleted items in DynamoDB Streams

The streams record contains a user identity field `Records[<index>].userIdentity`. Items that are deleted by the TTL process have the following fields:

```
Records[<index>].userIdentity.type
"Service"
```

```
Records[<index>].userIdentity.principalId
"dynamodb.amazonaws.com"
```

The following JSON shows the relevant portion of a single streams record:

```
"Records": [  
    {  
        ...  
        "userIdentity": {  
            "type": "Service",  
            "principalId": "dynamodb.amazonaws.com"  
        }  
        ...  
    }  
]
```

Working with items: Java

You can use the AWS SDK for Java Document API to perform typical create, read, update, and delete (CRUD) operations on Amazon DynamoDB items in a table.

Note

The SDK for Java also provides an object persistence model, allowing you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

This section contains Java examples to perform several Java Document API item actions and several complete working examples.

Topics

- [Putting an item](#)
- [Getting an item](#)
- [Batch write: Putting and deleting multiple items](#)
- [Batch get: Getting multiple items](#)
- [Updating an item](#)
- [Deleting an item](#)

Putting an item

The `putItem` method stores an item in a table. If the item exists, it replaces the entire item. Instead of replacing the entire item, if you want to update only specific attributes, you can use the `updateItem` method. For more information, see [Updating an item](#).

Follow these steps:

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the table you want to work with.
3. Create an instance of the Item class to represent the new item. You must specify the new item's primary key and its attributes.
4. Call the `putItem` method of the Table object, using the Item that you created in the preceding step.

The following Java code example demonstrates the preceding tasks. The code writes a new item to the `ProductCatalog` table.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

// Build a list of related items
List<Number> relatedItems = new ArrayList<Number>();
relatedItems.add(341);
relatedItems.add(472);
relatedItems.add(649);

//Build a map of product pictures
Map<String, String> pictures = new HashMap<String, String>();
pictures.put("FrontView", "http://example.com/products/123_front.jpg");
pictures.put("RearView", "http://example.com/products/123_rear.jpg");
pictures.put("SideView", "http://example.com/products/123_left_side.jpg");

//Build a map of product reviews
Map<String, List<String>> reviews = new HashMap<String, List<String>>();
```

```
List<String> fiveStarReviews = new ArrayList<String>();
fiveStarReviews.add("Excellent! Can't recommend it highly enough! Buy it!");
fiveStarReviews.add("Do yourself a favor and buy this");
reviews.put("FiveStar", fiveStarReviews);

List<String> oneStarReviews = new ArrayList<String>();
oneStarReviews.add("Terrible product! Do not buy this.");
reviews.put("OneStar", oneStarReviews);

// Build the item
Item item = new Item()
    .withPrimaryKey("Id", 123)
    .withString("Title", "Bicycle 123")
    .withString("Description", "123 description")
    .withString("BicycleType", "Hybrid")
    .withString("Brand", "Brand-Company C")
    .withNumber("Price", 500)
    .withStringSet("Color", new HashSet<String>(Arrays.asList("Red", "Black")))
    .withString("ProductCategory", "Bicycle")
    .withBoolean("InStock", true)
    .withNull("QuantityOnHand")
    .withList("RelatedItems", relatedItems)
    .withMap("Pictures", pictures)
    .withMap("Reviews", reviews);

// Write the item to the table
PutItemOutcome outcome = table.putItem(item);
```

In the preceding example, the item has attributes that are scalars (String, Number, Boolean, Null), sets (String Set), and document types (List, Map).

Specifying optional parameters

Along with the required parameters, you can also specify optional parameters to the `putItem` method. For example, the following Java code example uses an optional parameter to specify a condition for uploading the item. If the condition you specify is not met, the AWS SDK for Java throws a `ConditionalCheckFailedException`. The code example specifies the following optional parameters in the `putItem` method:

- A `ConditionExpression` that defines the conditions for the request. The code defines the condition that the existing item with the same primary key is replaced only if it has an ISBN attribute that equals a specific value.

- A map for ExpressionAttributeValues that is used in the condition. In this case, there is only one substitution required: The placeholder :val in the condition expression is replaced at runtime with the actual ISBN value to be checked.

The following example adds a new book item using these optional parameters.

Example

```
Item item = new Item()
    .withPrimaryKey("Id", 104)
    .withString("Title", "Book 104 Title")
    .withString("ISBN", "444-4444444444")
    .withNumber("Price", 20)
    .withStringSet("Authors",
        new HashSet<String>(Arrays.asList("Author1", "Author2")));
    
Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val", "444-4444444444");

PutItemOutcome outcome = table.putItem(
    item,
    "ISBN = :val", // ConditionExpression parameter
    null,           // ExpressionAttributeNames parameter - we're not using it for this
example
    expressionAttributeValues);
```

PutItem and JSON documents

You can store a JSON document as an attribute in a DynamoDB table. To do this, use the withJSON method of Item. This method parses the JSON document and maps each element to a native DynamoDB data type.

Suppose that you wanted to store the following JSON document, containing vendors that can fulfill orders for a particular product.

Example

```
{
    "V01": {
        "Name": "Acme Books",
        "Offices": [ "Seattle" ]
    },
}
```

```
"V02": {  
    "Name": "New Publishers, Inc.",  
    "Offices": ["London", "New York"  
    ]  
,  
"V03": {  
    "Name": "Better Buy Books",  
    "Offices": [ "Tokyo", "Los Angeles", "Sydney"  
    ]  
}  
}
```

You can use the `withJSON` method to store this in the `ProductCatalog` table, in a `Map` attribute named `VendorInfo`. The following Java code example demonstrates how to do this.

```
// Convert the document into a String. Must escape all double-quotes.  
String vendorDocument = "{"  
+ "    \"V01\": {"  
+ "        \"Name\": \"Acme Books\",  
+ "        \"Offices\": [ \"Seattle\" ]"  
+ "    },"  
+ "    \"V02\": {"  
+ "        \"Name\": \"New Publishers, Inc.\",  
+ "        \"Offices\": [ \"London\", \"New York\" + \"\"]" + "},"  
+ "    \"V03\": {"  
+ "        \"Name\": \"Better Buy Books\",  
+ "        \"Offices\": [ \"Tokyo\", \"Los Angeles\", \"Sydney\""  
+ "            ]"  
+ "        }"  
+ "    }";  
  
Item item = new Item()  
.withPrimaryKey("Id", 210)  
.withString("Title", "Book 210 Title")  
.withString("ISBN", "210-2102102102")  
.withNumber("Price", 30)  
.withJSON("VendorInfo", vendorDocument);  
  
PutItemOutcome outcome = table.putItem(item);
```

Getting an item

To retrieve a single item, use the `getItem` method of a `Table` object. Follow these steps:

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the table you want to work with.
3. Call the getItem method of the Table instance. You must specify the primary key of the item that you want to retrieve.

The following Java code example demonstrates the preceding steps. The code gets the item that has the specified partition key.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

Item item = table.getItem("Id", 210);
```

Specifying optional parameters

Along with the required parameters, you can also specify optional parameters for the getItem method. For example, the following Java code example uses an optional method to retrieve only a specific list of attributes and to specify strongly consistent reads. (To learn more about read consistency, see [Read consistency](#).)

You can use a ProjectionExpression to retrieve only specific attributes or elements, rather than an entire item. A ProjectionExpression can specify top-level or nested attributes using document paths. For more information, see [Projection expressions](#).

The parameters of the getItem method don't let you specify read consistency. However, you can create a GetItemSpec, which provides full access to all of the inputs to the low-level GetItem operation. The following code example creates a GetItemSpec and uses that spec as input to the getItem method.

Example

```
GetItemSpec spec = new GetItemSpec()
    .withPrimaryKey("Id", 206)
    .withProjectionExpression("Id, Title, RelatedItems[0], Reviews.FiveStar")
    .withConsistentRead(true);
```

```
Item item = table.getItem(spec);

System.out.println(item.toJSONString());
```

To print an Item in a human-readable format, use the `toJSONPretty` method. The output from the previous example looks like the following.

```
{
    "RelatedItems" : [ 341 ],
    "Reviews" : {
        "FiveStar" : [ "Excellent! Can't recommend it highly enough! Buy it!", "Do yourself
a favor and buy this" ]
    },
    "Id" : 123,
    "Title" : "20-Bicycle 123"
}
```

GetItem and JSON documents

In the [PutItem and JSON documents](#) section, you store a JSON document in a Map attribute named `VendorInfo`. You can use the `getItem` method to retrieve the entire document in JSON format. Or you can use document path notation to retrieve only some of the elements in the document. The following Java code example demonstrates these techniques.

```
GetItemSpec spec = new GetItemSpec()
    .withPrimaryKey("Id", 210);

System.out.println("All vendor info:");
spec.withProjectionExpression("VendorInfo");
System.out.println(table.getItem(spec).toJSON());

System.out.println("A single vendor:");
spec.withProjectionExpression("VendorInfo.V03");
System.out.println(table.getItem(spec).toJSON());

System.out.println("First office location for this vendor:");
spec.withProjectionExpression("VendorInfo.V03.Offices[0]");
System.out.println(table.getItem(spec).toJSON());
```

The output from the previous example looks like the following.

All vendor info:

```
{"VendorInfo":{"V03":{"Name":"Better Buy Books","Offices":["Tokyo","Los Angeles","Sydney"]}, "V02":{"Name":"New Publishers, Inc.","Offices":["London","New York"]}, "V01":{"Name":"Acme Books","Offices":["Seattle"]}}}
```

A single vendor:

```
{"VendorInfo":{"V03":{"Name":"Better Buy Books","Offices":["Tokyo","Los Angeles","Sydney"]}}}
```

First office location for a single vendor:

```
{"VendorInfo":{"V03":{"Offices":["Tokyo"]}}}
```

Note

You can use the `toJSON` method to convert any item (or its attributes) to a JSON-formatted string. The following code retrieves several top-level and nested attributes and prints the results as JSON.

```
GetItemSpec spec = new GetItemSpec()
    .withPrimaryKey("Id", 210)
    .withProjectionExpression("VendorInfo.V01, Title, Price");

Item item = table.getItem(spec);
System.out.println(item.toJSON());
```

The output looks like the following.

```
{"VendorInfo":{"V01":{"Name":"Acme Books","Offices":["Seattle"]}}, "Price":30, "Title":"Book 210 Title"}
```

Batch write: Putting and deleting multiple items

Batch write refers to putting and deleting multiple items in a batch. The `batchWriteItem` method enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to put or delete multiple items using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the `TableWriteItems` class that describes all the put and delete operations for a table. If you want to write to multiple tables in a single batch write operation, you must create one `TableWriteItems` instance per table.

3. Call the `batchWriteItem` method by providing the `TableWriteItems` objects that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed request items returned in the response. This could happen if you reach the provisioned throughput quota or some other transient error. Also, DynamoDB limits the request size and the number of operations you can specify in a request. If you exceed these limits, DynamoDB rejects the request. For more information, see [Service, account, and table quotas in Amazon DynamoDB](#).

The following Java code example demonstrates the preceding steps. The example performs a `batchWriteItem` operation on two tables: `Forum` and `Thread`. The corresponding `TableWriteItems` objects define the following actions:

- Put an item in the `Forum` table.
- Put and delete an item in the `Thread` table.

The code then calls `batchWriteItem` to perform the operation.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

TableWriteItems forumTableWriteItems = new TableWriteItems("Forum")
    .withItemsToPut(
        new Item()
            .withPrimaryKey("Name", "Amazon RDS")
            .withNumber("Threads", 0));

TableWriteItems threadTableWriteItems = new TableWriteItems("Thread")
    .withItemsToPut(
        new Item()
            .withPrimaryKey("ForumName", "Amazon RDS", "Subject", "Amazon RDS Thread 1")
            .withHashAndRangeKeysToDelete("ForumName", "Some partition key value", "Amazon S3",
                "Some sort key value"));

BatchWriteItemOutcome outcome = dynamoDB.batchWriteItem(forumTableWriteItems,
    threadTableWriteItems);

// Code for checking unprocessed items is omitted in this example
```

For a working example, see [Example: Batch write operation using the AWS SDK for Java document API](#).

Batch get: Getting multiple items

The `batchGetItem` method enables you to retrieve multiple items from one or more tables. To retrieve a single item, you can use the `getItem` method.

Follow these steps:

1. Create an instance of the DynamoDB class.
2. Create an instance of the `TableKeysAndAttributes` class that describes a list of primary key values to retrieve from a table. If you want to read from multiple tables in a single batch get operation, you must create one `TableKeysAndAttributes` instance per table.
3. Call the `batchGetItem` method by providing the `TableKeysAndAttributes` objects that you created in the preceding step.

The following Java code example demonstrates the preceding steps. The example retrieves two items from the `Forum` table and three items from the `Thread` table.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

    TableKeysAndAttributes forumTableKeysAndAttributes = new
TableKeysAndAttributes(forumTableName);
    forumTableKeysAndAttributes.addHashOnlyPrimaryKeys("Name",
    "Amazon S3",
    "Amazon DynamoDB");

TableKeysAndAttributes threadTableKeysAndAttributes = new
TableKeysAndAttributes(threadTableName);
threadTableKeysAndAttributes.addHashAndRangePrimaryKeys("ForumName", "Subject",
    "Amazon DynamoDB", "DynamoDB Thread 1",
    "Amazon DynamoDB", "DynamoDB Thread 2",
    "Amazon S3", "S3 Thread 1");

BatchGetItemOutcome outcome = dynamoDB.batchGetItem(
    forumTableKeysAndAttributes, threadTableKeysAndAttributes);

for (String tableName : outcome.getTableItems().keySet()) {
    System.out.println("Items in table " + tableName);
```

```
    List<Item> items = outcome.getTableItems().get(tableName);
    for (Item item : items) {
        System.out.println(item);
    }
}
```

Specifying optional parameters

Along with the required parameters, you can also specify optional parameters when using `batchGetItem`. For example, you can provide a `ProjectionExpression` with each `TableKeysAndAttributes` you define. This allows you to specify the attributes that you want to retrieve from the table.

The following code example retrieves two items from the `Forum` table. The `withProjectionExpression` parameter specifies that only the `Threads` attribute is to be retrieved.

Example

```
TableKeysAndAttributes forumTableKeysAndAttributes = new
TableKeysAndAttributes("Forum")
    .withProjectionExpression("Threads");

forumTableKeysAndAttributes.addHashOnlyPrimaryKeys("Name",
    "Amazon S3",
    "Amazon DynamoDB");

BatchGetItemOutcome outcome = dynamoDB.batchGetItem(forumTableKeysAndAttributes);
```

Updating an item

The `updateItem` method of a `Table` object can update existing attribute values, add new attributes, or delete attributes from an existing item.

The `updateItem` method behaves as follows:

- If an item does not exist (no item in the table with the specified primary key), `updateItem` adds a new item to the table.
- If an item exists, `updateItem` performs the update as specified by the `UpdateExpression` parameter.

Note

It is also possible to "update" an item using `putItem`. For example, if you call `putItem` to add an item to the table, but there is already an item with the specified primary key, `putItem` replaces the entire item. If there are attributes in the existing item that are not specified in the input, `putItem` removes those attributes from the item.

In general, we recommend that you use `updateItem` whenever you want to modify any item attributes. The `updateItem` method only modifies the item attributes that you specify in the input, and the other attributes in the item remain unchanged.

Follow these steps:

1. Create an instance of the `Table` class to represent the table that you want to work with.
2. Call the `updateTable` method of the `Table` instance. You must specify the primary key of the item that you want to retrieve, along with an `UpdateExpression` that describes the attributes to modify and how to modify them.

The following Java code example demonstrates the preceding tasks. The code updates a book item in the `ProductCatalog` table. It adds a new author to the set of `Authors` and deletes the existing `ISBN` attribute. It also reduces the price by one.

An `ExpressionAttributeValues` map is used in the `UpdateExpression`. The placeholders `:val1` and `:val2` are replaced at runtime with the actual values for `Authors` and `Price`.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

Map<String, String> expressionAttributeNames = new HashMap<String, String>();
expressionAttributeNames.put("#A", "Authors");
expressionAttributeNames.put("#P", "Price");
expressionAttributeNames.put("#I", "ISBN");

Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val1",
    new HashSet<String>(Arrays.asList("Author YY","Author ZZ")));
expressionAttributeValues.put(":val2", 1); //Price
```

```
UpdateItemOutcome outcome = table.updateItem(  
    "Id",           // key attribute name  
    101,            // key attribute value  
    "add #A :val1 set #P = #P - :val2 remove #I", // UpdateExpression  
    expressionAttributeNames,  
    expressionAttributeValues);
```

Specifying optional parameters

Along with the required parameters, you can also specify optional parameters for the updateItem method, including a condition that must be met in order for the update is to occur. If the condition you specify is not met, the AWS SDK for Java throws a ConditionalCheckFailedException. For example, the following Java code example conditionally updates a book item price to 25. It specifies a ConditionExpression stating that the price should be updated only if the existing price is 20.

Example

```
Table table = dynamoDB.getTable("ProductCatalog");  
  
Map<String, String> expressionAttributeNames = new HashMap<String, String>();  
expressionAttributeNames.put("#P", "Price");  
  
Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();  
expressionAttributeValues.put(":val1", 25); // update Price to 25...  
expressionAttributeValues.put(":val2", 20); //...but only if existing Price is 20  
  
UpdateItemOutcome outcome = table.updateItem(  
    new PrimaryKey("Id",101),  
    "set #P = :val1", // UpdateExpression  
    "#P = :val2",    // ConditionExpression  
    expressionAttributeNames,  
    expressionAttributeValues);
```

Atomic counter

You can use updateItem to implement an atomic counter, where you increment or decrement the value of an existing attribute without interfering with other write requests. To increment an atomic counter, use an UpdateExpression with a set action to add a numeric value to an existing attribute of type Number.

The following example demonstrates this, incrementing the `Quantity` attribute by one. It also demonstrates the use of the `ExpressionAttributeNames` parameter in an `UpdateExpression`.

```
Table table = dynamoDB.getTable("ProductCatalog");

Map<String, String> expressionAttributeNames = new HashMap<String, String>();
expressionAttributeNames.put("#p", "PageCount");

Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val", 1);

UpdateItemOutcome outcome = table.updateItem(
    "Id", 121,
    "set #p = #p + :val",
    expressionAttributeNames,
    expressionAttributeValues);
```

Deleting an item

The `deleteItem` method deletes an item from a table. You must provide the primary key of the item that you want to delete.

Follow these steps:

1. Create an instance of the DynamoDB client.
2. Call the `deleteItem` method by providing the key of the item you want to delete.

The following Java example demonstrates these tasks.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("ProductCatalog");

DeleteItemOutcome outcome = table.deleteItem("Id", 101);
```

Specifying optional parameters

You can specify optional parameters for `deleteItem`. For example, the following Java code example specifies a `ConditionExpression`, stating that a book item in `ProductCatalog` can only be deleted if the book is no longer in publication (the `InPublication` attribute is false).

Example

```
Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();
expressionAttributeValues.put(":val", false);

DeleteItemOutcome outcome = table.deleteItem("Id", 103,
    "InPublication = :val",
    null, // ExpressionAttributeNames - not used in this example
    expressionAttributeValues);
```

Example: CRUD operations using the AWS SDK for Java document API

The following code example illustrates CRUD operations on an Amazon DynamoDB item. The example creates an item, retrieves it, performs various updates, and finally deletes the item.

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

```
package com.amazonaws.codesamples.document;

import java.io.IOException;
```

```
import java.util.Arrays;
import java.util.HashMap;
import java.util.HashSet;
import java.util.Map;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DeleteItemOutcome;

Example: Batch operations using AWS SDK for Java document API

This section provides examples of batch write and batch get operations in Amazon DynamoDB using the AWS SDK for Java Document API.

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

Topics

- [Example: Batch get operation using the AWS SDK for Java document API](#)

Example: Batch write operation using the AWS SDK for Java document API

The following Java code example uses the `batchWriteItem` method to perform the following put and delete operations:

- Put one item in the `Forum` table.
- Put one item and delete one item from the `Thread` table.

You can specify any number of put and delete requests against one or more tables when creating your batch write request. However, `batchWriteItem` limits the size of a batch write request and the number of put and delete operations in a single batch write operation. If your request exceeds these limits, your request is rejected. If your table does not have sufficient provisioned throughput to serve this request, the unprocessed request items are returned in the response.

The following example checks the response to see if it has any unprocessed request items. If it does, it loops back and resends the `batchWriteItem` request with unprocessed items in the request. If you followed the [Creating tables and loading data for code examples in DynamoDB](#) section, you should already have created the `Forum` and `Thread` tables. You can also create these tables and upload sample data programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for Java](#).

For step-by-step instructions for testing the following sample, see [Java code examples](#).

Example

```
package com.amazonaws.codesamples.document;

import java.io.IOException;
import java.util.Arrays;
import java.util.HashSet;
import java.util.List;
import java.util.Map;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.BatchWriteItemOutcome;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
```

```
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.TableWriteItems;
import com.amazonaws.services.dynamodbv2.model.WriteRequest;

public class DocumentAPIBatchWrite {

    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
    static DynamoDB dynamoDB = new DynamoDB(client);

    static String forumTableName = "Forum";
    static String threadTableName = "Thread";

    public static void main(String[] args) throws IOException {

        writeMultipleItemsBatchWrite();

    }

    private static void writeMultipleItemsBatchWrite() {
        try {

            // Add a new item to Forum
            TableWriteItems forumTableWriteItems = new
TableWriteItems(forumTableName) // Forum
                .withItemsToPut(new Item().withPrimaryKey("Name", "Amazon
RDS").withNumber("Threads", 0));

            // Add a new item, and delete an existing item, from Thread
            // This table has a partition key and range key, so need to specify
            // both of them
            TableWriteItems threadTableWriteItems = new
TableWriteItems(threadTableName)
                .withItemsToPut(
                    new Item().withPrimaryKey("ForumName", "Amazon RDS",
"Subject", "Amazon RDS Thread 1")
                        .withString("Message", "ElastiCache Thread 1
message")
                        .withStringSet("Tags", new
HashSet<String>(Arrays.asList("cache", "in-memory"))))
                .withHashAndRangeKeysToDelete("ForumName", "Subject", "Amazon S3",
"S3 Thread 100");

            System.out.println("Making the request.");
        }
    }
}
```

```
        BatchWriteItemOutcome outcome =
dynamoDB.batchWriteItem(forumTableWriteItems, threadTableWriteItems);

        do {

            // Check for unprocessed keys which could happen if you exceed
            // provisioned throughput

            Map<String, List<WriteRequest>> unprocessedItems =
outcome.getUnprocessedItems();

            if (outcome.getUnprocessedItems().size() == 0) {
                System.out.println("No unprocessed items found");
            } else {
                System.out.println("Retrieving the unprocessed items");
                outcome = dynamoDB.batchWriteItemUnprocessed(unprocessedItems);
            }

        } while (outcome.getUnprocessedItems().size() > 0);

    } catch (Exception e) {
        System.err.println("Failed to retrieve items: ");
        e.printStackTrace(System.err);
    }
}

}
```

Example: Batch get operation using the AWS SDK for Java document API

The following Java code example uses the batchGetItem method to retrieve multiple items from the Forum and the Thread tables. The BatchGetItemRequest specifies the table names and a list of keys for each item to get. The example processes the response by printing the items retrieved.

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

Example

```
package com.amazonaws.codesamples.document;

import java.io.IOException;
import java.util.List;
import java.util.Map;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.BatchGetItemOutcome;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.TableKeysAndAttributes;
import com.amazonaws.services.dynamodbv2.model.KeysAndAttributes;

public class DocumentAPIBatchGet {
    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
    static DynamoDB dynamoDB = new DynamoDB(client);

    static String forumTableName = "Forum";
    static String threadTableName = "Thread";

    public static void main(String[] args) throws IOException {
        retrieveMultipleItemsBatchGet();
    }

    private static void retrieveMultipleItemsBatchGet() {

        try {

            TableKeysAndAttributes forumTableKeysAndAttributes = new
TableKeysAndAttributes(forumTableName);
                // Add a partition key
                forumTableKeysAndAttributes.addHashOnlyPrimaryKeys("Name", "Amazon S3",
"Amazon DynamoDB");

            TableKeysAndAttributes threadTableKeysAndAttributes = new
TableKeysAndAttributes(threadTableName);
```

```
// Add a partition key and a sort key
threadTableKeysAndAttributes.addHashAndRangePrimaryKeys("ForumName",
"Subject", "Amazon DynamoDB",
    "DynamoDB Thread 1", "Amazon DynamoDB", "DynamoDB Thread 2",
"Amazon S3", "S3 Thread 1");

System.out.println("Making the request.");

BatchGetItemOutcome outcome =
dynamoDB.batchGetItem(forumTableKeysAndAttributes,
    threadTableKeysAndAttributes);

Map<String, KeysAndAttributes> unprocessed = null;

do {
    for (String tableName : outcome.getTableItems().keySet()) {
        System.out.println("Items in table " + tableName);
        List<Item> items = outcome.getTableItems().get(tableName);
        for (Item item : items) {
            System.out.println(item.toJSONString());
        }
    }
}

// Check for unprocessed keys which could happen if you exceed
// provisioned
// throughput or reach the limit on response size.
unprocessed = outcome.getUnprocessedKeys();

if (unprocessed.isEmpty()) {
    System.out.println("No unprocessed keys found");
} else {
    System.out.println("Retrieving the unprocessed keys");
    outcome = dynamoDB.batchGetItemUnprocessed(unprocessed);
}

} while (!unprocessed.isEmpty());

} catch (Exception e) {
    System.err.println("Failed to retrieve items.");
    System.err.println(e.getMessage());
}

}
```

```
}
```

Example: Handling binary type attributes using the AWS SDK for Java document API

The following Java code example illustrates handling binary type attributes. The example adds an item to the Reply table. The item includes a binary type attribute (ExtendedMessage) that stores compressed data. The example then retrieves the item and prints all the attribute values. For illustration, the example uses the GZIPOutputStream class to compress a sample stream and assign it to the ExtendedMessage attribute. When the binary attribute is retrieved, it is decompressed using the GZIPInputStream class.

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

If you followed the [Creating tables and loading data for code examples in DynamoDB](#) section, you should already have created the Reply table. You can also create this table programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for Java](#).

For step-by-step instructions for testing the following sample, see [Java code examples](#).

Example

```
package com.amazonaws.codesamples.document;

import java.io.ByteArrayInputStream;
import java.io.ByteArrayOutputStream;
import java.io.IOException;
import java.nio.ByteBuffer;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.TimeZone;
import java.util.zip.GZIPInputStream;
import java.util.zip.GZIPOutputStream;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
```

```
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.Table;
import com.amazonaws.services.dynamodbv2.document.spec.GetItemSpec;

public class DocumentAPIItemBinaryExample {

    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
    static DynamoDB dynamoDB = new DynamoDB(client);

    static String tableName = "Reply";
    static SimpleDateFormat dateFormatter = new SimpleDateFormat("yyyy-MM-
dd'T'HH:mm:ss.SSS'Z'");

    public static void main(String[] args) throws IOException {
        try {

            // Format the primary key values
            String threadId = "Amazon DynamoDB#DynamoDB Thread 2";

            dateFormatter.setTimeZone(TimeZone.getTimeZone("UTC"));
            String replyDateTime = dateFormatter.format(new Date());

            // Add a new reply with a binary attribute type
            createItem(threadId, replyDateTime);

            // Retrieve the reply with a binary attribute type
            retrieveItem(threadId, replyDateTime);

            // clean up by deleting the item
            deleteItem(threadId, replyDateTime);
        } catch (Exception e) {
            System.err.println("Error running the binary attribute type example: " +
e);
            e.printStackTrace(System.err);
        }
    }

    public static void createItem(String threadId, String replyDateTime) throws
IOException {

        Table table = dynamoDB.getTable(tableName);
```

```

```
// Compress the UTF-8 encoded String into a byte[]
ByteArrayOutputStream baos = new ByteArrayOutputStream();
GZIPOutputStream os = new GZIPOutputStream(baos);
os.write(input.getBytes("UTF-8"));
os.close();
baos.close();
byte[] compressedBytes = baos.toByteArray();

// The following code writes the compressed bytes to a ByteBuffer.
// A simpler way to do this is by simply calling
// ByteBuffer.wrap(compressedBytes);
// However, the longer form below shows the importance of resetting the
// position of the buffer
// back to the beginning of the buffer if you are writing bytes directly
// to it, since the SDK
// will consider only the bytes after the current position when sending
// data to DynamoDB.
// Using the "wrap" method automatically resets the position to zero.
ByteBuffer buffer = ByteBuffer.allocate(compressedBytes.length);
buffer.put(compressedBytes, 0, compressedBytes.length);
buffer.position(0); // Important: reset the position of the ByteBuffer
                  // to the beginning
return buffer;
}

private static String uncompressString(ByteBuffer input) throws IOException {
    byte[] bytes = input.array();
    ByteArrayInputStream bais = new ByteArrayInputStream(bytes);
    ByteArrayOutputStream baos = new ByteArrayOutputStream();
    GZIPInputStream is = new GZIPInputStream(bais);

    int chunkSize = 1024;
    byte[] buffer = new byte[chunkSize];
    int length = 0;
    while ((length = is.read(buffer, 0, chunkSize)) != -1) {
        baos.write(buffer, 0, length);
    }

    String result = new String(baos.toByteArray(), "UTF-8");

    is.close();
    baos.close();
    bais.close();
}
```

```
        return result;
    }
}
```

Working with items: .NET

You can use the AWS SDK for .NET low-level API to perform typical create, read, update, and delete (CRUD) operations on an item in a table. The following are the common steps that you follow to perform data CRUD operations using the .NET low-level API:

1. Create an instance of the `AmazonDynamoDBClient` class (the client).
2. Provide the operation-specific required parameters in a corresponding request object.

For example, use the `PutItemRequest` request object when uploading an item and use the `GetItemRequest` request object when retrieving an existing item.

You can use the request object to provide both the required and optional parameters.

3. Run the appropriate method provided by the client by passing in the request object that you created in the preceding step.

The `AmazonDynamoDBClient` client provides `PutItem`, `GetItem`, `UpdateItem`, and `DeleteItem` methods for the CRUD operations.

Topics

- [Putting an item](#)
- [Getting an item](#)
- [Updating an item](#)
- [Atomic counter](#)
- [Deleting an item](#)
- [Batch write: Putting and deleting multiple items](#)
- [Batch get: Getting multiple items](#)
- [Example: CRUD operations using the AWS SDK for .NET low-level API](#)
- [Example: Batch operations using the AWS SDK for .NET low-level API](#)
- [Example: Handling binary type attributes using the AWS SDK for .NET low-level API](#)

Putting an item

The PutItem method uploads an item to a table. If the item exists, it replaces the entire item.

Note

Instead of replacing the entire item, if you want to update only specific attributes, you can use the UpdateItem method. For more information, see [Updating an item](#).

The following are the steps to upload an item using the low-level .NET SDK API:

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required parameters by creating an instance of the PutItemRequest class.

To put an item, you must provide the table name and the item.

3. Run the PutItem method by providing the PutItemRequest object that you created in the preceding step.

The following C# example demonstrates the preceding steps. The example uploads an item to the ProductCatalog table.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new PutItemRequest
{
    TableName = tableName,
    Item = new Dictionary<string, AttributeValue>()
    {
        { "Id", new AttributeValue { N = "201" } },
        { "Title", new AttributeValue { S = "Book 201 Title" } },
        { "ISBN", new AttributeValue { S = "11-11-11-11" } },
        { "Price", new AttributeValue { S = "20.00" } },
        {
            "Authors",
            new AttributeValue
            { SS = new List<string>{"Author1", "Author2"} }
        }
    }
}
```

```
    }
};

client.PutItem(request);
```

In the preceding example, you upload a book item that has the `Id`, `Title`, `ISBN`, and `Authors` attributes. Note that `Id` is a numeric type attribute, and all other attributes are of the string type. `Authors` is a `String` set.

Specifying optional parameters

You can also provide optional parameters using the `PutItemRequest` object as shown in the following C# example. The example specifies the following optional parameters:

- `ExpressionAttributeNames`, `ExpressionAttributeValues`, and `ConditionExpression` specify that the item can be replaced only if the existing item has the `ISBN` attribute with a specific value.
- `ReturnValues` parameter to request the old item in the response.

Example

```
var request = new PutItemRequest
{
    TableName = tableName,
    Item = new Dictionary<string, AttributeValue>()
    {
        { "Id", new AttributeValue { N = "104" } },
        { "Title", new AttributeValue { S = "Book 104 Title" } },
        { "ISBN", new AttributeValue { S = "444-4444444444" } },
        { "Authors",
            new AttributeValue { SS = new List<string>{"Author3"} }
        },
        // Optional parameters.
        ExpressionAttributeNames = new Dictionary<string, string>()
        {
            {"#I", "ISBN"}
        },
        ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
        {
            {":isbn", new AttributeValue { S = "444-4444444444" } }
        },
        ConditionExpression = "#I = :isbn"
```

```
};  
var response = client.PutItem(request);
```

For more information, see [PutItem](#).

Getting an item

The GetItem method retrieves an item.

Note

To retrieve multiple items, you can use the BatchGetItem method. For more information, see [Batch get: Getting multiple items](#).

The following are the steps to retrieve an existing item using the low-level AWS SDK for .NET API.

1. Create an instance of the AmazonDynamoDBClient class.
2. Provide the required parameters by creating an instance of the GetItemRequest class.

To get an item, you must provide the table name and primary key of the item.

3. Run the GetItem method by providing the GetItemRequest object that you created in the preceding step.

The following C# example demonstrates the preceding steps. The example retrieves an item from the ProductCatalog table.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();  
string tableName = "ProductCatalog";  
  
var request = new GetItemRequest  
{  
    TableName = tableName,  
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N = "202" } } },  
};  
var response = client.GetItem(request);  
  
// Check the response.  
var result = response.GetItemResult;
```

```
var attributeMap = result.Item; // Attribute list in the response.
```

Specifying optional parameters

You can also provide optional parameters using the `GetItemRequest` object, as shown in the following C# example. The sample specifies the following optional parameters:

- `ProjectionExpression` parameter to specify the attributes to retrieve.
- `ConsistentRead` parameter to perform a strongly consistent read. To learn more read consistency, see [Read consistency](#).

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new GetItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N =
"202" } } },
    // Optional parameters.
    ProjectionExpression = "Id, ISBN, Title, Authors",
    ConsistentRead = true
};

var response = client.GetItem(request);

// Check the response.
var result = response.GetItemResult;
var attributeMap = result.Item;
```

For more information, see [GetItem](#).

Updating an item

The `UpdateItem` method updates an existing item if it is present. You can use the `UpdateItem` operation to update existing attribute values, add new attributes, or delete attributes from the existing collection. If the item that has the specified primary key is not found, it adds a new item.

The `UpdateItem` operation uses the following guidelines:

- If the item does not exist, `UpdateItem` adds a new item using the primary key that is specified in the input.
- If the item exists, `UpdateItem` applies the updates as follows:
 - Replaces the existing attribute values by the values in the update.
 - If the attribute that you provide in the input does not exist, it adds a new attribute to the item.
 - If the input attribute is null, it deletes the attribute, if it is present.
 - If you use ADD for the Action, you can add values to an existing set (string or number set), or mathematically add (use a positive number) or subtract (use a negative number) from the existing numeric attribute value.

 **Note**

The `PutItem` operation also can perform an update. For more information, see [Putting an item](#). For example, if you call `PutItem` to upload an item and the primary key exists, the `PutItem` operation replaces the entire item. If there are attributes in the existing item and those attributes are not specified in the input, the `PutItem` operation deletes those attributes. However, `UpdateItem` updates only the specified input attributes. Any other existing attributes of that item remain unchanged.

The following are the steps to update an existing item using the low-level .NET SDK API:

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required parameters by creating an instance of the `UpdateItemRequest` class.

This is the request object in which you describe all the updates, such as add attributes, update existing attributes, or delete attributes. To delete an existing attribute, specify the attribute name with null value.

3. Run the `UpdateItem` method by providing the `UpdateItemRequest` object that you created in the preceding step.

The following C# code example demonstrates the preceding steps. The example updates a book item in the `ProductCatalog` table. It adds a new author to the `Authors` collection, and deletes the existing `ISBN` attribute. It also reduces the price by one.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N =
"202" } } },
    ExpressionAttributeNames = new Dictionary<string,string>()
    {
        {"#A", "Authors"},
        {"#P", "Price"},
        {"#NA", "NewAttribute"},
        {"#I", "ISBN"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {"":auth",new AttributeValue { SS = {"Author YY","Author ZZ"} } },
        {"":p",new AttributeValue { N = "1" } },
        {"":newattr",new AttributeValue { S = "someValue" } },
    },
    // This expression does the following:
    // 1) Adds two new authors to the list
    // 2) Reduces the price
    // 3) Adds a new attribute to the item
    // 4) Removes the ISBN attribute from the item
    UpdateExpression = "ADD #A :auth SET #P = #P - :p, #NA = :newattr REMOVE #I"
};

var response = client.UpdateItem(request);
```

Specifying optional parameters

You can also provide optional parameters using the `UpdateItemRequest` object, as shown in the following C# example. It specifies the following optional parameters:

- `ExpressionAttributeValues` and `ConditionExpression` to specify that the price can be updated only if the existing price is 20.00.
- `ReturnValues` parameter to request the updated item in the response.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
{
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N =
"202" } } },
    // Update price only if the current price is 20.00.
    ExpressionAttributeNames = new Dictionary<string,string>()
    {
        {"#P", "Price"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {"<:newprice",new AttributeValue {N = "22"}},
        {"<:currprice",new AttributeValue {N = "20"}}
    },
    UpdateExpression = "SET #P = :newprice",
    ConditionExpression = "#P = :currprice",
    TableName = tableName,
    ReturnValues = "ALL_NEW" // Return all the attributes of the updated item.
};

var response = client.UpdateItem(request);
```

For more information, see [UpdateItem](#).

Atomic counter

You can use `updateItem` to implement an atomic counter, where you increment or decrement the value of an existing attribute without interfering with other write requests. To update an atomic counter, use `updateItem` with an attribute of type `Number` in the `UpdateExpression` parameter, and `ADD` as the Action.

The following example demonstrates this, incrementing the `Quantity` attribute by one.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "ProductCatalog";

var request = new UpdateItemRequest
```

```
{  
    Key = new Dictionary<string, AttributeValue>() { { "Id", new AttributeValue { N =  
"121" } } },  
    ExpressionAttributeNames = new Dictionary<string, string>()  
    {  
        {"#Q", "Quantity"}  
    },  
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()  
    {  
        {":incr", new AttributeValue { N = "1"} }  
    },  
    UpdateExpression = "SET #Q = #Q + :incr",  
    TableName = tableName  
};  
  
var response = client.UpdateItem(request);
```

Deleting an item

The `DeleteItem` method deletes an item from a table.

The following are the steps to delete an item using the low-level .NET SDK API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required parameters by creating an instance of the `DeleteItemRequest` class.
To delete an item, the table name and item's primary key are required.
3. Run the `DeleteItem` method by providing the `DeleteItemRequest` object that you created in the preceding step.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();  
string tableName = "ProductCatalog";  
  
var request = new DeleteItemRequest  
{  
    TableName = tableName,  
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N =  
"201" } } },  
};
```

```
var response = client.DeleteItem(request);
```

Specifying optional parameters

You can also provide optional parameters using the `DeleteItemRequest` object as shown in the following C# code example. It specifies the following optional parameters:

- `ExpressionAttributeValues` and `ConditionExpression` to specify that the book item can be deleted only if it is no longer in publication (the `InPublication` attribute value is false).
- `ReturnValues` parameter to request the deleted item in the response.

Example

```
var request = new DeleteItemRequest
{
    TableName = tableName,
    Key = new Dictionary<string,AttributeValue>() { { "Id", new AttributeValue { N =
"201" } } },

    // Optional parameters.
    ReturnValues = "ALL_OLD",
    ExpressionAttributeNames = new Dictionary<string, string>()
    {
        {"#IP", "InPublication"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
    {
        {":inpub",new AttributeValue {BOOL = false}}
    },
    ConditionExpression = "#IP = :inpub"
};

var response = client.DeleteItem(request);
```

For more information, see [DeleteItem](#).

Batch write: Putting and deleting multiple items

Batch write refers to putting and deleting multiple items in a batch. The `BatchWriteItem` method enables you to put and delete multiple items from one or more tables in a single call. The following are the steps to retrieve multiple items using the low-level .NET SDK API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Describe all the put and delete operations by creating an instance of the `BatchWriteItemRequest` class.
3. Run the `BatchWriteItem` method by providing the `BatchWriteItemRequest` object that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed request items returned in the response. This could happen if you reach the provisioned throughput quota or some other transient error. Also, DynamoDB limits the request size and the number of operations you can specify in a request. If you exceed these limits, DynamoDB rejects the request. For more information, see [BatchWriteItem](#).

The following C# code example demonstrates the preceding steps. The example creates a `BatchWriteItemRequest` to perform the following write operations:

- Put an item in `Forum` table.
- Put and delete an item from `Thread` table.

The code runs `BatchWriteItem` to perform a batch operation.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

string table1Name = "Forum";
string table2Name = "Thread";

var request = new BatchWriteItemRequest
{
    RequestItems = new Dictionary<string, List<WriteRequest>>
    {
        {
            table1Name, new List<WriteRequest>
            {
                new WriteRequest
                {
                    PutRequest = new PutRequest
                    {
                        Item = new Dictionary<string,AttributeValue>
                        {
                            { "Name", new AttributeValue { S = "Amazon S3 forum" } },
                            { "Threads", new AttributeValue { N = "0" } }
                        }
                    }
                }
            }
        }
    }
}
```

```
        }
    }
}
},
{
    table2Name, new List<WriteRequest>
{
    new WriteRequest
    {
        PutRequest = new PutRequest
        {
            Item = new Dictionary<string,AttributeValue>
            {
                { "ForumName", new AttributeValue { S = "Amazon S3 forum" } },
                { "Subject", new AttributeValue { S = "My sample question" } },
                { "Message", new AttributeValue { S = "Message Text." } },
                { "KeywordTags", new AttributeValue { SS = new List<string> { "Amazon S3", "Bucket" } } }
            }
        }
    },
    new WriteRequest
    {
        DeleteRequest = new DeleteRequest
        {
            Key = new Dictionary<string,AttributeValue>()
            {
                { "ForumName", new AttributeValue { S = "Some forum name" } },
                { "Subject", new AttributeValue { S = "Some subject" } }
            }
        }
    }
}
};

response = client.BatchWriteItem(request);
```

For a working example, see [Example: Batch operations using the AWS SDK for .NET low-level API](#).

Batch get: Getting multiple items

The BatchGetItem method enables you to retrieve multiple items from one or more tables.

Note

To retrieve a single item, you can use the `GetItem` method.

The following are the steps to retrieve multiple items using the low-level AWS SDK for .NET API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required parameters by creating an instance of the `BatchGetItemRequest` class.

To retrieve multiple items, the table name and a list of primary key values are required.

3. Run the `BatchGetItem` method by providing the `BatchGetItemRequest` object that you created in the preceding step.
4. Process the response. You should check if there were any unprocessed keys, which could happen if you reach the provisioned throughput quota or some other transient error.

The following C# code example demonstrates the preceding steps. The example retrieves items from two tables, `Forum` and `Thread`. The request specifies two items in the `Forum` and three items in the `Thread` table. The response includes items from both of the tables. The code shows how you can process the response.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

string table1Name = "Forum";
string table2Name = "Thread";

var request = new BatchGetItemRequest
{
    RequestItems = new Dictionary<string, KeysAndAttributes>()
    {
        { table1Name,
            new KeysAndAttributes
            {
                Keys = new List<Dictionary<string, AttributeValue>>()
                {
                    new Dictionary<string, AttributeValue>()
                    {
                        { "Name", new AttributeValue { S = "DynamoDB" } }
                    },
                }
            }
        }
    }
};
```

```
        new Dictionary<string, AttributeValue>()
    {
        { "Name", new AttributeValue { S = "Amazon S3" } }
    }
}
},
{
    table2Name,
    new KeysAndAttributes
    {
        Keys = new List<Dictionary<string, AttributeValue>>()
        {
            new Dictionary<string, AttributeValue>()
            {
                { "ForumName", new AttributeValue { S = "DynamoDB" } },
                { "Subject", new AttributeValue { S = "DynamoDB Thread 1" } }
            },
            new Dictionary<string, AttributeValue>()
            {
                { "ForumName", new AttributeValue { S = "DynamoDB" } },
                { "Subject", new AttributeValue { S = "DynamoDB Thread 2" } }
            },
            new Dictionary<string, AttributeValue>()
            {
                { "ForumName", new AttributeValue { S = "Amazon S3" } },
                { "Subject", new AttributeValue { S = "Amazon S3 Thread 1" } }
            }
        }
    }
},
};

var response = client.BatchGetItem(request);

// Check the response.
var result = response.BatchGetItemResult;
var responses = result.Responses; // The attribute list in the response.

var table1Results = responses[table1Name];
Console.WriteLine("Items in table {0}" + table1Name);
foreach (var item1 in table1Results.Items)
{
```

```
    PrintItem(item1);
}

var table2Results = responses[table2Name];
Console.WriteLine("Items in table {1}" + table2Name);
foreach (var item2 in table2Results.Items)
{
    PrintItem(item2);
}
// Any unprocessed keys? could happen if you exceed ProvisionedThroughput or some other
// error.
Dictionary<string, KeysAndAttributes> unprocessedKeys = result.UnprocessedKeys;
foreach (KeyValuePair<string, KeysAndAttributes> pair in unprocessedKeys)
{
    Console.WriteLine(pair.Key, pair.Value);
}
```

Specifying optional parameters

You can also provide optional parameters using the `BatchGetItemRequest` object as shown in the following C# code example. The example retrieves two items from the `Forum` table. It specifies the following optional parameter:

- `ProjectionExpression` parameter to specify the attributes to retrieve.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

string table1Name = "Forum";

var request = new BatchGetItemRequest
{
    RequestItems = new Dictionary<string, KeysAndAttributes>()
    {
        { table1Name,
            new KeysAndAttributes
            {
                Keys = new List<Dictionary<string, AttributeValue>>()
                {
                    new Dictionary<string, AttributeValue>()
                    {

```

```
        { "Name", new AttributeValue { S = "DynamoDB" } }
    },
    new Dictionary<string, AttributeValue>()
    {
        { "Name", new AttributeValue { S = "Amazon S3" } }
    }
},
// Optional - name of an attribute to retrieve.
ProjectionExpression = "Title"
}
}
};

var response = client.BatchGetItem(request);
```

For more information, see [BatchGetItem](#).

Example: CRUD operations using the AWS SDK for .NET low-level API

The following C# code example illustrates CRUD operations on an Amazon DynamoDB item. The example adds an item to the ProductCatalog table, retrieves it, performs various updates, and finally deletes the item. If you followed the steps in [Creating tables and loading data for code examples in DynamoDB](#), you already have the ProductCatalog table created. You can also create these sample tables programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for .NET](#).

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class LowLevelItemCRUDExample
    {
        private static string tableName = "ProductCatalog";
```

```
private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

static void Main(string[] args)
{
    try
    {
        CreateItem();
        RetrieveItem();

        // Perform various updates.
        UpdateMultipleAttributes();
        UpdateExistingAttributeConditionally();

        // Delete item.
        DeleteItem();
        Console.WriteLine("To continue, press Enter");
        Console.ReadLine();
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
        Console.WriteLine("To continue, press Enter");
        Console.ReadLine();
    }
}

private static void CreateItem()
{
    var request = new PutItemRequest
    {
        TableName = tableName,
        Item = new Dictionary<string, AttributeValue>()
    };
    { "Id", new AttributeValue {
            N = "1000"
        }},
    { "Title", new AttributeValue {
            S = "Book 201 Title"
        }},
    { "ISBN", new AttributeValue {
            S = "11-11-11-11"
        }},
    { "Authors", new AttributeValue {
            SS = new List<string>{"Author1", "Author2" }
        }}
}
```

```
        },
        { "Price", new AttributeValue {
            N = "20.00"
        }},
        { "Dimensions", new AttributeValue {
            S = "8.5x11.0x.75"
        }},
        { "InPublication", new AttributeValue {
            BOOL = false
        } }
    }
};

client.PutItem(request);
}

private static void RetrieveItem()
{
    var request = new GetItemRequest
    {
        TableName = tableName,
        Key = new Dictionary<string, AttributeValue>()
    {
        { "Id", new AttributeValue {
            N = "1000"
        } }
    },
        ProjectionExpression = "Id, ISBN, Title, Authors",
        ConsistentRead = true
    };
    var response = client.GetItem(request);

    // Check the response.
    var attributeList = response.Item; // attribute list in the response.
    Console.WriteLine("\nPrinting item after retrieving it .....");
    PrintItem(attributeList);
}

private static void UpdateMultipleAttributes()
{
    var request = new UpdateItemRequest
    {
        Key = new Dictionary<string, AttributeValue>()
    {
        { "Id", new AttributeValue {
```

```
        N = "1000"
    }
},
// Perform the following updates:
// 1) Add two new authors to the list
// 1) Set a new attribute
// 2) Remove the ISBN attribute
ExpressionAttributeNames = new Dictionary<string, string>()
{
    {"#A", "Authors"},
    {"#NA", "NewAttribute"},
    {"#I", "ISBN"}
},
ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
{
    {":auth", new AttributeValue {
        SS = {"Author YY", "Author ZZ"}
    }},
    {":new", new AttributeValue {
        S = "New Value"
    }}
},
UpdateExpression = "ADD #A :auth SET #NA = :new REMOVE #I",
TableName = tableName,
ReturnValues = "ALL_NEW" // Give me all attributes of the updated item.
};

var response = client.UpdateItem(request);

// Check the response.
var attributeList = response.Attributes; // attribute list in the response.
                                         // print attributeList.
Console.WriteLine("\nPrinting item after multiple attribute
update .....");
PrintItem(attributeList);
}

private static void UpdateExistingAttributeConditionally()
{
    var request = new UpdateItemRequest
    {
        Key = new Dictionary<string, AttributeValue>()
    }
```

```
        { "Id", new AttributeValue {
            N = "1000"
        } }
    },
    ExpressionAttributeNames = new Dictionary<string, string>()
{
    {"#P", "Price"}
},
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
{
    {"<:newprice", new AttributeValue {
        N = "22.00"
    }},
    {"<:currprice", new AttributeValue {

Example: Batch operations using the AWS SDK for .NET low-level API

Topics

- [Example: Batch write operation using the AWS SDK for .NET low-level API](#)
- [Example: Batch get operation using the AWS SDK for .NET low-level API](#)

This section provides examples of batch operations, *batch write* and *batch get*, that Amazon DynamoDB supports.

Example: Batch write operation using the AWS SDK for .NET low-level API

The following C# code example uses the `BatchWriteItem` method to perform the following put and delete operations:

- Put one item in the `Forum` table.
- Put one item and delete one item from the `Thread` table.

You can specify any number of put and delete requests against one or more tables when creating your batch write request. However, DynamoDB `BatchWriteItem` limits the size of a batch write request and the number of put and delete operations in a single batch write operation. For more information, see [BatchWriteItem](#). If your request exceeds these limits, your request is rejected. If your table does not have sufficient provisioned throughput to serve this request, the unprocessed request items are returned in the response.

The following example checks the response to see if it has any unprocessed request items. If it does, it loops back and resends the `BatchWriteItem` request with unprocessed items in the request. If you followed the steps in [Creating tables and loading data for code examples in DynamoDB](#), you already have the `Forum` and `Thread` tables created. You can also create these sample tables and upload sample data programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for .NET](#).

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

Example

```
using System;
```

```
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class LowLevelBatchWrite
    {
        private static string table1Name = "Forum";
        private static string table2Name = "Thread";
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                TestBatchWrite();
            }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void TestBatchWrite()
        {
            var request = new BatchWriteItemRequest
            {
                ReturnConsumedCapacity = "TOTAL",
                RequestItems = new Dictionary<string, List<WriteRequest>>
            {
                {
                    table1Name, new List<WriteRequest>
                    {
                        new WriteRequest
                        {
                            PutRequest = new PutRequest
                            {
                                Item = new Dictionary<string, AttributeValue>
                                {
                                    { "Name", new AttributeValue { S = "S3 forum" }

```

```
        } },
        { "Threads", new AttributeValue {
            N = "0"
        }}
    }
}
},
{
    table2Name, new List<WriteRequest>
{
    new WriteRequest
{
    PutRequest = new PutRequest
{
    Item = new Dictionary<string, AttributeValue>
{
        { "ForumName", new AttributeValue {
            S = "S3 forum"
        }},
        { "Subject", new AttributeValue {
            S = "My sample question"
        }},
        { "Message", new AttributeValue {
            S = "Message Text."
        }},
        { "KeywordTags", new AttributeValue {
            SS = new List<string> { "S3", "Bucket" }
        }}
    }
},
    new WriteRequest
{
    // For the operation to delete an item, if you provide a
primary key value
    // that does not exist in the table, there is no error, it
is just a no-op.
    DeleteRequest = new DeleteRequest
{
    Key = new Dictionary<string, AttributeValue>()
{
        { "ForumName", new AttributeValue {
```

```
        S = "Some partition key value"
    } },
{ "Subject", new AttributeValue {
    S = "Some sort key value"
} }
}
}
}
}
}
};

CallBatchWriteTillCompletion(request);
}

private static void CallBatchWriteTillCompletion(BatchWriteItemRequest request)
{
    BatchWriteItemResponse response;

    int callCount = 0;
    do
    {
        Console.WriteLine("Making request");
        response = client.BatchWriteItem(request);
        callCount++;

        // Check the response.

        var tableConsumedCapacities = response.ConsumedCapacity;
        var unprocessed = response.UnprocessedItems;

        Console.WriteLine("Per-table consumed capacity");
        foreach (var tableConsumedCapacity in tableConsumedCapacities)
        {
            Console.WriteLine("{0} - {1}", tableConsumedCapacity.TableName,
tableConsumedCapacity.CapacityUnits);
        }

        Console.WriteLine("Unprocessed");
        foreach (var unp in unprocessed)
        {
            Console.WriteLine("{0} - {1}", unp.Key, unp.Value.Count);
        }
    }
}
```

```
        Console.WriteLine();

        // For the next iteration, the request will have unprocessed items.
        request.RequestItems = unprocessed;
    } while (response.UnprocessedItems.Count > 0);

    Console.WriteLine("Total # of batch write API calls made: {0}", callCount);
}
}
```

Example: Batch get operation using the AWS SDK for .NET low-level API

The following C# code example uses the BatchGetItem method to retrieve multiple items from the Forum and the Thread tables in Amazon DynamoDB. The BatchGetItemRequest specifies the table names and a list of primary keys for each table. The example processes the response by printing the items retrieved.

If you followed the steps in [Creating tables and loading data for code examples in DynamoDB](#), you already have these tables created with sample data. You can also create these sample tables and upload sample data programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for .NET](#).

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class LowLevelBatchGet
    {
        private static string table1Name = "Forum";
        private static string table2Name = "Thread";
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
```

```
try
{
    RetrieveMultipleItemsBatchGet();

    Console.WriteLine("To continue, press Enter");
    Console.ReadLine();
}
catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
catch (Exception e) { Console.WriteLine(e.Message); }
}

private static void RetrieveMultipleItemsBatchGet()
{
    var request = new BatchGetItemRequest
    {
        RequestItems = new Dictionary<string, KeysAndAttributes>()
    }

    { tableName,
        new KeysAndAttributes
        {
            Keys = new List<Dictionary<string, AttributeValue>>()
            {
                new Dictionary<string, AttributeValue>()
                {
                    { "Name", new AttributeValue {
                        S = "Amazon DynamoDB"
                    } },
                    { "Name", new AttributeValue {
                        S = "Amazon S3"
                    } }
                }
            }
        }
    },
    {
        tableName,
        new KeysAndAttributes
        {
            Keys = new List<Dictionary<string, AttributeValue>>()

} while (response.UnprocessedKeys.Count > 0);  
}  
  
private static void PrintItem(Dictionary<string, AttributeValue> attributeList)  
{  
    foreach (KeyValuePair<string, AttributeValue> kvp in attributeList)  
{  
        string attributeName = kvp.Key;  
        AttributeValue value = kvp.Value;  
  
        Console.WriteLine(  
            attributeName + " " +  
            (value.S == null ? "" : "S=[" + value.S + "]") +  
            (value.N == null ? "" : "N=[" + value.N + "]") +  
            (value.SS == null ? "" : "SS=[" + string.Join(",",  
value.SS.ToArray()) + "]") +  
            (value.NS == null ? "" : "NS=[" + string.Join(",",  
value.NS.ToArray()) + "]")  
        );  
    }  
}
```

```
        Console.WriteLine("*****");
    }
}
}
```

Example: Handling binary type attributes using the AWS SDK for .NET low-level API

The following C# code example illustrates the handling of binary type attributes. The example adds an item to the Reply table. The item includes a binary type attribute (ExtendedMessage) that stores compressed data. The example then retrieves the item and prints all the attribute values. For illustration, the example uses the GZipStream class to compress a sample stream and assigns it to the ExtendedMessage attribute, and decompresses it when printing the attribute value.

If you followed the steps in [Creating tables and loading data for code examples in DynamoDB](#), you already have the Reply table created. You can also create these sample tables programmatically. For more information, see [Creating example tables and uploading data using the AWS SDK for .NET](#).

For step-by-step instructions for testing the following example, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using System.IO;
using System.IO.Compression;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class LowLevelItemBinaryExample
    {
        private static string tableName = "Reply";
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            // Reply table primary key.
            string replyIdPartitionKey = "Amazon DynamoDB#DynamoDB Thread 1";
            string replyDateTimeSortKey = Convert.ToString(DateTime.UtcNow);
```

```
try
{
    CreateItem(replyIdPartitionKey, replyDateTimeSortKey);
    RetrieveItem(replyIdPartitionKey, replyDateTimeSortKey);
    // Delete item.
    DeleteItem(replyIdPartitionKey, replyDateTimeSortKey);
    Console.WriteLine("To continue, press Enter");
    Console.ReadLine();
}
catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
catch (Exception e) { Console.WriteLine(e.Message); }

private static void CreateItem(string partitionKey, string sortKey)
{
    MemoryStream compressedMessage = ToGzipMemoryStream("Some long extended
message to compress.");
    var request = new PutItemRequest
    {
        TableName = tableName,
        Item = new Dictionary<string, AttributeValue>()
    {
        { "Id", new AttributeValue {
            S = partitionKey
        }},
        { "ReplyDateTime", new AttributeValue {
            S = sortKey
        }},
        { "Subject", new AttributeValue {
            S = "Binary type "
        }},
        { "Message", new AttributeValue {
            S = "Some message about the binary type"
        }},

        using (StreamReader reader = new StreamReader(zipStream))
    {
        return reader.ReadToEnd();
    }
}
}
```

Item collections - how to model one-to-many relationships in DynamoDB

In DynamoDB, an *item collection* is a group of items that share the same partition key value, which means the items are related. Item collections are the primary mechanism to model one-to-many relationships in DynamoDB. Item collections can only exist on tables or indexes configured to use a [composite primary key](#).

 **Note**

Item collections can exist either in a base table or a secondary index. For more information specifically about how item collections interact with indexes, see [Item collections in Local Secondary Indexes](#).

Consider the following table showing three different users and their in-game inventories:

Primary key		Attributes		
Partition key: PK	Sort key: SK			
account1234	inventory::armor	data {"armor": [{"name": "Pauldron of the Paladin", "type": "chest", "gear score": 545}, {"name": "Greaves of the Ranger", "type": "sword", "gear score": 382}]}		
	inventory::weapons	data {"weapons": [{"name": "Sword of the Ancients", "type": "sword", "gear score": 320}]}		
	login-data	pw d1e8a70b5ccab1dc2f56bbf7e99f064a660c08e361a35751b9c483c88943d082	state	last-login Active 1649276737
account1387	info	data {"email": "bot123@gmail.com"}		
	inventory::armor	data {"armor": [{"name": "Pauldron of the Paladin", "type": "chest", "gear score": 545}, {"name": "Greaves of the Ranger", "type": "sword", "gear score": 382}]}		
	login-data	pw k2g8jk0m5ppab1dc2f56bbf7e99f064a660c08e361a35751b9c464r23943l082	state	last-login Banned 1649456737
account1138	info	data {"email": "luh-3417@gmail.com" }		
	login-data	pw 88A41A9A62B11CCC8C120861928765A3EA41DEB9EAFE261D90F619473B89A2D4	state	last-login Active 14275516966

For some items in each collection, the sort key is a concatenation made up of information used to group data, such as `inventory::armor`, `inventory::weapon` or `info`. Each item collection can have a different combination of these attributes as the sort key. User account1234 has an `inventory::weapons` item, while user account1387 does not (because they have not found any yet). User account1138 only uses two items for their sort key (since they have no inventory yet) while the other users use three.

DynamoDB lets you selectively retrieve items from these item collections to do the following:

- Retrieve all items from a particular user
- Retrieve only one item from a particular user
- Retrieve all the items of a specific type belonging to a particular user

Speed up queries by organizing your data with item collections

In this example, each of the items in these three item collections represents a player and the data model we have chosen, based off the game's and player's access patterns. What data does the game need? When does it need it? How frequently does it need it? What's the cost of doing it this way? These data modeling decisions were made based off the answers to these questions.

In this game, there is a different page presented to the player for their inventory for weapons and another page for armor. When the player opens their inventory, weapons are shown first because we want that page to load extremely fast, while subsequent inventory pages can load after that. Since each of these item types can be quite large as the player acquires more in-game items, we decided that each inventory page would be its own item in the player's item collection in the database.

The following section talks more about how you can interact with item collections through the [Query](#) operation.

Query operations in DynamoDB

You can use the [Query API](#) operation in Amazon DynamoDB to find items based on primary key values.

You must provide the name of the partition key attribute and a single value for that attribute. [Query](#) returns all items with that partition key value. Optionally, you can provide a sort key attribute and use a comparison operator to refine the search results.

For more information on how to use [Query](#), such as the request syntax, response parameters, and additional examples, see [Query](#) in the *Amazon DynamoDB API Reference*.

Topics

- [Querying tables and indexes: .NET](#)

Key condition expressions for the Query operation

To specify the search criteria, you use a *key condition expression*—a string that determines the items to be read from the table or index.

You must specify the partition key name and value as an equality condition. You cannot use a non-key attribute in a key condition expression.

You can optionally provide a second condition for the sort key (if present). The sort key condition must use one of the following comparison operators:

- $a = b$ — true if the attribute a is equal to the value b
- $a < b$ — true if a is less than b
- $a \leq b$ — true if a is less than or equal to b
- $a > b$ — true if a is greater than b
- $a \geq b$ — true if a is greater than or equal to b
- $a \text{ BETWEEN } b \text{ AND } c$ — true if a is greater than or equal to b , and less than or equal to c .

The following function is also supported:

- `begins_with (a, substr)`— true if the value of attribute a begins with a particular substring.

The following AWS Command Line Interface (AWS CLI) examples demonstrate the use of key condition expressions. These expressions use placeholders (such as `:name` and `:sub`) instead of actual values. For more information, see [Expression attribute names in DynamoDB](#) and [Expression attribute values](#).

Example

Query the Thread table for a particular ForumName (partition key). All of the items with that ForumName value are read by the query because the sort key (Subject) is not included in KeyConditionExpression.

```
aws dynamodb query \
--table-name Thread \
--key-condition-expression "ForumName = :name" \
--expression-attribute-values '{":name":{"S":"Amazon DynamoDB"}}'
```

Example

Query the Thread table for a particular ForumName (partition key), but this time return only the items with a given Subject (sort key).

```
aws dynamodb query \
--table-name Thread \
--key-condition-expression "ForumName = :name and Subject = :sub" \
--expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  ":name":{"S":"Amazon DynamoDB"},
  ":sub":{"S":"DynamoDB Thread 1"}
}
```

Example

Query the Reply table for a particular Id (partition key), but return only those items whose ReplyDateTime (sort key) begins with certain characters.

```
aws dynamodb query \
--table-name Reply \
--key-condition-expression "Id = :id and begins_with(ReplyDateTime, :dt)" \
--expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
```

```
:id":{"S":"Amazon DynamoDB#DynamoDB Thread 1"},  
":dt":{"S":"2015-09"}  
}
```

You can use any attribute name in a key condition expression, provided that the first character is a-z or A-Z and the rest of the characters (starting from the second character, if present) are a-z, A-Z, or 0-9. In addition, the attribute name must not be a DynamoDB reserved word. (For a complete list of these, see [Reserved words in DynamoDB](#).) If an attribute name does not meet these requirements, you must define an expression attribute name as a placeholder. For more information, see [Expression attribute names in DynamoDB](#).

For items with a given partition key value, DynamoDB stores these items close together, in sorted order by sort key value. In a Query operation, DynamoDB retrieves the items in sorted order, and then processes the items using KeyConditionExpression and any FilterExpression that might be present. Only then are the Query results sent back to the client.

A Query operation always returns a result set. If no matching items are found, the result set is empty.

Query results are always sorted by the sort key value. If the data type of the sort key is Number, the results are returned in numeric order. Otherwise, the results are returned in order of UTF-8 bytes. By default, the sort order is ascending. To reverse the order, set the ScanIndexForward parameter to false.

A single Query operation can retrieve a maximum of 1 MB of data. This limit applies before any FilterExpression or ProjectionExpression is applied to the results. If LastEvaluatedKey is present in the response and is non-null, you must paginate the result set (see [Paginating table query results](#)).

Filter expressions for the Query operation

If you need to further refine the Query results, you can optionally provide a filter expression. A *filter expression* determines which items within the Query results should be returned to you. All of the other results are discarded.

A filter expression is applied after a Query finishes, but before the results are returned. Therefore, a Query consumes the same amount of read capacity, regardless of whether a filter expression is present.

A Query operation can retrieve a maximum of 1 MB of data. This limit applies before the filter expression is evaluated.

A filter expression cannot contain partition key or sort key attributes. You need to specify those attributes in the key condition expression, not the filter expression.

The syntax for a filter expression is similar to that of a key condition expression. Filter expressions can use the same comparators, functions, and logical operators as a key condition expression. In addition, filter expressions can use the not-equals operator (\neq), the OR operator, the CONTAINS operator, the IN operator, the BEGINS_WITH operator, the BETWEEN operator, the EXISTS operator, and the SIZE operator. For more information, see [Key condition expressions for the Query operation](#) and [Syntax for filter and condition expressions](#).

Example

The following AWS CLI example queries the Thread table for a particular ForumName (partition key) and Subject (sort key). Of the items that are found, only the most popular discussion threads are returned—in other words, only those threads with more than a certain number of Views.

```
aws dynamodb query \
--table-name Thread \
--key-condition-expression "ForumName = :fn and Subject = :sub" \
--filter-expression "#v >= :num" \
--expression-attribute-names '{"#v": "Views"}' \
--expression-attribute-values file://values.json
```

The arguments for --expression-attribute-values are stored in the values.json file.

```
{
  ":fn": {"S": "Amazon DynamoDB"},
  ":sub": {"S": "DynamoDB Thread 1"},
  ":num": {"N": "3"}
}
```

Note that Views is a reserved word in DynamoDB (see [Reserved words in DynamoDB](#)), so this example uses #v as a placeholder. For more information, see [Expression attribute names in DynamoDB](#).

Note

A filter expression removes items from the Query result set. If possible, avoid using Query where you expect to retrieve a large number of items but also need to discard most of those items.

Paginating table query results

DynamoDB *paginates* the results from Query operations. With pagination, the Query results are divided into "pages" of data that are 1 MB in size (or less). An application can process the first page of results, then the second page, and so on.

A single Query only returns a result set that fits within the 1 MB size limit. To determine whether there are more results, and to retrieve them one page at a time, applications should do the following:

1. Examine the low-level Query result:

- If the result contains a LastEvaluatedKey element and it's non-null, proceed to step 2.
- If there is *not* a LastEvaluatedKey in the result, there are no more items to be retrieved.

2. Construct a new Query request, with the same parameters as the previous one. However, this time, take the LastEvaluatedKey value from step 1 and use it as the ExclusiveStartKey parameter in the new Query request.

3. Run the new Query request.

4. Go to step 1.

In other words, the LastEvaluatedKey from a Query response should be used as the ExclusiveStartKey for the next Query request. If there is not a LastEvaluatedKey element in a Query response, then you have retrieved the final page of results. If LastEvaluatedKey is not empty, it does not necessarily mean that there is more data in the result set. The only way to know when you have reached the end of the result set is when LastEvaluatedKey is empty.

You can use the AWS CLI to view this behavior. The AWS CLI sends low-level Query requests to DynamoDB repeatedly, until LastEvaluatedKey is no longer present in the results. Consider the following AWS CLI example that retrieves movie titles from a particular year.

```
aws dynamodb query --table-name Movies \
    --projection-expression "title" \
    --key-condition-expression "#y = :yyyy" \
    --expression-attribute-names '{"#y":"year"}' \
    --expression-attribute-values '{":yyyy":{"N":"1993"}}' \
    --page-size 5 \
    --debug
```

Ordinarily, the AWS CLI handles pagination automatically. However, in this example, the AWS CLI `--page-size` parameter limits the number of items per page. The `--debug` parameter prints low-level information about requests and responses.

If you run the example, the first response from DynamoDB looks similar to the following.

```
2017-07-07 11:13:15,603 - MainThread - botocore.parsers - DEBUG - Response body:  
b'{"Count":5,"Items":[{"title":{"S":"A Bronx Tale"}},  
 {"title":{"S":"A Perfect World"}}, {"title":{"S":"Addams Family Values"}},  
 {"title":{"S":"Alive"}}, {"title":{"S":"Benny & Joon"}]},  
 "LastEvaluatedKey":{"year":{"N":"1993"}, "title":{"S":"Benny & Joon"}},  
 "ScannedCount":5}'
```

The `LastEvaluatedKey` in the response indicates that not all of the items have been retrieved. The AWS CLI then issues another `Query` request to DynamoDB. This request and response pattern continues, until the final response.

```
2017-07-07 11:13:16,291 - MainThread - botocore.parsers - DEBUG - Response body:  
b'{"Count":1,"Items":[{"title":{"S":"What's Eating Gilbert  
Grape"}]}, "ScannedCount":1}'
```

The absence of `LastEvaluatedKey` indicates that there are no more items to retrieve.

Note

The AWS SDKs handle the low-level DynamoDB responses (including the presence or absence of `LastEvaluatedKey`) and provide various abstractions for paginating `Query` results. For example, the SDK for Java document interface provides `java.util.Iterator` support so that you can walk through the results one at a time.

For code examples in various programming languages, see the [Amazon DynamoDB Getting Started Guide](#) and the AWS SDK documentation for your language.

You can also reduce page size by limiting the number of items in the result set, with the `Limit` parameter of the `Query` operation.

For more information about querying with DynamoDB, see [Query operations in DynamoDB](#).

Other aspects of working with the Query operation

Limiting the number of items in the result set

With the Query operation, you can limit the number of items that it reads. To do this, set the Limit parameter to the maximum number of items that you want.

For example, suppose that you Query a table, with a Limit value of 6, and without a filter expression. The Query result contains the first six items from the table that match the key condition expression from the request.

Now suppose that you add a filter expression to the Query. In this case, DynamoDB reads up to six items, and then returns only those that match the filter expression. The final Query result contains six items or fewer, even if more items would have matched the filter expression if DynamoDB had kept reading more items.

Counting the items in the results

In addition to the items that match your criteria, the Query response contains the following elements:

- ScannedCount — The number of items that matched the key condition expression *before* a filter expression (if present) was applied.
- Count — The number of items that remain *after* a filter expression (if present) was applied.

Note

If you don't use a filter expression, ScannedCount and Count have the same value.

If the size of the Query result set is larger than 1 MB, ScannedCount and Count represent only a partial count of the total items. You need to perform multiple Query operations to retrieve all the results (see [Paginating table query results](#)).

Each Query response contains the ScannedCount and Count for the items that were processed by that particular Query request. To obtain grand totals for all of the Query requests, you could keep a running tally of both ScannedCount and Count.

Capacity units consumed by query

You can Query any table or secondary index, as long as you provide the name of the partition key attribute and a single value for that attribute. Query returns all items with that partition key value. Optionally, you can provide a sort key attribute and use a comparison operator to refine the search results. Query API operations consume read capacity units, as follows.

If you Query a...	DynamoDB consumes read capacity units from...
Table	The table's provisioned read capacity.
Global secondary index	The index's provisioned read capacity.
Local secondary index	The base table's provisioned read capacity.

By default, a Query operation does not return any data on how much read capacity it consumes. However, you can specify the `ReturnConsumedCapacity` parameter in a Query request to obtain this information. The following are the valid settings for `ReturnConsumedCapacity`:

- `NONE` — No consumed capacity data is returned. (This is the default.)
- `TOTAL` — The response includes the aggregate number of read capacity units consumed.
- `INDEXES` — The response shows the aggregate number of read capacity units consumed, together with the consumed capacity for each table and index that was accessed.

DynamoDB calculates the number of read capacity units consumed based on the number of items and the size of those items, not on the amount of data that is returned to an application. For this reason, the number of capacity units consumed is the same whether you request all of the attributes (the default behavior) or just some of them (using a projection expression). The number is also the same whether or not you use a filter expression. Query consumes a minimum read capacity unit to perform one strongly consistent read per second, or two eventually consistent reads per second for an item up to 4 KB. If you need to read an item that is larger than 4 KB, DynamoDB needs additional read request units. Empty tables and very large tables which have a sparse amount of partition keys might see some additional RCUs charged beyond the amount of data queried. This covers the cost of serving the Query request, even if no data exists.

Read consistency for query

A Query operation performs eventually consistent reads, by default. This means that the Query results might not reflect changes due to recently completed PutItem or UpdateItem operations. For more information, see [Read consistency](#).

If you require strongly consistent reads, set the ConsistentRead parameter to true in the Query request.

Querying tables and indexes: Java

The Query operation enables you to query a table or a secondary index in Amazon DynamoDB. You must provide a partition key value and an equality condition. If the table or index has a sort key, you can refine the results by providing a sort key value and a condition.

Note

The AWS SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

The following are the steps to retrieve an item using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the table you want to work with.
3. Call the query method of the Table instance. You must specify the partition key value of the items that you want to retrieve, along with any optional query parameters.

The response includes an ItemCollection object that provides all items returned by the query.

The following Java code example demonstrates the preceding tasks. The example assumes that you have a Reply table that stores replies for forum threads. For more information, see [Creating tables and loading data for code examples in DynamoDB](#).

```
Reply ( Id, ReplyDateTime, ... )
```

Each forum thread has a unique ID and can have zero or more replies. Therefore, the Id attribute of the Reply table is composed of both the forum name and forum subject. Id (partition key) and ReplyDateTime (sort key) make up the composite primary key for the table.

The following query retrieves all replies for a specific thread subject. The query requires both the table name and the Subject value.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard()
    .withRegion(Regions.US_WEST_2).build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("Reply");

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("Id = :v_id")
    .WithValueMap(new ValueMap()
        .withString(":v_id", "Amazon DynamoDB#DynamoDB Thread 1"));

ItemCollection<QueryOutcome> items = table.query(spec);

Iterator<Item> iterator = items.iterator();
Item item = null;
while (iterator.hasNext()) {
    item = iterator.next();
    System.out.println(item.toJSONPretty());
}
```

Specifying optional parameters

The `query` method supports several optional parameters. For example, you can optionally narrow the results from the preceding query to return replies in the past two weeks by specifying a condition. The condition is called a sort key condition, because DynamoDB evaluates the query condition that you specify against the sort key of the primary key. You can specify other optional parameters to retrieve only a specific list of attributes from items in the query result.

The following Java code example retrieves forum thread replies posted in the past 15 days. The example specifies optional parameters using the following:

- A `KeyConditionExpression` to retrieve the replies from a specific discussion forum (partition key) and, within that set of items, replies that were posted within the last 15 days (sort key).
- A `FilterExpression` to return only the replies from a specific user. The filter is applied after the query is processed, but before the results are returned to the user.
- A `ValueMap` to define the actual values for the `KeyConditionExpression` placeholders.

- A `ConsistentRead` setting of `true`, to request a strongly consistent read.

This example uses a `QuerySpec` object that gives access to all of the low-level `Query` input parameters.

Example

```
Table table = dynamoDB.getTable("Reply");

long twoWeeksAgoMilli = (new Date()).getTime() - (15L*24L*60L*60L*1000L);
Date twoWeeksAgo = new Date();
twoWeeksAgo.setTime(twoWeeksAgoMilli);
SimpleDateFormat df = new SimpleDateFormat("yyyy-MM-dd'T'HH:mm:ss.SSS'Z'");
String twoWeeksAgoStr = df.format(twoWeeksAgo);

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("Id = :v_id and ReplyDateTime > :v_reply_dt_tm")
    .withFilterExpression("PostedBy = :v_posted_by")
    .WithValueMap(new ValueMap()
        .withString(":v_id", "Amazon DynamoDB#DynamoDB Thread 1")
        .withString(":v_reply_dt_tm", twoWeeksAgoStr)
        .withString(":v_posted_by", "User B"))
    .withConsistentRead(true);

ItemCollection<QueryOutcome> items = table.query(spec);

Iterator<Item> iterator = items.iterator();
while (iterator.hasNext()) {
    System.out.println(iterator.next().toJSONPretty());
}
```

You can also optionally limit the number of items per page by using the `withMaxPageSize` method. When you call the `query` method, you get an `ItemCollection` that contains the resulting items. You can then step through the results, processing one page at a time, until there are no more pages.

The following Java code example modifies the query specification shown previously. This time, the query spec uses the `withMaxPageSize` method. The `Page` class provides an iterator that allows the code to process the items on each page.

Example

```
spec.withMaxPageSize(10);

ItemCollection<QueryOutcome> items = table.query(spec);

// Process each page of results
int pageNum = 0;
for (Page<Item, QueryOutcome> page : items.pages()) {

    System.out.println("\nPage: " + ++pageNum);

    // Process each item on the current page
    Iterator<Item> item = page.iterator();
    while (item.hasNext()) {
        System.out.println(item.next().toJSONPretty());
    }
}
```

Example - query using Java

The following tables store information about a collection of forums. For more information, see [Creating tables and loading data for code examples in DynamoDB](#).

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

Example

```
Forum ( Name, ... )
Thread ( ForumName, Subject, Message, LastPostedBy, LastPostDateTime, ... )
Reply ( Id, ReplyDateTime, Message, PostedBy, ... )
```

In this Java code example, you run variations of finding replies for a thread "DynamoDB Thread 1" in forum "DynamoDB".

- Find replies for a thread.
- Find replies for a thread, specifying a limit on the number of items per page of results. If the number of items in the result set exceeds the page size, you get only the first page of results. This coding pattern ensures that your code processes all the pages in the query result.
- Find replies in the last 15 days.
- Find replies in a specific date range.

The preceding two queries show how you can specify sort key conditions to narrow the query results and use other optional query parameters.

 **Note**

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

```
package com.amazonaws.codesamples.document;

import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.Iterator;

while (iterator.hasNext()) {
    System.out.println(iterator.next().toJSONPretty());
}
}
```

Querying tables and indexes: .NET

The `Query` operation enables you to query a table or a secondary index in Amazon DynamoDB. You must provide a partition key value and an equality condition. If the table or index has a sort key, you can refine the results by providing a sort key value and a condition.

The following are the steps to query a table using the low-level AWS SDK for .NET API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `QueryRequest` class and provide query operation parameters.
3. Run the `Query` method and provide the `QueryRequest` object that you created in the preceding step.

The response includes the `QueryResult` object that provides all items returned by the query.

The following C# code example demonstrates the preceding tasks. The code assumes that you have a `Reply` table that stores replies for forum threads. For more information, see [Creating tables and loading data for code examples in DynamoDB](#).

Example

```
Reply Id, ReplyDateTime, ... )
```

Each forum thread has a unique ID and can have zero or more replies. Therefore, the primary key is composed of both the Id (partition key) and ReplyDateTime (sort key).

The following query retrieves all replies for a specific thread subject. The query requires both the table name and the Subject value.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();

var request = new QueryRequest
{
    TableName = "Reply",
    KeyConditionExpression = "Id = :v_Id",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 1" }}}
};

var response = client.Query(request);

foreach (Dictionary<string, AttributeValue> item in response.Items)
{
    // Process the result.
    PrintItem(item);
}
```

Specifying optional parameters

The `Query` method supports several optional parameters. For example, you can optionally narrow the query result in the preceding query to return replies in the past two weeks by specifying a condition. The condition is called a *sort key condition*, because DynamoDB evaluates the query condition that you specify against the sort key of the primary key. You can specify other optional parameters to retrieve only a specific list of attributes from items in the query result. For more information, see [Query](#).

The following C# code example retrieves forum thread replies posted in the past 15 days. The example specifies the following optional parameters:

- A KeyConditionExpression to retrieve only the replies in the past 15 days.
- A ProjectionExpression parameter to specify a list of attributes to retrieve for items in the query result.
- A ConsistentRead parameter to perform a strongly consistent read.

Example

```
DateTime twoWeeksAgoDate = DateTime.UtcNow - TimeSpan.FromDays(15);
string twoWeeksAgoString = twoWeeksAgoDate.ToString(AWSSDKUtils.ISO8601DateFormat);

var request = new QueryRequest
{
    TableName = "Reply",
    KeyConditionExpression = "Id = :v_Id and ReplyDateTime > :v_twoWeeksAgo",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 2" }},
        {":v_twoWeeksAgo", new AttributeValue { S = twoWeeksAgoString }}
    },
    ProjectionExpression = "Subject, ReplyDateTime, PostedBy",
    ConsistentRead = true
};

var response = client.Query(request);

foreach (Dictionary<string, AttributeValue> item in response.Items)
{
    // Process the result.
    PrintItem(item);
}
```

You can also optionally limit the page size, or the number of items per page, by adding the optional Limit parameter. Each time you run the Query method, you get one page of results that has the specified number of items. To fetch the next page, you run the Query method again by providing the primary key value of the last item in the previous page so that the method can return the next set of items. You provide this information in the request by setting the ExclusiveStartKey property. Initially, this property can be null. To retrieve subsequent pages, you must update this property value to the primary key of the last item in the preceding page.

The following C# example queries the Reply table. In the request, it specifies the `Limit` and `ExclusiveStartKey` optional parameters. The do/while loop continues to scan one page at time until the `LastEvaluatedKey` returns a null value.

Example

```
Dictionary<string,AttributeValue> lastKeyEvaluated = null;

do
{
    var request = new QueryRequest
    {
        TableName = "Reply",
        KeyConditionExpression = "Id = :v_Id",
        ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
            {"":v_Id", new AttributeValue { S = "Amazon DynamoDB#DynamoDB Thread 2" }},
        },

        // Optional parameters.
        Limit = 1,
        ExclusiveStartKey = lastKeyEvaluated
    };

    var response = client.Query(request);

    // Process the query result.
    foreach (Dictionary<string, AttributeValue> item in response.Items)
    {
        PrintItem(item);
    }

    lastKeyEvaluated = response.LastEvaluatedKey;
} while (lastKeyEvaluated != null && lastKeyEvaluated.Count != 0);
```

Example - querying using the AWS SDK for .NET

The following tables store information about a collection of forums. For more information, see [Creating tables and loading data for code examples in DynamoDB](#).

Example

```
Forum ( Name, ... )
Thread ( ForumName, Subject, Message, LastPostedBy, LastPostDateTime, ... )
Reply ( Id, ReplyDateTime, Message, PostedBy, ... )
```

In this example, you run variations of "Find replies for a thread "DynamoDB Thread 1" in forum "DynamoDB".

- Find replies for a thread.
- Find replies for a thread. Specify the `Limit` query parameter to set page size.

This function illustrates the use of pagination to process multipage result. DynamoDB has a page size limit and if your result exceeds the page size, you get only the first page of results. This coding pattern ensures your code processes all the pages in the query result.

- Find replies in the last 15 days.
- Find replies in a specific date range.

The preceding two queries show how you can specify sort key conditions to narrow query results and use other optional query parameters.

For step-by-step instructions for testing the following example, see [.NET code examples](#).

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.Util;

namespace com.amazonaws.codesamples
{
    class LowLevelQuery
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
```

```
// Query a specific forum and thread.

```

Working with scans in DynamoDB

A Scan operation in Amazon DynamoDB reads every item in a table or a secondary index. By default, a Scan operation returns all of the data attributes for every item in the table or index. You can use the `ProjectionExpression` parameter so that Scan only returns some of the attributes, rather than all of them.

Scan always returns a result set. If no matching items are found, the result set is empty.

A single Scan request can retrieve a maximum of 1 MB of data. Optionally, DynamoDB can apply a filter expression to this data, narrowing the results before they are returned to the user.

Topics

- [Filter expressions for scan](#)
- [Limiting the number of items in the result set](#)
- [Paginating the results](#)
- [Counting the items in the results](#)
- [Capacity units consumed by scan](#)
- [Read consistency for scan](#)
- [Parallel scan](#)
- [Scanning tables and indexes: Java](#)
- [Scanning tables and indexes: .NET](#)

Filter expressions for scan

If you need to further refine the Scan results, you can optionally provide a filter expression. A *filter expression* determines which items within the Scan results should be returned to you. All of the other results are discarded.

A filter expression is applied after a Scan finishes but before the results are returned. Therefore, a Scan consumes the same amount of read capacity, regardless of whether a filter expression is present.

A Scan operation can retrieve a maximum of 1 MB of data. This limit applies before the filter expression is evaluated.

With Scan, you can specify any attributes in a filter expression—including partition key and sort key attributes.

The syntax for a filter expression is identical to that of a condition expression. Filter expressions can use the same comparators, functions, and logical operators as a condition expression. See [Comparison operator and function reference](#) for more information about logical operators.

Example

The following AWS Command Line Interface (AWS CLI) example scans the Thread table and returns only the items that were last posted to by a particular user.

```
aws dynamodb scan \
    --table-name Thread \
    --filter-expression "LastPostedBy = :name" \
    --expression-attribute-values '{":name":{"S":"User A"}}'
```

Limits the number of items in the result set

The Scan operation enables you to limit the number of items that it returns in the result. To do this, set the Limit parameter to the maximum number of items that you want the Scan operation to return, prior to filter expression evaluation.

For example, suppose that you Scan a table with a Limit value of 6 and without a filter expression. The Scan result contains the first six items from the table.

Now suppose that you add a filter expression to the Scan. In this case, DynamoDB applies the filter expression to the six items that were returned, discarding those that do not match. The final Scan result contains six items or fewer, depending on the number of items that were filtered.

Paginating the results

DynamoDB *paginates* the results from Scan operations. With pagination, the Scan results are divided into "pages" of data that are 1 MB in size (or less). An application can process the first page of results, then the second page, and so on.

A single Scan only returns a result set that fits within the 1 MB size limit.

To determine whether there are more results and to retrieve them one page at a time, applications should do the following:

1. Examine the low-level Scan result:
 - If the result contains a LastEvaluatedKey element, proceed to step 2.
 - If there is *not* a LastEvaluatedKey in the result, then there are no more items to be retrieved.
2. Construct a new Scan request, with the same parameters as the previous one. However, this time, take the LastEvaluatedKey value from step 1 and use it as the ExclusiveStartKey parameter in the new Scan request.
3. Run the new Scan request.
4. Go to step 1.

In other words, the `LastEvaluatedKey` from a `Scan` response should be used as the `ExclusiveStartKey` for the next `Scan` request. If there is not a `LastEvaluatedKey` element in a `Scan` response, you have retrieved the final page of results. (The absence of `LastEvaluatedKey` is the only way to know that you have reached the end of the result set.)

You can use the AWS CLI to view this behavior. The AWS CLI sends low-level `Scan` requests to DynamoDB, repeatedly, until `LastEvaluatedKey` is no longer present in the results. Consider the following AWS CLI example that scans the entire `Movies` table but returns only the movies from a particular genre.

```
aws dynamodb scan \
--table-name Movies \
--projection-expression "title" \
--filter-expression 'contains(info.genres,:gen)' \
--expression-attribute-values '{":gen":{"S":"Sci-Fi"}}' \
--page-size 100 \
--debug
```

Ordinarily, the AWS CLI handles pagination automatically. However, in this example, the AWS CLI `--page-size` parameter limits the number of items per page. The `--debug` parameter prints low-level information about requests and responses.

Note

Your pagination results will also differ based on the input parameters you pass.

- Using `aws dynamodb scan --table-name Prices --max-items 1` returns a `NextToken`
- Using `aws dynamodb scan --table-name Prices --limit 1` returns a `LastEvaluatedKey`.

Also be aware that using `--starting-token` in particular requires the `NextToken` value.

If you run the example, the first response from DynamoDB looks similar to the following.

```
2017-07-07 12:19:14,389 - MainThread - botocore.parsers - DEBUG - Response body:
b'{"Count":7,"Items":[{"title":{"S":"Monster on the Campus"}}, {"title":{"S":"+1"}},
```

```
{"title":{"S":"100 Degrees Below Zero"}}, {"title":{"S":"About Time"}}, {"title":{"S":"After Earth"}}, {"title":{"S":"Age of Dinosaurs"}}, {"title":{"S":"Cloudy with a Chance of Meatballs 2"}]}, {"LastEvaluatedKey": {"year": {"N": "2013"}, "title": {"S": "Curse of Chucky"}}, "ScannedCount": 100}
```

The `LastEvaluatedKey` in the response indicates that not all of the items have been retrieved. The AWS CLI then issues another Scan request to DynamoDB. This request and response pattern continues, until the final response.

```
2017-07-07 12:19:17,830 - MainThread - botocore.parsers - DEBUG - Response body:  
b'{"Count":1,"Items":[{"title":{"S":"WarGames"}}], "ScannedCount":6}'
```

The absence of `LastEvaluatedKey` indicates that there are no more items to retrieve.

Note

The AWS SDKs handle the low-level DynamoDB responses (including the presence or absence of `LastEvaluatedKey`) and provide various abstractions for paginating Scan results. For example, the SDK for Java document interface provides `java.util.Iterator` support so that you can walk through the results one at a time.

For code examples in various programming languages, see the [Amazon DynamoDB Getting Started Guide](#) and the AWS SDK documentation for your language.

Counting the items in the results

In addition to the items that match your criteria, the Scan response contains the following elements:

- `ScannedCount` — The number of items evaluated, before any `ScanFilter` is applied. A high `ScannedCount` value with few, or no, `Count` results indicates an inefficient Scan operation. If you did not use a filter in the request, `ScannedCount` is the same as `Count`.
- `Count` — The number of items that remain, *after* a filter expression (if present) was applied.

Note

If you do not use a filter expression, ScannedCount and Count have the same value.

If the size of the Scan result set is larger than 1 MB, ScannedCount and Count represent only a partial count of the total items. You need to perform multiple Scan operations to retrieve all the results (see [Paginating the results](#)).

Each Scan response contains the ScannedCount and Count for the items that were processed by that particular Scan request. To get grand totals for all of the Scan requests, you could keep a running tally of both ScannedCount and Count.

Capacity units consumed by scan

You can Scan any table or secondary index. Scan operations consume read capacity units, as follows.

If you Scan a...	DynamoDB consumes read capacity units from...
Table	The table's provisioned read capacity.
Global secondary index	The index's provisioned read capacity.
Local secondary index	The base table's provisioned read capacity.

By default, a Scan operation does not return any data on how much read capacity it consumes. However, you can specify the `ReturnConsumedCapacity` parameter in a Scan request to obtain this information. The following are the valid settings for `ReturnConsumedCapacity`:

- `NONE` — No consumed capacity data is returned. (This is the default.)
- `TOTAL` — The response includes the aggregate number of read capacity units consumed.
- `INDEXES` — The response shows the aggregate number of read capacity units consumed, together with the consumed capacity for each table and index that was accessed.

DynamoDB calculates the number of read capacity units consumed based on the number of items and the size of those items, not on the amount of data that is returned to an application.

For this reason, the number of capacity units consumed is the same whether you request all of the attributes (the default behavior) or just some of them (using a projection expression). The number is also the same whether or not you use a filter expression. Scan consumes a minimum read capacity unit to perform one strongly consistent read per second, or two eventually consistent reads per second for an item up to 4 KB. If you need to read an item that is larger than 4 KB, DynamoDB needs additional read request units. Empty tables and very large tables which have a sparse amount of partition keys might see some additional RCUs charged beyond the amount of data scanned. This covers the cost of serving the Scan request, even if no data exists.

Read consistency for scan

A Scan operation performs eventually consistent reads, by default. This means that the Scan results might not reflect changes due to recently completed PutItem or UpdateItem operations. For more information, see [Read consistency](#).

If you require strongly consistent reads, as of the time that the Scan begins, set the ConsistentRead parameter to true in the Scan request. This ensures that all of the write operations that completed before the Scan began are included in the Scan response.

Setting ConsistentRead to true can be useful in table backup or replication scenarios, in conjunction with [DynamoDB Streams](#). You first use Scan with ConsistentRead set to true to obtain a consistent copy of the data in the table. During the Scan, DynamoDB Streams records any additional write activity that occurs on the table. After the Scan is complete, you can apply the write activity from the stream to the table.

 **Note**

A Scan operation with ConsistentRead set to true consumes twice as many read capacity units as compared to leaving ConsistentRead at its default value (false).

Parallel scan

By default, the Scan operation processes data sequentially. Amazon DynamoDB returns data to the application in 1 MB increments, and an application performs additional Scan operations to retrieve the next 1 MB of data.

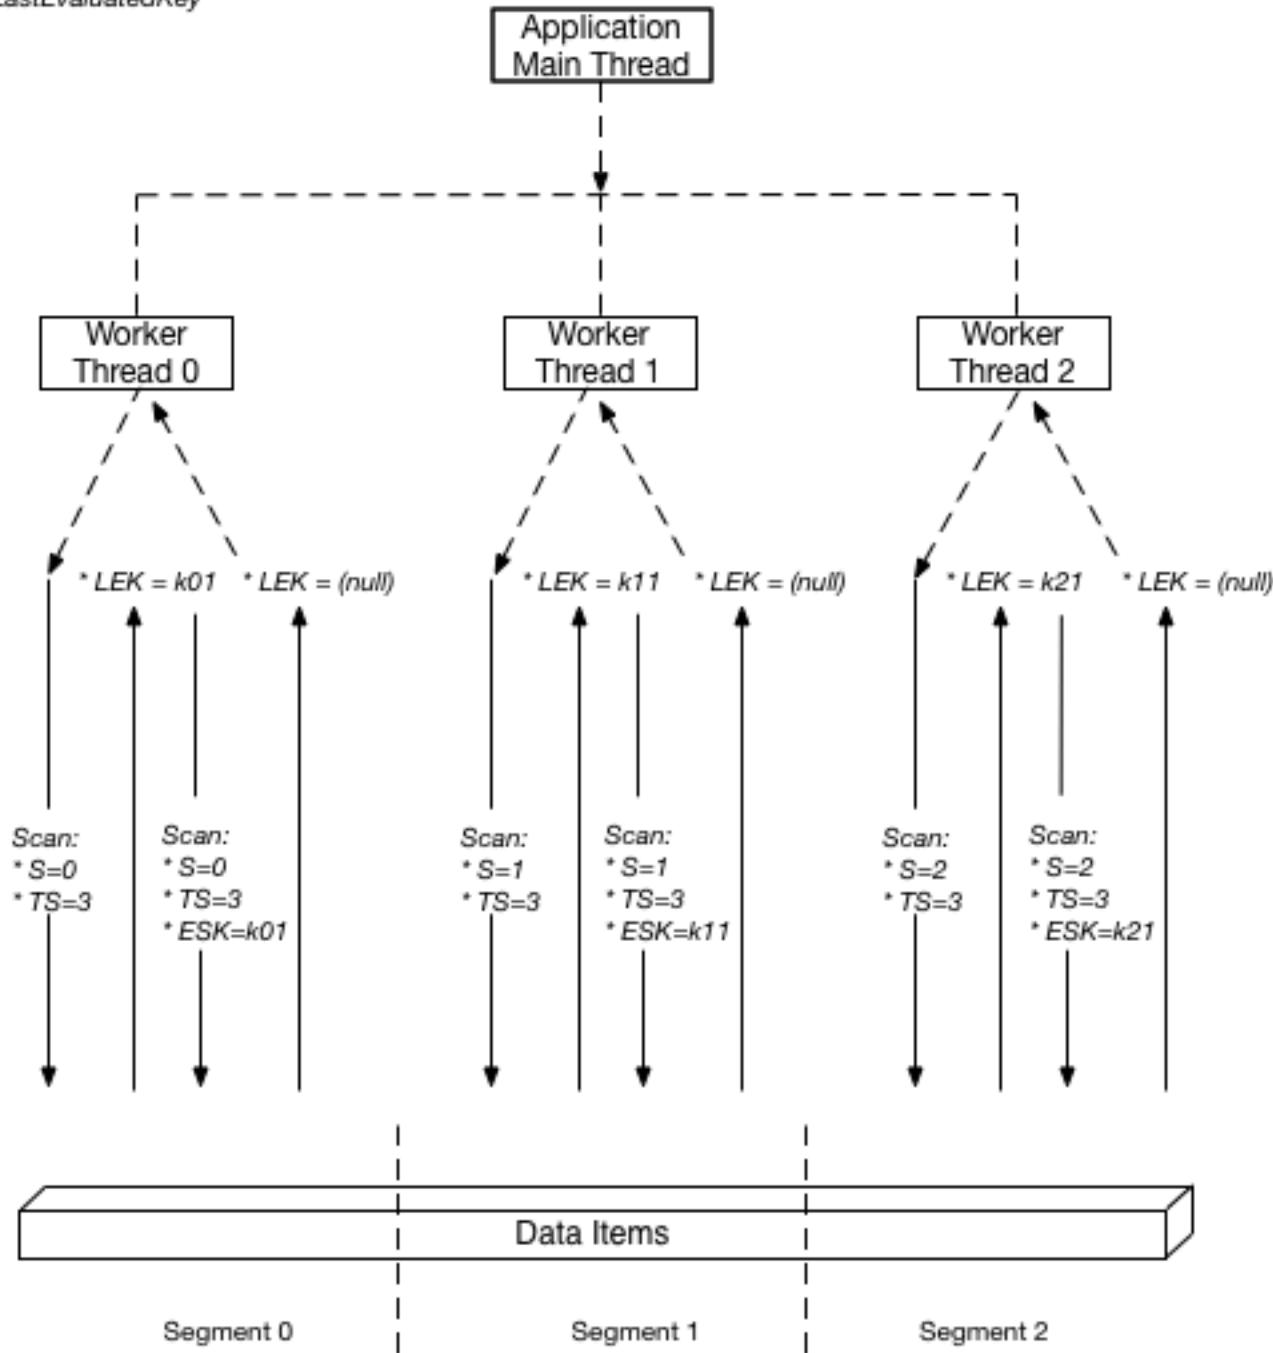

The larger the table or index being scanned, the more time the Scan takes to complete. In addition, a sequential Scan might not always be able to fully use the provisioned read throughput

capacity: Even though DynamoDB distributes a large table's data across multiple physical partitions, a Scan operation can only read one partition at a time. For this reason, the throughput of a Scan is constrained by the maximum throughput of a single partition.

To address these issues, the Scan operation can logically divide a table or secondary index into multiple *segments*, with multiple application workers scanning the segments in parallel. Each worker can be a thread (in programming languages that support multithreading) or an operating system process. To perform a parallel scan, each worker issues its own Scan request with the following parameters:

- Segment — A segment to be scanned by a particular worker. Each worker should use a different value for Segment.
- TotalSegments — The total number of segments for the parallel scan. This value must be the same as the number of workers that your application will use.

The following diagram shows how a multithreaded application performs a parallel Scan with three degrees of parallelism.

*S: Segment**TS: TotalSegments**ESK: ExclusiveStartKey**LEK: LastEvaluatedKey*

In this diagram, the application spawns three threads and assigns each thread a number. (Segments are zero-based, so the first number is always 0.) Each thread issues a Scan request, setting Segment to its designated number and setting TotalSegments to 3. Each thread scans its

designated segment, retrieving data 1 MB at a time, and returns the data to the application's main thread.

The values for Segment and TotalSegments apply to individual Scan requests, and you can use different values at any time. You might need to experiment with these values, and the number of workers you use, until your application achieves its best performance.

Note

A parallel scan with a large number of workers can easily consume all of the provisioned throughput for the table or index being scanned. It is best to avoid such scans if the table or index is also incurring heavy read or write activity from other applications.

To control the amount of data returned per request, use the Limit parameter. This can help prevent situations where one worker consumes all of the provisioned throughput, at the expense of all other workers.

Scanning tables and indexes: Java

The Scan operation reads all of the items in a table or index in Amazon DynamoDB.

The following are the steps to scan a table using the AWS SDK for Java Document API.

1. Create an instance of the AmazonDynamoDB class.
2. Create an instance of the ScanRequest class and provide scan parameter.

The only required parameter is the table name.

3. Run the scan method and provide the ScanRequest object that you created in the preceding step.

The following Reply table stores replies for forum threads.

Example

```
Reply ( Id, ReplyDateTime, Message, PostedBy )
```

The table maintains all the replies for various forum threads. Therefore, the primary key is composed of both the Id (partition key) and ReplyDateTime (sort key). The following Java code example scans the entire table. The ScanRequest instance specifies the name of the table to scan.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();

ScanRequest scanRequest = new ScanRequest()
    .withTableName("Reply");

ScanResponse result = client.scan(scanRequest);
for (Map<String, AttributeValue> item : result.getItems()){
    printItem(item);
}
```

Specifying optional parameters

The scan method supports several optional parameters. For example, you can optionally use a filter expression to filter the scan result. In a filter expression, you can specify a condition and attribute names and values on which you want the condition evaluated. For more information, see [Scan](#).

The following Java example scans the ProductCatalog table to find items that are priced less than 0. The example specifies the following optional parameters:

- A filter expression to retrieve only the items priced less than 0 (error condition).
- A list of attributes to retrieve for items in the query results.

Example

```
Map<String, AttributeValue> expressionAttributeValues =
    new HashMap<String, AttributeValue>();
expressionAttributeValues.put(":val", new AttributeValue().withN("0"));

ScanRequest scanRequest = new ScanRequest()
    .withTableName("ProductCatalog")
    .withFilterExpression("Price < :val")
    .withProjectionExpression("Id")
    .withExpressionAttributeValues(expressionAttributeValues);
```

```
ScanResponse result = client.scan(scanRequest);
for (Map<String, AttributeValue> item : result.getItems()) {
    printItem(item);
}
```

You can also optionally limit the page size, or the number of items per page, by using the `withLimit` method of the scan request. Each time you run the `scan` method, you get one page of results that has the specified number of items. To fetch the next page, you run the `scan` method again by providing the primary key value of the last item in the previous page so that the `scan` method can return the next set of items. You provide this information in the request by using the `withExclusiveStartKey` method. Initially, the parameter of this method can be null. To retrieve subsequent pages, you must update this property value to the primary key of the last item in the preceding page.

The following Java code example scans the `ProductCatalog` table. In the request, the `withLimit` and `withExclusiveStartKey` methods are used. The `do/while` loop continues to scan one page at time until the `getLastEvaluatedKey` method of the result returns a value of null.

Example

```
Map<String, AttributeValue> lastKeyEvaluated = null;
do {
    ScanRequest scanRequest = new ScanRequest()
        .withTableName("ProductCatalog")
        .withLimit(10)
        .withExclusiveStartKey(lastKeyEvaluated);

    ScanResponse result = client.scan(scanRequest);
    for (Map<String, AttributeValue> item : result.getItems()){
        printItem(item);
    }
    lastKeyEvaluated = result.getLastEvaluatedKey();
} while (lastKeyEvaluated != null);
```

Example - scan using Java

The following Java code example provides a working sample that scans the `ProductCatalog` table to find items that are priced less than 100.

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

```
package com.amazonaws.codesamples.document;

import java.util.HashMap;
import java.util.Iterator;
import java.util.Map;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
import com.amazonaws.services.dynamodbv2.AmazonDynamoDBClientBuilder;
import com.amazonaws.services.dynamodbv2.document.DynamoDB;
import com.amazonaws.services.dynamodbv2.document.Item;
import com.amazonaws.services.dynamodbv2.document.ItemCollection;
import com.amazonaws.services.dynamodbv2.document.ScanOutcome;
import com.amazonaws.services.dynamodbv2.document.Table;

public class DocumentAPIScan {

    static AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
    static DynamoDB dynamoDB = new DynamoDB(client);
    static String tableName = "ProductCatalog";

    public static void main(String[] args) throws Exception {
        findProductsForPriceLessThanOneHundred();
    }
}
```

```
private static void findProductsForPriceLessThanOneHundred() {  
  
    Table table = dynamoDB.getTable(tableName);  
  
    Map<String, Object> expressionAttributeValues = new HashMap<String, Object>();  
    expressionAttributeValues.put(":pr", 100);  
  
    ItemCollection<ScanOutcome> items = table.scan("Price < :pr", //  
FilterExpression  
        "Id, Title, ProductCategory, Price", // ProjectionExpression  
        null, // ExpressionAttributeNames - not used in this example  
        expressionAttributeValues);  
  
    System.out.println("Scan of " + tableName + " for items with a price less than  
100.");  
    Iterator<Item> iterator = items.iterator();  
    while (iterator.hasNext()) {  
        System.out.println(iterator.next().toJSONPretty());  
    }  
}  
  
}
```

Example - parallel scan using Java

The following Java code example demonstrates a parallel scan. The program deletes and re-creates a table named ParallelScanTest, and then loads the table with data. When the data load is finished, the program spawns multiple threads and issues parallel Scan requests. The program prints runtime statistics for each parallel request.

Note

The SDK for Java also provides an object persistence model, enabling you to map your client-side classes to DynamoDB tables. This approach can reduce the amount of code that you have to write. For more information, see [Java 1.x: DynamoDBMapper](#).

Note

This code example assumes that you have already loaded data into DynamoDB for your account by following the instructions in the [Creating tables and loading data for code examples in DynamoDB](#) section.

For step-by-step instructions to run the following example, see [Java code examples](#).

}  
}
```

Scanning tables and indexes: .NET

The Scan operation reads all of the items in a table or index in Amazon DynamoDB.

The following are the steps to scan a table using the AWS SDK for .NET low-level API:

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `ScanRequest` class and provide scan operation parameters.
The only required parameter is the table name.
3. Run the `Scan` method and provide the `ScanRequest` object that you created in the preceding step.

The following Reply table stores replies for forum threads.

Example

```
>Reply ( <emphasis role="underline">Id</emphasis>, <emphasis  
role="underline">ReplyDateTime</emphasis>, Message, PostedBy )
```

The table maintains all the replies for various forum threads. Therefore, the primary key is composed of both the `Id` (partition key) and `ReplyDateTime` (sort key). The following C# code example scans the entire table. The `ScanRequest` instance specifies the name of the table to scan.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();  
  
var request = new ScanRequest  
{  
    TableName = "Reply",  
};  
  
var response = client.Scan(request);  
var result = response.ScanResult;
```

```
foreach (Dictionary<string, AttributeValue> item in response.ScanResult.Items)
{
    // Process the result.
    PrintItem(item);
}
```

Specifying optional parameters

The Scan method supports several optional parameters. For example, you can optionally use a scan filter to filter the scan result. In a scan filter, you can specify a condition and an attribute name on which you want the condition evaluated. For more information, see [Scan](#).

The following C# code scans the ProductCatalog table to find items that are priced less than 0. The sample specifies the following optional parameters:

- A FilterExpression parameter to retrieve only the items priced less than 0 (error condition).
- A ProjectionExpression parameter to specify the attributes to retrieve for items in the query results.

The following C# example scans the ProductCatalog table to find all items priced less than 0.

Example

```
var forumScanRequest = new ScanRequest
{
    TableName = "ProductCatalog",
    // Optional parameters.
    ExpressionAttributeValues = new Dictionary<string,AttributeValue> {
        {":val", new AttributeValue { N = "0" }}
    },
    FilterExpression = "Price < :val",
    ProjectionExpression = "Id"
};
```

You can also optionally limit the page size or the number of items per page, by adding the optional Limit parameter. Each time you run the Scan method, you get one page of results that has the specified number of items. To fetch the next page, you run the Scan method again by providing the primary key value of the last item in the previous page so that the Scan method can return the next set of items. You provide this information in the request by setting the ExclusiveStartKey

property. Initially, this property can be null. To retrieve subsequent pages, you must update this property value to the primary key of the last item in the preceding page.

The following C# code example scans the ProductCatalog table. In the request, it specifies the Limit and ExclusiveStartKey optional parameters. The do/while loop continues to scan one page at time until the LastEvaluatedKey returns a null value.

Example

```
Dictionary<string, AttributeValue> lastKeyEvaluated = null;
do
{
    var request = new ScanRequest
    {
        TableName = "ProductCatalog",
        Limit = 10,
        ExclusiveStartKey = lastKeyEvaluated
    };

    var response = client.Scan(request);

    foreach (Dictionary<string, AttributeValue> item
        in response.Items)
    {
        PrintItem(item);
    }
    lastKeyEvaluated = response.LastEvaluatedKey;

} while (lastKeyEvaluated != null && lastKeyEvaluated.Count != 0);
```

Example - scan using .NET

The following C# code provides a working example that scans the ProductCatalog table to find items priced less than 0.

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

```
using System;
using System.Collections.Generic;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
```

```
namespace com.amazonaws.codesamples
{
    class LowLevelScan
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();

        static void Main(string[] args)
        {
            try
            {
                FindProductsForPriceLessThanZero();

                Console.WriteLine("Example complete. To continue, press Enter");
                Console.ReadLine();
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
                Console.WriteLine("To continue, press Enter");
                Console.ReadLine();
            }
        }

        private static void FindProductsForPriceLessThanZero()
        {
            Dictionary<string, AttributeValue> lastKeyEvaluated = null;
            do
            {
                var request = new ScanRequest
                {
                    TableName = "ProductCatalog",
                    Limit = 2,
                    ExclusiveStartKey = lastKeyEvaluated,
                    ExpressionAttributeValues = new Dictionary<string, AttributeValue>
                {
                    {":val", new AttributeValue {
                        N = "0"
                    }}
                },
                FilterExpression = "Price < :val",
                ProjectionExpression = "Id, Title, Price"
            };
        }
    }
}
```

```
        var response = client.Scan(request);

        foreach (Dictionary<string, AttributeValue> item
            in response.Items)
        {
            Console.WriteLine("\nScanThreadTableUsePaging - printing.....");
            PrintItem(item);
        }
        lastKeyEvaluated = response.LastEvaluatedKey;
    } while (lastKeyEvaluated != null && lastKeyEvaluated.Count != 0);

    Console.WriteLine("To continue, press Enter");
    Console.ReadLine();
}

private static void PrintItem(
    Dictionary<string, AttributeValue> attributeList)
{
    foreach (KeyValuePair<string, AttributeValue> kvp in attributeList)
    {
        string attributeName = kvp.Key;
        AttributeValue value = kvp.Value;

        Console.WriteLine(
            attributeName + " " +
            (value.S == null ? "" : "S=[[" + value.S + "]]") +
            (value.N == null ? "" : "N=[[" + value.N + "]]") +
            (value.SS == null ? "" : "SS=[[" + string.Join(",", 
value.SS.ToArray()) + "]]") +
            (value.NS == null ? "" : "NS=[[" + string.Join(",", 
value.NS.ToArray()) + "]]")
        );
    }
    Console.WriteLine("*****");
}
}
```

Example - parallel scan using .NET

The following C# code example demonstrates a parallel scan. The program deletes and then recreates the ProductCatalog table and then loads the table with data. When the data load is

finished, the program spawns multiple threads and issues parallel Scan requests. Finally, the program prints a summary of runtime statistics.

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

```
using System;
using System.Collections.Generic;
using System.Threading;
using System.Threading.Tasks;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;

namespace com.amazonaws.codesamples
{
    class LowLevelParallelScan
    {
        private static AmazonDynamoDBClient client = new AmazonDynamoDBClient();
        private static string tableName = "ProductCatalog";
        private static int exampleItemCount = 100;
        private static int scanItemLimit = 10;
        private static int totalSegments = 5;

        static void Main(string[] args)
        {
            try
            {
                DeleteExampleTable();
                CreateExampleTable();
                UploadExampleData();
                ParallelScanExampleTable();
            }
            catch (AmazonDynamoDBException e) { Console.WriteLine(e.Message); }
            catch (AmazonServiceException e) { Console.WriteLine(e.Message); }
            catch (Exception e) { Console.WriteLine(e.Message); }

            Console.WriteLine("To continue, press Enter");
            Console.ReadLine();
        }

        private static void ParallelScanExampleTable()
        {
```

```
        Console.WriteLine("\n*** Creating {0} Parallel Scan Tasks to scan {1}",  
totalSegments, tableName);  
        Task[] tasks = new Task[totalSegments];  
        for (int segment = 0; segment < totalSegments; segment++)  
{  
            int tmpSegment = segment;  
            Task task = Task.Factory.StartNew(() =>  
            {  
                ScanSegment(totalSegments, tmpSegment);  
            });  
  
            tasks[segment] = task;  
        }  
  
        Console.WriteLine("All scan tasks are created, waiting for them to  
complete.");  
        Task.WaitAll(tasks);  
  
        Console.WriteLine("All scan tasks are completed.");  
    }  
  
    private static void ScanSegment(int totalSegments, int segment)  
{  
        Console.WriteLine("**** Starting to Scan Segment {0} of {1} out of {2} total  
segments ****", segment, tableName, totalSegments);  
        Dictionary<string, AttributeValue> lastEvaluatedKey = null;  
        int totalScannedItemCount = 0;  
        int totalScanRequestCount = 0;

PartiQL - a SQL-compatible query language for Amazon DynamoDB

Amazon DynamoDB supports [PartiQL](#), a SQL-compatible query language, to select, insert, update, and delete data in Amazon DynamoDB. Using PartiQL, you can easily interact with DynamoDB tables and run ad hoc queries using the AWS Management Console, NoSQL Workbench, AWS Command Line Interface, and DynamoDB APIs for PartiQL.

PartiQL operations provide the same availability, latency, and performance as the other DynamoDB data plane operations.

The following sections describe the DynamoDB implementation of PartiQL.

Topics

- [What is PartiQL?](#)
- [PartiQL in Amazon DynamoDB](#)
- [Getting started with PartiQL for DynamoDB](#)
- [PartiQL data types for DynamoDB](#)
- [PartiQL statements for DynamoDB](#)
- [Use PartiQL functions with amazon DynamoDB](#)
- [PartiQL arithmetic, comparison, and logical operators for DynamoDB](#)
- [Performing transactions with PartiQL for DynamoDB](#)
- [Running batch operations with PartiQL for DynamoDB](#)
- [IAM security policies with PartiQL for DynamoDB](#)

What is PartiQL?

PartiQL provides SQL-compatible query access across multiple data stores containing structured data, semistructured data, and nested data. It is widely used within Amazon and is now available as part of many AWS services, including DynamoDB.

For the PartiQL specification and a tutorial on the core query language, see the [PartiQL documentation](#).

Note

- Amazon DynamoDB supports a *subset* of the [PartiQL](#) query language.
- Amazon DynamoDB does not support the [Amazon ion](#) data format or Amazon Ion literals.

PartiQL in Amazon DynamoDB

To run PartiQL queries in DynamoDB, you can use:

- The DynamoDB console
- The NoSQL Workbench
- The AWS Command Line Interface (AWS CLI)
- The DynamoDB APIs

For information about using these methods to access DynamoDB, see [Accessing DynamoDB](#).

Getting started with PartiQL for DynamoDB

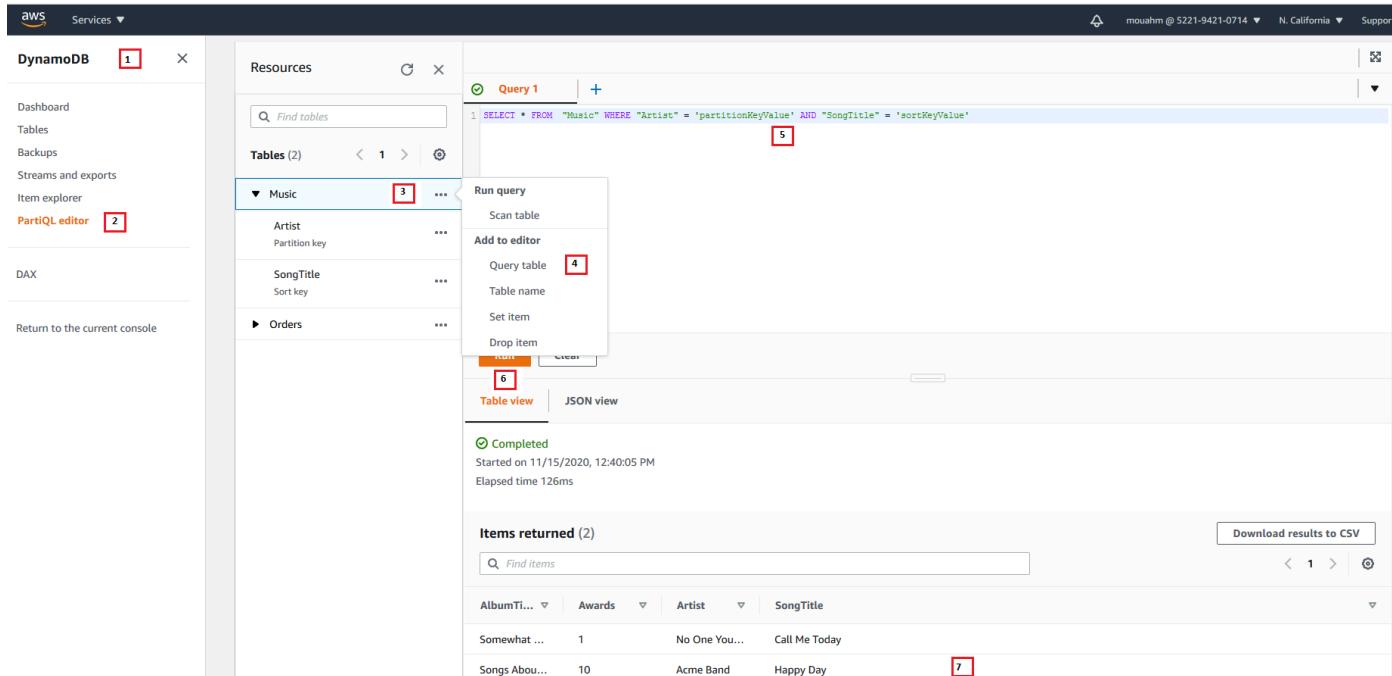

This section describes how to use PartiQL for DynamoDB from the Amazon DynamoDB console, the AWS Command Line Interface (AWS CLI), and DynamoDB APIs.

In the following examples, the DynamoDB table that is defined in the [Getting started with DynamoDB](#) tutorial is a pre-requisite.

For information about using the DynamoDB console, AWS Command Line Interface, or DynamoDB APIs to access DynamoDB, see [Accessing DynamoDB](#).

To [download](#) and use the [NoSQL workbench](#) to build [PartiQL for DynamoDB](#) statements choose **PartiQL operations** at the top right corner of the NoSQL Workbench for DynamoDB [Operation builder](#).

Console

Note

PartiQL for DynamoDB is only available in the new DynamoDB console. To use the new DynamoDB console, choose **Try the Preview of the new console** in the navigation pane on the left side of the console.

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **PartiQL editor**.
3. Choose the **Music** table.
4. Choose **Query table**. This action generates a query that will not result in a full table scan.
5. Replace `partitionKeyValue` with the string value `Acme Band`. Replace `sortKeyValue` with the string value `Happy Day`.
6. Choose the **Run** button.
7. You can view the results of the query by choosing the **Table view** or the **JSON view** buttons.

NoSQL workbench

The screenshot shows the NoSQL workbench interface. At the top, there are three radio button options: "PartiQL statement" (selected), "PartiQL transaction", and "PartiQL batch". Below this, a "Statement" input field contains the following PartiQL code:

```
1 | SELECT *
2 | FROM Music
3 | WHERE Artist=? and SongTitle=?
```

Number 1 is highlighted around the first line of the code. Number 2 is highlighted around the third line of the code.

Below the statement, there is a section for "Optional request parameters" with a dropdown menu showing "3.a". Number 3.a is highlighted around this dropdown.

Further down, there is a toggle switch for "Enable strongly consistent reads" and a "Parameters" section. The "Parameters" section contains two entries:

Attribute type	Attribute value
String	Acme Band
String	PartiQL Rocks

Number 3.c is highlighted around the "Attribute value" field for the first entry. Number 3.b is highlighted around the "+ Add new parameter" button.

At the bottom of the interface are four buttons: "Clear form", "Run", "Generate code", and "Save operation". Number 5 is highlighted around the "Run" button, number 4 is highlighted around the "Generate code" button, and number 6 is highlighted around the "Save operation" button.

1. Choose **PartiQL statement**.
2. Enter the following PartiQL [SELECT statement](#)

```
SELECT *
FROM Music
WHERE Artist=? and SongTitle=?
```

3. To specify a value for the Artist and SongTitle parameters:
 - a. Choose **Optional request parameters**.
 - b. Choose **Add new parameters**.
 - c. Choose the attribute type **string** and value **Acme Band**.

- d. Repeat steps b and c, and choose type **string** and value PartiQL Rocks.
4. If you want to generate code, choose **Generate code**.

Select your desired language from the displayed tabs. You can now copy this code and use it in your application.

5. If you want the operation to be run immediately, choose **Run**.

AWS CLI

1. Create an item in the Music table using the INSERT PartiQL statement.

```
aws dynamodb execute-statement --statement "INSERT INTO Music \
    VALUE \
    {'Artist':'Acme Band','SongTitle':'PartiQL Rocks'}"
```

2. Retrieve an item from the Music table using the SELECT PartiQL statement.

```
aws dynamodb execute-statement --statement "SELECT * FROM Music \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

3. Update an item in the Music table using the UPDATE PartiQL statement.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    SET AwardsWon=1 \
    SET AwardDetail={'Grammys':[2020,
    2018]} \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

Add a list value for an item in the Music table.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    SET AwardDetail.Grammys
    =list_append(AwardDetail.Grammys,[2016]) \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

Remove a list value for an item in the Music table.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    REMOVE AwardDetail.Grammys[2] \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

Add a new map member for an item in the `Music` table.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    SET AwardDetail.BillBoard=[2020] \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

Add a new string set attribute for an item in the `Music` table.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    SET BandMembers =<<'member1',
    'member2'>> \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

Update a string set attribute for an item in the `Music` table.

```
aws dynamodb execute-statement --statement "UPDATE Music \
    SET BandMembers
    =set_add(BandMembers, <<'newmember'>>) \
    WHERE Artist='Acme Band' AND
    SongTitle='PartiQL Rocks'"
```

4. Delete an item from the `Music` table using the `DELETE` PartiQL statement.

```
aws dynamodb execute-statement --statement "DELETE FROM Music \
    WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'"
```

}

PartiQL data types for DynamoDB

The following table lists the data types you can use with PartiQL for DynamoDB.

DynamoDB data type	PartiQL representation	Notes
Boolean	TRUE FALSE	Not case sensitive.
Binary	N/A	Only supported via code.
List	[value1, value2,...]	There are no restrictions on the data types that can be stored in a List type, and the elements in a List do not have to be of the same type.
Map	{ 'name' : value }	There are no restrictions on the data types that can be stored in a Map type, and the elements in a Map do not have to be of the same type.
Null	NULL	Not case sensitive.
Number	1, 1.0, 1e0	Numbers can be positive, negative, or zero. Numbers can have up to 38 digits of precision.
Number Set	<>number1, number2>>	The elements in a number set must be of type Number.
String Set	<>'string1', 'string2'>>	The elements in a string set must be of type String.
String	'string value'	Single quotes must be used to specify String values.

Examples

The following statement demonstrates how to insert the following data types: String, Number, Map, List, Number Set and String Set.

```
INSERT INTO TypesTable value {'primarykey':'1',
'NumberType':1,
'MapType' : {'entryname1': 'value', 'entryname2': 4},
'ListType': [1,'stringval'],
'NumberSetType':<<1,34,32,4.5>>,
'StringSetType':<<'stringval','stringval2'>>
}
```

The following statement demonstrates how to insert new elements into the Map, List, Number Set and String Set types and change the value of a Number type.

```
UPDATE TypesTable
SET NumberType=NumberType + 100
SET MapType.NewMapEntry=[2020, 'stringvalue', 2.4]
SET ListType = LIST_APPEND(ListType, [4, <<'string1', 'string2'>>])
SET NumberSetType= SET_ADD(NumberSetType, <<345, 48.4>>)
SET StringSetType = SET_ADD(StringSetType, <<'stringsetvalue1', 'stringsetvalue2'>>)
WHERE primarykey='1'
```

The following statement demonstrates how to remove elements from the Map, List, Number Set and String Set types and change the value of a Number type.

```
UPDATE TypesTable
SET NumberType=NumberType - 1
REMOVE ListType[1]
REMOVE MapType.NewMapEntry
SET NumberSetType = SET_DELETE( NumberSetType, <<345>>)
SET StringSetType = SET_DELETE( StringSetType, <<'stringsetvalue1'>>)
WHERE primarykey='1'
```

For more information, see [DynamoDB data types](#).

PartiQL statements for DynamoDB

Amazon DynamoDB supports the following PartiQL statements.

Note

DynamoDB does not support all PartiQL statements.

This reference provides basic syntax and usage examples of PartiQL statements that you manually run using the AWS CLI or APIs.

Data manipulation language (DML) is the set of PartiQL statements that you use to manage data in DynamoDB tables. You use DML statements to add, modify, or delete data in a table.

The following DML and query language statements are supported:

- [PartiQL select statements for DynamoDB](#)
- [PartiQL update statements for DynamoDB](#)
- [PartiQL insert statements for DynamoDB](#)
- [PartiQL delete statements for DynamoDB](#)

[Performing transactions with PartiQL for DynamoDB](#) and [Running batch operations with PartiQL for DynamoDB](#) are also supported by PartiQL for DynamoDB.

PartiQL select statements for DynamoDB

Use the SELECT statement to retrieve data from a table in Amazon DynamoDB.

Using the SELECT statement can result in a full table scan if an equality or IN condition with a partition key is not provided in the WHERE clause. A scan operation examines every item for the requested values and can use up the provisioned throughput for a large table or index in a single operation.

If you want to avoid full table scan in PartiQL, you can:

- Author your SELECT statements to not result in full table scans by making sure your [WHERE clause condition](#) is configured accordingly.
- Disable full table scans using the IAM policy specified at [Example: Allow select statements and deny full table scan statements in PartiQL for DynamoDB](#), in the DynamoDB developer guide.

For more information see [Best practices for querying and scanning data](#), in the DynamoDB developer guide.

Topics

- [Syntax](#)
- [Parameters](#)
- [Examples](#)

Syntax

```
SELECT expression [, ...]
FROM table[.index]
[ WHERE condition ] [ [ORDER BY key [DESC|ASC] , ...]
```

Parameters

expression

(Required) A projection formed from the * wildcard or a projection list of one or more attribute names or document paths from the result set. An expression can consist of calls to [Use PartiQL functions with amazon DynamoDB](#) or fields that are modified by [PartiQL arithmetic, comparison, and logical operators for DynamoDB](#).

table

(Required) The table name to query.

index

(Optional) The name of the index to query.

Note

You must add double quotation marks to the table name and index name when querying an index.

```
SELECT *
FROM "TableName"."IndexName"
```

condition

(Optional) The selection criteria for the query.

⚠ Important

To ensure that a SELECT statement does not result in a full table scan, the WHERE clause condition must specify a partition key. Use the equality or IN operator.

For example, if you have an Orders table with an OrderID partition key and other non-key attributes, including an Address, the following statements would not result in a full table scan:

```
SELECT *
FROM "Orders"
WHERE OrderID = 100
```

```
SELECT *
FROM "Orders"
WHERE OrderID = 100 and Address='some address'
```

```
SELECT *
FROM "Orders"
WHERE OrderID = 100 or pk = 200
```

```
SELECT *
FROM "Orders"
WHERE OrderID IN [100, 300, 234]
```

The following SELECT statements, however, will result in a full table scan:

```
SELECT *
FROM "Orders"
WHERE OrderID > 1
```

```
SELECT *
FROM "Orders"
WHERE Address='some address'
```

```
SELECT *
FROM "Orders"
WHERE OrderID = 100 OR Address='some address'
```

key

(Optional) A hash key or a sort key to use to order returned results. The default order is ascending (ASC) specify DESC if you want the results retuned in descending order.

Note

If you omit the WHERE clause, then all of the items in the table are retrieved.

Examples

The following query returns one item, if one exists, from the Orders table by specifying the partition key, OrderID, and using the equality operator.

```
SELECT OrderID, Total  
FROM "Orders"  
WHERE OrderID = 1
```

The following query returns all items in the Orders table that have a specific partition key, OrderID, values using the OR operator.

```
SELECT OrderID, Total  
FROM "Orders"  
WHERE OrderID = 1 OR OrderID = 2
```

The following query returns all items in the Orders table that have a specific partition key, OrderID, values using the IN operator. The returned results are in descending order, based on the OrderID key attribute value.

```
SELECT OrderID, Total  
FROM "Orders"  
WHERE OrderID IN [1, 2, 3] ORDER BY OrderID DESC
```

The following query shows a full table scan that returns all items from the Orders table that have a Total greater than 500, where Total is a non-key attribute.

```
SELECT OrderID, Total  
FROM "Orders"
```

```
WHERE Total > 500
```

The following query shows a full table scan that returns all items from the `Orders` table within a specific `Total` order range, using the `IN` operator and a non-key attribute `Total`.

```
SELECT OrderID, Total  
FROM "Orders"  
WHERE Total IN [500, 600]
```

The following query shows a full table scan that returns all items from the `Orders` table within a specific `Total` order range, using the `BETWEEN` operator and a non-key attribute `Total`.

```
SELECT OrderID, Total  
FROM "Orders"  
WHERE Total BETWEEN 500 AND 600
```

The following query returns the first date a firestick device was used to watch by specifying the partition key `CustomerID` and sort key `MovieID` in the `WHERE` clause condition and using document paths in the `SELECT` clause.

```
SELECT Devices.FireStick.DateWatched[0]  
FROM WatchList  
WHERE CustomerID= 'C1' AND MovieID= 'M1'
```

The following query shows a full table scan that returns the list of items where a firestick device was first used after 12/24/19 using document paths in the `WHERE` clause condition.

```
SELECT Devices  
FROM WatchList  
WHERE Devices.FireStick.DateWatched[0] >= '12/24/19'
```

PartiQL update statements for DynamoDB

Use the `UPDATE` statement to modify the value of one or more attributes within an item in an Amazon DynamoDB table.

Note

You can only update one item at a time; you cannot issue a single DynamoDB PartiQL statement that updates multiple items. For information on updating multiple items, see

[Performing transactions with PartiQL for DynamoDB](#) or [Running batch operations with PartiQL for DynamoDB](#).

Topics

- [Syntax](#)
- [Parameters](#)
- [Return value](#)
- [Examples](#)

Syntax

```
UPDATE table
[SET | REMOVE] path [= data] [...]
WHERE condition [RETURNING returnvalues]
<returnvalues> ::= [ALL OLD | MODIFIED OLD | ALL NEW | MODIFIED NEW] *
```

Parameters

table

(Required) The table containing the data to be modified.

path

(Required) An attribute name or document path to be created or modified.

data

(Required) An attribute value or the result of an operation.

The supported operations to use with SET:

- LIST_APPEND: adds a value to a list type.
- SET_ADD: adds a value to a number or string set.
- SET_DELETE: removes a value from a number or string set.

condition

(Required) The selection criteria for the item to be modified. This condition must resolve to a single primary key value.

returnvalues

(Optional) Use `returnvalues` if you want to get the item attributes as they appear before or after they are updated. The valid values are:

- `ALL OLD` * - Returns all of the attributes of the item, as they appeared before the update operation.
- `MODIFIED OLD` * - Returns only the updated attributes, as they appeared before the update operation.
- `ALL NEW` * - Returns all of the attributes of the item, as they appear after the update operation.
- `MODIFIED NEW` * - Returns only the updated attributes, as they appear after the `UpdateItem` operation.

Return value

This statement does not return a value unless `returnvalues` parameter is specified.

Note

If the WHERE clause of the UPDATE statement does not evaluate to true for any item in the DynamoDB table, `ConditionalCheckFailedException` is returned.

Examples

Update an attribute value in an existing item. If the attribute does not exist, it is created.

The following query updates an item in the "Music" table by adding an attribute of type number (`AwardsWon`) and an attribute of type map (`AwardDetail`).

```
UPDATE "Music"
SET AwardsWon=1
SET AwardDetail={'Grammys':[2020, 2018]}
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

You can add `RETURNING ALL OLD *` to return the attributes as they appeared before the Update operation.

```
UPDATE "Music"
SET AwardsWon=1
SET AwardDetail={'Grammys':[2020, 2018]}
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
RETURNING ALL OLD *
```

This returns the following:

```
{
  "Items": [
    {
      "Artist": {
        "S": "Acme Band"
      },
      "SongTitle": {
        "S": "PartiQL Rocks"
      }
    }
  ]
}
```

You can add RETURNING ALL NEW * to return the attributes as they appeared after the Update operation.

```
UPDATE "Music"
SET AwardsWon=1
SET AwardDetail={'Grammys':[2020, 2018]}
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
RETURNING ALL NEW *
```

This returns the following:

```
{
  "Items": [
    {
      "AwardDetail": {
        "M": {
          "Grammys": {
            "L": [
              {
                "N": "2020"
              }
            ]
          }
        }
      }
    }
  ]
}
```

```
        },
        {
            "N": "2018"
        }
    ]
}
},
"AwardsWon": {
    "N": "1"
}
]
}
```

The following query updates an item in the "Music" table by appending to a list AwardDetail.Grammys.

```
UPDATE "Music"
SET AwardDetail.Grammys =list_append(AwardDetail.Grammys,[2016])
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

The following query updates an item in the "Music" table by removing from a list AwardDetail.Grammys.

```
UPDATE "Music"
REMOVE AwardDetail.Grammys[2]
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

The following query updates an item in the "Music" table by adding BillBoard to the map AwardDetail.

```
UPDATE "Music"
SET AwardDetail.BillBoard=[2020]
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

The following query updates an item in the "Music" table by adding the string set attribute BandMembers.

```
UPDATE "Music"
SET BandMembers =<<'member1', 'member2'>>
```

```
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

The following query updates an item in the "Music" table by adding newbandmember to the string set BandMembers.

```
UPDATE "Music"
SET BandMembers =set_add(BandMembers, <<'newbandmember'>>)
WHERE Artist='Acme Band' AND SongTitle='PartiQL Rocks'
```

PartiQL delete statements for DynamoDB

Use the DELETE statement to delete an existing item from your Amazon DynamoDB table.

Note

You can only delete one item at a time. You cannot issue a single DynamoDB PartiQL statement that deletes multiple items. For information on deleting multiple items, see [Performing transactions with PartiQL for DynamoDB](#) or [Running batch operations with PartiQL for DynamoDB](#).

Topics

- [Syntax](#)
- [Parameters](#)
- [Return value](#)
- [Examples](#)

Syntax

```
DELETE FROM table
WHERE condition [RETURNING returnvalues]
<returnvalues> ::= ALL OLD *
```

Parameters

table

(Required) The DynamoDB table containing the item to be deleted.

condition

(Required) The selection criteria for the item to be deleted; this condition must resolve to a single primary key value.

returnvalues

(Optional) Use `returnvalues` if you want to get the item attributes as they appeared before they were deleted. The valid values are:

- `ALL OLD *` - The content of the old item is returned.

Return value

This statement does not return a value unless `returnvalues` parameter is specified.

Note

If the DynamoDB table does not have any item with the same primary key as that of the item for which the `DELETE` is issued, `SUCCESS` is returned with 0 items deleted. If the table has an item with same primary key, but the condition in the `WHERE` clause of the `DELETE` statement evaluates to false, `ConditionalCheckFailedException` is returned.

Examples

The following query deletes an item in the "Music" table.

```
DELETE FROM "Music" WHERE "Artist" = 'Acme Band' AND "SongTitle" = 'PartiQL Rocks'
```

You can add the parameter `RETURNING ALL OLD *` to return the data that was deleted.

```
DELETE FROM "Music" WHERE "Artist" = 'Acme Band' AND "SongTitle" = 'PartiQL Rocks'  
RETURNING ALL OLD *
```

The Delete statement now returns the following:

```
{  
  "Items": [  
    {
```

```
        "Artist": {  
            "S": "Acme Band"  
        },  
        "SongTitle": {  
            "S": "PartiQL Rocks"  
        }  
}
```

PartiQL insert statements for DynamoDB

Use the `INSERT` statement to add an item to a table in Amazon DynamoDB.

Note

You can only insert one item at a time; you cannot issue a single DynamoDB PartiQL statement that inserts multiple items. For information on inserting multiple items, see [Performing transactions with PartiQL for DynamoDB](#) or [Running batch operations with PartiQL for DynamoDB](#).

Topics

- [Syntax](#)
- [Parameters](#)
- [Return value](#)
- [Examples](#)

Syntax

Insert a single item.

```
INSERT INTO table VALUE item
```

Parameters

table

(Required) The table where you want to insert the data. The table must already exist.

item

(Required) A valid DynamoDB item represented as a [PartiQL tuple](#). You must specify only *one* item and each attribute name in the item is case-sensitive and can be denoted with *single* quotation marks (' . . . ') in PartiQL.

String values are also denoted with *single* quotation marks (' . . . ') in PartiQL.

Return value

This statement does not return any values.

Note

If the DynamoDB table already has an item with the same primary key as the primary key of the item being inserted, `DuplicateItemException` is returned.

Examples

```
INSERT INTO "Music" value {'Artist' : 'Acme Band', 'SongTitle' : 'PartiQL Rocks'}
```

Use PartiQL functions with amazon DynamoDB

PartiQL in Amazon DynamoDB supports the following built-in variants of SQL standard functions.

Note

Any SQL functions that are not included in this list are not currently supported in DynamoDB.

Aggregate functions

- [Using the SIZE function with PartiQL for amazon DynamoDB](#)

Conditional functions

- [Using the EXISTS function with PartiQL for DynamoDB](#)

- [Using the ATTRIBUTE_TYPE function with PartiQL for DynamoDB](#)
- [Using the BEGINS_WITH function with PartiQL for DynamoDB](#)
- [Using the CONTAINS function with PartiQL for DynamoDB](#)
- [Using the MISSING function with PartiQL for DynamoDB](#)

Using the EXISTS function with PartiQL for DynamoDB

You can use EXISTS to perform the same function as ConditionCheck does in the [TransactWriteItems](#) API. The EXISTS function can only be used in transactions.

Given a value, returns TRUE if the value is a non-empty collection. Otherwise, returns FALSE.

Note

This function can only be used in transactional operations.

Syntax

```
EXISTS ( statement )
```

Arguments

statement

(Required) The SELECT statement that the function evaluates.

Note

The SELECT statement must specify a full primary key and one other condition.

Return type

bool

Examples

```
EXISTS(  
    SELECT * FROM "Music"
```

```
WHERE "Artist" = 'Acme Band' AND "SongTitle" = 'PartiQL Rocks')
```

Using the `BEGINS_WITH` function with PartiQL for DynamoDB

Returns TRUE if the attribute specified begins with a particular substring.

Syntax

```
begins_with(path, value )
```

Arguments

path

(Required) The attribute name or document path to use.

value

(Required) The string to search for.

Return type

bool

Examples

```
SELECT * FROM "Orders" WHERE "OrderID"=1 AND begins_with("Address", '7834 24th')
```

Using the `MISSING` function with PartiQL for DynamoDB

Returns TRUE if the item does not contain the attribute specified. Only equality and inequality operators can be used with this function.

Syntax

```
attributename IS | IS NOT MISSING
```

Arguments

attributename

(Required) The attribute name to look for.

Return type

bool

Examples

```
SELECT * FROM Music WHERE "Awards" is MISSING
```

Using the ATTRIBUTE_TYPE function with PartiQL for DynamoDB

Returns TRUE if the attribute at the specified path is of a particular data type.

Syntax

```
attribute_type( attributename, type )
```

Arguments

attributename

(Required) The attribute name to use.

type

(Required) The attribute type to check for. For a list of valid values, see DynamoDB [attribute_type](#).

Return type

bool

Examples

```
SELECT * FROM "Music" WHERE attribute_type("Artist", 'S')
```

Using the CONTAINS function with PartiQL for DynamoDB

Returns TRUE if the attribute specified by the path is one of the following:

- A String that contains a particular substring.

- A Set that contains a particular element within the set.

For more information, see the DynamoDB [contains](#) function.

Syntax

```
contains( path, substring )
```

Arguments

path

(Required) The attribute name or document path to use.

substring

(Required) The attribute substring or set member to check for. For more information, see the DynamoDB [contains](#) function.

Return type

bool

Examples

```
SELECT * FROM "Orders" WHERE "OrderID"=1 AND contains("Address", 'Kirkland')
```

Using the SIZE function with PartiQL for amazon DynamoDB

Returns a number representing an attribute's size in bytes. The following are valid data types for use with size. For more information, see the DynamoDB [size](#) function.

Syntax

```
size( path )
```

Arguments

path

(Required) The attribute name or document path.

For supported types, see DynamoDB [size](#) function.

Return type

int

Examples

```
SELECT * FROM "Orders" WHERE "OrderID"=1 AND size("Image") >300
```

PartiQL arithmetic, comparison, and logical operators for DynamoDB

PartiQL in Amazon DynamoDB supports the following [SQL standard operators](#).

Note

Any SQL operators that are not included in this list are not currently supported in DynamoDB.

Arithmetic operators

Operator	Description
+	Add
-	Subtract

Comparison operators

Operator	Description
=	Equal to
<>	Not Equal to
!=	Not Equal to
>	Greater than

Operator	Description
<	Less than
>=	Greater than or equal to
<=	Less than or equal to

Logical operators

Operator	Description
AND	TRUE if all the conditions separated by AND are TRUE
BETWEEN	TRUE if the operand is within the range of comparisons
IN	TRUE if the operand is equal to one of a list of expressions (at max 50 hash attribute values or at max 100 non-key attribute values)
IS	TRUE if the operand is a given, PartiQL data type, including NULL or MISSING
NOT	Reverses the value of a given Boolean expression
OR	TRUE if any of the conditions separated by OR are TRUE

Performing transactions with PartiQL for DynamoDB

This section describes how to use transactions with PartiQL for DynamoDB. PartiQL transactions are limited to 100 total statements (actions).

For more information on DynamoDB transactions, see [Managing complex workflows with DynamoDB transactions](#).

Note

The entire transaction must consist of either read statements or write statements. You can't mix both in one transaction. The EXISTS function is an exception. You can use it to check the condition of specific attributes of the item in a similar manner to ConditionCheck in the [TransactWriteItems](#) API operation.

Topics

- [Syntax](#)
- [Parameters](#)
- [Return values](#)
- [Examples](#)

Syntax

```
[  
  {  
    "Statement": " statement ",  
    "Parameters": [  
      {  
        " parametertype " : " parametervalue "  
      }, ...]  
    } , ...  
  ]
```

Parameters***statement***

(Required) A PartiQL for DynamoDB supported statement.

Note

The entire transaction must consist of either read statements or write statements. You can't mix both in one transaction.

parameter type

(Optional) A DynamoDB type, if parameters were used when specifying the PartiQL statement.

parameter value

(Optional) A parameter value if parameters were used when specifying the PartiQL statement.

Return values

This statement doesn't return any values for Write operations (INSERT, UPDATE, or DELETE).

However, it returns different values for Read operations (SELECT) based on the conditions specified in the WHERE clause.

Note

If any of the singleton INSERT, UPDATE, or DELETE operations return an error, the transactions are canceled with the TransactionCanceledException exception, and the cancellation reason code includes the errors from the individual singleton operations.

Examples

The following example runs multiple statements as a transaction.

AWS CLI

1. Save the following JSON code to a file called partiq.json.

```
[  
  {  
    "Statement": "EXISTS(SELECT * FROM \"Music\" where Artist='No One You  
Know' and SongTitle='Call Me Today' and Awards is MISSING)"  
  },  
  {  
    "Statement": "INSERT INTO Music value {'Artist':?:,'SongTitle':?}',  
    "Parameters": [{\"S\": \"Acme Band\"}, {"S": \"Best Song\"}]  
  },  
  {  
    "Statement": "UPDATE \"Music\" SET AwardsWon=1 SET  
    AwardDetail={'Grammys':[2020, 2018]} where Artist='Acme Band' and  
    SongTitle='PartiQL Rocks'"  
  }]
```

```
    }  
]
```

- Run the following command in a command prompt.

```
aws dynamodb execute-transaction --transact-statements file://partiql.json
```

Java

```
public class DynamoDBPartiqlTransaction {  
  
    public static void main(String[] args) {  
        // Create the DynamoDB Client with the region you want  
        AmazonDynamoDB dynamoDB = createDynamoDbClient("us-west-2");  
  
        try {  
            // Create ExecuteTransactionRequest  
            ExecuteTransactionRequest executeTransactionRequest =  
createExecuteTransactionRequest();  
            ExecuteTransactionResult executeTransactionResult =  
dynamoDB.executeTransaction(executeTransactionRequest);  
            System.out.println("ExecuteTransaction successful.");  
            // Handle executeTransactionResult  
  
        } catch (Exception e) {  
            handleExecuteTransactionErrors(e);  
        }  
    }  
  
    private static AmazonDynamoDB createDynamoDbClient(String region) {  
        return AmazonDynamoDBClientBuilder.standard().withRegion(region).build();  
    }  
  
    private static ExecuteTransactionRequest createExecuteTransactionRequest() {  
        ExecuteTransactionRequest request = new ExecuteTransactionRequest();  
  
        // Create statements  
        List<ParameterizedStatement> statements = getPartiQLTransactionStatements();  
  
        request.setTransactStatements(statements);  
        return request;  
    }  
}
```

```
private static List<ParameterizedStatement> getPartiQLTransactionStatements() {  
    List<ParameterizedStatement> statements = new  
    ArrayList<ParameterizedStatement>();  
  
    statements.add(new ParameterizedStatement()  
        .withStatement("EXISTS(SELECT * FROM \"Music\" where  
Artist='No One You Know' and SongTitle='Call Me Today' and Awards is MISSING)"));  
  
    statements.add(new ParameterizedStatement()  
        .withStatement("INSERT INTO \"Music\" value  
{'Artist':'?', 'SongTitle':'?'})")  
        .withParameters(new AttributeValue("Acme Band"), new  
AttributeValue("Best Song")));  
  
    statements.add(new ParameterizedStatement()  
        .withStatement("UPDATE \"Music\" SET AwardsWon=1  
SET AwardDetail={'Grammys':[2020, 2018]} where Artist='Acme Band' and  
SongTitle='PartiQL Rocks'"));  
  
    return statements;  
}  
  
// Handles errors during ExecuteTransaction execution. Use recommendations in  
error messages below to add error handling specific to  
// your application use-case.  
private static void handleExecuteTransactionErrors(Exception exception) {  
    try {  
        throw exception;  
    } catch (TransactionCanceledException tce) {  
        System.out.println("Transaction Cancelled, implies a client issue, fix  
before retrying. Error: " + tce.getErrorMessage());  
    } catch (TransactionInProgressException tipe) {  
        System.out.println("The transaction with the given request token is  
already in progress, consider changing " +  
            "retry strategy for this type of error. Error: " +  
tipe.getErrorMessage());  
    } catch (IdempotentParameterMismatchException ipme) {  
        System.out.println("Request rejected because it was retried with a  
different payload but with a request token that was already used, " +  
            "change request token for this payload to be accepted. Error: " +  
ipme.getErrorMessage());  
    } catch (Exception e) {  
        handleCommonErrors(e);  
    }  
}
```

```
        }

    }

    private static void handleCommonErrors(Exception exception) {
        try {
            throw exception;
        } catch (InternalServerErrorException isee) {
            System.out.println("Internal Server Error, generally safe to retry with exponential back-off. Error: " + isee.getErrorMessage());
        } catch (RequestLimitExceededException rlee) {
            System.out.println("Throughput exceeds the current throughput limit for your account, increase account level throughput before " +
                "retrying. Error: " + rlee.getErrorMessage());
        } catch (ProvisionedThroughputExceededException ptee) {
            System.out.println("Request rate is too high. If you're using a custom retry strategy make sure to retry with exponential back-off. " +
                "Otherwise consider reducing frequency of requests or increasing provisioned capacity for your table or secondary index. Error: " +
                ptee.getErrorMessage());
        } catch (ResourceNotFoundException rafe) {
            System.out.println("One of the tables was not found, verify table exists before retrying. Error: " + rafe.getErrorMessage());
        } catch (AmazonServiceException ase) {
            System.out.println("An AmazonServiceException occurred, indicates that the request was correctly transmitted to the DynamoDB " +
                "service, but for some reason, the service was not able to process it, and returned an error response instead. Investigate and " +
                "configure retry strategy. Error type: " + ase.getErrorType() + ". Error message: " + ase.getErrorMessage());
        } catch (AmazonClientException ace) {
            System.out.println("An AmazonClientException occurred, indicates that the client was unable to get a response from DynamoDB " +
                "service, or the client was unable to parse the response from the service. Investigate and configure retry strategy. " +
                "Error: " + ace.getMessage());
        } catch (Exception e) {
            System.out.println("An exception occurred, investigate and configure retry strategy. Error: " + e.getMessage());
        }
    }
}
```

The following example shows the different return values when DynamoDB reads items with different conditions specified in the WHERE clause.

AWS CLI

1. Save the following JSON code to a file called partiqql.json.

```
[  
    // Item exists and projected attribute exists  
    {  
        "Statement": "SELECT * FROM \"Music\" WHERE Artist='No One You Know' and SongTitle='Call Me Today'"  
    },  
    // Item exists but projected attributes do not exist  
    {  
        "Statement": "SELECT non_existent_projected_attribute FROM \"Music\" WHERE Artist='No One You Know' and SongTitle='Call Me Today'"  
    },  
    // Item does not exist  
    {  
        "Statement": "SELECT * FROM \"Music\" WHERE Artist='No One I Know' and SongTitle='Call You Today'"  
    }  
]
```

2. following command in a command prompt.

```
aws dynamodb execute-transaction --transact-statements file://partiqql.json
```

3. The following response is returned:

```
{  
    "Responses": [  
        // Item exists and projected attribute exists  
        {  
            "Item": {  
                "Artist":{  
                    "S": "No One You Know"  
                },  
                "SongTitle":{  
                    "S": "Call Me Today"  
                }  
            }  
        }  
    ]
```

```
        },
        // Item exists but projected attributes do not exist
        {
            "Item": {}
        },
        // Item does not exist
        {}
    ]
}
```

Running batch operations with PartiQL for DynamoDB

This section describes how to use batch statements with PartiQL for DynamoDB.

Note

- The entire batch must consist of either read statements or write statements; you cannot mix both in one batch.
- BatchExecuteStatement and BatchWriteItem can perform no more than 25 statements per batch.

Topics

- [Syntax](#)
- [Parameters](#)
- [Examples](#)

Syntax

```
[
{
    "Statement": "statement",
    "Parameters": [
        {
            "parametertype": "parametervalue"
        }, ...
    ], ...
}]
```

Parameters

statement

(Required) A PartiQL for DynamoDB supported statement.

Note

- The entire batch must consist of either read statements or write statements; you cannot mix both in one batch.
- BatchExecuteStatement and BatchWriteItem can perform no more than 25 statements per batch.

parametertype

(Optional) A DynamoDB type, if parameters were used when specifying the PartiQL statement.

parametervalue

(Optional) A parameter value if parameters were used when specifying the PartiQL statement.

Examples

AWS CLI

1. Save the following json to a file called partiql.json

```
[  
  {  
    "Statement": "INSERT INTO Music value {'Artist':'?', 'SongTitle':'?'}",  
    "Parameters": [{"S": "Acme Band"}, {"S": "Best Song"}]  
  },  
  {  
    "Statement": "UPDATE Music SET AwardsWon=1 SET AwardDetail={'Grammys':[2020,  
    2018]} where Artist='Acme Band' and SongTitle='PartiQL Rocks'"  
  }  
]
```

2. Run the following command in a command prompt.

```
aws dynamodb batch-execute-statement --statements file://partiql.json
```

Java

```
public class DynamoDBPartiqlBatch {  
  
    public static void main(String[] args) {  
        // Create the DynamoDB Client with the region you want  
        AmazonDynamoDB dynamoDB = createDynamoDbClient("us-west-2");  
  
        try {  
            // Create BatchExecuteStatementRequest  
            BatchExecuteStatementRequest batchExecuteStatementRequest =  
createBatchExecuteStatementRequest();  
            BatchExecuteStatementResult batchExecuteStatementResult =  
dynamoDB.batchExecuteStatement(batchExecuteStatementRequest);  
            System.out.println("BatchExecuteStatement successful.");  
            // Handle batchExecuteStatementResult  
  
        } catch (Exception e) {  
            handleBatchExecuteStatementErrors(e);  
        }  
    }  
  
    private static AmazonDynamoDB createDynamoDbClient(String region) {  
  
        return AmazonDynamoDBClientBuilder.standard().withRegion(region).build();  
    }  
  
    private static BatchExecuteStatementRequest createBatchExecuteStatementRequest()  
{  
        BatchExecuteStatementRequest request = new BatchExecuteStatementRequest();  
  
        // Create statements  
        List<BatchStatementRequest> statements = getPartiQLBatchStatements();  
  
        request.setStatements(statements);  
        return request;  
    }  
  
    private static List<BatchStatementRequest> getPartiQLBatchStatements() {
```

```
        List<BatchStatementRequest> statements = new
ArrayList<BatchStatementRequest>();

        statements.add(new BatchStatementRequest()
                        .withStatement("INSERT INTO Music value
{'Artist':'Acme Band', 'SongTitle':'PartiQL Rocks'}"));

        statements.add(new BatchStatementRequest()
                        .withStatement("UPDATE Music set
AwardDetail.BillBoard=[2020] where Artist='Acme Band' and SongTitle='PartiQL
Rocks'"));

        return statements;
    }

// Handles errors during BatchExecuteStatement execution. Use recommendations in
error messages below to add error handling specific to
// your application use-case.
private static void handleBatchExecuteStatementErrors(Exception exception) {
    try {
        throw exception;
    } catch (Exception e) {
        // There are no API specific errors to handle for BatchExecuteStatement,
common DynamoDB API errors are handled below
        handleCommonErrors(e);
    }
}

private static void handleCommonErrors(Exception exception) {
    try {
        throw exception;
    } catch (InternalServerErrorException isee) {
        System.out.println("Internal Server Error, generally safe to retry with
exponential back-off. Error: " + isee.getErrorMessage());
    } catch (RequestLimitExceededException rlee) {
        System.out.println("Throughput exceeds the current throughput limit for
your account, increase account level throughput before " +
                "retrying. Error: " + rlee.getErrorMessage());
    } catch (ProvisionedThroughputExceededException ptee) {
        System.out.println("Request rate is too high. If you're using a custom
retry strategy make sure to retry with exponential back-off. " +
                "Otherwise consider reducing frequency of requests or increasing
provisioned capacity for your table or secondary index. Error: " +
                ptee.getErrorMessage());
    }
}
```

```
        } catch (ResourceNotFoundException rufe) {
            System.out.println("One of the tables was not found, verify table exists before retrying. Error: " + rufe.getErrorMessage());
        } catch (AmazonServiceException ase) {
            System.out.println("An AmazonServiceException occurred, indicates that the request was correctly transmitted to the DynamoDB " +
                "service, but for some reason, the service was not able to process it, and returned an error response instead. Investigate and " +
                "configure retry strategy. Error type: " + ase.getErrorType() + ". Error message: " + ase.getErrorMessage());
        } catch (AmazonClientException ace) {
            System.out.println("An AmazonClientException occurred, indicates that the client was unable to get a response from DynamoDB " +
                "service, or the client was unable to parse the response from the service. Investigate and configure retry strategy. " +
                "Error: " + ace.getMessage());
        } catch (Exception e) {
            System.out.println("An exception occurred, investigate and configure retry strategy. Error: " + e.getMessage());
        }
    }

}
```

IAM security policies with PartiQL for DynamoDB

The following permissions are required:

- To read items using PartiQL for DynamoDB, you must have dynamodb:PartiQLSelect permission on the table or index.
- To insert items using PartiQL for DynamoDB, you must have dynamodb:PartiQLInsert permission on the table or index.
- To update items using PartiQL for DynamoDB, you must have dynamodb:PartiQLUpdate permission on the table or index.
- To delete items using PartiQL for DynamoDB, you must have dynamodb:PartiQLDelete permission on the table or index.

Example: Allow all PartiQL for DynamoDB statements (Select/Insert/Update/Delete) on a table

The following IAM policy grants permissions to run all PartiQL for DynamoDB statements on a table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:PartiQLInsert",  
                "dynamodb:PartiQLUpdate",  
                "dynamodb:PartiQLDelete",  
                "dynamodb:PartiQLSelect"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Music"  
            ]  
        }  
    ]  
}
```

Example: Allow PartiQL for DynamoDB select statements on a table

The following IAM policy grants permissions to run the select statement on a specific table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:PartiQLSelect"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Music"  
            ]  
        }  
    ]  
}
```

Example: Allow PartiQL for DynamoDB insert statements on an index

The following IAM policy grants permissions to run the `insert` statement on a specific index.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:PartiQLInsert"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Music/index/index1"  
            ]  
        }  
    ]  
}
```

Example: Allow PartiQL for DynamoDB transactional statements only on a table

The following IAM policy grants permissions to run only transactional statements on a specific table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:PartiQLInsert",  
                "dynamodb:PartiQLUpdate",  
                "dynamodb:PartiQLDelete",  
                "dynamodb:PartiQLSelect"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:us-west-2:123456789012:table/Music"  
            ],  
            "Condition": {  
                "StringEquals": {  
                    "dynamodb:EnclosingOperation": [  
                        "ExecuteTransaction"  
                    ]  
                }  
            }  
        }  
    ]  
}
```

```
        }
    }
}
]
```

Example: Allow PartiQL for DynamoDB non-transactional reads and writes and block PartiQL transactional reads and writes on a table.

The following IAM policy grants permissions to run PartiQL for DynamoDB non-transactional reads and writes while blocking PartiQL for DynamoDB transactional reads and writes.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:PartiQLInsert",
                "dynamodb:PartiQLUpdate",
                "dynamodb:PartiQLDelete",
                "dynamodb:PartiQLSelect"
            ],
            "Resource": [
                "arn:aws:dynamodb:us-west-2:123456789012:table/Music"
            ],
            "Condition": {
                "StringEquals": {
                    "dynamodb:EnclosingOperation": [
                        "ExecuteTransaction"
                    ]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:PartiQLInsert",
                "dynamodb:PartiQLUpdate",
                "dynamodb:PartiQLDelete",
                "dynamodb:PartiQLSelect"
            ],
            "Resource": [

```

```
        "arn:aws:dynamodb:us-west-2:123456789012:table/Music"
    ]
}
]
```

Example: Allow select statements and deny full table scan statements in PartiQL for DynamoDB

The following IAM policy grants permissions to run the `select` statement on a specific table while blocking select statements that result in a full table scan.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "dynamodb:PartiQLSelect"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/WatchList"
      ],
      "Condition": {
        "Bool": {
          "dynamodb:FullTableScan": [
            "true"
          ]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "dynamodb:PartiQLSelect"
      ],
      "Resource": [
        "arn:aws:dynamodb:us-west-2:123456789012:table/WatchList"
      ]
    }
  ]
}
```

Improving data access with secondary indexes

Topics

- [Using Global Secondary Indexes in DynamoDB](#)
- [Local Secondary Indexes](#)

Amazon DynamoDB provides fast access to items in a table by specifying primary key values. However, many applications might benefit from having one or more secondary (or alternate) keys available, to allow efficient access to data with attributes other than the primary key. To address this, you can create one or more secondary indexes on a table and issue Query or Scan requests against these indexes.

A *secondary index* is a data structure that contains a subset of attributes from a table, along with an alternate key to support Query operations. You can retrieve data from the index using a Query, in much the same way as you use Query with a table. A table can have multiple secondary indexes, which give your applications access to many different query patterns.

 **Note**

You can also Scan an index, in much the same way as you would Scan a table.

Every secondary index is associated with exactly one table, from which it obtains its data. This is called the *base table* for the index. When you create an index, you define an alternate key for the index (partition key and sort key). You also define the attributes that you want to be *projected*, or copied, from the base table into the index. DynamoDB copies these attributes into the index, along with the primary key attributes from the base table. You can then query or scan the index just as you would query or scan a table.

Every secondary index is automatically maintained by DynamoDB. When you add, modify, or delete items in the base table, any indexes on that table are also updated to reflect these changes.

DynamoDB supports two types of secondary indexes:

- [**Global secondary index**](#) — An index with a partition key and a sort key that can be different from those on the base table. A global secondary index is considered "global" because queries on the index can span all of the data in the base table, across all partitions. A global secondary

index is stored in its own partition space away from the base table and scales separately from the base table.

- **Local secondary index** — An index that has the same partition key as the base table, but a different sort key. A local secondary index is "local" in the sense that every partition of a local secondary index is scoped to a base table partition that has the same partition key value.

For a comparison of global secondary indexes and local secondary indexes, see this video.

[Making the right choice between GSI and LSI](#)

You should consider your application's requirements when you determine which type of index to use. The following table shows the main differences between a global secondary index and a local secondary index.

Characteristic	Global secondary index	Local secondary index
Key Schema	The primary key of a global secondary index can be either simple (partition key) or composite (partition key and sort key).	The primary key of a local secondary index must be composite (partition key and sort key).
Key Attributes	The index partition key and sort key (if present) can be any base table attributes of type string, number, or binary.	The partition key of the index is the same attribute as the partition key of the base table. The sort key can be any base table attribute of type string, number, or binary.
Size Restrictions Per Partition Key Value	There are no size restrictions for global secondary indexes.	For each partition key value, the total size of all indexed items must be 10 GB or less.
Online Index Operations	Global secondary indexes can be created at the same time that you create a table. You can also add a new global secondary index to an existing	Local secondary indexes are created at the same time that you create a table. You cannot add a local secondary index to an existing table, nor can you

Characteristic	Global secondary index	Local secondary index
	<p>table, or delete an existing global secondary index.</p> <p>For more information, see Managing Global Secondary Indexes.</p>	delete any local secondary indexes that currently exist.
Queries and Partitions	A global secondary index lets you query over the entire table, across all partitions.	A local secondary index lets you query over a single partition, as specified by the partition key value in the query.
Read Consistency	Queries on global secondary indexes support eventual consistency only.	When you query a local secondary index, you can choose either eventual consistency or strong consistency.
Provisioned Throughput Consumption	Every global secondary index has its own provisioned throughput settings for read and write activity. Queries or scans on a global secondary index consume capacity units from the index, not from the base table. The same holds true for global secondary index updates due to table writes. A global secondary index associated with global tables consumes write capacity units.	Queries or scans on a local secondary index consume read capacity units from the base table. When you write to a table its local secondary indexes are also updated, and these updates consume write capacity units from the base table. A local secondary index associated with global tables consumes replicated write capacity units.

Characteristic	Global secondary index	Local secondary index
Projected Attributes	With global secondary index queries or scans, you can only request the attributes that are projected into the index. DynamoDB does not fetch any attributes from the table.	If you query or scan a local secondary index, you can request attributes that are not projected in to the index. DynamoDB automatically fetches those attributes from the table.

If you want to create more than one table with secondary indexes, you must do so sequentially. For example, you would create the first table and wait for it to become ACTIVE, create the next table and wait for it to become ACTIVE, and so on. If you try to concurrently create more than one table with a secondary index, DynamoDB returns a `LimitExceededException`.

Each secondary index uses the same [table class](#) and [capacity mode](#) as the base table it is associated with. For each secondary index, you must specify the following:

- The type of index to be created – either a global secondary index or a local secondary index.
- A name for the index. The naming rules for indexes are the same as those for tables, as listed in [Service, account, and table quotas in Amazon DynamoDB](#). The name must be unique for the base table it is associated with, but you can use the same name for indexes that are associated with different base tables.
- The key schema for the index. Every attribute in the index key schema must be a top-level attribute of type String, Number, or Binary. Other data types, including documents and sets, are not allowed. Other requirements for the key schema depend on the type of index:
 - For a global secondary index, the partition key can be any scalar attribute of the base table. A sort key is optional, and it too can be any scalar attribute of the base table.
 - For a local secondary index, the partition key must be the same as the base table's partition key, and the sort key must be a non-key base table attribute.
- Additional attributes, if any, to project from the base table into the index. These attributes are in addition to the table's key attributes, which are automatically projected into every index. You can project attributes of any data type, including scalars, documents, and sets.
- The provisioned throughput settings for the index, if necessary:

- For a global secondary index, you must specify read and write capacity unit settings. These provisioned throughput settings are independent of the base table's settings.
- For a local secondary index, you do not need to specify read and write capacity unit settings. Any read and write operations on a local secondary index draw from the provisioned throughput settings of its base table.

For maximum query flexibility, you can create up to 20 global secondary indexes (default quota) and up to 5 local secondary indexes per table.

The quota of global secondary indexes per table is five for the following AWS Regions:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)
- Europe (Stockholm)

To get a detailed listing of secondary indexes on a table, use the `DescribeTable` operation. `DescribeTable` returns the name, storage size, and item counts for every secondary index on the table. These values are not updated in real time, but they are refreshed approximately every six hours.

You can access the data in a secondary index using either the `Query` or `Scan` operation. You must specify the name of the base table and the name of the index that you want to use, the attributes to be returned in the results, and any condition expressions or filters that you want to apply. DynamoDB can return the results in ascending or descending order.

When you delete a table, all of the indexes associated with that table are also deleted.

For best practices, see [Best practices for using secondary indexes in DynamoDB](#).

Using Global Secondary Indexes in DynamoDB

Some applications might need to perform many kinds of queries, using a variety of different attributes as query criteria. To support these requirements, you can create one or more *global secondary indexes* and issue `Query` requests against these indexes in Amazon DynamoDB.

- [Managing Global Secondary Indexes](#)
- [Working with Global Secondary Indexes: Java](#)
- [Working with Global Secondary Indexes: .NET](#)
- [Working with Global Secondary Indexes: AWS CLI](#)

Scenario: Using a Global Secondary Index

To illustrate, consider a table named GameScores that tracks users and scores for a mobile gaming application. Each item in GameScores is identified by a partition key (UserId) and a sort key (GameTitle). The following diagram shows how the items in the table would be organized. (Not all of the attributes are shown.)

GameScores

UserId	GameTitle	TopScore	TopScoreDateTime	Wins	Losses	
"101"	"Galaxy Invaders"	5842	"2015-09-15:17:24:31"	21	72	...
"101"	"Meteor Blasters"	1000	"2015-10-22:23:18:01"	12	3	...
"101"	"Starship X"	24	"2015-08-31:13:14:21"	4	9	...
"102"	"Alien Adventure"	192	"2015-07-12:11:07:56"	32	192	...
"102"	"Galaxy Invaders"	0	"2015-09-18:07:33:42"	0	5	...
"103"	"Attack Ships"	3	"2015-10-19:01:13:24"	1	8	...
"103"	"Galaxy Invaders"	2317	"2015-09-11:06:53:00"	40	3	...
"103"	"Meteor Blasters"	723	"2015-10-19:01:13:24"	22	12	...
"103"	"Starship X"	42	"2015-07-11:06:53:00"	4	19	...
...

Now suppose that you wanted to write a leaderboard application to display top scores for each game. A query that specified the key attributes (`UserId` and `GameTitle`) would be very efficient. However, if the application needed to retrieve data from `GameScores` based on `GameTitle` only, it would need to use a `Scan` operation. As more items are added to the table, scans of all the data would become slow and inefficient. This makes it difficult to answer questions such as the following:

- What is the top score ever recorded for the game Meteor Blasters?
- Which user had the highest score for Galaxy Invaders?
- What was the highest ratio of wins vs. losses?

To speed up queries on non-key attributes, you can create a global secondary index. A global secondary index contains a selection of attributes from the base table, but they are organized by a primary key that is different from that of the table. The index key does not need to have any of the key attributes from the table. It doesn't even need to have the same key schema as a table.

For example, you could create a global secondary index named `GameTitleIndex`, with a partition key of `GameTitle` and a sort key of `TopScore`. The base table's primary key attributes are always projected into an index, so the `UserId` attribute is also present. The following diagram shows what `GameTitleIndex` index would look like.

GameTitleIndex

GameTitle	TopScore	UserId
"Alien Adventure"	192	"102"
"Attack Ships"	3	"103"
"Galaxy Invaders"	0	"102"
"Galaxy Invaders"	2317	"103"
"Galaxy Invaders"	5842	"101"
"Meteor Blasters"	723	"103"
"Meteor Blasters"	1000	"101"
"Starship X"	24	"101"
"Starship X"	42	"103"
...

Now you can query GameTitleIndex and easily obtain the scores for Meteor Blasters. The results are ordered by the sort key values, TopScore. If you set the ScanIndexForward parameter to false, the results are returned in descending order, so the highest score is returned first.

Every global secondary index must have a partition key, and can have an optional sort key. The index key schema can be different from the base table schema. You could have a table with a simple primary key (partition key), and create a global secondary index with a composite primary key (partition key and sort key)—or vice versa. The index key attributes can consist of any top-level String, Number, or Binary attributes from the base table. Other scalar types, document types, and set types are not allowed.

You can project other base table attributes into the index if you want. When you query the index, DynamoDB can retrieve these projected attributes efficiently. However, global secondary index queries cannot fetch attributes from the base table. For example, if you query GameTitleIndex as shown in the previous diagram, the query could not access any non-key attributes other than TopScore (although the key attributes GameTitle and UserId would automatically be projected).

In a DynamoDB table, each key value must be unique. However, the key values in a global secondary index do not need to be unique. To illustrate, suppose that a game named Comet Quest is especially difficult, with many new users trying but failing to get a score above zero. The following is some data that could represent this.

UserId	GameTitle	TopScore
123	Comet Quest	0
201	Comet Quest	0
301	Comet Quest	0

When this data is added to the GameScores table, DynamoDB propagates it to GameTitleIndex. If we then query the index using Comet Quest for GameTitle and 0 for TopScore, the following data is returned.

GameTitle	TopScore	Userid
"Comet Quest"	0	"123"
"Comet Quest"	0	"201"
"Comet Quest"	0	"301"

Only the items with the specified key values appear in the response. Within that set of data, the items are in no particular order.

A global secondary index only tracks data items where its key attributes actually exist. For example, suppose that you added another new item to the GameScores table, but only provided the required primary key attributes.

UserId	GameTitle
400	Comet Quest

Because you didn't specify the `TopScore` attribute, DynamoDB would not propagate this item to `GameTitleIndex`. Thus, if you queried `GameScores` for all the `Comet Quest` items, you would get the following four items.

UserId	GameTitle	TopScore
"123"	"Comet Quest"	0
"201"	"Comet Quest"	0
"301"	"Comet Quest"	0
"400"	"Comet Quest"	

A similar query on `GameTitleIndex` would still return three items, rather than four. This is because the item with the nonexistent `TopScore` is not propagated to the index.

GameTitle	TopScore	Userid
"Comet Quest"	0	"123"
"Comet Quest"	0	"201"
"Comet Quest"	0	"301"

Attribute projections

A *projection* is the set of attributes that is copied from a table into a secondary index. The partition key and sort key of the table are always projected into the index; you can project other attributes to support your application's query requirements. When you query an index, Amazon DynamoDB can access any attribute in the projection as if those attributes were in a table of their own.

When you create a secondary index, you need to specify the attributes that will be projected into the index. DynamoDB provides three different options for this:

- *KEYS_ONLY* – Each item in the index consists only of the table partition key and sort key values, plus the index key values. The *KEYS_ONLY* option results in the smallest possible secondary index.
- *INCLUDE* – In addition to the attributes described in *KEYS_ONLY*, the secondary index will include other non-key attributes that you specify.

- **ALL** – The secondary index includes all of the attributes from the source table. Because all of the table data is duplicated in the index, an ALL projection results in the largest possible secondary index.

In the previous diagram, GameTitleIndex has only one projected attribute: UserId. So while an application can efficiently determine the UserId of the top scorers for each game using GameTitle and TopScore in queries, it can't efficiently determine the highest ratio of wins vs. losses for the top scorers. To do so, it would have to perform an additional query on the base table to fetch the wins and losses for each of the top scorers. A more efficient way to support queries on this data would be to project these attributes from the base table into the global secondary index, as shown in this diagram.

GameTitleIndex

<i>GameTitle</i>	<i>TopScore</i>	<i>UserId</i>	<i>Wins</i>	<i>Losses</i>
“Alien Adventure”	192	“102”	32	192
“Attack Ships”	3	“103”	1	8
“Galaxy Invaders”	0	“102”	0	5
“Galaxy Invaders”	2317	“103”	40	3
“Galaxy Invaders”	5842	“101”	21	72
“Meteor Blasters”	723	“103”	22	12
“Meteor Blasters”	1000	“101”	12	3
“Starship X”	24	“101”	4	9
“Starship X”	42	“103”	4	19
***	***	***	***	***

Because the non-key attributes Wins and Losses are projected into the index, an application can determine the wins vs. losses ratio for any game, or for any combination of game and user ID.

When you choose the attributes to project into a global secondary index, you must consider the tradeoff between provisioned throughput costs and storage costs:

- If you need to access just a few attributes with the lowest possible latency, consider projecting only those attributes into a global secondary index. The smaller the index, the less that it costs to store it, and the less your write costs are.
- If your application frequently accesses some non-key attributes, you should consider projecting those attributes into a global secondary index. The additional storage costs for the global secondary index offset the cost of performing frequent table scans.
- If you need to access most of the non-key attributes on a frequent basis, you can project these attributes—or even the entire base table—into a global secondary index. This gives you maximum flexibility. However, your storage cost would increase, or even double.
- If your application needs to query a table infrequently, but must perform many writes or updates against the data in the table, consider projecting KEYS_ONLY. The global secondary index would be of minimal size, but would still be available when needed for query activity.

Reading data from a Global Secondary Index

You can retrieve items from a global secondary index using the Query and Scan operations. The GetItem and BatchGetItem operations can't be used on a global secondary index.

Querying a Global Secondary Index

You can use the Query operation to access one or more items in a global secondary index. The query must specify the name of the base table and the name of the index that you want to use, the attributes to be returned in the query results, and any query conditions that you want to apply. DynamoDB can return the results in ascending or descending order.

Consider the following data returned from a Query that requests gaming data for a leaderboard application.

```
{  
    "TableName": "GameScores",  
    "IndexName": "GameTitleIndex",  
    "KeyConditionExpression": "GameTitle = :v_title",  
    "ExpressionAttributeValues": {  
        ":v_title": {"S": "Meteor Blasters"}  
    "ProjectionExpression": "UserId, TopScore",  
    "ScanIndexForward": false  
}
```

In this query:

- DynamoDB accesses *GameTitleIndex*, using the *GameTitle* partition key to locate the index items for Meteor Blasters. All of the index items with this key are stored adjacent to each other for rapid retrieval.
- Within this game, DynamoDB uses the index to access all of the user IDs and top scores for this game.
- The results are returned, sorted in descending order because the *ScanIndexForward* parameter is set to false.

Scanning a Global Secondary Index

You can use the Scan operation to retrieve all of the data from a global secondary index. You must provide the base table name and the index name in the request. With a Scan, DynamoDB reads all of the data in the index and returns it to the application. You can also request that only some of the data be returned, and that the remaining data should be discarded. To do this, use the *FilterExpression* parameter of the Scan operation. For more information, see [Filter expressions for scan](#).

Data synchronization between tables and Global Secondary Indexes

DynamoDB automatically synchronizes each global secondary index with its base table. When an application writes or deletes items in a table, any global secondary indexes on that table are updated asynchronously, using an eventually consistent model. Applications never write directly to an index. However, it is important that you understand the implications of how DynamoDB maintains these indexes.

Global secondary indexes inherit the read/write capacity mode from the base table. For more information, see [Considerations when changing read/write Capacity Mode](#).

When you create a global secondary index, you specify one or more index key attributes and their data types. This means that whenever you write an item to the base table, the data types for those attributes must match the index key schema's data types. In the case of *GameTitleIndex*, the *GameTitle* partition key in the index is defined as a *String* data type. The *TopScore* sort key in the index is of type *Number*. If you try to add an item to the *GameScores* table and specify a different data type for either *GameTitle* or *TopScore*, DynamoDB returns a *ValidationException* because of the data type mismatch.

When you put or delete items in a table, the global secondary indexes on that table are updated in an eventually consistent fashion. Changes to the table data are propagated to the global secondary indexes within a fraction of a second, under normal conditions. However, in some unlikely failure scenarios, longer propagation delays might occur. Because of this, your applications need to anticipate and handle situations where a query on a global secondary index returns results that are not up to date.

If you write an item to a table, you don't have to specify the attributes for any global secondary index sort key. Using GameTitleIndex as an example, you would not need to specify a value for the TopScore attribute to write a new item to the GameScores table. In this case, DynamoDB does not write any data to the index for this particular item.

A table with many global secondary indexes incurs higher costs for write activity than tables with fewer indexes. For more information, see [Provisioned throughput considerations for Global Secondary Indexes](#).

Table classes with Global Secondary Index

A global secondary index will always use the same table class as its base table. Any time a new global secondary index is added for a table, the new index will use the same table class as its base table. When a table's table class is updated, all associated global secondary indexes are updated as well.

Provisioned throughput considerations for Global Secondary Indexes

When you create a global secondary index on a provisioned mode table, you must specify read and write capacity units for the expected workload on that index. The provisioned throughput settings of a global secondary index are separate from those of its base table. A Query operation on a global secondary index consumes read capacity units from the index, not the base table. When you put, update or delete items in a table, the global secondary indexes on that table are also updated. These index updates consume write capacity units from the index, not from the base table.

For example, if you Query a global secondary index and exceed its provisioned read capacity, your request will be throttled. If you perform heavy write activity on the table, but a global secondary index on that table has insufficient write capacity, the write activity on the table will be throttled.

⚠ Important

To avoid potential throttling, the provisioned write capacity for a global secondary index should be equal or greater than the write capacity of the base table because new updates write to both the base table and global secondary index.

To view the provisioned throughput settings for a global secondary index, use the [DescribeTable](#) operation. Detailed information about all of the table's global secondary indexes is returned.

Read capacity units

Global secondary indexes support eventually consistent reads, each of which consume one half of a read capacity unit. This means that a single global secondary index query can retrieve up to 2×4 KB = 8 KB per read capacity unit.

For global secondary index queries, DynamoDB calculates the provisioned read activity in the same way as it does for queries against tables. The only difference is that the calculation is based on the sizes of the index entries, rather than the size of the item in the base table. The number of read capacity units is the sum of all projected attribute sizes across all of the items returned. The result is then rounded up to the next 4 KB boundary. For more information about how DynamoDB calculates provisioned throughput usage, see [Managing settings on DynamoDB provisioned capacity tables](#).

The maximum size of the results returned by a `Query` operation is 1 MB. This includes the sizes of all the attribute names and values across all of the items returned.

For example, consider a global secondary index where each item contains 2,000 bytes of data. Now suppose that you `Query` this index and that the query's `KeyConditionExpression` matches eight items. The total size of the matching items is $2,000 \text{ bytes} \times 8 \text{ items} = 16,000 \text{ bytes}$. This result is then rounded up to the nearest 4 KB boundary. Because global secondary index queries are eventually consistent, the total cost is $0.5 \times (16 \text{ KB} / 4 \text{ KB})$, or 2 read capacity units.

Write capacity units

When an item in a table is added, updated, or deleted, and a global secondary index is affected by this, the global secondary index consumes provisioned write capacity units for the operation. The total provisioned throughput cost for a write consists of the sum of write capacity units consumed by writing to the base table and those consumed by updating the global secondary indexes. If a

write to a table does not require a global secondary index update, no write capacity is consumed from the index.

For a table write to succeed, the provisioned throughput settings for the table and all of its global secondary indexes must have enough write capacity to accommodate the write. Otherwise, the write to the table is throttled.

The cost of writing an item to a global secondary index depends on several factors:

- If you write a new item to the table that defines an indexed attribute, or you update an existing item to define a previously undefined indexed attribute, one write operation is required to put the item into the index.
- If an update to the table changes the value of an indexed key attribute (from A to B), two writes are required, one to delete the previous item from the index and another write to put the new item into the index.
- If an item was present in the index, but a write to the table caused the indexed attribute to be deleted, one write is required to delete the old item projection from the index.
- If an item is not present in the index before or after the item is updated, there is no additional write cost for the index.
- If an update to the table only changes the value of projected attributes in the index key schema, but does not change the value of any indexed key attribute, one write is required to update the values of the projected attributes into the index.

All of these factors assume that the size of each item in the index is less than or equal to the 1 KB item size for calculating write capacity units. Larger index entries require additional write capacity units. You can minimize your write costs by considering which attributes your queries will need to return and projecting only those attributes into the index.

Storage considerations for Global Secondary Indexes

When an application writes an item to a table, DynamoDB automatically copies the correct subset of attributes to any global secondary indexes in which those attributes should appear. Your AWS account is charged for storage of the item in the base table and also for storage of attributes in any global secondary indexes on that table.

The amount of space used by an index item is the sum of the following:

- The size in bytes of the base table primary key (partition key and sort key)

- The size in bytes of the index key attribute
- The size in bytes of the projected attributes (if any)
- 100 bytes of overhead per index item

To estimate the storage requirements for a global secondary index, you can estimate the average size of an item in the index and then multiply by the number of items in the base table that have the global secondary index key attributes.

If a table contains an item where a particular attribute is not defined, but that attribute is defined as an index partition key or sort key, DynamoDB doesn't write any data for that item to the index.

Managing Global Secondary Indexes

This section describes how to create, modify, and delete global secondary indexes in Amazon DynamoDB.

Topics

- [Creating a table with Global Secondary Indexes](#)
- [Describing the Global Secondary Indexes on a table](#)
- [Adding a Global Secondary Index to an existing table](#)
- [Deleting a Global Secondary Index](#)
- [Modifying a Global Secondary Index during creation](#)
- [Detecting and correcting index key violations](#)

Creating a table with Global Secondary Indexes

To create a table with one or more global secondary indexes, use the `CreateTable` operation with the `GlobalSecondaryIndexes` parameter. For maximum query flexibility, you can create up to 20 global secondary indexes (default quota) per table.

You must specify one attribute to act as the index partition key. You can optionally specify another attribute for the index sort key. It is not necessary for either of these key attributes to be the same as a key attribute in the table. For example, in the *GameScores* table (see [Using Global Secondary Indexes in DynamoDB](#)), neither `TopScore` nor `TopScoreDateTime` are key attributes. You could create a global secondary index with a partition key of `TopScore` and a sort key of

TopScoreDateTime. You might use such an index to determine whether there is a correlation between high scores and the time of day a game is played.

Each index key attribute must be a scalar of type String, Number, or Binary. (It cannot be a document or a set.) You can project attributes of any data type into a global secondary index. This includes scalars, documents, and sets. For a complete list of data types, see [Data types](#).

If using provisioned mode, you must provide ProvisionedThroughput settings for the index, consisting of ReadCapacityUnits and WriteCapacityUnits. These provisioned throughput settings are separate from those of the table, but behave in similar ways. For more information, see [Provisioned throughput considerations for Global Secondary Indexes](#).

Global secondary indexes inherit the read/write capacity mode from the base table. For more information, see [Considerations when changing read/write Capacity Mode](#).

Note

Backfill operations and ongoing write operations share write throughput within the global secondary index. When creating a new GSI, it can be important to check if your choice of partition key is producing uneven or narrowed distribution of data or traffic across the new index's partition key values. If this occurs, you could be seeing backfill and write operations occurring at the same time and throttling writes to the base table. The service takes measures to minimize the potential for this scenario, but has no insight into the shape of customer data with respect to the index partition key, the chosen projection, or the sparseness of the index primary key.

If you suspect that your new global secondary index might have narrow or skewed data or traffic distribution across partition key values, consider the following before adding new indexes to operationally important tables.

- It might be safest to add the index at a time when your application is driving the least amount of traffic.
- Consider enabling CloudWatch Contributor Insights on your base table and indexes. This will give you valuable insight into your traffic distribution.
- For provisioned capacity mode base tables and indexes, set the provisioned write capacity of your new index to at least double that of your base table. Watch WriteThrottleEvents, ThrottledRequests, OnlineIndexPercentageProgress, OnlineIndexConsumedWriteCapacity and OnlineIndexThrottleEvents CloudWatch metrics throughout the process. Adjust the provisioned write capacity as

- required to complete the backfill in a reasonable time without any significant throttling effects on your ongoing operations.
- Be prepared to cancel the index creation if you experience operational impact due to write throttling, and increasing the provisioned write capacity in your new GSI does not resolve it.

Describing the Global Secondary Indexes on a table

To view the status of all the global secondary indexes on a table, use the `DescribeTable` operation. The `GlobalSecondaryIndexes` portion of the response shows all of the indexes on the table, along with the current status of each (`IndexStatus`).

The `IndexStatus` for a global secondary index will be one of the following:

- `CREATING` — The index is currently being created, and is not yet available for use.
- `ACTIVE` — The index is ready for use, and applications can perform `Query` operations on the index.
- `UPDATING` — The provisioned throughput settings of the index are being changed.
- `DELETING` — The index is currently being deleted, and can no longer be used.

When DynamoDB has finished building a global secondary index, the index status changes from `CREATING` to `ACTIVE`.

Adding a Global Secondary Index to an existing table

To add a global secondary index to an existing table, use the `UpdateTable` operation with the `GlobalSecondaryIndexUpdates` parameter. You must provide the following:

- An index name. The name must be unique among all the indexes on the table.
- The key schema of the index. You must specify one attribute for the index partition key; you can optionally specify another attribute for the index sort key. It is not necessary for either of these key attributes to be the same as a key attribute in the table. The data types for each schema attribute must be scalar: `String`, `Number`, or `Binary`.
- The attributes to be projected from the table into the index:
 - `KEYS_ONLY` — Each item in the index consists only of the table partition key and sort key values, plus the index key values.

- **INCLUDE** — In addition to the attributes described in KEYS_ONLY, the secondary index includes other non-key attributes that you specify.
- **ALL** — The index includes all of the attributes from the source table.
- The provisioned throughput settings for the index, consisting of ReadCapacityUnits and WriteCapacityUnits. These provisioned throughput settings are separate from those of the table.

You can only create one global secondary index per `UpdateTable` operation.

Phases of index creation

When you add a new global secondary index to an existing table, the table continues to be available while the index is being built. However, the new index is not available for Query operations until its status changes from CREATING to ACTIVE.

Note

Global secondary index creation does not use Application Auto Scaling. Increasing the MIN Application Auto Scaling capacity will not decrease the creation time of the global secondary index.

Behind the scenes, DynamoDB builds the index in two phases:

Resource Allocation

DynamoDB allocates the compute and storage resources that are needed for building the index.

During the resource allocation phase, the `IndexStatus` attribute is CREATING and the `Backfilling` attribute is false. Use the `DescribeTable` operation to retrieve the status of a table and all of its secondary indexes.

While the index is in the resource allocation phase, you can't delete the index or delete its parent table. You also can't modify the provisioned throughput of the index or the table. You cannot add or delete other indexes on the table. However, you can modify the provisioned throughput of these other indexes.

Backfilling

For each item in the table, DynamoDB determines which set of attributes to write to the index based on its projection (KEYS_ONLY, INCLUDE, or ALL). It then writes these attributes to the index. During the backfill phase, DynamoDB tracks the items that are being added, deleted, or updated in the table. The attributes from these items are also added, deleted, or updated in the index as appropriate.

During the backfilling phase, the `IndexStatus` attribute is set to CREATING, and the `Backfilling` attribute is true. Use the `DescribeTable` operation to retrieve the status of a table and all of its secondary indexes.

While the index is backfilling, you cannot delete its parent table. However, you can still delete the index or modify the provisioned throughput of the table and any of its global secondary indexes.

Note

During the backfilling phase, some writes of violating items might succeed while others are rejected. After backfilling, all writes to items that violate the new index's key schema are rejected. We recommend that you run the Violation Detector tool after the backfill phase finishes to detect and resolve any key violations that might have occurred. For more information, see [Detecting and correcting index key violations](#).

While the resource allocation and backfilling phases are in progress, the index is in the CREATING state. During this time, DynamoDB performs read operations on the table. You are not charged for read operations from the base table to populate the global secondary index. However, you are charged for write operations to populate the newly created global secondary index.

When the index build is complete, its status changes to ACTIVE. You can't Query or Scan the index until it is ACTIVE.

Note

In some cases, DynamoDB can't write data from the table to the index because of index key violations. This can occur if:

- The data type of an attribute value does not match the data type of an index key schema data type.

- The size of an attribute exceeds the maximum length for an index key attribute.
- An index key attribute has an empty String or empty Binary attribute value.

Index key violations do not interfere with global secondary index creation. However, when the index becomes ACTIVE, the violating keys are not present in the index.

DynamoDB provides a standalone tool for finding and resolving these issues. For more information, see [Detecting and correcting index key violations](#).

Adding a Global Secondary Index to a large table

The time required for building a global secondary index depends on several factors, such as the following:

- The size of the table
- The number of items in the table that qualify for inclusion in the index
- The number of attributes projected into the index
- The provisioned write capacity of the index
- Write activity on the main table during index builds

If you are adding a global secondary index to a very large table, it might take a long time for the creation process to complete. To monitor progress and determine whether the index has sufficient write capacity, consult the following Amazon CloudWatch metrics:

- `OnlineIndexPercentageProgress`
- `OnlineIndexConsumedWriteCapacity`
- `OnlineIndexThrottleEvents`

Note

For more information about CloudWatch metrics related to DynamoDB, see [DynamoDB metrics](#).

If the provisioned write throughput setting on the index is too low, the index build will take longer to complete. To shorten the time it takes to build a new global secondary index, you can increase its provisioned write capacity temporarily.

Note

As a general rule, we recommend setting the provisioned write capacity of the index to 1.5 times the write capacity of the table. This is a good setting for many use cases. However, your actual requirements might be higher or lower.

While an index is being backfilled, DynamoDB uses internal system capacity to read from the table. This is to minimize the impact of the index creation and to assure that your table does not run out of read capacity.

However, it is possible that the volume of incoming write activity might exceed the provisioned write capacity of the index. This is a bottleneck scenario, in which the index creation takes more time because the write activity to the index is throttled. During the index build, we recommend that you monitor the Amazon CloudWatch metrics for the index to determine whether its consumed write capacity is exceeding its provisioned capacity. In a bottleneck scenario, you should increase the provisioned write capacity on the index to avoid write throttling during the backfill phase.

After the index has been created, you should set its provisioned write capacity to reflect the normal usage of your application.

Deleting a Global Secondary Index

If you no longer need a global secondary index, you can delete it using the `UpdateTable` operation.

You can delete only one global secondary index per `UpdateTable` operation.

While the global secondary index is being deleted, there is no effect on any read or write activity in the parent table. While the deletion is in progress, you can still modify the provisioned throughput on other indexes.

Note

- When you delete a table using the DeleteTable action, all of the global secondary indexes on that table are also deleted.
- Your account will not be charged for the delete operation of the global secondary index.

Modifying a Global Secondary Index during creation

While an index is being built, you can use the `DescribeTable` operation to determine what phase it is in. The description for the index includes a Boolean attribute, `Backfilling`, to indicate whether DynamoDB is currently loading the index with items from the table. If `Backfilling` is true, the resource allocation phase is complete and the index is now backfilling.

While the backfill is proceeding, you can update the provisioned throughput parameters for the index. You might decide to do this in order to speed up the index build: You can increase the write capacity of the index while it is being built, and then decrease it afterward. To modify the provisioned throughput settings of the index, use the `UpdateTable` operation. The index status changes to `UPDATING`, and `Backfilling` is true until the index is ready for use.

During the backfilling phase, you can delete the index that is being created. During this phase, you can't add or delete other indexes on the table.

Note

For indexes that were created as part of a `CreateTable` operation, the `Backfilling` attribute does not appear in the `DescribeTable` output. For more information, see [Phases of index creation](#).

Detecting and correcting index key violations

During the backfill phase of global secondary index creation, Amazon DynamoDB examines each item in the table to determine whether it is eligible for inclusion in the index. Some items might not be eligible because they would cause index key violations. In these cases, the items remain in the table, but the index doesn't have a corresponding entry for that item.

An *index key violation* occurs in the following situations:

- There is a data type mismatch between an attribute value and the index key schema data type. For example, suppose that one of the items in the GameScores table had a TopScore value of type String. If you added a global secondary index with a partition key of TopScore, of type Number, the item from the table would violate the index key.
- An attribute value from the table exceeds the maximum length for an index key attribute. The maximum length of a partition key is 2048 bytes, and the maximum length of a sort key is 1024 bytes. If any of the corresponding attribute values in the table exceed these limits, the item from the table would violate the index key.

 **Note**

If a String or Binary attribute value is set for an attribute that is used as an index key, then the attribute value must have a length greater than zero; otherwise, the item from the table would violate the index key.

This tool does not flag this index key violation, at this time.

If an index key violation occurs, the backfill phase continues without interruption. However, any violating items are not included in the index. After the backfill phase completes, all writes to items that violate the new index's key schema will be rejected.

To identify and fix attribute values in a table that violate an index key, use the Violation Detector tool. To run Violation Detector, you create a configuration file that specifies the name of a table to be scanned, the names and data types of the global secondary index partition key and sort key, and what actions to take if any index key violations are found. Violation Detector can run in one of two different modes:

- **Detection mode** — Detect index key violations. Use detection mode to report the items in the table that would cause key violations in a global secondary index. (You can optionally request that these violating table items be deleted immediately when they are found.) The output from detection mode is written to a file, which you can use for further analysis.
- **Correction mode** — Correct index key violations. In correction mode, Violation Detector reads an input file with the same format as the output file from detection mode. Correction mode reads the records from the input file and, for each record, it either deletes or updates the corresponding items in the table. (Note that if you choose to update the items, you must edit the input file and set appropriate values for these updates.)

Downloading and running Violation Detector

Violation Detector is available as an executable Java Archive (.jar file), and runs on Windows, macOS, or Linux computers. Violation Detector requires Java 1.7 (or later) and Apache Maven.

- [Download violation detector from GitHub](#)

Follow the instructions in the README.md file to download and install Violation Detector using Maven.

To start Violation Detector, go to the directory where you have built `ViolationDetector.java` and enter the following command.

```
java -jar ViolationDetector.jar [options]
```

The Violation Detector command line accepts the following options:

- `-h | --help` — Prints a usage summary and options for Violation Detector.
- `-p | --configFilePath value` — The fully qualified name of a Violation Detector configuration file. For more information, see [The Violation Detector configuration file](#).
- `-t | --detect value` — Detect index key violations in the table, and write them to the Violation Detector output file. If the value of this parameter is set to `keep`, items with key violations are not modified. If the value is set to `delete`, items with key violations are deleted from the table.
- `-c | --correct value` — Read index key violations from an input file, and take corrective actions on the items in the table. If the value of this parameter is set to `update`, items with key violations are updated with new, non-violating values. If the value is set to `delete`, items with key violations are deleted from the table.

The Violation Detector configuration file

At runtime, the Violation Detector tool requires a configuration file. The parameters in this file determine which DynamoDB resources that Violation Detector can access, and how much provisioned throughput it can consume. The following table describes these parameters.

Parameter name	Description	Required?
awsCredentialsFile	The fully qualified name of a file containing your AWS credentials. The credentials file must be in the following format: <pre>accessKey = access_key y_id_goes_here secretKey = secret_key y_goes_here</pre>	Yes
dynamoDBRegion	The AWS Region in which the table resides. For example: us-west-2 .	Yes
tableName	The name of the DynamoDB table to be scanned.	Yes
gsiHashKeyName	The name of the index partition key.	Yes
gsiHashKeyType	The data type of the index partition key—String, Number, or Binary: S N B	Yes
gsiRangeKeyName	The name of the index sort key. Do not specify this parameter if the index only has a simple primary key (partition key).	No
gsiRangeKeyType	The data type of the index sort key—String, Number, or Binary:	No

Parameter name	Description	Required?
	S N B Do not specify this parameter if the index only has a simple primary key (partition key).	
recordDetails	Whether to write the full details of index key violations to the output file. If set to true (the default), full information about the violating items is reported. If set to false, only the number of violations is reported.	No
recordGsiValueInViolationRecord	Whether to write the values of the violating index keys to the output file. If set to true (default), the key values are reported. If set to false, the key values are not reported.	No

Parameter name	Description	Required?
detectionOutputPath	<p>The full path of the Violation Detector output file. This parameter supports writing to a local directory or to Amazon Simple Storage Service (Amazon S3). The following are examples:</p> <pre>detectionOutputPath = //local/path/<i>filename.csv</i> detection OutputPath = s3://<i>bucket/filename.csv</i></pre> <p>Information in the output file appears in comma-separated values (CSV) format. If you don't set <code>detection OutputPath</code>, the output file is named <code>violation_detection.csv</code> and is written to your current working directory.</p>	No

Parameter name	Description	Required?
numOfSegments	<p>The number of parallel scan segments to be used when Violation Detector scans the table. The default value is 1, meaning that the table is scanned in a sequential manner. If the value is 2 or higher, then Violation Detector divides the table into that many logical segments and an equal number of scan threads.</p> <p>The maximum setting for <code>numOfSegments</code> is 4096.</p> <p>For larger tables, a parallel scan is generally faster than a sequential scan. In addition, if the table is large enough to span multiple partitions, a parallel scan distributes its read activity evenly across multiple partitions.</p> <p>For more information about parallel scans in DynamoDB, see Parallel scan.</p>	No

Parameter name	Description	Required?
numOfViolations	<p>The upper limit of index key violations to write to the output file. If set to -1 (the default), the entire table is scanned. If set to a positive integer, then Violation Detector stops after it encounters that number of violations.</p>	No
numOfRecords	<p>The number of items in the table to be scanned. If set to -1 (the default), the entire table is scanned. If set to a positive integer, Violation Detector stops after it scans that many items in the table.</p>	No
readWriteIOPSPercent	<p>Regulates the percentage of provisioned read capacity units that are consumed during the table scan. Valid values range from 1 to 100. The default value (25) means that Violation Detector will consume no more than 25% of the table's provisioned read throughput.</p>	No

Parameter name	Description	Required?
correctionInputPath	<p>The full path of the Violation Detector correction input file. If you run Violation Detector in correction mode, the contents of this file are used to modify or delete data items in the table that violate the global secondary index.</p> <p>The format of the <code>correctionInputPath</code> file is the same as that of the <code>detectionOutputPath</code> file. This lets you process the output from detection mode as input in correction mode.</p>	No

Parameter name	Description	Required?
	<p>correctionOutputPath</p> <p>The full path of the Violation Detector correction output file. This file is created only if there are update errors.</p> <p>This parameter supports writing to a local directory or to Amazon S3. The following are examples:</p> <pre>correctionOutputPath = //<i>local/path/</i> <i>filename.csv</i></pre> <pre>correctionOutputPath = s3://<i>bucket/filename.csv</i></pre> <p>Information in the output file appears in CSV format. If you don't set <code>correctionOutputPath</code>, the output file is named <code>violation_update_errors.csv</code> and is written to your current working directory.</p>	No

Detection

To detect index key violations, use Violation Detector with the `--detect` command line option. To show how this option works, consider the `ProductCatalog` table shown in [Creating tables and loading data for code examples in DynamoDB](#). The following is a list of items in the table. Only the primary key (`Id`) and the `Price` attribute are shown.

Id (primary key)	Price
101	5
102	20
103	200
201	100
202	200
203	300
204	400
205	500

All of the values for Price are of type Number. However, because DynamoDB is schemaless, it is possible to add an item with a non-numeric Price. For example, suppose that you add another item to the ProductCatalog table.

Id (primary key)	Price
999	"Hello"

The table now has a total of nine items.

Now you add a new global secondary index to the table: PriceIndex. The primary key for this index is a partition key, Price, which is of type Number. After the index has been built, it will contain eight items—but the ProductCatalog table has nine items. The reason for this discrepancy is that the value "Hello" is of type String, but PriceIndex has a primary key of type Number. The String value violates the global secondary index key, so it is not present in the index.

To use Violation Detector in this scenario, you first create a configuration file such as the following.

```
# Properties file for violation detection tool configuration.  
# Parameters that are not specified will use default values.  
  
awsCredentialsFile = /home/alice/credentials.txt  
dynamoDBRegion = us-west-2  
tableName = ProductCatalog  
gsiHashKeyName = Price  
gsiHashKeyType = N  
recordDetails = true  
recordGsiValueInViolationRecord = true  
detectionOutputPath = ./gsiViolationCheck.csv  
correctionInputPath = ./gsiViolationCheck.csv  
numOfSegments = 1  
readWriteIOPSPercent = 40
```

Next, you run Violation Detector as in the following example.

```
$ java -jar ViolationDetector.jar --configFilePath config.txt --detect keep  
  
Violation detection started: sequential scan, Table name: ProductCatalog, GSI name:  
PriceIndex  
Progress: Items scanned in total: 9, Items scanned by this thread: 9, Violations  
found by this thread: 1, Violations deleted by this thread: 0  
Violation detection finished: Records scanned: 9, Violations found: 1, Violations  
deleted: 0, see results at: ./gsiViolationCheck.csv
```

If the `recordDetails` config parameter is set to `true`, Violation Detector writes details of each violation to the output file, as in the following example.

```
Table Hash Key,GSI Hash Key Value,GSI Hash Key Violation Type,GSI Hash Key Violation  
Description,GSI Hash Key Update Value(FOR USER),Delete Blank Attributes When Updating?  
(Y/N)  
  
999,"{""S"":""Hello""}",Type Violation,Expected: N Found: S,,
```

The output file is in CSV format. The first line in the file is a header, followed by one record per item that violates the index key. The fields of these violation records are as follows:

- **Table hash key** — The partition key value of the item in the table.
- **Table range key** — The sort key value of the item in the table.
- **GSI hash key value** — The partition key value of the global secondary index.

- **GSI hash key violation type** — Either Type Violation or Size Violation.
- **GSI hash key violation description** — The cause of the violation.
- **GSI hash key update Value(FOR USER)** — In correction mode, a new user-supplied value for the attribute.
- **GSI range key value** — The sort key value of the global secondary index.
- **GSI range key violation type** — Either Type Violation or Size Violation.
- **GSI range key violation description** — The cause of the violation.
- **GSI range key update Value(FOR USER)** — In correction mode, a new user-supplied value for the attribute.
- **Delete blank attribute when Updating(Y/N)** — In correction mode, determines whether to delete (Y) or keep (N) the violating item in the table—but only if either of the following fields are blank:
 - GSI Hash Key Update Value(FOR USER)
 - GSI Range Key Update Value(FOR USER)

If either of these fields are non-blank, then Delete Blank Attribute When Updating(Y/N) has no effect.

 **Note**

The output format might vary, depending on the configuration file and command line options. For example, if the table has a simple primary key (without a sort key), no sort key fields will be present in the output.

The violation records in the file might not be in sorted order.

Correction

To correct index key violations, use Violation Detector with the `--correct` command line option. In correction mode, Violation Detector reads the input file specified by the `correctionInputPath` parameter. This file has the same format as the `detectionOutputPath` file, so that you can use the output from detection as input for correction.

Violation Detector provides two different ways to correct index key violations:

- **Delete violations** — Delete the table items that have violating attribute values.

- **Update violations** — Update the table items, replacing the violating attributes with non-violating values.

In either case, you can use the output file from detection mode as input for correction mode.

Continuing with the ProductCatalog example, suppose that you want to delete the violating item from the table. To do this, you use the following command line.

```
$ java -jar ViolationDetector.jar --configFilePath config.txt --correct delete
```

At this point, you are asked to confirm whether you want to delete the violating items.

```
Are you sure to delete all violations on the table?y/n  
y  
Confirmed, will delete violations on the table...  
Violation correction from file started: Reading records from file: ./  
gsiViolationCheck.csv, will delete these records from table.  
Violation correction from file finished: Violations delete: 1, Violations Update: 0
```

Now both ProductCatalog and PriceIndex have the same number of items.

Working with Global Secondary Indexes: Java

You can use the AWS SDK for Java Document API to create an Amazon DynamoDB table with one or more global secondary indexes, describe the indexes on the table, and perform queries using the indexes.

The following are the common steps for table operations.

1. Create an instance of the DynamoDB class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
3. Call the appropriate method provided by the client that you created in the preceding step.

Topics

- [Create a table with a Global Secondary Index](#)
- [Describe a table with a Global Secondary Index](#)
- [Query a Global Secondary Index](#)

- [Example: Global Secondary Indexes using the AWS SDK for Java document API](#)

Create a table with a Global Secondary Index

You can create global secondary indexes at the same time that you create a table. To do this, use `CreateTable` and provide your specifications for one or more global secondary indexes. The following Java code example creates a table to hold information about weather data. The partition key is `Location` and the sort key is `Date`. A global secondary index named `PrecipIndex` allows fast access to precipitation data for various locations.

The following are the steps to create a table with a global secondary index, using the DynamoDB document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.

You must provide the table name, its primary key, and the provisioned throughput values. For the global secondary index, you must provide the index name, its provisioned throughput settings, the attribute definitions for the index sort key, the key schema for the index, and the attribute projection.

3. Call the `createTable` method by providing the request object as a parameter.

The following Java code example demonstrates the preceding steps. The code creates a table (`WeatherData`) with a global secondary index (`PrecipIndex`). The index partition key is `Date` and its sort key is `Precipitation`. All of the table attributes are projected into the index. Users can query this index to obtain weather data for a particular date, optionally sorting the data by precipitation amount.

Because `Precipitation` is not a key attribute for the table, it is not required. However, `WeatherData` items without `Precipitation` do not appear in `PrecipIndex`.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

// Attribute definitions
ArrayList<AttributeDefinition> attributeDefinitions = new
    ArrayList<AttributeDefinition>();

attributeDefinitions.add(new AttributeDefinition()
```

```
.withAttributeName("Location")
.withAttributeType("S"));
attributeDefinitions.add(new AttributeDefinition()
.withAttributeName("Date")
.withAttributeType("S"));
attributeDefinitions.add(new AttributeDefinition()
.withAttributeName("Precipitation")
.withAttributeType("N"));

// Table key schema
ArrayList<KeySchemaElement> tableKeySchema = new ArrayList<KeySchemaElement>();
tableKeySchema.add(new KeySchemaElement()
.withAttributeName("Location")
.withKeyType(KeyType.HASH)); //Partition key
tableKeySchema.add(new KeySchemaElement()
.withAttributeName("Date")
.withKeyType(KeyType.RANGE)); //Sort key

// PrecipIndex
GlobalSecondaryIndex precipIndex = new GlobalSecondaryIndex()
.withIndexName("PrecipIndex")
.withProvisionedThroughput(new ProvisionedThroughput()
.withReadCapacityUnits((long) 10)
.withWriteCapacityUnits((long) 1))
.withProjection(new Projection().withProjectionType(ProjectionType.ALL));

ArrayList<KeySchemaElement> indexKeySchema = new ArrayList<KeySchemaElement>();

indexKeySchema.add(new KeySchemaElement()
.withAttributeName("Date")
.withKeyType(KeyType.HASH)); //Partition key
indexKeySchema.add(new KeySchemaElement()
.withAttributeName("Precipitation")
.withKeyType(KeyType.RANGE)); //Sort key

precipIndex.setKeySchema(indexKeySchema);

CreateTableRequest createTableRequest = new CreateTableRequest()
.withTableName("WeatherData")
.withProvisionedThroughput(new ProvisionedThroughput()
.withReadCapacityUnits((long) 5)
.withWriteCapacityUnits((long) 1))
.withAttributeDefinitions(attributeDefinitions)
.withKeySchema(tableKeySchema)
```

```
.withGlobalSecondaryIndexes(precipIndex);

Table table = dynamoDB.createTable(createTableRequest);
System.out.println(table.getDescription());
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.

Describe a table with a Global Secondary Index

To get information about global secondary indexes on a table, use `DescribeTable`. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access global secondary index information a table.

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class to represent the index you want to work with.
3. Call the `describe` method on the Table object.

The following Java code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("WeatherData");
TableDescription tableDesc = table.describe();

Iterator<GlobalSecondaryIndexDescription> gsiIter =
    tableDesc.getGlobalSecondaryIndexes().iterator();
while (gsiIter.hasNext()) {
    GlobalSecondaryIndexDescription gsiDesc = gsiIter.next();
    System.out.println("Info for index "
        + gsiDesc.getIndexName() + ":");

    Iterator<KeySchemaElement> kseIter = gsiDesc.getKeySchema().iterator();
    while (kseIter.hasNext()) {
        KeySchemaElement kse = kseIter.next();
        System.out.printf("\t%s: %s\n", kse.getAttributeName(), kse.getKeyType());
    }
}
```

```
Projection projection = gsiDesc.getProjection();
System.out.println("\tThe projection type is: "
    + projection.getProjectionType());
if (projection.getProjectionType().toString().equals("INCLUDE")) {
    System.out.println("\t\tThe non-key projected attributes are: "
        + projection.getNonKeyAttributes());
}
}
```

Query a Global Secondary Index

You can use `Query` on a global secondary index, in much the same way you `Query` a table. You need to specify the index name, the query criteria for the index partition key and sort key (if present), and the attributes that you want to return. In this example, the index is `PrecipIndex`, which has a partition key of `Date` and a sort key of `Precipitation`. The index query returns all of the weather data for a particular date, where the precipitation is greater than zero.

The following are the steps to query a global secondary index using the AWS SDK for Java Document API.

1. Create an instance of the `DynamoDB` class.
2. Create an instance of the `Table` class to represent the index you want to work with.
3. Create an instance of the `Index` class for the index you want to query.
4. Call the `query` method on the `Index` object.

The attribute name `Date` is a `DynamoDB` reserved word. Therefore, you must use an expression attribute name as a placeholder in the `KeyConditionExpression`.

The following Java code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

Table table = dynamoDB.getTable("WeatherData");
Index index = table.getIndex("PrecipIndex");

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("#d = :v_date and Precipitation = :v_precip")
    .withNameMap(new NameMap()
```

```
.with("#d", "Date")
.withValueMap(new ValueMap()
    .withString(":v_date", "2013-08-10")
    .withNumber(":v_precip", 0));

ItemCollection<QueryOutcome> items = index.query(spec);
Iterator<Item> iter = items.iterator();
while (iter.hasNext()) {
    System.out.println(iter.next().toJSONPretty());
}
```

Example: Global Secondary Indexes using the AWS SDK for Java document API

The following Java code example shows how to work with global secondary indexes. The example creates a table named `Issues`, which might be used in a simple bug tracking system for software development. The partition key is `IssueId` and the sort key is `Title`. There are three global secondary indexes on this table:

- `CreateDateIndex` — The partition key is `CreateDate` and the sort key is `IssueId`. In addition to the table keys, the attributes `Description` and `Status` are projected into the index.
- `TitleIndex` — The partition key is `Title` and the sort key is `IssueId`. No attributes other than the table keys are projected into the index.
- `DueDateIndex` — The partition key is `DueDate`, and there is no sort key. All of the table attributes are projected into the index.

After the `Issues` table is created, the program loads the table with data representing software bug reports. It then queries the data using the global secondary indexes. Finally, the program deletes the `Issues` table.

For step-by-step instructions for testing the following example, see [Java code examples](#).

Example

```
package com.amazonaws.codesamples.document;

import java.util.ArrayList;
import java.util.Iterator;

import com.amazonaws.services.dynamodbv2.AmazonDynamoDB;
```

```

```

Working with Global Secondary Indexes: .NET

You can use the AWS SDK for .NET low-level API to create an Amazon DynamoDB table with one or more global secondary indexes, describe the indexes on the table, and perform queries using the indexes. These operations map to the corresponding DynamoDB operations. For more information, see the [Amazon DynamoDB API Reference](#).

The following are the common steps for table operations using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.

2. Provide the required and optional parameters for the operation by creating the corresponding request objects.

For example, create a `CreateTableRequest` object to create a table and `QueryRequest` object to query a table or an index.

3. Run the appropriate method provided by the client that you created in the preceding step.

Topics

- [Create a table with a Global Secondary Index](#)
- [Describe a table with a Global Secondary Index](#)
- [Query a Global Secondary Index](#)
- [Example: Global Secondary Indexes using the AWS SDK for .NET low-level API](#)

Create a table with a Global Secondary Index

You can create global secondary indexes at the same time that you create a table. To do this, use `CreateTable` and provide your specifications for one or more global secondary indexes. The following C# code example creates a table to hold information about weather data. The partition key is `Location` and the sort key is `Date`. A global secondary index named `PrecipIndex` allows fast access to precipitation data for various locations.

The following are the steps to create a table with a global secondary index, using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.

You must provide the table name, its primary key, and the provisioned throughput values.

For the global secondary index, you must provide the index name, its provisioned throughput settings, the attribute definitions for the index sort key, the key schema for the index, and the attribute projection.

3. Run the `CreateTable` method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps. The code creates a table (`WeatherData`) with a global secondary index (`PrecipIndex`). The index partition key is `Date` and its sort key is `Precipitation`. All of the table attributes are projected into the index. Users

can query this index to obtain weather data for a particular date, optionally sorting the data by precipitation amount.

Because Precipitation is not a key attribute for the table, it is not required. However, WeatherData items without Precipitation do not appear in PrecipIndex.

```
client = new AmazonDynamoDBClient();
string tableName = "WeatherData";

// Attribute definitions
var attributeDefinitions = new List<AttributeDefinition>()
{
    {new AttributeDefinition{
        AttributeName = "Location",
        AttributeType = "S"}},
    {new AttributeDefinition{
        AttributeName = "Date",
        AttributeType = "S"}},
    {new AttributeDefinition(){
        AttributeName = "Precipitation",
        AttributeType = "N"}
    }
};

// Table key schema
var tableKeySchema = new List<KeySchemaElement>()
{
    {new KeySchemaElement {
        AttributeName = "Location",
        KeyType = "HASH"}}, //Partition key
    {new KeySchemaElement {
        AttributeName = "Date",
        KeyType = "RANGE"} //Sort key
};
};

// PrecipIndex
var precipIndex = new GlobalSecondaryIndex
{
    IndexName = "PrecipIndex",
    ProvisionedThroughput = new ProvisionedThroughput
    {
        ReadCapacityUnits = (long)10,
```

```
        WriteCapacityUnits = (long)1
    },
    Projection = new Projection { ProjectionType = "ALL" }
};

var indexKeySchema = new List<KeySchemaElement> {
    {new KeySchemaElement { AttributeName = "Date", KeyType = "HASH"}}, //Partition key
    {new KeySchemaElement{AttributeName = "Precipitation",KeyType = "RANGE"}} //Sort key
};

precipIndex.KeySchema = indexKeySchema;

CreateTableRequest createTableRequest = new CreateTableRequest
{
    TableName = tableName,
    ProvisionedThroughput = new ProvisionedThroughput
    {
        ReadCapacityUnits = (long)5,
        WriteCapacityUnits = (long)1
    },
    AttributeDefinitions = attributeDefinitions,
    KeySchema = tableKeySchema,
    GlobalSecondaryIndexes = { precipIndex }
};

CreateTableResponse response = client.CreateTable(createTableRequest);
Console.WriteLine(response.CreateTableResult.TableDescription.TableName);
Console.WriteLine(response.CreateTableResult.TableDescription.TableStatus);
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.

Describe a table with a Global Secondary Index

To get information about global secondary indexes on a table, use `DescribeTable`. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access global secondary index information for a table using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.

2. Run the `describeTable` method by providing the request object as a parameter.

Create an instance of the `DescribeTableRequest` class to provide the request information. You must provide the table name.

3.

The following C# code example demonstrates the preceding steps.

Example

```
client = new AmazonDynamoDBClient();
string tableName = "WeatherData";

DescribeTableResponse response = client.DescribeTable(new DescribeTableRequest
{ TableName = tableName });

List<GlobalSecondaryIndexDescription> globalSecondaryIndexes =
response.DescribeTableResult.Table.GlobalSecondaryIndexes;

// This code snippet will work for multiple indexes, even though
// there is only one index in this example.

foreach (GlobalSecondaryIndexDescription gsiDescription in globalSecondaryIndexes) {
    Console.WriteLine("Info for index " + gsiDescription.IndexName + ":");

    foreach (KeySchemaElement kse in gsiDescription.KeySchema) {
        Console.WriteLine("\t" + kse.AttributeName + ": key type is " + kse.KeyType);
    }

    Projection projection = gsiDescription.Projection;
    Console.WriteLine("\tThe projection type is: " + projection.ProjectionType);

    if (projection.ProjectionType.ToString().Equals("INCLUDE")) {
        Console.WriteLine("\t\tThe non-key projected attributes are: "
+ projection.NonKeyAttributes);
    }
}
```

Query a Global Secondary Index

You can use `Query` on a global secondary index, in much the same way you `Query` a table. You need to specify the index name, the query criteria for the index partition key and sort key (if

present), and the attributes that you want to return. In this example, the index is `PrecipIndex`, which has a partition key of `Date` and a sort key of `Precipitation`. The index query returns all of the weather data for a particular date, where the precipitation is greater than zero.

The following are the steps to query a global secondary index using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `QueryRequest` class to provide the request information.
3. Run the `query` method by providing the request object as a parameter.

The attribute name `Date` is a DynamoDB reserved word. Therefore, you must use an expression attribute name as a placeholder in the `KeyConditionExpression`.

The following C# code example demonstrates the preceding steps.

Example

```
client = new AmazonDynamoDBClient();

QueryRequest queryRequest = new QueryRequest
{
    TableName = "WeatherData",
    IndexName = "PrecipIndex",
    KeyConditionExpression = "#dt = :v_date and Precipitation > :v_precip",
    ExpressionAttributeNames = new Dictionary<String, String> {
        {"#dt", "Date"}
    },
    ExpressionAttributeValues = new Dictionary<string, AttributeValue> {
        {":v_date", new AttributeValue { S = "2013-08-01" }},
        {":v_precip", new AttributeValue { N = "0" }}
    },
    ScanIndexForward = true
};

var result = client.Query(queryRequest);

var items = result.Items;
foreach (var currentItem in items)
{
    foreach (string attr in currentItem.Keys)
    {
        Console.Write(attr + "---> ");
    }
}
```

```
        if (attr == "Precipitation")
    {
        Console.WriteLine(currentItem[attr].N);
    }
    else
    {
        Console.WriteLine(currentItem[attr].S);
    }

}
Console.WriteLine();
}
```

Example: Global Secondary Indexes using the AWS SDK for .NET low-level API

The following C# code example shows how to work with global secondary indexes. The example creates a table named `Issues`, which might be used in a simple bug tracking system for software development. The partition key is `IssueId` and the sort key is `Title`. There are three global secondary indexes on this table:

- `CreateDateIndex` — The partition key is `CreateDate` and the sort key is `IssueId`. In addition to the table keys, the attributes `Description` and `Status` are projected into the index.
- `TitleIndex` — The partition key is `Title` and the sort key is `IssueId`. No attributes other than the table keys are projected into the index.
- `DueDateIndex` — The partition key is `DueDate`, and there is no sort key. All of the table attributes are projected into the index.

After the `Issues` table is created, the program loads the table with data representing software bug reports. It then queries the data using the global secondary indexes. Finally, the program deletes the `Issues` table.

For step-by-step instructions for testing the following sample, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
```

```
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class LowLevelGlobalSecondaryIndexExample

Working with Global Secondary Indexes: AWS CLI

You can use the AWS CLI to create an Amazon DynamoDB table with one or more global secondary indexes, describe the indexes on the table, and perform queries using the indexes.

Topics

- [Create a table with a Global Secondary Index](#)
- [Add a Global Secondary Index to an existing table](#)
- [Describe a table with a Global Secondary Index](#)
- [Query a Global Secondary Index](#)

Create a table with a Global Secondary Index

Global secondary indexes may be created at the same time you create a table. To do this, use the `create-table` parameter and provide your specifications for one or more global secondary indexes. The following example creates a table named `GameScores` with a global secondary index called `GameTitleIndex`. The base table has a partition key of `UserId` and a sort key of `GameTitle`, allowing you to find an individual user's best score for a specific game efficiently, whereas the GSI has a partition key of `GameTitle` and a sort key of `TopScore`, allowing you to quickly find the overall highest score for a particular game.

```
aws dynamodb create-table \
  --table-name GameScores \
  --attribute-definitions AttributeName=UserId,AttributeType=S \
    AttributeName=GameTitle,AttributeType=S \
    AttributeName=TopScore,AttributeType=N \
  --key-schema AttributeName=UserId,KeyType=HASH \
    AttributeName=GameTitle,KeyType=RANGE \
  --provisioned-throughput ReadCapacityUnits=10,WriteCapacityUnits=5 \
  --global-secondary-indexes \
  "[
    {
      \"IndexName\": \"GameTitleIndex\",
      \"KeySchema\": [{\"AttributeName\": \"GameTitle\", \"KeyType\": \"HASH\"}, \
        {\"AttributeName\": \"TopScore\", \"KeyType\": \"RANGE\"}]
    }]
  ]"
```

```
  \"Projection\":{  
    \"ProjectionType\":\"INCLUDE\",  
    \"NonKeyAttributes\":[\"UserId\"]  
  },  
  \"ProvisionedThroughput\": {  
    \"ReadCapacityUnits\": 10,  
    \"WriteCapacityUnits\": 5  
  }  
}  
]  
]"
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table. You can use [describe-table](#) to determine the status of the table creation.

Add a Global Secondary Index to an existing table

Global secondary indexes may also be added or modified after table creation. To do this, use the update-table parameter and provide your specifications for one or more global secondary indexes. The following example uses the same schema as the previous example, but assumes that the table has already been created and we're adding the GSI later.

```
aws dynamodb update-table \  
  --table-name GameScores \  
  --attribute-definitions AttributeName=TopScore,AttributeType=N \  
  --global-secondary-index-updates \  
  "[  
    {  
      \"Create\": {  
        \"IndexName\": \"GameTitleIndex\",  
        \"KeySchema\": [{\"AttributeName\": \"GameTitle\", \"KeyType\": \"HASH\"},  
                      {\"AttributeName\": \"TopScore\", \"KeyType\": \"RANGE\"}],  
        \"Projection\":{  
          \"ProjectionType\":\"INCLUDE\",  
          \"NonKeyAttributes\":[\"UserId\"]  
        }  
      }  
    }  
  ]"
```

Describe a table with a Global Secondary Index

To get information about Global Secondary Indexes on a table, use the `describe-table` parameter. For each index, you can access its name, key schema, and projected attributes.

```
aws dynamodb describe-table --table-name GameScores
```

Query a Global Secondary Index

You can use the query operation on a global secondary index in much the same way that you query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is `GameTitleIndex` and the index sort key is `GameTitle`.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see [Attribute projections](#).

```
aws dynamodb query --table-name GameScores\  
  --index-name GameTitleIndex \  
  --key-condition-expression "GameTitle = :v_game" \  
  --expression-attribute-values '{":v_game":{"S":"Alien Adventure"} }'
```

Local Secondary Indexes

Some applications only need to query data using the base table's primary key. However, there might be situations where an alternative sort key would be helpful. To give your application a choice of sort keys, you can create one or more local secondary indexes on an Amazon DynamoDB table and issue Query or Scan requests against these indexes.

Scenario: Using a Local Secondary Index

As an example, consider the `Thread` table that is defined in [Creating tables and loading data for code examples in DynamoDB](#). This table is useful for an application such as the [AWS discussion forums](#). The following diagram shows how the items in the table would be organized. (Not all of the attributes are shown.)

Thread

ForumName	Subject	LastPostDateTime	Replies	
"S3"	"aaa"	"2015-03-15:17:24:31"	12	...

...

DynamoDB stores all of the items with the same partition key value continuously. In this example, given a particular `ForumName`, a `Query` operation could immediately locate all of the threads for that forum. Within a group of items with the same partition key value, the items are sorted by sort key value. If the sort key (`Subject`) is also provided in the query, DynamoDB can narrow down the results that are returned—for example, returning all of the threads in the "S3" forum that have a `Subject` beginning with the letter "a".

Some requests might require more complex data access patterns. For example:

- Which forum threads get the most views and replies?
- Which thread in a particular forum has the largest number of messages?

- How many threads were posted in a particular forum within a particular time period?

To answer these questions, the `Query` action would not be sufficient. Instead, you would have to Scan the entire table. For a table with millions of items, this would consume a large amount of provisioned read throughput and take a long time to complete.

However, you can specify one or more local secondary indexes on non-key attributes, such as `Replies` or `LastPostDateTime`.

A *local secondary index* maintains an alternate sort key for a given partition key value. A local secondary index also contains a copy of some or all of the attributes from its base table. You specify which attributes are projected into the local secondary index when you create the table. The data in a local secondary index is organized by the same partition key as the base table, but with a different sort key. This lets you access data items efficiently across this different dimension. For greater query or scan flexibility, you can create up to five local secondary indexes per table.

Suppose that an application needs to find all of the threads that have been posted within the last three months in a particular forum. Without a local secondary index, the application would have to Scan the entire `Thread` table and discard any posts that were not within the specified time frame. With a local secondary index, a `Query` operation could use `LastPostDateTime` as a sort key and find the data quickly.

The following diagram shows a local secondary index named `LastPostIndex`. Note that the partition key is the same as that of the `Thread` table, but the sort key is `LastPostDateTime`.

LastPostIndex

*** *** ***

Every local secondary index must meet the following conditions:

- The partition key is the same as that of its base table.
- The sort key consists of exactly one scalar attribute.
- The sort key of the base table is projected into the index, where it acts as a non-key attribute.

In this example, the partition key is ForumName and the sort key of the local secondary index is LastPostDateTime. In addition, the sort key value from the base table (in this example, Subject) is projected into the index, but it is not a part of the index key. If an application needs a list that is based on ForumName and LastPostDateTime, it can issue a Query request against LastPostIndex. The query results are sorted by LastPostDateTime, and can be returned in ascending or descending order. The query can also apply key conditions, such as returning only items that have a LastPostDateTime within a particular time span.

Every local secondary index automatically contains the partition and sort keys from its base table; you can optionally project non-key attributes into the index. When you query the index, DynamoDB can retrieve these projected attributes efficiently. When you query a local secondary index, the

query can also retrieve attributes that are *not* projected into the index. DynamoDB automatically fetches these attributes from the base table, but at a greater latency and with higher provisioned throughput costs.

For any local secondary index, you can store up to 10 GB of data per distinct partition key value. This figure includes all of the items in the base table, plus all of the items in the indexes, that have the same partition key value. For more information, see [Item collections in Local Secondary Indexes](#).

Attribute projections

With LastPostIndex, an application could use ForumName and LastPostDateTime as query criteria. However, to retrieve any additional attributes, DynamoDB must perform additional read operations against the Thread table. These extra reads are known as *fetches*, and they can increase the total amount of provisioned throughput required for a query.

Suppose that you wanted to populate a webpage with a list of all the threads in "S3" and the number of replies for each thread, sorted by the last reply date/time beginning with the most recent reply. To populate this list, you would need the following attributes:

- Subject
- Replies
- LastPostDateTime

The most efficient way to query this data and to avoid fetch operations would be to project the Replies attribute from the table into the local secondary index, as shown in this diagram.

LastPostIndex

ForumName	LastPostDateTime	Subject	Replies
"S3"	"2015-01-03:09:21:11"	"ddd"	9

...

A *projection* is the set of attributes that is copied from a table into a secondary index. The partition key and sort key of the table are always projected into the index; you can project other attributes to support your application's query requirements. When you query an index, Amazon DynamoDB can access any attribute in the projection as if those attributes were in a table of their own.

When you create a secondary index, you need to specify the attributes that will be projected into the index. DynamoDB provides three different options for this:

- *KEYS_ONLY* – Each item in the index consists only of the table partition key and sort key values, plus the index key values. The *KEYS_ONLY* option results in the smallest possible secondary index.
- *INCLUDE* – In addition to the attributes described in *KEYS_ONLY*, the secondary index will include other non-key attributes that you specify.
- *ALL* – The secondary index includes all of the attributes from the source table. Because all of the table data is duplicated in the index, an *ALL* projection results in the largest possible secondary index.

In the previous diagram, the non-key attribute `Replies` is projected into `LastPostIndex`. An application can query `LastPostIndex` instead of the full `Thread` table to populate a webpage with `Subject`, `Replies`, and `LastPostDateTime`. If any other non-key attributes are requested, DynamoDB would need to fetch those attributes from the `Thread` table.

From an application's point of view, fetching additional attributes from the base table is automatic and transparent, so there is no need to rewrite any application logic. However, such fetching can greatly reduce the performance advantage of using a local secondary index.

When you choose the attributes to project into a local secondary index, you must consider the tradeoff between provisioned throughput costs and storage costs:

- If you need to access just a few attributes with the lowest possible latency, consider projecting only those attributes into a local secondary index. The smaller the index, the less that it costs to store it, and the less your write costs are. If there are attributes that you occasionally need to fetch, the cost for provisioned throughput may well outweigh the longer-term cost of storing those attributes.
- If your application frequently accesses some non-key attributes, you should consider projecting those attributes into a local secondary index. The additional storage costs for the local secondary index offset the cost of performing frequent table scans.
- If you need to access most of the non-key attributes on a frequent basis, you can project these attributes—or even the entire base table—into a local secondary index. This gives you maximum flexibility and lowest provisioned throughput consumption, because no fetching would be required. However, your storage cost would increase, or even double if you are projecting all attributes.
- If your application needs to query a table infrequently, but must perform many writes or updates against the data in the table, consider projecting `KEYS_ONLY`. The local secondary index would be of minimal size, but would still be available when needed for query activity.

Creating a Local Secondary Index

To create one or more local secondary indexes on a table, use the `LocalSecondaryIndexes` parameter of the `CreateTable` operation. Local secondary indexes on a table are created when the table is created. When you delete a table, any local secondary indexes on that table are also deleted.

You must specify one non-key attribute to act as the sort key of the local secondary index. The attribute that you choose must be a scalar String, Number, or Binary. Other scalar types, document types, and set types are not allowed. For a complete list of data types, see [Data types](#).

Important

For tables with local secondary indexes, there is a 10 GB size limit per partition key value. A table with local secondary indexes can store any number of items, as long as the total size for any one partition key value does not exceed 10 GB. For more information, see [Item collection size limit](#).

You can project attributes of any data type into a local secondary index. This includes scalars, documents, and sets. For a complete list of data types, see [Data types](#).

Reading data from a Local Secondary Index

You can retrieve items from a local secondary index using the Query and Scan operations. The GetItem and BatchGetItem operations can't be used on a local secondary index.

Querying a Local Secondary Index

In a DynamoDB table, the combined partition key value and sort key value for each item must be unique. However, in a local secondary index, the sort key value does not need to be unique for a given partition key value. If there are multiple items in the local secondary index that have the same sort key value, a Query operation returns all of the items that have the same partition key value. In the response, the matching items are not returned in any particular order.

You can query a local secondary index using either eventually consistent or strongly consistent reads. To specify which type of consistency you want, use the ConsistentRead parameter of the Query operation. A strongly consistent read from a local secondary index always returns the latest updated values. If the query needs to fetch additional attributes from the base table, those attributes will be consistent with respect to the index.

Example

Consider the following data returned from a Query that requests data from the discussion threads in a particular forum.

```
{  
  "TableName": "Thread",
```

```
"IndexName": "LastPostIndex",
"ConsistentRead": false,
"ProjectionExpression": "Subject, LastPostDateTime, Replies, Tags",
"KeyConditionExpression":
    "ForumName = :v_forum and LastPostDateTime between :v_start and :v_end",
"ExpressionAttributeValues": {
    ":v_start": {"S": "2015-08-31T00:00:00.000Z"},
    ":v_end": {"S": "2015-11-31T00:00:00.000Z"},
    ":v_forum": {"S": "EC2"}
}
}
```

In this query:

- DynamoDB accesses `LastPostIndex`, using the `ForumName` partition key to locate the index items for "EC2". All of the index items with this key are stored adjacent to each other for rapid retrieval.
- Within this forum, DynamoDB uses the index to look up the keys that match the specified `LastPostDateTime` condition.
- Because the `Replies` attribute is projected into the index, DynamoDB can retrieve this attribute without consuming any additional provisioned throughput.
- The `Tags` attribute is not projected into the index, so DynamoDB must access the `Thread` table and fetch this attribute.
- The results are returned, sorted by `LastPostDateTime`. The index entries are sorted by partition key value and then by sort key value, and `Query` returns them in the order they are stored. (You can use the `ScanIndexForward` parameter to return the results in descending order.)

Because the `Tags` attribute is not projected into the local secondary index, DynamoDB must consume additional read capacity units to fetch this attribute from the base table. If you need to run this query often, you should project `Tags` into `LastPostIndex` to avoid fetching from the base table. However, if you needed to access `Tags` only occasionally, the additional storage cost for projecting `Tags` into the index might not be worthwhile.

Scanning a Local Secondary Index

You can use `Scan` to retrieve all of the data from a local secondary index. You must provide the base table name and the index name in the request. With a `Scan`, DynamoDB reads all of

the data in the index and returns it to the application. You can also request that only some of the data be returned, and that the remaining data should be discarded. To do this, use the `FilterExpression` parameter of the Scan API. For more information, see [Filter expressions for scan](#).

Item writes and Local Secondary Indexes

DynamoDB automatically keeps all local secondary indexes synchronized with their respective base tables. Applications never write directly to an index. However, it is important that you understand the implications of how DynamoDB maintains these indexes.

When you create a local secondary index, you specify an attribute to serve as the sort key for the index. You also specify a data type for that attribute. This means that whenever you write an item to the base table, if the item defines an index key attribute, its type must match the index key schema's data type. In the case of `LastPostIndex`, the `LastPostDateTime` sort key in the index is defined as a `String` data type. If you try to add an item to the `Thread` table and specify a different data type for `LastPostDateTime` (such as `Number`), DynamoDB returns a `ValidationException` because of the data type mismatch.

There is no requirement for a one-to-one relationship between the items in a base table and the items in a local secondary index. In fact, this behavior can be advantageous for many applications.

A table with many local secondary indexes incurs higher costs for write activity than tables with fewer indexes. For more information, see [Provisioned throughput considerations for Local Secondary Indexes](#).

Important

For tables with local secondary indexes, there is a 10 GB size limit per partition key value. A table with local secondary indexes can store any number of items, as long as the total size for any one partition key value does not exceed 10 GB. For more information, see [Item collection size limit](#).

Provisioned throughput considerations for Local Secondary Indexes

When you create a table in DynamoDB, you provision read and write capacity units for the table's expected workload. That workload includes read and write activity on the table's local secondary indexes.

To view the current rates for provisioned throughput capacity, see [Amazon DynamoDB pricing](#).

Read capacity units

When you query a local secondary index, the number of read capacity units consumed depends on how the data is accessed.

As with table queries, an index query can use either eventually consistent or strongly consistent reads depending on the value of `ConsistentRead`. One strongly consistent read consumes one read capacity unit; an eventually consistent read consumes only half of that. Thus, by choosing eventually consistent reads, you can reduce your read capacity unit charges.

For index queries that request only index keys and projected attributes, DynamoDB calculates the provisioned read activity in the same way as it does for queries against tables. The only difference is that the calculation is based on the sizes of the index entries, rather than the size of the item in the base table. The number of read capacity units is the sum of all projected attribute sizes across all of the items returned; the result is then rounded up to the next 4 KB boundary. For more information about how DynamoDB calculates provisioned throughput usage, see [Managing settings on DynamoDB provisioned capacity tables](#).

For index queries that read attributes that are not projected into the local secondary index, DynamoDB needs to fetch those attributes from the base table, in addition to reading the projected attributes from the index. These fetches occur when you include any non-projected attributes in the `Select` or `ProjectionExpression` parameters of the `Query` operation. Fetching causes additional latency in query responses, and it also incurs a higher provisioned throughput cost: In addition to the reads from the local secondary index described previously, you are charged for read capacity units for every base table item fetched. This charge is for reading each entire item from the table, not just the requested attributes.

The maximum size of the results returned by a `Query` operation is 1 MB. This includes the sizes of all the attribute names and values across all of the items returned. However, if a `Query` against a local secondary index causes DynamoDB to fetch item attributes from the base table, the maximum size of the data in the results might be lower. In this case, the result size is the sum of:

- The size of the matching items in the index, rounded up to the next 4 KB.
- The size of each matching item in the base table, with each item individually rounded up to the next 4 KB.

Using this formula, the maximum size of the results returned by a `Query` operation is still 1 MB.

For example, consider a table where the size of each item is 300 bytes. There is a local secondary index on that table, but only 200 bytes of each item is projected into the index. Now suppose that you Query this index, that the query requires table fetches for each item, and that the query returns 4 items. DynamoDB sums up the following:

- The size of the matching items in the index: $200 \text{ bytes} \times 4 \text{ items} = 800 \text{ bytes}$; this is then rounded up to 4 KB.
- The size of each matching item in the base table: $(300 \text{ bytes, rounded up to 4 KB}) \times 4 \text{ items} = 16 \text{ KB}$.

The total size of the data in the result is therefore 20 KB.

Write capacity units

When an item in a table is added, updated, or deleted, updating the local secondary indexes consumes provisioned write capacity units for the table. The total provisioned throughput cost for a write is the sum of write capacity units consumed by writing to the table and those consumed by updating the local secondary indexes.

The cost of writing an item to a local secondary index depends on several factors:

- If you write a new item to the table that defines an indexed attribute, or you update an existing item to define a previously undefined indexed attribute, one write operation is required to put the item into the index.
- If an update to the table changes the value of an indexed key attribute (from A to B), two writes are required: one to delete the previous item from the index and another write to put the new item into the index.
- If an item was present in the index, but a write to the table caused the indexed attribute to be deleted, one write is required to delete the old item projection from the index.
- If an item is not present in the index before or after the item is updated, there is no additional write cost for the index.

All of these factors assume that the size of each item in the index is less than or equal to the 1 KB item size for calculating write capacity units. Larger index entries require additional write capacity units. You can minimize your write costs by considering which attributes your queries need to return and projecting only those attributes into the index.

Storage considerations for Local Secondary Indexes

When an application writes an item to a table, DynamoDB automatically copies the correct subset of attributes to any local secondary indexes in which those attributes should appear. Your AWS account is charged for storage of the item in the base table and also for storage of attributes in any local secondary indexes on that table.

The amount of space used by an index item is the sum of the following:

- The size in bytes of the base table primary key (partition key and sort key)
- The size in bytes of the index key attribute
- The size in bytes of the projected attributes (if any)
- 100 bytes of overhead per index item

To estimate the storage requirements for a local secondary index, you can estimate the average size of an item in the index and then multiply by the number of items in the index.

If a table contains an item where a particular attribute is not defined, but that attribute is defined as an index sort key, then DynamoDB does not write any data for that item to the index.

Item collections in Local Secondary Indexes

Note

This section pertains only to tables that have local secondary indexes.

In DynamoDB, an *item collection* is any group of items that have the same partition key value in a table and all of its local secondary indexes. In the examples used throughout this section, the partition key for the Thread table is ForumName, and the partition key for LastPostIndex is also ForumName. All the table and index items with the same ForumName are part of the same item collection. For example, in the Thread table and the LastPostIndex local secondary index, there is an item collection for forum EC2 and a different item collection for forum RDS.

The following diagram shows the item collection for forum S3.

Thread

ForumName	Subject	LastPostDateTime	Thread

LastPostIndex

ForumName	LastPostDateTime	Subject	Replies
ForumName: "S3"	"2015-01-03:09:21:11"	"ddd"	9
	"2015-01-22:23:18:01"	"bbb"	3
	"2015-02-31:13:14:21"	"ccc"	4
	"2015-03-15:17:24:31"	"aaa"	12
	"2015-01-18:07:33:42"	"zzz"	0
	"2015-02-12:11:07:56"	"yyy"	18
	"2015-01-19:01:13:24"	"rrr"	3
	"2015-02-22:12:19:44"	"ttt"	5
	"2015-03-11:06:53:00"	"sss"	11

In this diagram, the item collection consists of all the items in Thread and LastPostIndex where the ForumName partition key value is "S3". If there were other local secondary indexes on the table, any items in those indexes with ForumName equal to "S3" would also be part of the item collection.

You can use any of the following operations in DynamoDB to return information about item collections:

- BatchWriteItem
- DeleteItem
- PutItem
- UpdateItem
- TransactWriteItems

Each of these operations supports the `ReturnItemCollectionMetrics` parameter. When you set this parameter to `SIZE`, you can view information about the size of each item collection in the index.

Example

The following is an example from the output of an `UpdateItem` operation on the `Thread` table, with `ReturnItemCollectionMetrics` set to `SIZE`. The item that was updated had a `ForumName` value of "EC2", so the output includes information about that item collection.

```
{  
    ItemCollectionMetrics: {  
        ItemCollectionKey: {  
            ForumName: "EC2"  
        },  
        SizeEstimateRangeGB: [0.0, 1.0]  
    }  
}
```

The `SizeEstimateRangeGB` object shows that the size of this item collection is between 0 and 1 GB. DynamoDB periodically updates this size estimate, so the numbers might be different next time the item is modified.

Item collection size limit

The maximum size of any item collection for a table which has one or more local secondary indexes is 10 GB. This does not apply to item collections in tables without local secondary indexes, and also does not apply to item collections in global secondary indexes. Only tables that have one or more local secondary indexes are affected.

If an item collection exceeds the 10 GB limit, DynamoDB returns an `ItemCollectionSizeLimitExceededException`, and you won't be able to add more items to the item collection or increase the sizes of items that are in the item collection. (Read and write operations that shrink the size of the item collection are still allowed.) You can still add items to other item collections.

To reduce the size of an item collection, you can do one of the following:

- Delete any unnecessary items with the partition key value in question. When you delete these items from the base table, DynamoDB also removes any index entries that have the same partition key value.
- Update the items by removing attributes or by reducing the size of the attributes. If these attributes are projected into any local secondary indexes, DynamoDB also reduces the size of the corresponding index entries.
- Create a new table with the same partition key and sort key, and then move items from the old table to the new table. This might be a good approach if a table has historical data that is infrequently accessed. You might also consider archiving this historical data to Amazon Simple Storage Service (Amazon S3).

When the total size of the item collection drops below 10 GB, you can once again add items with the same partition key value.

We recommend as a best practice that you instrument your application to monitor the sizes of your item collections. One way to do so is to set the `ReturnItemCollectionMetrics` parameter to `SIZE` whenever you use `BatchWriteItem`, `DeleteItem`, `PutItem`, or `UpdateItem`. Your application should examine the `ReturnItemCollectionMetrics` object in the output and log an error message whenever an item collection exceeds a user-defined limit (8 GB, for example). Setting a limit that is less than 10 GB would provide an early warning system so you know that an item collection is approaching the limit in time to do something about it.

Item collections and partitions

In a table with one or more local secondary indexes, each item collection is stored in one partition. The total size of such an item collection is limited to the capability of that partition: 10 GB. For an application where the data model includes item collections which are unbounded in size, or where you might reasonably expect some item collections to grow beyond 10 GB in the future, you should consider using a global secondary index instead.

You should design your applications so that table data is evenly distributed across distinct partition key values. For tables with local secondary indexes, your applications should not create "hot spots" of read and write activity within a single item collection on a single partition.

Working with Local Secondary Indexes: Java

You can use the AWS SDK for Java Document API to create an Amazon DynamoDB table with one or more local secondary indexes, describe the indexes on the table, and perform queries using the indexes.

The following are the common steps for table operations using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.
3. Call the appropriate method provided by the client that you created in the preceding step.

Topics

- [Example: Local Secondary Indexes using the Java document API](#)

Create a table with a Local Secondary Index

Local secondary indexes must be created at the same time you create a table. To do this, use the `createTable` method and provide your specifications for one or more local secondary

indexes. The following Java code example creates a table to hold information about songs in a music collection. The partition key is `Artist` and the sort key is `SongTitle`. A secondary index, `AlbumTitleIndex`, facilitates queries by album title.

The following are the steps to create a table with a local secondary index, using the DynamoDB document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.

You must provide the table name, its primary key, and the provisioned throughput values. For the local secondary index, you must provide the index name, the name and data type for the index sort key, the key schema for the index, and the attribute projection.

3. Call the `createTable` method by providing the request object as a parameter.

The following Java code example demonstrates the preceding steps. The code creates a table (`Music`) with a secondary index on the `AlbumTitle` attribute. The table partition key and sort key, plus the index sort key, are the only attributes projected into the index.

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";

CreateTableRequest createTableRequest = new
CreateTableRequest().withTableName(tableName);

//ProvisionedThroughput
createTableRequest.setProvisionedThroughput(new
ProvisionedThroughput().withReadCapacityUnits((long)5).withWriteCapacityUnits((long)5));

//AttributeDefinitions
ArrayList<AttributeDefinition> attributeDefinitions= new
ArrayList<AttributeDefinition>();
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("Artist").withAttributeType("S"));
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("SongTitle").withAttributeType("S"));
attributeDefinitions.add(new
AttributeDefinition().withAttributeName("AlbumTitle").withAttributeType("S"));
```

```
createTableRequest.setAttributeDefinitions(attributeDefinitions);

//KeySchema
ArrayList<KeySchemaElement> tableKeySchema = new ArrayList<KeySchemaElement>();
tableKeySchema.add(new
    KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH)); // Partition key
tableKeySchema.add(new
    KeySchemaElement().withAttributeName("SongTitle").withKeyType(KeyType.RANGE)); //Sort key

createTableRequest.setKeySchema(tableKeySchema);

ArrayList<KeySchemaElement> indexKeySchema = new ArrayList<KeySchemaElement>();
indexKeySchema.add(new
    KeySchemaElement().withAttributeName("Artist").withKeyType(KeyType.HASH)); // Partition key
indexKeySchema.add(new
    KeySchemaElement().withAttributeName("AlbumTitle").withKeyType(KeyType.RANGE)); // Sort key

Projection projection = new Projection().withProjectionType(ProjectionType.INCLUDE);
ArrayList<String> nonKeyAttributes = new ArrayList<String>();
nonKeyAttributes.add("Genre");
nonKeyAttributes.add("Year");
projection.setNonKeyAttributes(nonKeyAttributes);

LocalSecondaryIndex localSecondaryIndex = new LocalSecondaryIndex()
    .withIndexName("AlbumTitleIndex").withKeySchema(indexKeySchema).withProjection(projection);

ArrayList<LocalSecondaryIndex> localSecondaryIndexes = new
    ArrayList<LocalSecondaryIndex>();
localSecondaryIndexes.add(localSecondaryIndex);
createTableRequest.setLocalSecondaryIndexes(localSecondaryIndexes);

Table table = dynamoDB.createTable(createTableRequest);
System.out.println(table.getDescription());
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.

Describe a table with a Local Secondary Index

To get information about local secondary indexes on a table, use the `describeTable` method. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access local secondary index information of a table using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class. You must provide the table name.
3. Call the `describeTable` method on the Table object.

The following Java code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";

Table table = dynamoDB.getTable(tableName);

TableDescription tableDescription = table.describe();

List<LocalSecondaryIndexDescription> localSecondaryIndexes
    = tableDescription.getLocalSecondaryIndexes();

// This code snippet will work for multiple indexes, even though
// there is only one index in this example.

Iterator<LocalSecondaryIndexDescription> lsiIter = localSecondaryIndexes.iterator();
while (lsiIter.hasNext()) {

    LocalSecondaryIndexDescription lsiDescription = lsiIter.next();
    System.out.println("Info for index " + lsiDescription.getIndexName() + ":");
    Iterator<KeySchemaElement> kseIter = lsiDescription.getKeySchema().iterator();
    while (kseIter.hasNext()) {
        KeySchemaElement kse = kseIter.next();
        System.out.printf("\t%s: %s\n", kse.getAttributeName(), kse.getKeyType());
    }
    Projection projection = lsiDescription.getProjection();
```

```
System.out.println("\tThe projection type is: " + projection.getProjectionType());
if (projection.getProjectionType().toString().equals("INCLUDE")) {
    System.out.println("\t\tThe non-key projected attributes are: " +
projection.getNonKeyAttributes());
}
}
```

Query a Local Secondary Index

You can use the Query operation on a local secondary index in much the same way that you Query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is `AlbumTitleIndex` and the index sort key is `AlbumTitle`.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see [Attribute projections](#).

The following are the steps to query a local secondary index using the AWS SDK for Java Document API.

1. Create an instance of the DynamoDB class.
2. Create an instance of the Table class. You must provide the table name.
3. Create an instance of the Index class. You must provide the index name.
4. Call the query method of the Index class.

The following Java code example demonstrates the preceding steps.

Example

```
AmazonDynamoDB client = AmazonDynamoDBClientBuilder.standard().build();
DynamoDB dynamoDB = new DynamoDB(client);

String tableName = "Music";

Table table = dynamoDB.getTable(tableName);
Index index = table.getIndex("AlbumTitleIndex");

QuerySpec spec = new QuerySpec()
    .withKeyConditionExpression("Artist = :v_artist and AlbumTitle = :v_title")
    .WithValueMap(new ValueMap()
```

```
.withString(":v_artist", "Acme Band")
.withString(":v_title", "Songs About Life"));

ItemCollection<QueryOutcome> items = index.query(spec);

Iterator<Item> itemsIter = items.iterator();

while (itemsIter.hasNext()) {
    Item item = itemsIter.next();
    System.out.println(item.toJSONPretty());
}
```

Example: Local Secondary Indexes using the Java document API

The following Java code example shows how to work with local secondary indexes in Amazon DynamoDB. The example creates a table named `CustomerOrders` with a partition key of `CustomerId` and a sort key of `OrderId`. There are two local secondary indexes on this table:

- `OrderCreationDateIndex` — The sort key is `OrderCreationDate`, and the following attributes are projected into the index:
 - `ProductCategory`
 - `ProductName`
 - `OrderStatus`
 - `ShipmentTrackingId`
- `IsOpenIndex` — The sort key is `IsOpen`, and all of the table attributes are projected into the index.

After the `CustomerOrders` table is created, the program loads the table with data representing customer orders. It then queries the data using the local secondary indexes. Finally, the program deletes the `CustomerOrders` table.

For step-by-step instructions for testing the following sample, see [Java code examples](#).

Example

```
package com.amazonaws.codesamples.document;

import java.util.ArrayList;

- [Describe a table with a Local Secondary Index](#)
- [Query a Local Secondary Index](#)
- [Example: Local Secondary Indexes using the AWS SDK for .NET low-level API](#)

You can use the AWS SDK for .NET low-level API to create an Amazon DynamoDB table with one or more local secondary indexes, describe the indexes on the table, and perform queries using the indexes. These operations map to the corresponding low-level DynamoDB API actions. For more information, see [.NET code examples](#).

The following are the common steps for table operations using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Provide the required and optional parameters for the operation by creating the corresponding request objects.

For example, create a `CreateTableRequest` object to create a table and an `QueryRequest` object to query a table or an index.
3. Run the appropriate method provided by the client that you created in the preceding step.

Create a table with a Local Secondary Index

Local secondary indexes must be created at the same time that you create a table. To do this, use `CreateTable` and provide your specifications for one or more local secondary indexes. The following C# code example creates a table to hold information about songs in a music collection. The partition key is `Artist` and the sort key is `SongTitle`. A secondary index, `AlbumTitleIndex`, facilitates queries by album title.

The following are the steps to create a table with a local secondary index, using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `CreateTableRequest` class to provide the request information.

You must provide the table name, its primary key, and the provisioned throughput values. For the local secondary index, you must provide the index name, the name and data type of the index sort key, the key schema for the index, and the attribute projection.

3. Run the `CreateTable` method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps. The code creates a table (Music) with a secondary index on the AlbumTitle attribute. The table partition key and sort key, plus the index sort key, are the only attributes projected into the index.

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "Music";

CreateTableRequest createTableRequest = new CreateTableRequest()
{
    TableName = tableName
};

//ProvisionedThroughput
createTableRequest.ProvisionedThroughput = new ProvisionedThroughput()
{
    ReadCapacityUnits = (long)5,
    WriteCapacityUnits = (long)5
};

//AttributeDefinitions
List<AttributeDefinition> attributeDefinitions = new List<AttributeDefinition>();

attributeDefinitions.Add(new AttributeDefinition()
{
   AttributeName = "Artist",
   AttributeType = "S"
});

attributeDefinitions.Add(new AttributeDefinition()
{
   AttributeName = "SongTitle",
   AttributeType = "S"
});

attributeDefinitions.Add(new AttributeDefinition()
{
   AttributeName = "AlbumTitle",
   AttributeType = "S"
});

createTableRequest.AttributeDefinitions = attributeDefinitions;

//KeySchema
```

```
List<KeySchemaElement> tableKeySchema = new List<KeySchemaElement>();

tableKeySchema.Add(new KeySchemaElement() { AttributeName = "Artist", KeyType =
    "HASH" }); //Partition key
tableKeySchema.Add(new KeySchemaElement() { AttributeName = "SongTitle", KeyType =
    "RANGE" }); //Sort key

createTableRequest.KeySchema = tableKeySchema;

List<KeySchemaElement> indexKeySchema = new List<KeySchemaElement>();
indexKeySchema.Add(new KeySchemaElement() { AttributeName = "Artist", KeyType =
    "HASH" }); //Partition key
indexKeySchema.Add(new KeySchemaElement() { AttributeName = "AlbumTitle", KeyType =
    "RANGE" }); //Sort key

Projection projection = new Projection() { ProjectionType = "INCLUDE" };

List<string> nonKeyAttributes = new List<string>();
nonKeyAttributes.Add("Genre");
nonKeyAttributes.Add("Year");
projection.NonKeyAttributes = nonKeyAttributes;

LocalSecondaryIndex localSecondaryIndex = new LocalSecondaryIndex()
{
    IndexName = "AlbumTitleIndex",
    KeySchema = indexKeySchema,
    Projection = projection
};

List<LocalSecondaryIndex> localSecondaryIndexes = new List<LocalSecondaryIndex>();
localSecondaryIndexes.Add(localSecondaryIndex);
createTableRequest.LocalSecondaryIndexes = localSecondaryIndexes;

CreateTableResponse result = client.CreateTable(createTableRequest);
Console.WriteLine(result.CreateTableResult.TableDescription.TableName);
Console.WriteLine(result.CreateTableResult.TableDescription.TableStatus);
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table.

Describe a table with a Local Secondary Index

To get information about local secondary indexes on a table, use the `DescribeTable` API. For each index, you can access its name, key schema, and projected attributes.

The following are the steps to access local secondary index information a table using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `DescribeTableRequest` class to provide the request information. You must provide the table name.
3. Run the `describeTable` method by providing the request object as a parameter.
- 4.

The following C# code example demonstrates the preceding steps.

Example

```
AmazonDynamoDBClient client = new AmazonDynamoDBClient();
string tableName = "Music";

DescribeTableResponse response = client.DescribeTable(new DescribeTableRequest()
{ TableName = tableName });
List<LocalSecondaryIndexDescription> localSecondaryIndexes =
    response.DescribeTableResult.Table.LocalSecondaryIndexes;

// This code snippet will work for multiple indexes, even though
// there is only one index in this example.
foreach (LocalSecondaryIndexDescription lsiDescription in localSecondaryIndexes)
{
    Console.WriteLine("Info for index " + lsiDescription.IndexName + ":");

    foreach (KeySchemaElement kse in lsiDescription.KeySchema)
    {
        Console.WriteLine("\t" + kse.AttributeName + ": key type is " + kse.KeyType);
    }

    Projection projection = lsiDescription.Projection;

    Console.WriteLine("\tThe projection type is: " + projection.ProjectionType);
```

```
if (projection.ProjectionType.ToString().Equals("INCLUDE"))
{
    Console.WriteLine("\t\tThe non-key projected attributes are:");

    foreach (String s in projection.NonKeyAttributes)
    {
        Console.WriteLine("\t\t" + s);
    }
}
```

Query a Local Secondary Index

You can use Query on a local secondary index in much the same way you Query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is `AlbumTitleIndex`, and the index sort key is `AlbumTitle`.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see [Attribute projections](#)

The following are the steps to query a local secondary index using the .NET low-level API.

1. Create an instance of the `AmazonDynamoDBClient` class.
2. Create an instance of the `QueryRequest` class to provide the request information.
3. Run the `query` method by providing the request object as a parameter.

The following C# code example demonstrates the preceding steps.

Example

```
QueryRequest queryRequest = new QueryRequest
{
    TableName = "Music",
    IndexName = "AlbumTitleIndex",
    Select = "ALL_ATTRIBUTES",
    ScanIndexForward = true,
    KeyConditionExpression = "Artist = :v_artist and AlbumTitle = :v_title",
    ExpressionAttributeValues = new Dictionary<string, AttributeValue>()
```

```
{  
    ":v_artist", new AttributeValue {S = "Acme Band"}},  
    ":v_title", new AttributeValue {S = "Songs About Life"}}  
,  
};  
  
QueryResponse response = client.Query(queryRequest);  
  
foreach (var attrs in response.Items)  
{  
    foreach (var attrib in attrs)  
    {  
        Console.WriteLine(attrib.Key + " ---> " + attrib.Value.S);  
    }  
    Console.WriteLine();  
}
```

Example: Local Secondary Indexes using the AWS SDK for .NET low-level API

The following C# code example shows how to work with local secondary indexes in Amazon DynamoDB. The example creates a table named `CustomerOrders` with a partition key of `CustomerId` and a sort key of `OrderId`. There are two local secondary indexes on this table:

- `OrderCreationDateIndex` — The sort key is `OrderCreationDate`, and the following attributes are projected into the index:
 - `ProductCategory`
 - `ProductName`
 - `OrderStatus`
 - `ShipmentTrackingId`
- `IsOpenIndex` — The sort key is `IsOpen`, and all of the table attributes are projected into the index.

After the `CustomerOrders` table is created, the program loads the table with data representing customer orders. It then queries the data using the local secondary indexes. Finally, the program deletes the `CustomerOrders` table.

For step-by-step instructions for testing the following example, see [.NET code examples](#).

Example

```
using System;
using System.Collections.Generic;
using System.Linq;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.DataModel;
using Amazon.DynamoDBv2.DocumentModel;
using Amazon.DynamoDBv2.Model;
using Amazon.Runtime;
using Amazon.SecurityToken;

namespace com.amazonaws.codesamples
{
    class LowLevelLocalSecondaryIndexExample

                TableName = tableName
            });

            Console.WriteLine("Table name: {0}, status: {1}",
                           res.Table.TableName,
                           res.Table.TableStatus);
        }
        catch (ResourceNotFoundException)
        {
            tablePresent = false;
        }
    }
}
}
```

Working with Local Secondary Indexes: AWS CLI

You can use the AWS CLI to create an Amazon DynamoDB table with one or more Local Secondary Indexes, describe the indexes on the table, and perform queries using the indexes.

Topics

- [Create a table with a Local Secondary Index](#)
- [Describe a table with a Local Secondary Index](#)
- [Query a Local Secondary Index](#)

Create a table with a Local Secondary Index

Local Secondary Indexes must be created at the same time you create a table. To do this, use the `create-table` parameter and provide your specifications for one or more Local Secondary Indexes. The following example creates a table (`Music`) to hold information about songs in a music collection. The partition key is `Artist` and the sort key is `SongTitle`. A secondary index, `AlbumTitleIndex` on the `AlbumTitle` attribute facilitates queries by album title.

```
aws dynamodb create-table \
  --table-name Music \
  --attribute-definitions AttributeName=Artist,AttributeType=S
  AttributeName=SongTitle,AttributeType=S \
    AttributeName=AlbumTitle,AttributeType=S \
  --key-schema AttributeName=Artist,KeyType=HASH
  AttributeName=SongTitle,KeyType=RANGE \
  --provisioned-throughput \
    ReadCapacityUnits=10,WriteCapacityUnits=5 \
  --local-secondary-indexes \
    "[{\\"IndexName\\": \\"AlbumTitleIndex\\",
    \\"KeySchema\\": [{\\"AttributeName\\":\\"Artist\\",\\"KeyType\\":\\"HASH\\"},
      {\\"AttributeName\\":\\"AlbumTitle\\",\\"KeyType\\":\\"RANGE\\"}],
    \\"Projection\\":{\\"ProjectionType\\":\\"INCLUDE\\", \\"NonKeyAttributes\\":[\\"Genre\\",
      \\"Year\\"]}}]"
```

You must wait until DynamoDB creates the table and sets the table status to ACTIVE. After that, you can begin putting data items into the table. You can use [describe-table](#) to determine the status of the table creation.

Describe a table with a Local Secondary Index

To get information about local secondary indexes on a table, use the `describe-table` parameter. For each index, you can access its name, key schema, and projected attributes.

```
aws dynamodb describe-table --table-name Music
```

Query a Local Secondary Index

You can use the `query` operation on a Local Secondary Index in much the same way that you query a table. You must specify the index name, the query criteria for the index sort key, and the attributes that you want to return. In this example, the index is `AlbumTitleIndex` and the index sort key is `AlbumTitle`.

The only attributes returned are those that have been projected into the index. You could modify this query to select non-key attributes too, but this would require table fetch activity that is relatively expensive. For more information about table fetches, see [Attribute projections](#).

```
aws dynamodb query \  
  --table-name Music \  
  --index-name AlbumTitleIndex \  
  --key-condition-expression "Artist = :v_artist and AlbumTitle = :v_title" \  
  --expression-attribute-values '{":v_artist":{"S":"Acme Band"},":v_title":  
  {"S":"Songs About Life"} }'
```

Managing complex workflows with DynamoDB transactions

Amazon DynamoDB transactions simplify the developer experience of making coordinated, all-or-nothing changes to multiple items both within and across tables. Transactions provide atomicity, consistency, isolation, and durability (ACID) in DynamoDB, helping you to maintain data correctness in your applications.

You can use the DynamoDB transactional read and write APIs to manage complex business workflows that require adding, updating, or deleting multiple items as a single, all-or-nothing operation. For example, a video game developer can ensure that players' profiles are updated correctly when they exchange items in a game or make in-game purchases.

With the transaction write API, you can group multiple `Put`, `Update`, `Delete`, and `ConditionCheck` actions. You can then submit the actions as a single `TransactWriteItems`

operation that either succeeds or fails as a unit. The same is true for multiple Get actions, which you can group and submit as a single `TransactGetItems` operation.

There is no additional cost to enable transactions for your DynamoDB tables. You pay only for the reads or writes that are part of your transaction. DynamoDB performs two underlying reads or writes of every item in the transaction: one to prepare the transaction and one to commit the transaction. These two underlying read/write operations are visible in your Amazon CloudWatch metrics.

To get started with DynamoDB transactions, download the latest AWS SDK or the AWS Command Line Interface (AWS CLI). Then follow the [DynamoDB transactions example](#).

The following sections provide a detailed overview of the transaction APIs and how you can use them in DynamoDB.

Amazon DynamoDB Transactions: How it works

With Amazon DynamoDB transactions, you can group multiple actions together and submit them as a single all-or-nothing `TransactWriteItems` or `TransactGetItems` operation. The following sections describe API operations, capacity management, best practices, and other details about using transactional operations in DynamoDB.

Topics

- [TransactWriteItems API](#)
- [TransactGetItems API](#)
- [Isolation levels for DynamoDB transactions](#)
- [Transaction conflict handling in DynamoDB](#)
- [Using transactional APIs in DynamoDB Accelerator \(DAX\)](#)
- [Capacity management for transactions](#)
- [Best practices for transactions](#)
- [Using transactional APIs with global tables](#)

- [DynamoDB Transactions vs. the AWSLabs transactions client library](#)

TransactWriteItems API

TransactWriteItems is a synchronous and idempotent write operation that groups up to 100 write actions in a single all-or-nothing operation. These actions can target up to 100 distinct items in one or more DynamoDB tables within the same AWS account and in the same Region. The aggregate size of the items in the transaction cannot exceed 4 MB. The actions are completed atomically so that either all of them succeed or none of them succeeds.

Note

- A TransactWriteItems operation differs from a BatchWriteItem operation in that all the actions it contains must be completed successfully, or no changes are made at all. With a BatchWriteItem operation, it is possible that only some of the actions in the batch succeed while the others do not.
- Transactions cannot be performed using indexes.

You can't target the same item with multiple operations within the same transaction. For example, you can't perform a ConditionCheck and also an Update action on the same item in the same transaction.

You can add the following types of actions to a transaction:

- Put — Initiates a PutItem operation to create a new item or replace an old item with a new item, conditionally or without specifying any condition.
- Update — Initiates an UpdateItem operation to edit an existing item's attributes or add a new item to the table if it does not already exist. Use this action to add, delete, or update attributes on an existing item conditionally or without a condition.
- Delete — Initiates a DeleteItem operation to delete a single item in a table identified by its primary key.
- ConditionCheck — Checks that an item exists or checks the condition of specific attributes of the item.

Once a transaction completes, the changes made within that transaction are propagated to global secondary indexes (GSIs), streams, and backups. Since propagation is not immediate or instantaneous, if a table is restored from backup ([RestoreTableFromBackup](#)) or exported to a point in time ([ExportTableToPointInTime](#)) mid-propagation, it might contain some but not all of the changes made during a recent transaction.

Idempotency

You can optionally include a client token when you make a `TransactWriteItems` call to ensure that the request is *idempotent*. Making your transactions idempotent helps prevent application errors if the same operation is submitted multiple times due to a connection time-out or other connectivity issue.

If the original `TransactWriteItems` call was successful, then subsequent `TransactWriteItems` calls with the same client token return successfully without making any changes. If the `ReturnConsumedCapacity` parameter is set, the initial `TransactWriteItems` call returns the number of write capacity units consumed in making the changes. Subsequent `TransactWriteItems` calls with the same client token return the number of read capacity units consumed in reading the item.

Important points about idempotency

- A client token is valid for 10 minutes after the request that uses it finishes. After 10 minutes, any request that uses the same client token is treated as a new request. You should not reuse the same client token for the same request after 10 minutes.
- If you repeat a request with the same client token within the 10-minute idempotency window but change some other request parameter, DynamoDB returns an `IdempotentParameterMismatch` exception.

Error handling for writing

Write transactions don't succeed under the following circumstances:

- When a condition in one of the condition expressions is not met.
- When a transaction validation error occurs because more than one action in the same `TransactWriteItems` operation targets the same item.

- When a `TransactWriteItems` request conflicts with an ongoing `TransactWriteItems` operation on one or more items in the `TransactWriteItems` request. In this case, the request fails with a `TransactionCanceledException`.
- When there is insufficient provisioned capacity for the transaction to be completed.
- When an item size becomes too large (larger than 400 KB), or a local secondary index (LSI) becomes too large, or a similar validation error occurs because of changes made by the transaction.
- When there is a user error, such as an invalid data format.

For more information about how conflicts with `TransactWriteItems` operations are handled, see [Transaction conflict handling in DynamoDB](#).

TransactGetItems API

`TransactGetItems` is a synchronous read operation that groups up to 100 Get actions together. These actions can target up to 100 distinct items in one or more DynamoDB tables within the same AWS account and Region. The aggregate size of the items in the transaction can't exceed 4 MB.

The Get actions are performed atomically so that either all of them succeed or all of them fail:

- Get — Initiates a `GetItem` operation to retrieve a set of attributes for the item with the given primary key. If no matching item is found, Get does not return any data.

Error handling for reading

Read transactions don't succeed under the following circumstances:

- When a `TransactGetItems` request conflicts with an ongoing `TransactWriteItems` operation on one or more items in the `TransactGetItems` request. In this case, the request fails with a `TransactionCanceledException`.
- When there is insufficient provisioned capacity for the transaction to be completed.
- When there is a user error, such as an invalid data format.

For more information about how conflicts with `TransactGetItems` operations are handled, see [Transaction conflict handling in DynamoDB](#).

Isolation levels for DynamoDB transactions

The isolation levels of transactional operations (`TransactWriteItems` or `TransactGetItems`) and other operations are as follows.

SERIALIZABLE

Serializable isolation ensures that the results of multiple concurrent operations are the same as if no operation begins until the previous one has finished.

There is serializable isolation between the following types of operation:

- Between any transactional operation and any standard write operation (`PutItem`, `UpdateItem`, or `DeleteItem`).
- Between any transactional operation and any standard read operation (`GetItem`).
- Between a `TransactWriteItems` operation and a `TransactGetItems` operation.

Although there is serializable isolation between transactional operations, and each individual standard write in a `BatchWriteItem` operation, there is no serializable isolation between the transaction and the `BatchWriteItem` operation as a unit.

Similarly, the isolation level between a transactional operation and individual `GetItems` in a `BatchGetItem` operation is serializable. But the isolation level between the transaction and the `BatchGetItem` operation as a unit is *read-committed*.

A single `GetItem` request is serializable with respect to a `TransactWriteItems` request in one of two ways, either before or after the `TransactWriteItems` request. Multiple `GetItem` requests, against keys in a concurrent `TransactWriteItems` requests can be run in any order, and therefore the results are *read-committed*.

For example, if `GetItem` requests for item A and item B are run concurrently with a `TransactWriteItems` request that modifies both item A and item B, there are four possibilities:

- Both `GetItem` requests are run before the `TransactWriteItems` request.
- Both `GetItem` requests are run after the `TransactWriteItems` request.
- `GetItem` request for item A is run before the `TransactWriteItems` request. For item B the `GetItem` is run after `TransactWriteItems`.
- `GetItem` request for item B is run before the `TransactWriteItems` request. For item A the `GetItem` is run after `TransactWriteItems`.

You should use `TransactGetItems` if you prefer serializable isolation level for multiple `GetItem` requests.

If a non-transactional read is made on multiple items that were part of the same transaction write request in-flight, it is possible that you'll be able to read new state of some of the items and old state of the other items. You'll be able to read new state of all items that were part of the transaction write request only when a successful response is received for the transactional write.

READ-COMMITTED

Read-committed isolation ensures that read operations always return committed values for an item - the read will never present a view to the item representing a state from a transactional write which did not ultimately succeed. Read-committed isolation does not prevent modifications of the item immediately after the read operation.

The isolation level is read-committed between any transactional operation and any read operation that involves multiple standard reads (`BatchGetItem`, `Query`, or `Scan`). If a transactional write updates an item in the middle of a `BatchGetItem`, `Query`, or `Scan` operation, the subsequent part of the read operation returns the newly committed value (with `ConsistentRead`) or possibly a prior committed value (eventually consistent reads).

Operation summary

To summarize, the following table shows the isolation levels between a transaction operation (`TransactWriteItems` or `TransactGetItems`) and other operations.

Operation	Isolation Level
<code>DeleteItem</code>	<i>Serializable</i>
<code>PutItem</code>	<i>Serializable</i>
<code>UpdateItem</code>	<i>Serializable</i>
<code>GetItem</code>	<i>Serializable</i>
<code>BatchGetItem</code>	<i>Read-committed*</i>
<code>BatchWriteItem</code>	<i>NOT Serializable*</i>
<code>Query</code>	<i>Read-committed</i>

Operation	Isolation Level
Scan	<i>Read-committed</i>
Other transactional operation	<i>Serializable</i>

Levels marked with an asterisk (*) apply to the operation as a unit. However, individual actions within those operations have a *serializable* isolation level.

Transaction conflict handling in DynamoDB

A transactional conflict can occur during concurrent item-level requests on an item within a transaction. Transaction conflicts can occur in the following scenarios:

- A PutItem, UpdateItem, or DeleteItem request for an item conflicts with an ongoing TransactWriteItems request that includes the same item.
- An item within a TransactWriteItems request is part of another ongoing TransactWriteItems request.
- An item within a TransactGetItems request is part of an ongoing TransactWriteItems, BatchWriteItem, PutItem, UpdateItem, or DeleteItem request.

Note

- When a PutItem, UpdateItem, or DeleteItem request is rejected, the request fails with a TransactionConflictException.
- If any item-level request within TransactWriteItems or TransactGetItems is rejected, the request fails with a TransactionCanceledException. If that request fails, AWS SDKs do not retry the request.

If you are using the AWS SDK for Java, the exception contains the list of [CancellationReasons](#), ordered according to the list of items in the TransactItems request parameter. For other languages, a string representation of the list is included in the exception's error message.

- If an ongoing TransactWriteItems or TransactGetItems operation conflicts with a concurrent GetItem request, both operations can succeed.

The [TransactionConflict CloudWatch metric](#) is incremented for each failed item-level request.

Using transactional APIs in DynamoDB Accelerator (DAX)

`TransactWriteItems` and `TransactGetItems` are both supported in DynamoDB Accelerator (DAX) with the same isolation levels as in DynamoDB.

`TransactWriteItems` writes through DAX. DAX passes a `TransactWriteItems` call to DynamoDB and returns the response. To populate the cache after the write, DAX calls `TransactGetItems` in the background for each item in the `TransactWriteItems` operation, which consumes additional read capacity units. (For more information, see [Capacity management for transactions](#).) This functionality enables you to keep your application logic simple and use DAX for both transactional operations and nontransactional ones.

`TransactGetItems` calls are passed through DAX without the items being cached locally. This is the same behavior as for strongly consistent read APIs in DAX.

Capacity management for transactions

There is no additional cost to enable transactions for your DynamoDB tables. You pay only for the reads or writes that are part of your transaction. DynamoDB performs two underlying reads or writes of every item in the transaction: one to prepare the transaction and one to commit the transaction. The two underlying read/write operations are visible in your Amazon CloudWatch metrics.

Plan for the additional reads and writes that are required by transactional APIs when you are provisioning capacity to your tables. For example, suppose that your application runs one transaction per second, and each transaction writes three 500-byte items in your table. Each item requires two write capacity units (WCUs): one to prepare the transaction and one to commit the transaction. Therefore, you would need to provision six WCUs to the table.

If you were using DynamoDB Accelerator (DAX) in the previous example, you would also use two read capacity units (RCUs) for each item in the `TransactWriteItems` call. So you would need to provision six additional RCUs to the table.

Similarly, if your application runs one read transaction per second, and each transaction reads three 500-byte items in your table, you would need to provision six read capacity units (RCUs) to the table. Reading each item requires two RCUs: one to prepare the transaction and one to commit the transaction.

Also, default SDK behavior is to retry transactions in case of a `TransactionInProgressException` exception. Plan for the additional read-capacity units (RCUs) that these retries consume. The same is true if you are retrying transactions in your own code using a `ClientRequestToken`.

Best practices for transactions

Consider the following recommended practices when using DynamoDB transactions.

- Enable automatic scaling on your tables, or ensure that you have provisioned enough throughput capacity to perform the two read or write operations for every item in your transaction.
- If you are not using an AWS provided SDK, include a `ClientRequestToken` attribute when you make a `TransactWriteItems` call to ensure that the request is idempotent.
- Don't group operations together in a transaction if it's not necessary. For example, if a single transaction with 10 operations can be broken up into multiple transactions without compromising the application correctness, we recommend splitting up the transaction. Simpler transactions improve throughput and are more likely to succeed.
- Multiple transactions updating the same items simultaneously can cause conflicts that cancel the transactions. We recommend following DynamoDB best practices for data modeling to minimize such conflicts.
- If a set of attributes is often updated across multiple items as part of a single transaction, consider grouping the attributes into a single item to reduce the scope of the transaction.
- Avoid using transactions for ingesting data in bulk. For bulk writes, it is better to use `BatchWriteItem`.

Using transactional APIs with global tables

Operations contained within a DynamoDB transaction are only guaranteed transactional in the region where the transaction is originally executed. Transactionality is not preserved when changes applied within a transaction are replicated across Regions to global tables replicas.

DynamoDB Transactions vs. the AWSLabs transactions client library

DynamoDB transactions provide a more cost-effective, robust, and performant replacement for the [AWSLabs](#) transactions client library. We suggest that you update your applications to use the native, server-side transaction APIs.

Using IAM with DynamoDB transactions

You can use AWS Identity and Access Management (IAM) to restrict the actions that transactional operations can perform in Amazon DynamoDB. For more information about using IAM policies in DynamoDB, see [Identity-based policies for DynamoDB](#).

Permissions for Put, Update, Delete, and Get actions are governed by the permissions used for the underlying PutItem, UpdateItem, DeleteItem, and GetItem operations. For the ConditionCheck action, you can use the dynamodb:ConditionCheck permission in IAM policies.

The following are examples of IAM policies that you can use to configure the DynamoDB transactions.

Example 1: Allow transactional operations

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:ConditionCheckItem",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:GetItem"  
            ],  
            "Resource": [  
                "arn:aws:dynamodb:*:*:table/table04"  
            ]  
        }  
    ]  
}
```

Example 2: Allow only transactional operations

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb:ConditionCheckItem"],  
            "Resource": [  
                "arn:aws:dynamodb:*:*:table/table04"  
            ]  
        }  
    ]  
}
```

```
"Effect": "Allow",
"Action": [
    "dynamodb:ConditionCheckItem",
    "dynamodb:PutItem",
    "dynamodb:UpdateItem",
    "dynamodb>DeleteItem",
    "dynamodb:GetItem"
],
"Resource": [
    "arn:aws:dynamodb:*:*:table/table04"
],
"Condition": {
    "ForAnyValue:StringEquals": {
        "dynamodb:EnclosingOperation": [
            "TransactWriteItems",
            "TransactGetItems"
        ]
    }
}
]
}
```

Example 3: Allow nontransactional reads and writes, and block transactional reads and writes

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "dynamodb:ConditionCheckItem",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb>DeleteItem",
                "dynamodb:GetItem"
            ],
            "Resource": [
                "arn:aws:dynamodb:*:*:table/table04"
            ],
            "Condition": {
                "ForAnyValue:StringEquals": {
```

```
        "dynamodb:EnclosingOperation": [
            "TransactWriteItems",
            "TransactGetItems"
        ],
    }
},
{
    "Effect": "Allow",
    "Action": [
        "dynamodb:PutItem",
        "dynamodb:DeleteItem",
        "dynamodb:GetItem",
        "dynamodb:UpdateItem"
    ],
    "Resource": [
        "arn:aws:dynamodb:*:*:table/table04"
    ]
}
]
```

Example 4: Prevent information from being returned on a ConditionCheck failure

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dynamodb:ConditionCheckItem",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:GetItem"
            ],
            "Resource": "arn:aws:dynamodb:*:*:table/table01",
            "Condition": {
                "StringEqualsIfExists": {
                    "dynamodb:ReturnValues": "NONE"
                }
            }
        }
    ]
}
```

```
    ]  
}
```

DynamoDB transactions example

As an example of a situation in which Amazon DynamoDB transactions can be useful, consider this sample Java application for an online marketplace.

The application has three DynamoDB tables in the backend:

- **Customers** — This table stores details about the marketplace customers. Its primary key is a `CustomerId` unique identifier.
- **ProductCatalog** — This table stores details such as price and availability about the products for sale in the marketplace. Its primary key is a `ProductId` unique identifier.
- **Orders** — This table stores details about orders from the marketplace. Its primary key is an `OrderId` unique identifier.

Making an order

The following code snippets illustrate how to use DynamoDB transactions to coordinate the multiple steps that are required to create and process an order. Using a single all-or-nothing operation ensures that if any part of the transaction fails, no actions in the transaction are run and no changes are made.

In this example, you set up an order from a customer whose `customerId` is `09e8e9c8-ec48`. You then run it as a single transaction using the following simple order-processing workflow:

1. Determine that the customer ID is valid.
2. Make sure that the product is `IN_STOCK`, and update the product status to `SOLD`.
3. Make sure that the order does not already exist, and create the order.

Validate the customer

First, define an action to verify that a customer with `customerId` equal to `09e8e9c8-ec48` exists in the customer table.

```
final String CUSTOMER_TABLE_NAME = "Customers";  
final String CUSTOMER_PARTITION_KEY = "CustomerId";
```

```
final String customerId = "09e8e9c8-ec48";
final HashMap<String, AttributeValue> customerItemKey = new HashMap<>();
customerItemKey.put(CUSTOMER_PARTITION_KEY, new AttributeValue(customerId));

ConditionCheck checkCustomerValid = new ConditionCheck()
    .withTableName(CUSTOMER_TABLE_NAME)
    .withKey(customerItemKey)
    .withConditionExpression("attribute_exists(" + CUSTOMER_PARTITION_KEY + ")");
```

Update the product status

Next, define an action to update the product status to SOLD if the condition that the product status is currently set to IN_STOCK is true. Setting the `ReturnValuesOnConditionCheckFailure` parameter returns the item if the item's product status attribute was not equal to IN_STOCK.

```
final String PRODUCT_TABLE_NAME = "ProductCatalog";
final String PRODUCT_PARTITION_KEY = "ProductId";
HashMap<String, AttributeValue> productItemKey = new HashMap<>();
productItemKey.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));

Map<String, AttributeValue> expressionAttributeValues = new HashMap<>();
expressionAttributeValues.put(":new_status", new AttributeValue("SOLD"));
expressionAttributeValues.put(":expected_status", new AttributeValue("IN_STOCK"));

Update markItemSold = new Update()
    .withTableName(PRODUCT_TABLE_NAME)
    .withKey(productItemKey)
    .withUpdateExpression("SET ProductStatus = :new_status")
    .withExpressionAttributeValues(expressionAttributeValues)
    .withConditionExpression("ProductStatus = :expected_status")

    .withReturnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD);
```

Create the order

Lastly, create the order as long as an order with that OrderId does not already exist.

```
final String ORDER_PARTITION_KEY = "OrderId";
final String ORDER_TABLE_NAME = "Orders";

HashMap<String, AttributeValue> orderItem = new HashMap<>();
orderItem.put(ORDER_PARTITION_KEY, new AttributeValue(orderId));
orderItem.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));
```

```
orderItem.put(CUSTOMER_PARTITION_KEY, new AttributeValue(customerId));
orderItem.put("OrderStatus", new AttributeValue("CONFIRMED"));
orderItem.put("OrderTotal", new AttributeValue("100"));

Put createOrder = new Put()
    .withTableName(ORDER_TABLE_NAME)
    .withItem(orderItem)

    .withReturnValuesOnConditionCheckFailure(ReturnValuesOnConditionCheckFailure.ALL_OLD)
    .withConditionExpression("attribute_not_exists(" + ORDER_PARTITION_KEY + ")");
```

Run the transaction

The following example illustrates how to run the actions defined previously as a single all-or-nothing operation.

```
Collection<TransactWriteItem> actions = Arrays.asList(
    new TransactWriteItem().withConditionCheck(checkCustomerValid),
    new TransactWriteItem().withUpdate(markItemSold),
    new TransactWriteItem().withPut(createOrder));

TransactWriteItemsRequest placeOrderTransaction = new TransactWriteItemsRequest()
    .withTransactItems(actions)
    .withReturnConsumedCapacity(ReturnConsumedCapacity.TOTAL);

// Run the transaction and process the result.
try {
    client.transactWriteItems(placeOrderTransaction);
    System.out.println("Transaction Successful");

} catch (ResourceNotFoundException rnf) {
    System.err.println("One of the table involved in the transaction is not found"
+ rnf.getMessage());
} catch (InternalServerException ise) {
    System.err.println("Internal Server Error" + ise.getMessage());
} catch (TransactionCanceledException tce) {
    System.out.println("Transaction Canceled " + tce.getMessage());
}
```

Reading the order details

The following example shows how to read the completed order transactionally across the Orders and ProductCatalog tables.

```
HashMap<String,AttributeValue> productItemKey = new HashMap<>();
productItemKey.put(PRODUCT_PARTITION_KEY, new AttributeValue(productKey));

HashMap<String,AttributeValue> orderKey = new HashMap<>();
orderKey.put(ORDER_PARTITION_KEY, new AttributeValue(orderId));

Get readProductSold = new Get()
    .withTableName(PRODUCT_TABLE_NAME)
    .withKey(productItemKey);
Get readCreatedOrder = new Get()
    .withTableName(ORDER_TABLE_NAME)
    .withKey(orderKey);

Collection<TransactGetItem> getActions = Arrays.asList(
    new TransactGetItem().withGet(readProductSold),
    new TransactGetItem().withGet(readCreatedOrder));

TransactGetItemsRequest readCompletedOrder = new TransactGetItemsRequest()
    .withTransactItems(getActions)
    .withReturnConsumedCapacity(ReturnConsumedCapacity.TOTAL);

// Run the transaction and process the result.
try {
    TransactGetItemsResult result = client.transactGetItems(readCompletedOrder);
    System.out.println(result.getResponses());
} catch (ResourceNotFoundException rnf) {
    System.err.println("One of the table involved in the transaction is not found" +
        rnf.getMessage());
} catch (InternalServerException ise) {
    System.err.println("Internal Server Error" + ise.getMessage());
} catch (TransactionCanceledException tce) {
    System.err.println("Transaction Canceled" + tce.getMessage());
}
```

Change data capture with Amazon DynamoDB

Many applications benefit from capturing changes to items stored in a DynamoDB table, at the point in time when such changes occur. The following are some example use cases:

- A popular mobile app modifies data in a DynamoDB table, at the rate of thousands of updates per second. Another application captures and stores data about these updates, providing near-real-time usage metrics for the mobile app.
- A financial application modifies stock market data in a DynamoDB table. Different applications running in parallel track these changes in real time, compute value-at-risk, and automatically rebalance portfolios based on stock price movements.
- Sensors in transportation vehicles and industrial equipment send data to a DynamoDB table. Different applications monitor performance and send messaging alerts when a problem is detected, predict any potential defects by applying machine learning algorithms, and compress and archive data to Amazon Simple Storage Service (Amazon S3).
- An application automatically sends notifications to the mobile devices of all friends in a group as soon as one friend uploads a new picture.
- A new customer adds data to a DynamoDB table. This event invokes another application that sends a welcome email to the new customer.

DynamoDB supports streaming of item-level change data capture records in near-real time. You can build applications that consume these streams and take action based on the contents.

The following video will give you an introductory look at the change data capture concept.

[Table capacity modes](#)

Topics

- [Streaming options for change data capture](#)
- [Using Kinesis Data Streams to capture changes to DynamoDB](#)
- [Change data capture for DynamoDB Streams](#)

Streaming options for change data capture

DynamoDB offers two streaming models for change data capture: Kinesis Data Streams for DynamoDB and DynamoDB Streams.

To help you choose the right solution for your application, the following table summarizes the features of each streaming model.

Properties	Kinesis Data Streams for DynamoDB	DynamoDB Streams
Data retention	Up to 1 year .	24 hours.
Kinesis Client Library (KCL) support	Supports KCL versions 1.X and 2.X .	Supports KCL version 1.X .
Number of consumers	Up to 5 simultaneous consumers per shard, or up to 20 simultaneous consumers per shard with enhanced fan-out .	Up to 2 simultaneous consumers per shard.
Throughput quotas	Unlimited.	Subject to throughput quotas by DynamoDB table and AWS Region.
Record delivery model	Pull model over HTTP using GetRecords and with enhanced fan-out , Kinesis Data Streams pushes the records over HTTP/2 by using SubscribeToShard .	Pull model over HTTP using GetRecords .
Ordering of records	The timestamp attribute on each stream record can be used to identify the actual order in which changes occurred in the DynamoDB table.	For each item that is modified in a DynamoDB table, the stream records appear in the same sequence as the actual modifications to the item.
Duplicate records	Duplicate records might occasionally appear in the stream.	No duplicate records appear in the stream.

Properties	Kinesis Data Streams for DynamoDB	DynamoDB Streams
Stream processing options	Process stream records using AWS Lambda , Amazon Managed Service for Apache Flink , Kinesis data firehose , or AWS Glue streaming ETL .	Process stream records using AWS Lambda or DynamoDB Streams Kinesis adapter .
Durability level	Availability zones to provide automatic failover without interruption.	Availability zones to provide automatic failover without interruption.

You can enable both streaming models on the same DynamoDB table.

The following video talks more about the differences between the two options.

[DynamoDB Streams vs Kinesis Data Streams](#)

Using Kinesis Data Streams to capture changes to DynamoDB

You can use Amazon Kinesis Data Streams to capture changes to Amazon DynamoDB.

Kinesis Data Streams captures item-level modifications in any DynamoDB table and replicates them to a [Kinesis data stream](#). Your applications can access this stream and view item-level changes in near-real time. You can continuously capture and store terabytes of data per hour. You can take advantage of longer data retention time—and with enhanced fan-out capability, you can simultaneously reach two or more downstream applications. Other benefits include additional audit and security transparency.

Kinesis Data Streams also gives you access to [Amazon Data Firehose](#) and [Amazon Managed Service for Apache Flink](#). These services can help you build applications that power real-time dashboards, generate alerts, implement dynamic pricing and advertising, and implement sophisticated data analytics and machine learning algorithms.

Note

Using Kinesis data streams for DynamoDB is subject to both [Kinesis Data Streams pricing](#) for the data stream and [DynamoDB pricing](#) for the source table.

How Kinesis Data Streams works with DynamoDB

When a Kinesis data stream is enabled for a DynamoDB table, the table sends out a data record that captures any changes to that table's data. This data record includes:

- The specific time any item was recently created, updated, or deleted
- That item's primary key
- A snapshot of the record before the modification
- A snapshot of the record after the modification

These data records are captured and published in near-real time. After they are written to the Kinesis data stream, they can be read just like any other record. You can use the Kinesis Client Library, use AWS Lambda, call the Kinesis Data Streams API, and use other connected services. For more information, see [Reading Data from Amazon Kinesis Data Streams](#) in the Amazon Kinesis Data Streams Developer Guide.

These changes to data are also captured asynchronously. Kinesis has no performance impact on a table that it's streaming from. The stream records stored in your Kinesis data stream are also encrypted at rest. For more information, see [Data Protection in Amazon Kinesis Data Streams](#).

The Kinesis data stream records might appear in a different order than when the item changes occurred. The same item notifications might also appear more than once in the stream. You can check the `ApproximateCreationDateTime` attribute to identify the order that the item modifications occurred in, and to identify duplicate records.

When you enable a Kinesis data stream as a streaming destination of a DynamoDB table, you can configure the precision of `ApproximateCreationDateTime` values in either milliseconds or microseconds. By default, `ApproximateCreationDateTime` indicates the time of the change in milliseconds. Additionally, you can change this value on an active streaming destination. After such an update, stream records written to Kinesis will have `ApproximateCreationDateTime` values of the desired precision.

Binary values written to DynamoDB must be encoded in [base64-encoded format](#). However, when data records are written to a Kinesis data stream, these encoded binary values are encoded with base64-encoding a second time. When reading these records from a Kinesis data stream, in order to retrieve the raw binary values, applications must decode these values twice.

DynamoDB charges for using Kinesis Data Streams in change data capture units. 1 KB of change per single item counts as one change data capture unit. The KB of change in each item is calculated by the larger of the “before” and “after” images of the item written to the stream, using the same logic as [capacity unit consumption for write operations](#). Similar to how DynamoDB [on-demand](#) mode works, you don't need to provision capacity throughput for change data capture units.

Turning on a Kinesis data stream for your DynamoDB table

You can enable or disable streaming to Kinesis from your existing DynamoDB table by using the AWS Management Console, the AWS SDK, or the AWS Command Line Interface (AWS CLI).

- You can only stream data from DynamoDB to Kinesis Data Streams in the same AWS account and AWS Region as your table.
- You can only stream data from a DynamoDB table to one Kinesis data stream.

Making changes to a Kinesis Data Streams destination on your DynamoDB table

By default, all Kinesis data stream records include an `ApproximateCreationDateTime` attribute. This attribute represents a timestamp in milliseconds of the approximate time when each record was created. You can change the precision of these values by using the <https://console.aws.amazon.com/kinesis>, the SDK or the AWS CLI

Getting started with Kinesis Data Streams for Amazon DynamoDB

This section describes how to use Kinesis Data Streams for Amazon DynamoDB tables with the Amazon DynamoDB console, the AWS Command Line Interface (AWS CLI), and the API.

All of these examples use the Music DynamoDB table that was created as part of the [Getting started with DynamoDB](#) tutorial.

To learn more about how to build consumers and connect your Kinesis data stream to other AWS services, see [Reading data from Kinesis Data Streams](#) in the *Amazon Kinesis Data Streams developer guide*.

Note

When you're first using KDS shards, we recommend setting your shards to scale up and down with usage patterns. After you have accumulated more data on usage patterns, you can adjust the shards in your stream to match.

Console

1. Sign in to the AWS Management Console and open the Kinesis console at <https://console.aws.amazon.com/kinesis/>.
2. Choose **Create data stream** and follow the instructions to create a stream called **samplestream**.
3. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
4. In the navigation pane on the left side of the console, choose **Tables**.
5. Choose the **Music** table.
6. Choose the **Exports and streams** tab.

Music

Amazon Kinesis data stream details

Edit record timestamp precision | Turn off

Status: **On** | Destination stream: **test**

Record timestamp precision: Microsecond

7. (Optional) Under **Amazon Kinesis data stream details**, you can change the record timestamp precision from microsecond (default) to millisecond.
8. Choose **samplestream** from the dropdown list.
9. Choose the **Turn On** button.

AWS CLI

1. Create a Kinesis Data Streams named `samplestream` by using the [create-stream command](#).

```
aws kinesis create-stream --stream-name samplestream --shard-count 3
```

See [Shard management considerations for Kinesis Data Streams](#) before setting the number of shards for the Kinesis data stream.

2. Check that the Kinesis stream is active and ready for use by using the [describe-stream command](#).

```
aws kinesis describe-stream --stream-name samplestream
```

3. Enable Kinesis streaming on the DynamoDB table by using the DynamoDB enable-kinesis-streaming-destination command. Replace the stream-arn value with the one that was returned by describe-stream in the previous step. Optionally, enable streaming with a more granular (microsecond) precision of timestamp values returned on each record.

Enable streaming with microsecond timestamp precision:

```
aws dynamodb enable-kinesis-streaming-destination \
--table-name Music \
--stream-arn arn:aws:kinesis:us-west-2:12345678901:stream/samplestream
--enable-kinesis-streaming-configuration
ApproximateCreationDateTimePrecision=MICROSECOND
```

Or enable streaming with default timestamp precision (millisecond):

```
aws dynamodb enable-kinesis-streaming-destination \
--table-name Music \
--stream-arn arn:aws:kinesis:us-west-2:12345678901:stream/samplestream
```

4. Check if Kinesis streaming is active on the table by using the DynamoDB describe-kinesis-streaming-destination command.

```
aws dynamodb describe-kinesis-streaming-destination --table-name Music
```

5. Write data to the DynamoDB table by using the put-item command, as described in the [DynamoDB Developer Guide](#).

```
aws dynamodb put-item \
--table-name Music \
--item \
'{"Artist": {"S": "No One You Know"}, "SongTitle": {"S": "Call Me Today"}, "AlbumTitle": {"S": "Somewhat Famous"}, "Awards": {"N": "1"}}'

aws dynamodb put-item \
--table-name Music \
--item \
```

```
'{"Artist": {"S": "Acme Band"}, "SongTitle": {"S": "Happy Day"},  
"AlbumTitle": {"S": "Songs About Life"}, "Awards": {"N": "10"} }'
```

6. Use the Kinesis [get-records](#) CLI command to retrieve the Kinesis stream contents. Then use the following code snippet to deserialize the stream content.

```
/**  
 * Takes as input a Record fetched from Kinesis and does arbitrary processing as  
an example.  
 */  
public void processRecord(Record kinesisRecord) throws IOException {  
    ByteBuffer kdsRecordByteBuffer = kinesisRecord.getData();  
    JsonNode rootNode = OBJECT_MAPPER.readTree(kdsRecordByteBuffer.array());  
    JsonNode dynamoDBRecord = rootNode.get("dynamodb");  
    JsonNode oldItemImage = dynamoDBRecord.get("OldImage");  
    JsonNode newItemImage = dynamoDBRecord.get("NewImage");  
    Instant recordTimestamp = fetchTimestamp(dynamoDBRecord);  
  
    /**  
     * Say for example our record contains a String attribute named "stringName"  
and we want to fetch the value  
     * of this attribute from the new item image. The following code fetches  
this value.  
     */  
    JsonNode attributeNode = newItemImage.get("stringName");  
    JsonNode attributeValueNode = attributeNode.get("S"); // Using DynamoDB "S"  
type attribute  
    String attributeValue = attributeValueNode.textValue();  
    System.out.println(attributeValue);  
}  
  
private Instant fetchTimestamp(JsonNode dynamoDBRecord) {  
    JsonNode timestampJson = dynamoDBRecord.get("ApproximateCreationDateTime");  
    JsonNode timestampPrecisionJson =  
dynamoDBRecord.get("ApproximateCreationDateTimePrecision");  
    if (timestampPrecisionJson != null &&  
timestampPrecisionJson.equals("MICROSECOND")) {  
        return Instant.EPOCH.plus(timestampJson.longValue(), ChronoUnit.MICROS);  
    }  
    return Instant.ofEpochMilli(timestampJson.longValue());  
}
```

Java

1. Follow the instructions in the Kinesis Data Streams developer guide to [create](#) a Kinesis data stream named `samplestream` using Java.

See [Shard management considerations for Kinesis Data Streams](#) before setting the number of shards for the Kinesis data stream.

2. Use the following code snippet to enable Kinesis streaming on the DynamoDB table. Optionally, enable streaming with a more granular (microsecond) precision of timestamp values returned on each record.

Enable streaming with microsecond timestamp precision:

```
EnableKinesisStreamingConfiguration enableKdsConfig =
    EnableKinesisStreamingConfiguration.builder()

    .approximateCreationDateTimePrecision(ApproximateCreationDateTimePrecision.MICROSECOND)
    .build();

EnableKinesisStreamingDestinationRequest enableKdsRequest =
    EnableKinesisStreamingDestinationRequest.builder()
    .tableName(tableName)
    .streamArn(kdsArn)
    .enableKinesisStreamingConfiguration(enableKdsConfig)
    .build();

EnableKinesisStreamingDestinationResponse enableKdsResponse =
    ddbClient.enableKinesisStreamingDestination(enableKdsRequest);
```

Or enable streaming with default timestamp precision (millisecond):

```
EnableKinesisStreamingDestinationRequest enableKdsRequest =
    EnableKinesisStreamingDestinationRequest.builder()
    .tableName(tableName)
    .streamArn(kdsArn)
    .build();

EnableKinesisStreamingDestinationResponse enableKdsResponse =
    ddbClient.enableKinesisStreamingDestination(enableKdsRequest);
```

3. Follow the instructions in the *Kinesis Data Streams developer guide* to [read](#) from the created data stream.
4. Use the following code snippet to deserialize the stream content

```
/**  
 * Takes as input a Record fetched from Kinesis and does arbitrary processing as  
an example.  
 */  
public void processRecord(Record kinesisRecord) throws IOException {  
    ByteBuffer kdsRecordByteBuffer = kinesisRecord.getData();  
    JsonNode rootNode = OBJECT_MAPPER.readTree(kdsRecordByteBuffer.array());  
    JsonNode dynamoDBRecord = rootNode.get("dynamodb");  
    JsonNode oldItemImage = dynamoDBRecord.get("OldImage");  
    JsonNode newItemImage = dynamoDBRecord.get("NewImage");  
    Instant recordTimestamp = fetchTimestamp(dynamoDBRecord);  
  
    /**  
     * Say for example our record contains a String attribute named "stringName"  
and we wanted to fetch the value  
     * of this attribute from the new item image, the below code would fetch  
this.  
     */  
    JsonNode attributeNode = newItemImage.get("stringName");  
    JsonNode attributeValueNode = attributeNode.get("S"); // Using DynamoDB "S"  
type attribute  
    String attributeValue = attributeValueNode.textValue();  
    System.out.println(attributeValue);  
}  
  
private Instant fetchTimestamp(JsonNode dynamoDBRecord) {  
    JsonNode timestampJson = dynamoDBRecord.get("ApproximateCreationDateTime");  
    JsonNode timestampPrecisionJson =  
dynamoDBRecord.get("ApproximateCreationDateTimePrecision");  
    if (timestampPrecisionJson != null &&  
timestampPrecisionJson.equals("MICROSECOND")) {  
        return Instant.EPOCH.plus(timestampJson.longValue(), ChronoUnit.MICROS);  
    }  
    return Instant.ofEpochMilli(timestampJson.longValue());  
}
```

Making changes to an active Amazon Kinesis data stream

This section describes how to make changes to an active Kinesis Data Streams for DynamoDB setup by using the console, AWS CLI and the API.

AWS Management Console

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>
2. Go to your table.
3. Choose **Exports and Streams**.

AWS CLI

1. Call `describe-kinesis-streaming-destination` to confirm that the stream is ACTIVE.
2. Call `UpdateKinesisStreamingDestination`, such as in this example:

```
aws dynamodb update-kinesis-streaming-destination --table-name
    enable_test_table --stream-arn arn:aws:kinesis:us-east-1:12345678901:stream/
    enable_test_stream --update-kinesis-streaming-configuration
        ApproximateCreationDateTimePrecision=MICROSECOND
```

3. Call `describe-kinesis-streaming-destination` to confirm that the stream is UPDATING.
4. Call `describe-kinesis-streaming-destination` periodically until the streaming status is ACTIVE again. It typically takes up to 5 minutes for the timestamp precision updates to take effect. Once this status updates, that indicates that the update is complete and the new precision value will be applied on future records.
5. Write to the table using `putItem`.
6. Use the Kinesis `get-records` command to get the stream contents.
7. Confirm that the `ApproximateCreationDateTime` of the writes have the desired precision.

Java API

1. Provide a code snippet that constructs an `UpdateKinesisStreamingDestination` request and an `UpdateKinesisStreamingDestination` response.
2. Provide a code snippet that constructs a `DescribeKinesisStreamingDestination` request and a `DescribeKinesisStreamingDestination` response.

3. Call `describe-kinesis-streaming-destination` periodically until the streaming status is ACTIVE again, indicating that the update is complete and the new precision value will be applied on future records.
4. Perform writes to the table.
5. Read from the stream and deserialize the stream content.
6. Confirm that the `ApproximateCreationDateTime` of the writes have the desired precision.

Configuring shards and monitoring change data capture with Kinesis Data Streams in DynamoDB

Shard management considerations for Kinesis Data Streams

A Kinesis data stream counts its throughput in [shards](#). In Amazon Kinesis Data streams, you can choose between an **on-demand** mode and a **provisioned** mode for your data streams.

We recommend using on-demand mode for your Kinesis Data Stream if your DynamoDB write workload is highly variable and unpredictable. With on-demand mode, there is no capacity planning required as Kinesis Data Streams automatically manages the shards in order to provide the necessary throughput.

For predictable workloads, you can use provisioned mode for your Kinesis Data Stream. With provisioned mode, you must specify the number of shards for the data stream to accommodate the change data capture records from DynamoDB. To determine the number of shards that the Kinesis data stream will need to support your DynamoDB table, you need the following input values:

- The average size of your DynamoDB table's record in bytes (`average_record_size_in_bytes`).
- The maximum number of write operations that your DynamoDB table will perform per second. This includes create, delete, and update operations performed by your applications, as well as automatically generated operations like Time to Live generated delete operations(`write_throughput`).
- The percentage of update and overwrite operations that you perform on your table, as compared to create or delete operations (`percentage_of_updates`). Keep in mind that update and overwrite operations replicate both the old and new images of the modified item to the stream. This generates twice the DynamoDB item size.

You can calculate the number of shards (`number_of_shards`) that your Kinesis data stream needs by using the input values in the following formula:

```
number_of_shards = ceiling( max( ((write_throughput * (4+percentage_of_updates) * average_record_size_in_bytes) / 1024 / 1024), (write_throughput/1000)), 1)
```

For example, you might have a maximum throughput of 1040 write operations per second (`write_throughput`) with an average record size of 800 bytes (`average_record_size_in_bytes`). If 25 percent of those write operations are update operations (`percentage_of_updates`), then you will need two shards (`number_of_shards`) to accommodate your DynamoDB streaming throughput:

```
ceiling( max( ((1040 * (4+25/100) * 800)/ 1024 / 1024), (1040/1000)), 1).
```

Consider the following before using the formula to calculate the number of shards required with provisioned mode for Kinesis data streams:

- This formula helps estimate the number of shards that will be required to accommodate your DynamoDB change data records. It doesn't represent the total number of shards needed in your Kinesis data stream, such as the number of shards required to support additional Kinesis data stream consumers.
- You may still experience read and write throughput exceptions in the provisioned mode if you don't configure your data stream to handle your peak throughput. In this case, you must manually scale your data stream to accommodate your data traffic.
- This formula takes into consideration the additional bloat generated by DynamoDB before streaming the change logs data records to Kinesis Data Stream.

To learn more about capacity modes on Kinesis Data Stream see [Choosing the Data Stream Capacity Mode](#). To learn more about pricing difference between different capacity modes, see [Amazon Kinesis Data Streams pricing](#).

Monitoring change data capture with Kinesis Data Streams

DynamoDB provides several Amazon CloudWatch metrics to help you monitor the replication of change data capture to Kinesis. For a full list of CloudWatch metrics, see [DynamoDB Metrics and dimensions](#).

To determine whether your stream has sufficient capacity, we recommend that you monitor the following items both during stream enabling and in production:

- **ThrottledPutRecordCount:** The number of records that were throttled by your Kinesis data stream because of insufficient Kinesis data stream capacity. You might experience some throttling during exceptional usage peaks, but the ThrottledPutRecordCount should remain as low as possible. DynamoDB retries sending throttled records to the Kinesis data stream, but this might result in higher replication latency.

If you experience excessive and regular throttling, you might need to increase the number of Kinesis stream shards proportionally to the observed write throughput of your table. To learn more about determining the size of a Kinesis data stream, see [Determining the Initial Size of a Kinesis Data Stream](#).

- **AgeOfOldestUnreplicatedRecord:** The elapsed time since the oldest item-level change yet to replicate to the Kinesis data stream appeared in the DynamoDB table. Under normal operation, AgeOfOldestUnreplicatedRecord should be in the order of milliseconds. This number grows based on unsuccessful replication attempts when these are caused by customer-controlled configuration choices.

If AgeOfOldestUnreplicatedRecord metric exceeds 168 hours, replication of item-level changes from the DynamoDB table to Kinesis data stream will be automatically disabled.

Customer-controlled configuration examples that leads to unsuccessful replication attempts are an under-provisioned Kinesis data stream capacity that leads to excessive throttling, or a manual update to your Kinesis data stream's access policies that prevents DynamoDB from adding data to your data stream. To keep this metric as low as possible, you might need to ensure the right provisioning of your Kinesis data stream capacity, and make sure that DynamoDB's permissions are unchanged.

- **FailedToReplicateRecordCount:** The number of records that DynamoDB failed to replicate to your Kinesis data stream. Certain items larger than 34 KB might expand in size to change data records that are larger than the 1 MB item size limit of Kinesis Data Streams. This size expansion occurs when these larger than 34 KB items include a large number of Boolean or empty attribute values. Boolean and empty attribute values are stored as 1 byte in DynamoDB, but expand up to 5 bytes when they're serialized using standard JSON for Kinesis Data Streams replication. DynamoDB can't replicate such change records to your Kinesis data stream. DynamoDB skips these change data records, and automatically continues replicating subsequent records.

You can create Amazon CloudWatch alarms that send an Amazon Simple Notification Service (Amazon SNS) message for notification when any of the preceding metrics exceed a specific threshold. For more information, see [Creating CloudWatch alarms to monitor DynamoDB](#).

Using IAM policies for Amazon Kinesis Data Streams and Amazon DynamoDB

The first time that you enable Amazon Kinesis Data Streams for Amazon DynamoDB, DynamoDB automatically creates an AWS Identity and Access Management (IAM) service-linked role for you. This role, AWSServiceRoleForDynamoDBKinesisDataStreamsReplication, allows DynamoDB to manage the replication of item-level changes to Kinesis Data Streams on your behalf. Don't delete this service-linked role.

For more information about service-linked roles, see [Using service-linked roles in the IAM User Guide](#).

To enable Amazon Kinesis Data Streams for Amazon DynamoDB, you must have the following permissions on the table:

- dynamodb:EnableKinesisStreamingDestination
- kinesis>ListStreams
- kinesis:PutRecords
- kinesis:DescribeStream

To describe Amazon Kinesis Data Streams for Amazon DynamoDB for a given DynamoDB table, you must have the following permissions on the table.

- dynamodb:DescribeKinesisStreamingDestination
- kinesis:DescribeStreamSummary
- kinesis:DescribeStream

To disable Amazon Kinesis Data Streams for Amazon DynamoDB, you must have the following permissions on the table.

- dynamodb:DisableKinesisStreamingDestination

To update Amazon Kinesis Data Streams for Amazon DynamoDB, you must have the following permissions on the table.

- `dynamodb:UpdateKinesisStreamingDestination`

The following examples show how to use IAM policies to grant permissions for Amazon Kinesis Data Streams for Amazon DynamoDB.

Example: Enable Amazon Kinesis Data Streams for Amazon DynamoDB

The following IAM policy grants permissions to enable Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table. It does not grant permissions to disable, update or describe Kinesis Data Streams for DynamoDB for the Music table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "iam:CreateServiceLinkedRole",  
            "Resource": "arn:aws:iam::*:role/aws-service-role/  
kinesisreplication.dynamodb.amazonaws.com/  
AWSServiceRoleForDynamoDBKinesisDataStreamsReplication",  
            "Condition": {"StringLike": {"iam:AWSServiceName":  
"kinesisreplication.dynamodb.amazonaws.com"}}  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
  
                "dynamodb:EnableKinesisStreamingDestination"  
  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:12345678901:table/Music"  
        }  
    ]  
}
```

Example: Update Amazon Kinesis Data Streams for Amazon DynamoDB

The following IAM policy grants permissions to update Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table. It does not grant permissions to enable, disable or describe Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table.

```
{
```

```
"Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
        "Action": [
          "dynamodb:UpdateKinesisStreamingDestination"
        ],
      "Resource": "arn:aws:dynamodb:us-west-2:12345678901:table/Music"
    }
  ]
}
```

Example: Disable Amazon Kinesis Data Streams for Amazon DynamoDB

The following IAM policy grants permissions to disable Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table. It does not grant permissions to enable, update or describe Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
        "Action": [
          "dynamodb:DisableKinesisStreamingDestination"
        ],
      "Resource": "arn:aws:dynamodb:us-west-2:12345678901:table/Music"
    }
  ]
}
```

Example: Selectively apply permissions for Amazon Kinesis Data Streams for Amazon DynamoDB based on resource

The following IAM policy grants permissions to enable and describe Amazon Kinesis Data Streams for Amazon DynamoDB for the Music table, and denies permissions to disable Amazon Kinesis Data Streams for Amazon DynamoDB for the Orders table.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "dynamodb:EnableKinesisStreamingDestination",  
        "dynamodb:DescribeKinesisStreamingDestination"  
    ],  
    "Resource": "arn:aws:dynamodb:us-west-2:12345678901:table/Music"  
},  
{  
    "Effect": "Deny",  
    "Action": [  
        "dynamodb:DisableKinesisStreamingDestination"  
    ],  
    "Resource": "arn:aws:dynamodb:us-west-2:12345678901:table/Orders"  
}  
]  
}
```

Using service-linked roles for Kinesis Data Streams for DynamoDB

Amazon Kinesis Data Streams for Amazon DynamoDB uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Kinesis Data Streams for DynamoDB. Service-linked roles are predefined by Kinesis Data Streams for DynamoDB and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Kinesis Data Streams for DynamoDB easier because you don't have to manually add the necessary permissions. Kinesis Data Streams for DynamoDB defines the permissions of its service-linked roles, and unless defined otherwise, only Kinesis Data Streams for DynamoDB can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Kinesis Data Streams for DynamoDB

Kinesis Data Streams for DynamoDB uses the service-linked role named **AWSServiceRoleForDynamoDBKinesisDataStreamsReplication**. The purpose of the service-linked

role is to allow Amazon DynamoDB to manage the replication of item-level changes to Kinesis Data Streams, on your behalf.

The `AWSServiceRoleForDynamoDBKinesisDataStreamsReplication` service-linked role trusts the following services to assume the role:

- `kinesisreplication.dynamodb.amazonaws.com`

The role permissions policy allows Kinesis Data Streams for DynamoDB to complete the following actions on the specified resources:

- Action: `Put records` and `describe` on Kinesis stream
- Action: `Generate data keys` on AWS KMS in order to put data on Kinesis streams that are encrypted using User-Generated AWS KMS keys.

For the exact contents of the policy document, see [DynamoDBKinesisReplicationServiceRolePolicy](#).

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Creating a service-linked role for Kinesis Data Streams for DynamoDB

You don't need to manually create a service-linked role. When you enable Kinesis Data Streams for DynamoDB in the AWS Management Console, the AWS CLI, or the AWS API, Kinesis Data Streams for DynamoDB creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you enable Kinesis Data Streams for DynamoDB, Kinesis Data Streams for DynamoDB creates the service-linked role for you again.

Editing a service-linked role for Kinesis Data Streams for DynamoDB

Kinesis Data Streams for DynamoDB does not allow you to edit the `AWSServiceRoleForDynamoDBKinesisDataStreamsReplication` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Deleting a service-linked role for Kinesis Data Streams for DynamoDB

You can also use the IAM console, the AWS CLI or the AWS API to manually delete the service-linked role. To do this, you must first manually clean up the resources for your service-linked role and then you can manually delete it.

Note

If the Kinesis Data Streams for DynamoDB service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To manually delete the service-linked role using IAM

Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForDynamoDBKinesisDataStreamsReplication` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Change data capture for DynamoDB Streams

DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table and stores this information in a log for up to 24 hours. Applications can access this log and view the data items as they appeared before and after they were modified, in near-real time.

Encryption at rest encrypts the data in DynamoDB streams. For more information, see [DynamoDB encryption at rest](#).

A *DynamoDB stream* is an ordered flow of information about changes to items in a DynamoDB table. When you enable a stream on a table, DynamoDB captures information about every modification to data items in the table.

Whenever an application creates, updates, or deletes items in the table, DynamoDB Streams writes a stream record with the primary key attributes of the items that were modified. A *stream record* contains information about a data modification to a single item in a DynamoDB table. You can configure the stream so that the stream records capture additional information, such as the "before" and "after" images of modified items.

DynamoDB Streams helps ensure the following:

- Each stream record appears exactly once in the stream.
- For each item that is modified in a DynamoDB table, the stream records appear in the same sequence as the actual modifications to the item.

DynamoDB Streams writes stream records in near-real time so that you can build applications that consume these streams and take action based on the contents.

Topics

- [Endpoints for DynamoDB Streams](#)
- [Enabling a stream](#)
- [Reading and processing a stream](#)
- [DynamoDB Streams and Time to Live](#)
- [Using the DynamoDB Streams Kinesis adapter to process stream records](#)
- [DynamoDB Streams low-level API: Java example](#)
- [DynamoDB Streams and AWS Lambda triggers](#)

Endpoints for DynamoDB Streams

AWS maintains separate endpoints for DynamoDB and DynamoDB Streams. To work with database tables and indexes, your application must access a DynamoDB endpoint. To read and process DynamoDB Streams records, your application must access a DynamoDB Streams endpoint in the same Region.

The naming convention for DynamoDB Streams endpoints is `streams.dynamodb.<region>.amazonaws.com`. For example, if you use the endpoint `dynamodb.us-west-2.amazonaws.com` to access DynamoDB, you would use the endpoint `streams.dynamodb.us-west-2.amazonaws.com` to access DynamoDB Streams.

Note

For a complete list of DynamoDB and DynamoDB Streams Regions and endpoints, see [Regions and endpoints](#) in the *AWS General Reference*.

The AWS SDKs provide separate clients for DynamoDB and DynamoDB Streams. Depending on your requirements, your application can access a DynamoDB endpoint, a DynamoDB Streams

endpoint, or both at the same time. To connect to both endpoints, your application must instantiate two clients—one for DynamoDB and one for DynamoDB Streams.

Enabling a stream

You can enable a stream on a new table when you create it using the AWS CLI or one of the AWS SDKs. You can also enable or disable a stream on an existing table, or change the settings of a stream. DynamoDB Streams operates asynchronously, so there is no performance impact on a table if you enable a stream.

The easiest way to manage DynamoDB Streams is by using the AWS Management Console.

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. On the DynamoDB console dashboard, choose **Tables** and select an existing table.
3. Choose the **Exports and streams** tab.
4. In the **DynamoDB stream details** section, choose **Turn on**.
5. On the **Turn on DynamoDB stream** page, choose the information that will be written to the stream whenever the data in the table is modified:
 - **Key attributes only** — Only the key attributes of the modified item.
 - **New image** — The entire item, as it appears after it was modified.
 - **Old image** — The entire item, as it appeared before it was modified.
 - **New and old images** — Both the new and the old images of the item.

When the settings are as you want them, choose **Turn on stream**.

6. (Optional) To disable an existing stream, choose **Turn off** under **DynamoDB stream details**.

You can also use the `CreateTable` or `UpdateTable` API operations to enable or modify a stream. The `StreamSpecification` parameter determines how the stream is configured:

- `StreamEnabled` — Specifies whether a stream is enabled (`true`) or disabled (`false`) for the table.
- `StreamViewType` — Specifies the information that will be written to the stream whenever data in the table is modified:
 - `KEYS_ONLY` — Only the key attributes of the modified item.

- NEW_IMAGE — The entire item, as it appears after it was modified.
- OLD_IMAGE — The entire item, as it appeared before it was modified.
- NEW_AND_OLD_IMAGES — Both the new and the old images of the item.

You can enable or disable a stream at any time. However, you receive a `ResourceInUseException` if you try to enable a stream on a table that already has a stream. You receive a `ValidationException` if you try to disable a stream on a table that doesn't have a stream.

When you set `StreamEnabled` to `true`, DynamoDB creates a new stream with a unique stream descriptor assigned to it. If you disable and then re-enable a stream on the table, a new stream is created with a different stream descriptor.

Every stream is uniquely identified by an Amazon Resource Name (ARN). The following is an example ARN for a stream on a DynamoDB table named `TestTable`.

```
arn:aws:dynamodb:us-west-2:111122223333:table/TestTable/stream/2015-05-11T21:21:33.291
```

To determine the latest stream descriptor for a table, issue a DynamoDB `DescribeTable` request and look for the `LatestStreamArn` element in the response.

 **Note**

It is not possible to edit a `StreamViewType` once a stream has been setup. If you need to make changes to a stream after it has been setup, you must disable the current stream and create a new one.

Reading and processing a stream

To read and process a stream, your application must connect to a DynamoDB Streams endpoint and issue API requests.

A stream consists of *stream records*. Each stream record represents a single data modification in the DynamoDB table to which the stream belongs. Each stream record is assigned a sequence number, reflecting the order in which the record was published to the stream.

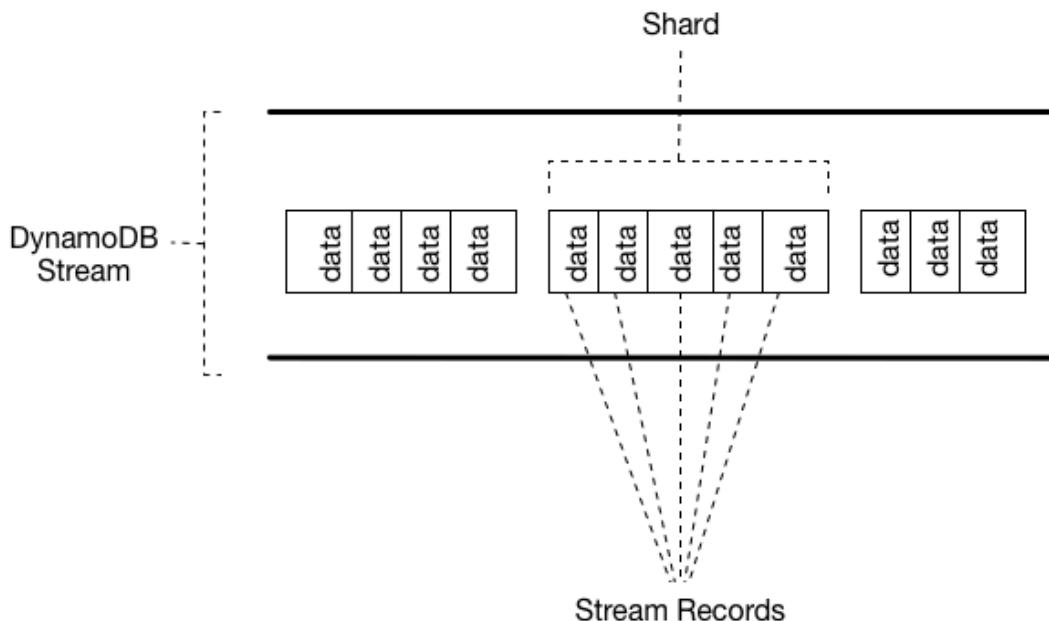

Stream records are organized into groups, or *shards*. Each shard acts as a container for multiple stream records, and contains information required for accessing and iterating through these records. The stream records within a shard are removed automatically after 24 hours.

Shards are ephemeral: They are created and deleted automatically, as needed. Any shard can also split into multiple new shards; this also occurs automatically. (It's also possible for a parent shard to have just one child shard.) A shard might split in response to high levels of write activity on its parent table, so that applications can process records from multiple shards in parallel.

If you disable a stream, any shards that are open will be closed. The data in the stream will continue to be readable for 24 hours.

Because shards have a lineage (parent and children), an application must always process a parent shard before it processes a child shard. This helps ensure that the stream records are also processed in the correct order. (If you use the DynamoDB Streams Kinesis Adapter, this is handled for you. Your application processes the shards and stream records in the correct order. It automatically handles new or expired shards, in addition to shards that split while the application is running. For more information, see [Using the DynamoDB Streams Kinesis adapter to process stream records.](#))

The following diagram shows the relationship between a stream, shards in the stream, and stream records in the shards.

Note

If you perform a `PutItem` or `UpdateItem` operation that does not change any data in an item, DynamoDB Streams does *not* write a stream record for that operation.

To access a stream and process the stream records within, you must do the following:

- Determine the unique ARN of the stream that you want to access.
- Determine which shards in the stream contain the stream records that you are interested in.
- Access the shards and retrieve the stream records that you want.

Note

No more than two processes at most should be reading from the same stream's shard at the same time. Having more than two readers per shard can result in throttling.

The DynamoDB Streams API provides the following actions for use by application programs:

- [ListStreams](#) — Returns a list of stream descriptors for the current account and endpoint. You can optionally request just the stream descriptors for a particular table name.
- [DescribeStream](#) — Returns detailed information about a given stream. The output includes a list of shards associated with the stream, including the shard IDs.
- [GetShardIterator](#) — Returns a *shard iterator*, which describes a location within a shard. You can request that the iterator provide access to the oldest point, the newest point, or a particular point in the stream.
- [GetRecords](#) — Returns the stream records from within a given shard. You must provide the shard iterator returned from a `GetShardIterator` request.

For complete descriptions of these API operations, including example requests and responses, see the [Amazon DynamoDB Streams API Reference](#).

Data retention limit for DynamoDB Streams

All data in DynamoDB Streams is subject to a 24-hour lifetime. You can retrieve and analyze the last 24 hours of activity for any given table. However, data that is older than 24 hours is susceptible to trimming (removal) at any moment.

If you disable a stream on a table, the data in the stream continues to be readable for 24 hours. After this time, the data expires and the stream records are automatically deleted. There is no mechanism for manually deleting an existing stream. You must wait until the retention limit expires (24 hours), and all the stream records will be deleted.

DynamoDB Streams and Time to Live

You can back up, or otherwise process, items that are deleted by [Time to Live](#) (TTL) by enabling Amazon DynamoDB Streams on the table and processing the streams records of the expired items. For more information, see [Reading and processing a stream](#).

The streams record contains a user identity field `Records[<index>].userIdentity`.

Items that are deleted by the Time to Live process after expiration have the following fields:

- `Records[<index>].userIdentity.type`
"Service"
- `Records[<index>].userIdentity.principalId`
"dynamodb.amazonaws.com"

Note

When you use TTL in a global table, the region the TTL was performed in will have the `userIdentity` field set. This field won't be set in other regions when the delete is replicated.

The following JSON shows the relevant portion of a single streams record.

```
"Records": [  
  {
```

```
...  
  "userIdentity": {  
    "type": "Service",  
    "principalId": "dynamodb.amazonaws.com"  
  }  
...  
}  
]
```

Using DynamoDB Streams and Lambda to archive TTL deleted items

Combining [DynamoDB Time to Live \(TTL\)](#), [DynamoDB Streams](#), and [AWS Lambda](#) can help simplify archiving data, reduce DynamoDB storage costs, and reduce code complexity. Using Lambda as the stream consumer provides many advantages, most notably the cost reduction compared to other consumers such as Kinesis Client Library (KCL). You aren't charged for GetRecords API calls on your DynamoDB stream when using Lambda to consume events, and Lambda can provide event filtering by identifying JSON patterns in a stream event. With event-pattern content filtering, you can define up to five different filters to control which events are sent to Lambda for processing. This helps reduce invocations of your Lambda functions, simplifies code, and reduces overall cost.

While DynamoDB Streams contains all data modifications, such as Create, Modify, and Remove actions, this can result in unwanted invocations of your archive Lambda function. For example, say you have a table with 2 million data modifications per hour flowing into the stream, but less than 5 percent of these are item deletes that will expire through the TTL process and need to be archived. With [Lambda event source filters](#), the Lambda function will only invoke 100,000 times per hour. The result with event filtering is that you're charged only for the needed invocations instead of the 2 million invocations you would have without event filtering.

Event filtering is applied to the [Lambda event source mapping](#), which is a resource that reads from a chosen event—the DynamoDB stream—and invokes a Lambda function. In the following diagram, you can see how a Time to Live deleted item is consumed by a Lambda function using streams and event filters.

DynamoDB Time to Live event filter pattern

Adding the following JSON to your event source mapping [filter criteria](#) allows invocation of your Lambda function only for TTL deleted items:

```
{  
    "Filters": [  
        {  
            "Pattern": { "userIdentity": { "type": ["Service"], "principalId":  
                ["dynamodb.amazonaws.com"] } }  
        }  
    ]  
}
```

Create an AWS Lambda event source mapping

Use the following code snippets to create a filtered event source mapping which you can connect to a table's DynamoDB stream. Each code block includes the event filter pattern.

AWS CLI

```
aws lambda create-event-source-mapping \  
--event-source-arn 'arn:aws:dynamodb:eu-west-1:012345678910:table/test/  
stream/2021-12-10T00:00:00.000' \  
--batch-size 10 \  
--enabled \  
--function-name test_func \  
--starting-position LATEST \  
--filter-criteria '{"Filters": [{"Pattern": {"userIdentity": {"type": ["Service"], "principalId": ["dynamodb.amazonaws.com"]}}}]}'
```

Java

```
LambdaClient client = LambdaClient.builder()  
    .region(Region.EU_WEST_1)  
    .build();  
  
Filter userIdentity = Filter.builder()  
    .pattern("{\"userIdentity\":{\"type\": [\"Service\"], \"principalId\":  
        [\"dynamodb.amazonaws.com\"]}}")  
    .build();
```

```
FilterCriteria filterCriteria = FilterCriteria.builder()
    .filters(userIdentity)
    .build();

CreateEventSourceMappingRequest mappingRequest =
CreateEventSourceMappingRequest.builder()
    .eventSourceArn("arn:aws:dynamodb:eu-west-1:012345678910:table/test/
stream/2021-12-10T00:00:00.000")
    .batchSize(10)
    .enabled(Boolean.TRUE)
    .functionName("test_func")
    .startingPosition("LATEST")
    .filterCriteria(filterCriteria)
    .build();

try{
    CreateEventSourceMappingResponse eventSourceMappingResponse =
client.createEventSourceMapping(mappingRequest);
    System.out.println("The mapping ARN is
"+eventSourceMappingResponse.eventSourceArn());

}catch (ServiceException e){
    System.out.println(e.getMessage());
}
```

Node

```
const client = new LambdaClient({ region: "eu-west-1" });

const input = {
  EventSourceArn: "arn:aws:dynamodb:eu-west-1:012345678910:table/test/
stream/2021-12-10T00:00:00.000",
  BatchSize: 10,
  Enabled: true,
  FunctionName: "test_func",
  StartingPosition: "LATEST",
  FilterCriteria: { "Filters": [{ "Pattern": "{\"userIdentity\":{\"type\":\"[\\"Service\\\"],\\\"principalId\\\":["dynamodb.amazonaws.com\"]}}"} ] }
}

const command = new CreateEventSourceMappingCommand(input);
```

```
try {
    const results = await client.send(command);
    console.log(results);
} catch (err) {
    console.error(err);
}
```

Python

```
session = boto3.session.Session(region_name = 'eu-west-1')
client = session.client('lambda')

try:
    response = client.create_event_source_mapping(
        EventSourceArn='arn:aws:dynamodb:eu-west-1:012345678910:table/test/
stream/2021-12-10T00:00:00.000',
        BatchSize=10,
        Enabled=True,
        FunctionName='test_func',
        StartingPosition='LATEST',
        FilterCriteria={
            'Filters': [
                {
                    'Pattern': "{\"userIdentity\":{\"type\":[\"Service\"],"
                    \"principalId\":[\"dynamodb.amazonaws.com\"]}}"
                },
            ]
        }
    )
    print(response)
except Exception as e:
    print(e)
```

JSON

```
{
    "userIdentity": {
        "type": ["Service"],
        "principalId": ["dynamodb.amazonaws.com"]
    }
}
```

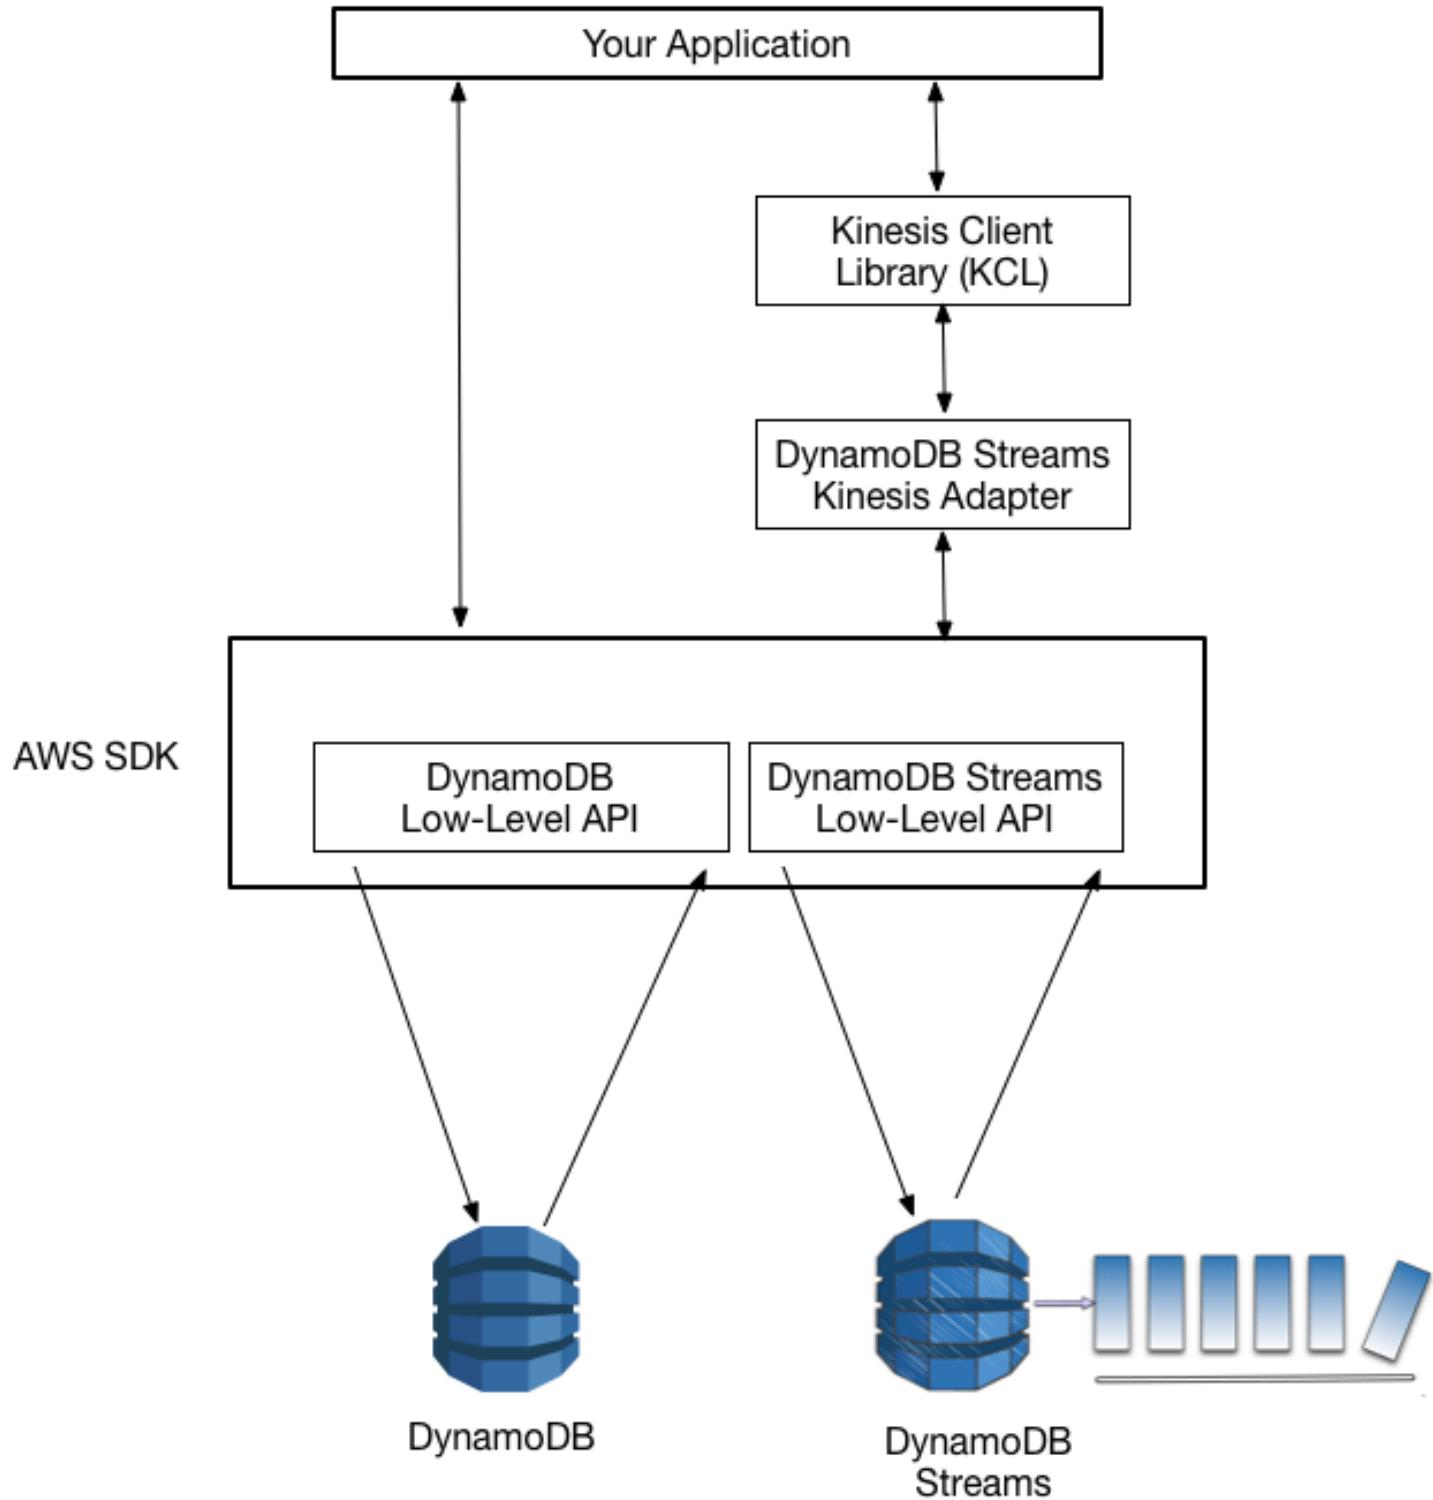

Using the DynamoDB Streams Kinesis adapter to process stream records

Using the Amazon Kinesis Adapter is the recommended way to consume streams from Amazon DynamoDB. The DynamoDB Streams API is intentionally similar to that of Kinesis Data Streams, a service for real-time processing of streaming data at massive scale. In both services, data streams are composed of shards, which are containers for stream records. Both services' APIs contain `ListStreams`, `DescribeStream`, `GetShards`, and `GetShardIterator` operations. (Although these DynamoDB Streams actions are similar to their counterparts in Kinesis Data Streams, they are not 100 percent identical.)

You can write applications for Kinesis Data Streams using the Kinesis Client Library (KCL). The KCL simplifies coding by providing useful abstractions above the low-level Kinesis Data Streams API. For more information about the KCL, see the [Developing consumers using the Kinesis client library](#) in the *Amazon Kinesis Data Streams Developer Guide*.

As a DynamoDB Streams user, you can use the design patterns found within the KCL to process DynamoDB Streams shards and stream records. To do this, you use the DynamoDB Streams Kinesis Adapter. The Kinesis Adapter implements the Kinesis Data Streams interface so that the KCL can be used for consuming and processing records from DynamoDB Streams. For instructions on how to set up and install the DynamoDB Streams Kinesis Adapter, see the [GitHub repository](#) .

The following diagram shows how these libraries interact with one another.

With the DynamoDB Streams Kinesis Adapter in place, you can begin developing against the KCL interface, with the API calls seamlessly directed at the DynamoDB Streams endpoint.

When your application starts, it calls the KCL to instantiate a worker. You must provide the worker with configuration information for the application, such as the stream descriptor and AWS credentials, and the name of a record processor class that you provide. As it runs the code in the record processor, the worker performs the following tasks:

- Connects to the stream
- Enumerates the shards within the stream
- Coordinates shard associations with other workers (if any)
- Instantiates a record processor for every shard it manages
- Pulls records from the stream
- Pushes the records to the corresponding record processor
- Checkpoints processed records
- Balances shard-worker associations when the worker instance count changes
- Balances shard-worker associations when shards are split

 **Note**

For a description of the KCL concepts listed here, see [Developing consumers using the Kinesis client library](#) in the *Amazon Kinesis Data Streams Developer Guide*.

For more information on using streams with AWS Lambda see [DynamoDB Streams and AWS Lambda triggers](#)

Walkthrough: DynamoDB Streams Kinesis adapter

This section is a walkthrough of a Java application that uses the Amazon Kinesis Client Library and the Amazon DynamoDB Streams Kinesis Adapter. The application shows an example of data replication, in which write activity from one table is applied to a second table, with both tables' contents staying in sync. For the source code, see [Complete program: DynamoDB Streams Kinesis adapter](#).

The program does the following:

1. Creates two DynamoDB tables named KCL-Demo-src and KCL-Demo-dst. Each of these tables has a stream enabled on it.

2. Generates update activity in the source table by adding, updating, and deleting items. This causes data to be written to the table's stream.
3. Reads the records from the stream, reconstructs them as DynamoDB requests, and applies the requests to the destination table.
4. Scans the source and destination tables to ensure that their contents are identical.
5. Cleans up by deleting the tables.

These steps are described in the following sections, and the complete application is shown at the end of the walkthrough.

Topics

- [Step 1: Create DynamoDB tables](#)
- [Step 2: Generate update activity in source table](#)
- [Step 3: Process the stream](#)
- [Step 4: Ensure that both tables have identical contents](#)
- [Step 5: Clean up](#)
- [Complete program: DynamoDB Streams Kinesis adapter](#)

Step 1: Create DynamoDB tables

The first step is to create two DynamoDB tables—a source table and a destination table. The `StreamViewType` on the source table's stream is `NEW_IMAGE`. This means that whenever an item is modified in this table, the item's "after" image is written to the stream. In this way, the stream keeps track of all write activity on the table.

The following example shows the code that is used for creating both tables.

```
java.util.List<AttributeDefinition> attributeDefinitions = new
    ArrayList<AttributeDefinition>();
attributeDefinitions.add(new
    AttributeDefinition().withAttributeName("Id").withAttributeType("N"));

java.util.List<KeySchemaElement> keySchema = new ArrayList<KeySchemaElement>();
keySchema.add(new
    KeySchemaElement().withAttributeName("Id").withKeyType(KeyType.HASH)); // Partition
```

```
// key

ProvisionedThroughput provisionedThroughput = new
ProvisionedThroughput().withReadCapacityUnits(2L)
.withWriteCapacityUnits(2L);

StreamSpecification streamSpecification = new StreamSpecification();
streamSpecification.setStreamEnabled(true);
streamSpecification.setStreamViewType(StreamViewType.NEW_IMAGE);
CreateTableRequest createTableRequest = new
CreateTableRequest().withTableName(tableName)
.withAttributeDefinitions(attributeDefinitions).withKeySchema(keySchema)

.withProvisionedThroughput(provisionedThroughput).withStreamSpecification(streamSpecification)
```

Step 2: Generate update activity in source table

The next step is to generate some write activity on the source table. While this activity is taking place, the source table's stream is also updated in near-real time.

The application defines a helper class with methods that call the PutItem, UpdateItem, and DeleteItem API operations for writing the data. The following code example shows how these methods are used.

```
StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, "101", "test1");
StreamsAdapterDemoHelper.updateItem(dynamoDBClient, tableName, "101", "test2");
StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName, "101");
StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName, "102", "demo3");
StreamsAdapterDemoHelper.updateItem(dynamoDBClient, tableName, "102", "demo4");
StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName, "102");
```

Step 3: Process the stream

Now the program begins processing the stream. The DynamoDB Streams Kinesis Adapter acts as a transparent layer between the KCL and the DynamoDB Streams endpoint, so that the code can fully use KCL rather than having to make low-level DynamoDB Streams calls. The program performs the following tasks:

- It defines a record processor class, `StreamsRecordProcessor`, with methods that comply with the KCL interface definition: `initialize`, `processRecords`, and `shutdown`. The `processRecords` method contains the logic required for reading from the source table's stream and writing to the destination table.
- It defines a class factory for the record processor class (`StreamsRecordProcessorFactory`). This is required for Java programs that use the KCL.
- It instantiates a new KCL Worker, which is associated with the class factory.
- It shuts down the Worker when record processing is complete.

To learn more about the KCL interface definition, see [Developing consumers using the Kinesis client library](#) in the *Amazon Kinesis Data Streams Developer Guide*.

The following code example shows the main loop in `StreamsRecordProcessor`. The case statement determines what action to perform, based on the `OperationType` that appears in the stream record.

```
for (Record record : records) {  
    String data = new String(record.getData().array(), Charset.forName("UTF-8"));  
    System.out.println(data);  
    if (record instanceof RecordAdapter) {  
        com.amazonaws.services.dynamodbv2.model.Record streamRecord =  
        ((RecordAdapter) record)  
            .getInternalObject();  
  
        switch (streamRecord.getEventName()) {  
            case "INSERT":  
            case "MODIFY":  
                StreamsAdapterDemoHelper.putItem(dynamoDBClient, tableName,  
                    streamRecord.getDynamodb().getNewImage());  
                break;  
            case "REMOVE":  
                StreamsAdapterDemoHelper.deleteItem(dynamoDBClient, tableName,  
                    streamRecord.getDynamodb().getKeys().get("Id").getN());  
        }  
    }  
    checkpointCounter += 1;  
    if (checkpointCounter % 10 == 0) {  
        try {  
            checkpointer.checkpoint();  
        } catch (Exception e) {  
            logger.error("Error during checkpoint: " + e.getMessage());  
        }  
    }  
}
```

```
        }
    catch (Exception e) {
        e.printStackTrace();
    }
}
```

Step 4: Ensure that both tables have identical contents

At this point, the source and destination tables' contents are in sync. The application issues Scan requests against both tables to verify that their contents are, in fact, identical.

The DemoHelper class contains a ScanTable method that calls the low-level Scan API. The following example shows how this is used.

```
if (StreamsAdapterDemoHelper.scanTable(dynamoDBClient, srcTable).getItems()
    .equals(StreamsAdapterDemoHelper.scanTable(dynamoDBClient, destTable).getItems()))
{
    System.out.println("Scan result is equal.");
}
else {
    System.out.println("Tables are different!");
}
```

Step 5: Clean up

The demo is complete, so the application deletes the source and destination tables. See the following code example. Even after the tables are deleted, their streams remain available for up to 24 hours, after which they are automatically deleted.

```
dynamoDBClient.deleteTable(new DeleteTableRequest().withTableName(srcTable));
dynamoDBClient.deleteTable(new DeleteTableRequest().withTableName(destTable));
```

Complete program: DynamoDB Streams Kinesis adapter

The following is the complete Java program that performs the tasks described in [Walkthrough: DynamoDB Streams Kinesis adapter](#). When you run it, you should see output similar to the following.

```
Creating table KCL-Demo-src
```

```
Creating table KCL-Demo-dest
Table is active.
Creating worker for stream: arn:aws:dynamodb:us-west-2:111122223333:table/KCL-Demo-src/
stream/2015-05-19T22:48:56.601
Starting worker...
Scan result is equal.
Done.
```

Important

To run this program, ensure that the client application has access to DynamoDB and Amazon CloudWatch using policies. For more information, see [Identity-based policies for DynamoDB](#).

The source code consists of four .java files:

- StreamsAdapterDemo.java
- StreamsRecordProcessor.java
- StreamsRecordProcessorFactory.java
- StreamsAdapterDemoHelper.java

DynamoDB Streams low-level API: Java example

Note

The code on this page is not exhaustive and does not handle all scenarios for consuming Amazon DynamoDB Streams. The recommended way to consume stream records from DynamoDB is through the Amazon Kinesis Adapter using the Kinesis Client Library (KCL), as described in [Using the DynamoDB Streams Kinesis adapter to process stream records](#).

This section contains a Java program that shows DynamoDB Streams in action. The program does the following:

1. Creates a DynamoDB table with a stream enabled.
2. Describes the stream settings for this table.
3. Modifies data in the table.
4. Describes the shards in the stream.
5. Reads the stream records from the shards.
6. Cleans up.

When you run the program, you will see output similar to the following.

```
Issuing CreateTable request for TestTableForStreams
Waiting for TestTableForStreams to be created...
Current stream ARN for TestTableForStreams: arn:aws:dynamodb:us-
east-2:123456789012:table/TestTableForStreams/stream/2018-03-20T16:49:55.208
Stream enabled: true
Update view type: NEW_AND_OLD_IMAGES

Performing write activities on TestTableForStreams
Processing item 1 of 100
Processing item 2 of 100
Processing item 3 of 100
...
Processing item 100 of 100

Shard: {ShardId: shardId-1234567890-...,SequenceNumberRange: {StartingSequenceNumber:
01234567890...,},}
    Shard iterator: EjYFEkX2a26eVTWe...
        ApproximateCreationDateTime: Tue Mar 20 09:50:00 PDT 2018,Keys:
        {Id={N: 1,}},NewImage: {Message={S: New item!,}, Id={N: 1,}},SequenceNumber:
        10000000003218256368,SizeBytes: 24,StreamViewType: NEW_AND_OLD_IMAGES}

// at least one more page of shard IDs to retrieve
lastEvaluatedShardId =
describeStreamResult.getStreamDescription().getLastEvaluatedShardId();

} while (lastEvaluatedShardId != null);

// Delete the table
System.out.println("Deleting the table...");
```

```
dynamoDBClient.deleteTable(tableName);

System.out.println("Demo complete");

}
```

DynamoDB Streams and AWS Lambda triggers

Topics

- [Tutorial #1: Using filters to process all events with Amazon DynamoDB and AWS Lambda using the AWS CLI](#)
- [Tutorial #2: Using filters to process some events with DynamoDB and Lambda.](#)
- [Best practices with Lambda](#)

Amazon DynamoDB is integrated with AWS Lambda so that you can create *triggers*—pieces of code that automatically respond to events in DynamoDB Streams. With triggers, you can build applications that react to data modifications in DynamoDB tables.

If you enable DynamoDB Streams on a table, you can associate the stream Amazon Resource Name (ARN) with an AWS Lambda function that you write. All mutation actions to that DynamoDB table can then be captured as an item on the stream. For example, you can set a trigger so that when an item in a table is modified a new record immediately appears in that table's stream.

 **Note**

You can have more than two Lambda functions subscribed, but this may result in read throttling if using more than two Lambda functions to one DynamoDB stream.

The [AWS Lambda](#) service polls the stream for new records four times per second. When new stream records are available, your Lambda function is synchronously invoked. You can subscribe up to two Lambda functions to the same DynamoDB stream.

The Lambda function can send a notification, initiate a workflow, or perform many other actions that you specify. You can write a Lambda function to simply copy each stream record to persistent storage, such as Amazon S3 File Gateway (Amazon S3), and create a permanent audit trail of write activity in your table. Or suppose that you have a mobile gaming app that writes to a GameScores

table. Whenever the TopScore attribute of the GameScores table is updated, a corresponding stream record is written to the table's stream. This event could then trigger a Lambda function that posts a congratulatory message on a social media network. This function could also be written to ignore any stream records that are not updates to GameScores, or that do not modify the TopScore attribute.

If your function returns an error, Lambda retries the batch until it processes successfully or the data expires. You can also configure Lambda to retry with a smaller batch, limit the number of retries, discard records once they become too old, and other options.

As performance best practices, the Lambda function needs to be short lived. To avoid introducing unnecessary processing delays, it also should not execute complex logic. For a high velocity stream in particular, it is better to trigger an asynchronous post-processing step function workflows than synchronous long running Lambdas.

You cannot use the same Lambda trigger across different AWS accounts. Both the DynamoDB table and the Lambda functions must belong to the same AWS account.

For more information about AWS Lambda, see the [AWS Lambda Developer Guide](#).

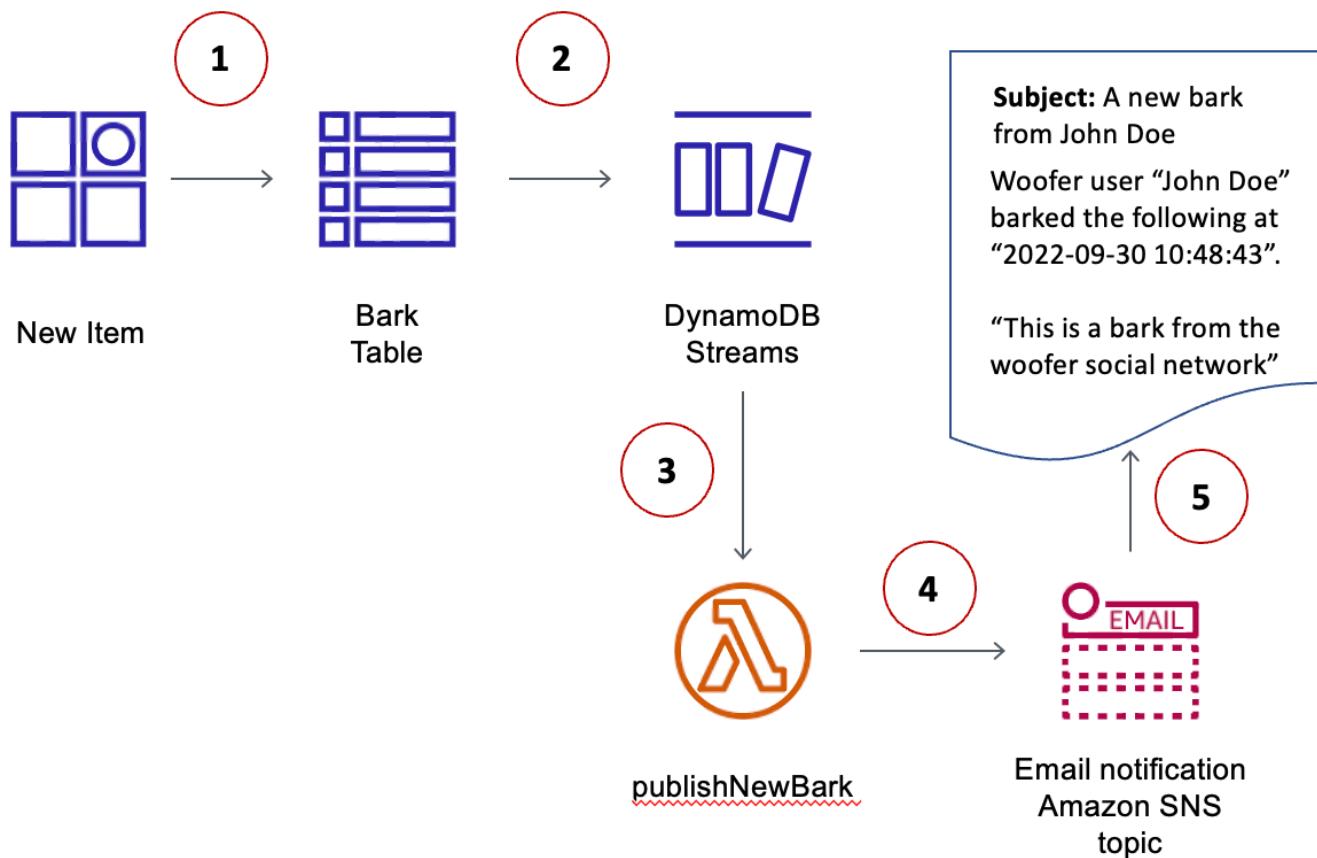

Tutorial #1: Using filters to process all events with Amazon DynamoDB and AWS Lambda using the AWS CLI

Topics

- [Step 1: Create a DynamoDB table with a stream enabled](#)
- [Step 2: Create a Lambda execution role](#)
- [Step 3: Create an Amazon SNS topic](#)
- [Step 4: Create and test a Lambda function](#)
- [Step 5: Create and test a trigger](#)

In this tutorial, you will create an AWS Lambda trigger to process a stream from a DynamoDB table.

The scenario for this tutorial is Woofer, a simple social network. Woofer users communicate using *barks* (short text messages) that are sent to other Woofer users. The following diagram shows the components and workflow for this application.

1. A user writes an item to a DynamoDB table (BarkTable). Each item in the table represents a bark.
2. A new stream record is written to reflect that a new item has been added to BarkTable.
3. The new stream record triggers an AWS Lambda function (`publishNewBark`).
4. If the stream record indicates that a new item was added to BarkTable, the Lambda function reads the data from the stream record and publishes a message to a topic in Amazon Simple Notification Service (Amazon SNS).
5. The message is received by subscribers to the Amazon SNS topic. (In this tutorial, the only subscriber is an email address.)

Before You Begin

This tutorial uses the AWS Command Line Interface AWS CLI. If you have not done so already, follow the instructions in the [AWS Command Line Interface User Guide](#) to install and configure the AWS CLI.

Step 1: Create a DynamoDB table with a stream enabled

In this step, you create a DynamoDB table (BarkTable) to store all of the barks from Woofer users. The primary key is composed of Username (partition key) and Timestamp (sort key). Both of these attributes are of type string.

BarkTable has a stream enabled. Later in this tutorial, you create a trigger by associating an AWS Lambda function with the stream.

1. Enter the following command to create the table.

```
aws dynamodb create-table \
    --table-name BarkTable \
    --attribute-definitions AttributeName=Username,AttributeType=S
    AttributeName=Timestamp,AttributeType=S \
    --key-schema AttributeName=Username,KeyType=HASH
    AttributeName=Timestamp,KeyType=RANGE \
    --provisioned-throughput ReadCapacityUnits=5,WriteCapacityUnits=5 \
    --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
```

2. In the output, look for the LatestStreamArn.

```
...
"LatestStreamArn": "arn:aws:dynamodb:region:accountID:table/BarkTable/
stream/timestamp
..."
```

Make a note of the *region* and the *accountID*, because you need them for the other steps in this tutorial.

Step 2: Create a Lambda execution role

In this step, you create an AWS Identity and Access Management (IAM) role (WooferLambdaRole) and assign permissions to it. This role is used by the Lambda function that you create in [Step 4: Create and test a Lambda function](#).

You also create a policy for the role. The policy contains all of the permissions that the Lambda function needs at runtime.

1. Create a file named trust-relationship.json with the following contents.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "lambda.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

2. Enter the following command to create WooferLambdaRole.

```
aws iam create-role --role-name WooferLambdaRole \  
    --path "/service-role/" \  
    --assume-role-policy-document file://trust-relationship.json
```

3. Create a file named role-policy.json with the following contents. (Replace *region* and *accountID* with your AWS Region and account ID.)

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "logs>CreateLogGroup",  
                "logs>CreateLogStream",  
                "logs>PutLogEvents"  
            ],  
            "Resource": "arn:aws:logs:region:accountID:*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:DescribeStream",  
                "dynamodb:GetRecords",  
                "dynamodb:GetShardIterator",  
                "dynamodb>ListStreams"  
            ],  
            "Resource": "arn:aws:dynamodb:region:accountID:  
        }  
    ]  
}
```

```
"Resource": "arn:aws:dynamodb:region:accountID:table/BarkTable/stream/*",
},
{
    "Effect": "Allow",
    "Action": [
        "sns:Publish"
    ],
    "Resource": [
        "*"
    ]
}
]
```

The policy has four statements that allow `WooferLambdaRole` to do the following:

- Run a Lambda function (`publishNewBark`). You create the function later in this tutorial.
- Access Amazon CloudWatch Logs. The Lambda function writes diagnostics to CloudWatch Logs at runtime.
- Read data from the DynamoDB stream for `BarkTable`.
- Publish messages to Amazon SNS.

4. Enter the following command to attach the policy to `WooferLambdaRole`.

```
aws iam put-role-policy --role-name WooferLambdaRole \
    --policy-name WooferLambdaRolePolicy \
    --policy-document file://role-policy.json
```

Step 3: Create an Amazon SNS topic

In this step, you create an Amazon SNS topic (`wooferTopic`) and subscribe an email address to it. Your Lambda function uses this topic to publish new barks from Woofer users.

1. Enter the following command to create a new Amazon SNS topic.

```
aws sns create-topic --name wooferTopic
```

2. Enter the following command to subscribe an email address to `wooferTopic`.
(Replace `region` and `accountID` with your AWS Region and account ID, and replace `example@example.com` with a valid email address.)

```
aws sns subscribe \
--topic-arn arn:aws:sns:region:accountID:wooferTopic \
--protocol email \
--notification-endpoint example@example.com
```

3. Amazon SNS sends a confirmation message to your email address. Choose the **Confirm subscription** link in that message to complete the subscription process.

Step 4: Create and test a Lambda function

In this step, you create an AWS Lambda function (`publishNewBark`) to process stream records from `BarkTable`.

The `publishNewBark` function processes only the stream events that correspond to new items in `BarkTable`. The function reads data from such an event, and then invokes Amazon SNS to publish it.

1. Create a file named `publishNewBark.js` with the following contents. Replace `region` and `accountID` with your AWS Region and account ID.

```
'use strict';
var AWS = require("aws-sdk");
var sns = new AWS.SNS();

exports.handler = (event, context, callback) => {

    event.Records.forEach((record) => {
        console.log('Stream record: ', JSON.stringify(record, null, 2));

        if (record.eventName == 'INSERT') {
            var who = JSON.stringify(record.dynamodb.NewImage.Username.S);
            var when = JSON.stringify(record.dynamodb.NewImage.Timestamp.S);
            var what = JSON.stringify(record.dynamodb.NewImage.Message.S);
            var params = {
                Subject: 'A new bark from ' + who,
                Message: 'Woofer user ' + who + ' barked the following at ' + when
                + ':\n\n' + what,
            };
            sns.publish(params).promise();
        }
    });
}
```

```
        TopicArn: 'arn:aws:sns:region:accountID:wooferTopic'
    };
    sns.publish(params, function(err, data) {
        if (err) {
            console.error("Unable to send message. Error JSON:",
JSON.stringify(err, null, 2));
        } else {
            console.log("Results from sending message: ",
JSON.stringify(data, null, 2));
        }
    });
});
callback(null, `Successfully processed ${event.Records.length} records.`);
};
```

2. Create a zip file to contain publishNewBark.js. If you have the zip command-line utility, you can enter the following command to do this.

```
zip publishNewBark.zip publishNewBark.js
```

3. When you create the Lambda function, you specify the Amazon Resource Name (ARN) for WooferLambdaRole, which you created in [Step 2: Create a Lambda execution role](#). Enter the following command to retrieve this ARN.

```
aws iam get-role --role-name WooferLambdaRole
```

In the output, look for the ARN for WooferLambdaRole.

```
...
"Arn": "arn:aws:iam::region:role/service-role/WooferLambdaRole"
...
```

Enter the following command to create the Lambda function. Replace *roleARN* with the ARN for WooferLambdaRole.

```
aws lambda create-function \
--region region \
--function-name publishNewBark \
--zip-file fileb://publishNewBark.zip \
```

```
--role roleARN \
--handler publishNewBark.handler \
--timeout 5 \
--runtime nodejs16.x
```

- Now test `publishNewBark` to verify that it works. To do this, you provide input that resembles a real record from DynamoDB Streams.

Create a file named `payload.json` with the following contents. Replace `region` and `accountID` with your AWS Region and account ID.

```
{
  "Records": [
    {
      "eventID": "7de3041dd709b024af6f29e4fa13d34c",
      "eventName": "INSERT",
      "eventVersion": "1.1",
      "eventSource": "aws:dynamodb",
      "awsRegion": "region",
      "dynamodb": {
        "ApproximateCreationDateTime": 1479499740,
        "Keys": {
          "Timestamp": {
            "S": "2016-11-18:12:09:36"
          },
          "Username": {
            "S": "John Doe"
          }
        },
        "NewImage": {
          "Timestamp": {
            "S": "2016-11-18:12:09:36"
          },
          "Message": {
            "S": "This is a bark from the Woofer social network"
          },
          "Username": {
            "S": "John Doe"
          }
        },
        "SequenceNumber": "13021600000000001596893679",
        "SizeBytes": 112,
        "StreamViewType": "NEW_IMAGE"
      }
    }
  ]
}
```

```
    },
    "eventSourceARN": "arn:aws:dynamodb:region:account ID:table/BarkTable/
stream/2016-11-16T20:42:48.104"
}
]
```

Enter the following command to test the publishNewBark function.

```
aws lambda invoke --function-name publishNewBark --payload file://payload.json --
cli-binary-format raw-in-base64-out output.txt
```

If the test was successful, you will see the following output.

```
{  
  "StatusCode": 200,  
  "ExecutedVersion": "$LATEST"  
}
```

In addition, the output.txt file will contain the following text.

```
"Successfully processed 1 records."
```

You will also receive a new email message within a few minutes.

Note

AWS Lambda writes diagnostic information to Amazon CloudWatch Logs. If you encounter errors with your Lambda function, you can use these diagnostics for troubleshooting purposes:

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Logs**.
3. Choose the following log group: /aws/lambda/publishNewBark
4. Choose the latest log stream to view the output (and errors) from the function.

Step 5: Create and test a trigger

In [Step 4: Create and test a Lambda function](#), you tested the Lambda function to ensure that it ran correctly. In this step, you create a *trigger* by associating the Lambda function (publishNewBark) with an event source (the BarkTable stream).

- When you create the trigger, you need to specify the ARN for the BarkTable stream. Enter the following command to retrieve this ARN.

```
aws dynamodb describe-table --table-name BarkTable
```

In the output, look for the LatestStreamArn.

```
...
"LatestStreamArn": "arn:aws:dynamodb:<region>:<accountID>:table/BarkTable/
stream/<timestamp>
..."
```

- Enter the following command to create the trigger. Replace *streamARN* with the actual stream ARN.

```
aws lambda create-event-source-mapping \
--region <region> \
--function-name publishNewBark \
--event-source <streamARN> \
--batch-size 1 \
--starting-position TRIM_HORIZON
```

- Test the trigger. Enter the following command to add an item to BarkTable.

```
aws dynamodb put-item \
--table-name BarkTable \
--item Username={"S": "Jane
Doe"},Timestamp={"S": "2016-11-18:14:32:17"},Message={"S": "Testing...1...2...3"}
```

You should receive a new email message within a few minutes.

- Open the DynamoDB console and add a few more items to BarkTable. You must specify values for the Username and Timestamp attributes. (You should also specify a value for Message, even though it is not required.) You should receive a new email message for each item you add to BarkTable.

The Lambda function processes only new items that you add to BarkTable. If you update or delete an item in the table, the function does nothing.

Note

AWS Lambda writes diagnostic information to Amazon CloudWatch Logs. If you encounter errors with your Lambda function, you can use these diagnostics for troubleshooting purposes.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Logs**.
3. Choose the following log group: /aws/lambda/publishNewBark
4. Choose the latest log stream to view the output (and errors) from the function.

Tutorial #2: Using filters to process some events with DynamoDB and Lambda.

Topics

- [Putting it all together - AWS CloudFormation](#)
- [Putting it all together - CDK](#)

In this tutorial, you will create an AWS Lambda trigger to process only some events in a stream from a DynamoDB table.

With [Lambda event filtering](#) you can use filter expressions to control which events Lambda sends to your function for processing. You can configure up to 5 different filters per DynamoDB streams. If you are using batching windows, Lambda applies the filter criteria to each new event to see if it should be included in the current batch.

Filters are applied via structures called `FilterCriteria`. The 3 main attributes of `FilterCriteria` are `metadata properties`, `data properties` and `filter patterns`.

Here is an example structure of a DynamoDB Streams event:

{

```
"eventID": "c9fbe7d0261a5163fc6940593e41797",
"eventName": "INSERT",
"eventVersion": "1.1",
"eventSource": "aws:dynamodb",
"awsRegion": "us-east-2",
"dynamodb": {
    "ApproximateCreationDateTime": 1664559083.0,
    "Keys": {
        "SK": { "S": "PRODUCT#CHOCOLATE#DARK#1000" },
        "PK": { "S": "COMPANY#1000" }
    },
    "NewImage": {
        "quantity": { "N": "50" },
        "company_id": { "S": "1000" },
        "fabric": { "S": "Florida Chocolates" },
        "price": { "N": "15" },
        "stores": { "N": "5" },
        "product_id": { "S": "1000" },
        "SK": { "S": "PRODUCT#CHOCOLATE#DARK#1000" },
        "PK": { "S": "COMPANY#1000" },
        "state": { "S": "FL" },
        "type": { "S": "" }
    },
    "SequenceNumber": "700000000000888747038",
    "SizeBytes": 174,
    "StreamViewType": "NEW_AND_OLD_IMAGES"
},
"eventSourceARN": "arn:aws:dynamodb:us-east-2:111122223333:table/chocolate-table-StreamsSampleDDBTable-LU0I6UXQY7J1/stream/2022-09-30T17:05:53.209"
}
```

The `metadata` properties are the fields of the event object. In the case of DynamoDB Streams, the `metadata` properties are fields like `dynamodb` or `eventName`.

The `data` properties are the fields of the event body. To filter on `data` properties, make sure to contain them in `FilterCriteria` within the proper key. For DynamoDB event sources, the data key is `NewImage` or `OldImage`.

Finally, the filter rules will define the filter expression that you want to apply to a specific property. Here are some examples:

Comparison operator	Example	Rule syntax (Partial)
Null	Product Type is null	{ "product_type": { "S": null } }
Empty	Product name is empty	{ "product_name": { "S": [""] } }
Equals	State equals Florida	{ "state": { "S": ["FL"] } }
And	Product state equals Florida and product category Chocolate	{ "state": { "S": ["FL"] }, "category": { "S": ["CHOCOLATE"] } }
Or	Product state is Florida or California	{ "state": { "S": ["FL", "CA"] } }
Not	Product state is not Florida	{"state": {"S": [{"anything-but": ["FL"]}]} }
Exists	Product Homemade exists	{"homemade": {"S": [{"exists": true}]} }
Does not exist	Product Homemade does not exist	{"homemade": {"S": [{"exists": false}]} }
Begins with	PK begins with COMPANY	{"PK": {"S": [{"prefix": "COMPANY"}]} }

You can specify up to 5 event filtering patterns for a Lambda function. Notice that each one of those 5 events will be evaluated as a logical OR. So if you configure two filters named `Filter_One` and `Filter_Two`, the Lambda function will execute `Filter_One OR Filter_Two`.

Note

In the [Lambda event filtering](#) page there are some options to filter and compare numeric values, however in the case of DynamoDB filter events it doesn't apply because numbers in DynamoDB are stored as strings. For example "quantity": { "N": "50" }, we know its a number because of the "N" property.

Putting it all together - AWS CloudFormation

To show event filtering functionality in practice, here is a sample CloudFormation template. This template will generate a Simple DynamoDB table with a Partition Key PK and a Sort Key SK with Amazon DynamoDB Streams enabled. It will create a lambda function and a simple Lambda Execution role that will allow write logs to Amazon Cloudwatch, and read the events from the Amazon DynamoDB Stream. It will also add the event source mapping between the DynamoDB Streams and the Lambda function, so the function can be executed every time there is an event in the Amazon DynamoDB Stream.

```
AWSTemplateFormatVersion: "2010-09-09"

Description: Sample application that presents AWS Lambda event source filtering
with Amazon DynamoDB Streams.
```

Resources:

```
StreamsSampleDDBTable:
  Type: AWS::DynamoDB::Table
  Properties:
    AttributeDefinitions:
      - AttributeName: "PK"
        AttributeType: "S"
      - AttributeName: "SK"
        AttributeType: "S"
    KeySchema:
      - AttributeName: "PK"
        KeyType: "HASH"
      - AttributeName: "SK"
        KeyType: "RANGE"
    StreamSpecification:
      StreamViewType: "NEW_AND_OLD_IMAGES"
    ProvisionedThroughput:
      ReadCapacityUnits: 5
```

```
        WriteCapacityUnits: 5

    LambdaExecutionRole:
        Type: AWS::IAM::Role
        Properties:
            AssumeRolePolicyDocument:
                Version: "2012-10-17"
                Statement:
                    - Effect: Allow
                    Principal:
                        Service:
                            - lambda.amazonaws.com
                    Action:
                        - sts:AssumeRole
            Path: "/"
            Policies:
                - PolicyName: root
                PolicyDocument:
                    Version: "2012-10-17"
                    Statement:
                        - Effect: Allow
                        Action:
                            - logs>CreateLogGroup
                            - logs>CreateLogStream
                            - logs>PutLogEvents
                        Resource: arn:aws:logs:*:*:*
                    - Effect: Allow
                    Action:
                        - dynamodb>DescribeStream
                        - dynamodb>GetRecords
                        - dynamodb>GetShardIterator
                        - dynamodb>ListStreams
                    Resource: !GetAtt StreamsSampleDDBTable.StreamArn

    EventSourceDDBTableStream:
        Type: AWS::Lambda::EventSourceMapping
        Properties:
            BatchSize: 1
            Enabled: True
            EventSourceArn: !GetAtt StreamsSampleDDBTable.StreamArn
            FunctionName: !GetAtt ProcessEventLambda.Arn
            StartingPosition: LATEST

    ProcessEventLambda:
```

```
Type: AWS::Lambda::Function
Properties:
  Runtime: python3.7
  Timeout: 300
  Handler: index.handler
  Role: !GetAtt LambdaExecutionRole.Arn
Code:
  ZipFile: |
    import logging

    LOGGER = logging.getLogger()
    LOGGER.setLevel(logging.INFO)

    def handler(event, context):
        LOGGER.info('Received Event: %s', event)
        for rec in event['Records']:
            LOGGER.info('Record: %s', rec)

Outputs:
StreamsSampleDDBTable:
  Description: DynamoDB Table ARN created for this example
  Value: !GetAtt StreamsSampleDDBTable.Arn
StreamARN:
  Description: DynamoDB Table ARN created for this example
  Value: !GetAtt StreamsSampleDDBTable.StreamArn
```

After you deploy this cloud formation template you can insert the following Amazon DynamoDB Item:

```
{
  "PK": "COMPANY#1000",
  "SK": "PRODUCT#CHOCOLATE#DARK",
  "company_id": "1000",
  "type": "",
  "state": "FL",
  "stores": 5,
  "price": 15,
  "quantity": 50,
  "fabric": "Florida Chocolates"
}
```

Thanks to the simple lambda function included inline in this cloud formation template, you will see the events in the Amazon CloudWatch log groups for the lambda function as follows:

```
{  
    "eventID": "c9fbe7d0261a5163fcb6940593e41797",  
    "eventName": "INSERT",  
    "eventVersion": "1.1",  
    "eventSource": "aws:dynamodb",  
    "awsRegion": "us-east-2",  
    "dynamodb": {  
        "ApproximateCreationDateTime": 1664559083.0,  
        "Keys": {  
            "SK": { "S": "PRODUCT#CHOCOLATE#DARK#1000" },  
            "PK": { "S": "COMPANY#1000" }  
        },  
        "NewImage": {  
            "quantity": { "N": "50" },  
            "company_id": { "S": "1000" },  
            "fabric": { "S": "Florida Chocolates" },  
            "price": { "N": "15" },  
            "stores": { "N": "5" },  
            "product_id": { "S": "1000" },  
            "SK": { "S": "PRODUCT#CHOCOLATE#DARK#1000" },  
            "PK": { "S": "COMPANY#1000" },  
            "state": { "S": "FL" },  
            "type": { "S": "" }  
        },  
        "SequenceNumber": "700000000000888747038",  
        "SizeBytes": 174,  
        "StreamViewType": "NEW_AND_OLD_IMAGES"  
    },  
    "eventSourceARN": "arn:aws:dynamodb:us-east-2:111122223333:table/chocolate-table-StreamsSampleDDBTable-LU0I6UXQY7J1/stream/2022-09-30T17:05:53.209"  
}
```

Filter Examples

- Only products that matches a given state

This example modifies the CloudFormation template to include a filter to match all products which come from Florida, with the abbreviation “FL”.

```
EventSourceDDBTableStream:  
  Type: AWS::Lambda::EventSourceMapping  
  Properties:
```

```
BatchSize: 1
Enabled: True
FilterCriteria:
  Filters:
    - Pattern: '{ "dynamodb": { "NewImage": { "state": { "S": ["FL"] } } } }'
EventSourceArn: !GetAtt StreamsSampleDDBTable.StreamArn
FunctionName: !GetAtt ProcessEventLambda.Arn
StartingPosition: LATEST
```

Once you redeploy the stack, you can add the following DynamoDB item to the table. Note that it will not appear in the Lambda function logs, because the product in this example is from California.

```
{
  "PK": "COMPANY#1000",
  "SK": "PRODUCT#CHOCOLATE#DARK#1000",
  "company_id": "1000",
  "fabric": "Florida Chocolates",
  "price": 15,
  "product_id": "1000",
  "quantity": 50,
  "state": "CA",
  "stores": 5,
  "type": ""
}
```

- **Only the items that starts with some values in the PK and SK**

This example modifies the CloudFormation template to include the following condition:

```
EventSourceDDBTableStream:
  Type: AWS::Lambda::EventSourceMapping
  Properties:
    BatchSize: 1
    Enabled: True
    FilterCriteria:
      Filters:
        - Pattern: '{"dynamodb": {"Keys": {"PK": { "S": [{"prefix": "COMPANY"}]}, "SK": { "S": [{"prefix": "PRODUCT"}]} }} }'
    EventSourceArn: !GetAtt StreamsSampleDDBTable.StreamArn
    FunctionName: !GetAtt ProcessEventLambda.Arn
    StartingPosition: LATEST
```

Notice the AND condition requires the condition to be inside the pattern, where Keys PK and SK are in the same expression separated by comma.

Either start with some values on PK and SK or is from certain state.

This example modifies the CloudFormation template to include the following conditions:

```
EventSourceDDBTableStream:  
  Type: AWS::Lambda::EventSourceMapping  
  Properties:  
    BatchSize: 1  
    Enabled: True  
    FilterCriteria:  
      Filters:  
        - Pattern: '{"dynamodb": {"Keys": {"PK": {"S": [{"prefix": "COMPANY"}]}, "SK": {"S": [{"prefix": "PRODUCT"}]}}}}'  
        - Pattern: '{ "dynamodb": { "NewImage": { "state": { "S": ["FL"] } } } }'  
  EventSourceArn: !GetAtt StreamsSampleDDBTable.StreamArn  
  FunctionName: !GetAtt ProcessEventLambda.Arn  
  StartingPosition: LATEST
```

Notice the OR condition is added by introducing new patterns in the filter section.

Putting it all together - CDK

The following sample CDK project formation template walks through event filtering functionality. Before working with this CDK project you will need to [install the pre-requisites](#) including [running preparation scripts](#).

Create a CDK project

First create a new AWS CDK project, by invoking `cdk init` in an empty directory.

```
mkdir ddb_filters  
cd ddb_filters  
cdk init app --language python
```

The `cdk init` command uses the name of the project folder to name various elements of the project, including classes, subfolders, and files. Any hyphens in the folder name are converted to underscores. The name should otherwise follow the form of a Python identifier. For example, it should not start with a number or contain spaces.

To work with the new project, activate its virtual environment. This allows the project's dependencies to be installed locally in the project folder, instead of globally.

```
source .venv/bin/activate  
python -m pip install -r requirements.txt
```

Note

You may recognize this as the Mac/Linux command to activate a virtual environment. The Python templates include a batch file, `source.bat`, that allows the same command to be used on Windows. The traditional Windows command `.venv\Scripts\activate.bat` works too. If you initialized your AWS CDK project using AWS CDK Toolkit v1.70.0 or earlier, your virtual environment is in the `.env` directory instead of `.venv`.

Base Infrastructure

Open the file `./ddb_filters/ddb_filters_stack.py` with your preferred text editor. This file was auto generated when you created the AWS CDK project.

Next, add the functions `_create_ddb_table` and `_set_ddb_trigger_function`. These functions will create a DynamoDB table with partition key PK and sort key SK in provision mode on-demand mode, with Amazon DynamoDB Streams enabled by default to show New and Old images.

The Lambda function will be stored in the folder `lambda` under the file `app.py`. This file will be created later. It will include an environment variable `APP_TABLE_NAME`, which will be the name of the Amazon DynamoDB Table created by this stack. In the same function we will grant stream read permissions to the Lambda function. Finally, it will subscribe to the DynamoDB Streams as the event source for the lambda function.

At the end of the file in the `__init__` method, you will call the respective constructs to initialize them in the stack. For bigger projects that require additional components and services, it might be best to define these constructs outside the base stack.

```
import os  
import json  
  
import aws_cdk as cdk  
from aws_cdk import (
```

```
Stack,
aws_lambda as _lambda,
aws_dynamodb as dynamodb,
)
from constructs import Construct

class DdbFiltersStack(Stack):

    def _create_ddb_table(self):
        dynamodb_table = dynamodb.Table(
            self,
            "AppTable",
            partition_key=dynamodb.Attribute(
                name="PK", type=dynamodb.AttributeType.STRING
            ),
            sort_key=dynamodb.Attribute(
                name="SK", type=dynamodb.AttributeType.STRING),
            billing_mode=dynamodb.BillingMode.PAY_PER_REQUEST,
            stream=dynamodb.StreamViewType.NEW_AND_OLD_IMAGES,
            removal_policy=cdk.RemovalPolicy.DESTROY,
        )

        cdk.CfnOutput(self, "AppTableName", value=dynamodb_table.table_name)
        return dynamodb_table

    def _set_ddb_trigger_function(self, ddb_table):
        events_lambda = _lambda.Function(
            self,
            "LambdaHandler",
            runtime=_lambda.Runtime.PYTHON_3_9,
            code=_lambda.Code.from_asset("lambda"),
            handler="app.handler",
            environment={
                "APP_TABLE_NAME": ddb_table.table_name,
            },
        )

        ddb_table.grant_stream_read(events_lambda)

        event_subscription = _lambda.CfnEventSourceMapping(
            scope=self,
            id="companyInsertsOnlyEventSourceMapping",
            function_name=events_lambda.function_name,
```

```
        event_source_arn=ddb_table.table_stream_arn,
        maximum_batching_window_in_seconds=1,
        starting_position="LATEST",
        batch_size=1,
    )

def __init__(self, scope: Construct, construct_id: str, **kwargs) -> None:
    super().__init__(scope, construct_id, **kwargs)

    ddb_table = self._create_ddb_table()
    self._set_ddb_trigger_function(ddb_table)
```

Now we will create a very simple lambda function that will print the logs into Amazon CloudWatch. To do this, create a new folder called `lambda`.

```
mkdir lambda
touch app.py
```

Using your favorite text editor, add the following content to the `app.py` file:

```
import logging

LOGGER = logging.getLogger()
LOGGER.setLevel(logging.INFO)

def handler(event, context):
    LOGGER.info('Received Event: %s', event)
    for rec in event['Records']:
        LOGGER.info('Record: %s', rec)
```

Ensuring you are in the `/ddb_filters/` folder, type the following command to create the sample application:

```
cdk deploy
```

At some point you will be asked to confirm if you want to deploy the solution. Accept the changes by typing Y.

```
#####
#####
```

```
# + # ${LambdaHandler/ServiceRole} # arn:${AWS::Partition}:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole #
#####
Do you wish to deploy these changes (y/n)? y
...
# Deployment time: 67.73s

Outputs:
DdbFiltersStack.AppTableName = DdbFiltersStack-AppTable815C50BC-1M1W7209V5YPP
Stack ARN:
arn:aws:cloudformation:us-east-2:111122223333:stack/
DdbFiltersStack/66873140-40f3-11ed-8e93-0a74f296a8f6
```

Once the changes are deployed, open your AWS console and add one item to your table.

```
{
    "PK": "COMPANY#1000",
    "SK": "PRODUCT#CHOCOLATE#DARK",
    "company_id": "1000",
    "type": "",
    "state": "FL",
    "stores": 5,
    "price": 15,
    "quantity": 50,
    "fabric": "Florida Chocolates"
}
```

The CloudWatch logs should now contain all the information from this entry.

Filter Examples

- **Only products that matches a given state**

Open the file `ddb_filters/ddb_filters/ddb_filters_stack.py`, and modify it to include the filter that matches all the products that are equals to "FL". This can be revised just below the `event_subscription` in line 45.

```
event_subscription.add_property_override(
    property_path="FilterCriteria",
```

```
value={  
    "Filters": [  
        {  
            "Pattern": json.dumps(  
                {"dynamodb": {"NewImage": {"state": {"S": ["FL"]}}}}  
            )  
        },  
    ],  
},  
)
```

- Only the items that starts with some values in the PK and SK

Modify the python script to include the following condition:

```
event_subscription.add_property_override(  
    property_path="FilterCriteria",  
    value={  
        "Filters": [  
            {  
                "Pattern": json.dumps(  
                    {  
                        "dynamodb": {  
                            "Keys": {  
                                "PK": {"S": [{"prefix": "COMPANY"}]},  
                                "SK": {"S": [{"prefix": "PRODUCT"}]},  
                            }  
                        }  
                    }  
                )  
            },  
        ],  
    },  
)
```

- Either start with some values on PK and SK or is from certain state.

Modify the python script to include the following conditions:

```
event_subscription.add_property_override(  
)
```

```
property_path="FilterCriteria",
value={
    "Filters": [
        {
            "Pattern": json.dumps(
                {
                    "dynamodb": {
                        "Keys": {
                            "PK": {"S": [{"prefix": "COMPANY"}]},
                            "SK": {"S": [{"prefix": "PRODUCT"}]}
                        }
                    }
                }
            )
        },
        {
            "Pattern": json.dumps(
                {"dynamodb": {"NewImage": {"state": {"S": ["FL"]}}}}
            )
        },
    ],
},
)
```

Notice that the OR condition is added by adding more elements to the Filters array.

Cleanup

Locate the filter stack in the base of your working directory, and execute `cdk destroy`. You will be asked to confirm the resource deletion:

```
cdk destroy
Are you sure you want to delete: DdbFiltersStack (y/n)? y
```

Best practices with Lambda

An AWS Lambda function runs within a *container*—an execution environment that is isolated from other functions. When you run a function for the first time, AWS Lambda creates a new container and begins executing the function's code.

A Lambda function has a *handler* that is run once per invocation. The handler contains the main business logic for the function. For example, the Lambda function shown in [Step 4: Create and test a Lambda function](#) has a handler that can process records in a DynamoDB stream.

You can also provide initialization code that runs one time only—after the container is created, but before AWS Lambda runs the handler for the first time. The Lambda function shown in [Step 4: Create and test a Lambda function](#) has initialization code that imports the SDK for JavaScript in Node.js, and creates a client for Amazon SNS. These objects should only be defined once, outside of the handler.

After the function runs, AWS Lambda might opt to reuse the container for subsequent invocations of the function. In this case, your function handler might be able to reuse the resources that you defined in your initialization code. (You cannot control how long AWS Lambda will retain the container, or whether the container will be reused at all.)

For DynamoDB triggers using AWS Lambda, we recommend the following:

- AWS service clients should be instantiated in the initialization code, not in the handler. This allows AWS Lambda to reuse existing connections, for the duration of the container's lifetime.
- In general, you do not need to explicitly manage connections or implement connection pooling because AWS Lambda manages this for you.

A Lambda consumer for a DynamoDB stream doesn't guarantee exactly once delivery and may lead to occasional duplicates. Make sure your Lambda function code is idempotent to prevent unexpected issues from arising because of duplicate processing.

For more information, see [Best practices for working with AWS Lambda functions](#) in the *AWS Lambda Developer Guide*.

Using On-Demand backup and restore for DynamoDB

You can use the DynamoDB on-demand backup capability to create full backups of your tables for long-term retention, and archiving for regulatory compliance needs. You can back up and restore your table data anytime with a single click on the AWS Management Console or with a single API call. Backup and restore actions run with no impact on table performance or availability.

The following video will give you an introductory look at the backup and restore concept.

[Backup and restore](#)

There are two options available for creating and managing DynamoDB on-demand backups:

- AWS Backup service
- DynamoDB

With AWS Backup, you can configure backup policies and monitor activity for your AWS resources and on-premises workloads in one place. Using DynamoDB with AWS Backup, you can copy your on-demand backups across AWS accounts and Regions, add cost allocation tags to on-demand backups, and transition on-demand backups to cold storage for lower costs. To use these advanced features, you must [opt in](#) to AWS Backup. Opt-in choices apply to the specific account and AWS Region, so you might have to opt in to multiple Regions using the same account. For more information, see the [AWS Backup Developer Guide](#).

The on-demand backup and restore process scales without degrading the performance or availability of your applications. It uses a new and unique distributed technology that lets you complete backups in seconds regardless of table size. You can create backups that are consistent within seconds across thousands of partitions without worrying about schedules or long-running backup processes. All on-demand backups are cataloged, discoverable, and retained until they are explicitly deleted.

In addition, on-demand backup and restore operations don't affect performance or API latencies. Backups are preserved regardless of table deletion. For more information, see [Using DynamoDB backup and restore](#).

DynamoDB on-demand backups are available at no additional cost beyond the normal pricing that's associated with backup storage size. DynamoDB on-demand backups cannot be copied to a different account or Region. To create backup copies across AWS accounts and Regions and for other advanced features, you should use AWS Backup. If you use AWS Backup features you will be billed for them by AWS Backup. For more information about AWS Region availability and pricing, see [Amazon DynamoDB pricing](#).

Topics

- [Using AWS Backup with DynamoDB](#)
- [Using DynamoDB backup and restore](#)

Using AWS Backup with DynamoDB

Amazon DynamoDB can help you meet regulatory compliance and business continuity requirements through enhanced backup features in AWS Backup. AWS Backup is a fully managed data protection service that makes it easy to centralize and automate backups across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. To use AWS Backup, you must affirmatively [opt-in](#). Opt-in choices apply to the specific account and AWS Region, so you might have to opt in to multiple Regions using the same account. For more information, see the [AWS Backup Developer Guide](#).

Amazon DynamoDB is natively integrated with AWS Backup. You can use AWS Backup to schedule, copy, tag and life cycle your DynamoDB on-demand backups automatically. You can continue to view and restore these backups from the DynamoDB console. You can use the DynamoDB console, API, and AWS Command Line Interface (AWS CLI) to enable automatic backups for your DynamoDB tables.

 **Note**

Any backups made through DynamoDB will remain unchanged. You will still be able to create backups through the current DynamoDB workflow.

Enhanced backup features available through AWS Backup include:

Scheduled backups - You can set up regularly scheduled backups of your DynamoDB tables using backup plans.

Cross-account and cross-Region copying - You can automatically copy your backups to another backup vault in a different AWS Region or account, which allows you to support your data protection requirements.

Cold storage tiering - You can configure your backups to implement life cycle rules to delete or transition backups to colder storage. This can help you optimize your backup costs.

Tags - You can automatically tag your backups for billing and cost allocation purposes.

Encryption – DynamoDB on-demand backups managed through AWS Backup are now stored in the AWS Backup vault. This allows you to encrypt and secure your backups by using an AWS KMS key that is independent from your DynamoDB table encryption key.

Audit backups – You can use AWS Backup Audit Manager to audit the compliance of your AWS Backup policies and to find backup activity and resources that are not yet compliant with the controls that you defined. You can also use it to automatically generate an audit trail of daily and on-demand reports for your backup governance purposes.

Secure backups using the WORM model – You can use AWS Backup Vault Lock to enable a write-once-read-many (WORM) setting for your backups. With AWS Backup Vault Lock, you can add an additional layer of defense that protects backups from inadvertent or malicious delete operations, changes to backup retention periods, and updates to lifecycle settings. To learn more, see [AWS Backup Vault Lock](#).

These enhanced backup features are available in all AWS Regions. To learn more about these features, see the [AWS Backup Developer Guide](#).

- [Usage notes](#)

Backing up and restoring DynamoDB tables with AWS Backup: How it works

You can use the on-demand backup feature to create full backups of your Amazon DynamoDB tables. This section provides an overview of what happens during the backup and restore process.

Backups

When you create an on-demand backup with AWS Backup, a time marker of the request is cataloged. The backup is created asynchronously by applying all changes until the time of the request to the last full table snapshot.

Each time you create an on-demand backup, the entire table data is backed up. There is no limit to the number of on-demand backups that can be taken.

Note

Unlike DynamoDB Backups, backups made with AWS Backup are not instantaneous.

While a backup is in progress, you can't do the following:

- Pause or cancel the backup operation.
- Delete the source table of the backup.
- Disable backups on a table if a backup for that table is in progress.

AWS Backup provides automated backup schedules, retention management, and lifecycle management. This removes the need for custom scripts and manual processes. AWS Backup runs the backups and deletes them when they expire. For more information, see the [AWS Backup Developer Guide](#).

If you're using the console, any backups created using AWS Backup are listed on the **Backups** tab with the **Backup type** set to AWS_BACKUP.

Note

You can't delete backups marked with a **Backup type** of AWS_BACKUP using the DynamoDB console. To manage these backups, use the AWS Backup console.

To learn how to perform a backup, see [Backing up a DynamoDB table](#).

Restores

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore from your DynamoDB backup, or you can configure the destination table settings. When you do a restore, you can change the following table settings:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity

- Encryption settings

 **Important**

When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units that the source table had when the backup was requested. The restore process also restores the local secondary indexes and the global secondary indexes.

You can copy a backup of your DynamoDB table data to a different AWS Region and then restore it in that new Region. You can copy and then restore backups between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you copy from the source Region and the data you restore to a new table in the destination Region.

AWS Backup will restore the tables with all the original indexes.

You must manually set up the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings
- Deletion protection settings
- Point in time recovery (PITR) settings

You can only restore the entire table data to a new table from a backup. You can write to the restored table only after it becomes active.

 **Note**

AWS Backup restores are nondestructive. You can't overwrite an existing table during a restore operation.

Service metrics show that 95 percent of customers' table restores complete in less than one hour. However, restore times are directly related to the configuration of your tables (such as the size of your tables and the number of underlying partitions) and other related variables. A best practice when planning for disaster recovery is to regularly document average restore completion times and establish how these times affect your overall Recovery Time Objective.

To learn how to perform a restore, see [Restoring a DynamoDB table from a backup](#).

You can use IAM policies for access control. For more information, see [Using IAM with DynamoDB backup and restore](#).

All backup and restore console and API actions are captured and recorded in AWS CloudTrail for logging, continuous monitoring, and auditing.

Creating backups of DynamoDB tables with AWS Backup

This section describes how to turn on AWS Backup to create on-demand and scheduled backups from your DynamoDB tables.

Topics

- [Turning on AWS Backup features](#)
- [On-demand backups](#)
- [Scheduled backups](#)

Turning on AWS Backup features

You must turn on AWS Backup to use it with DynamoDB.

To turn on AWS Backup, go through the following steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the Backup Settings window, choose **Turn on**.
4. A confirmation screen will appear. Choose **Turn on features**.

AWS Backup features are now available for your DynamoDB tables.

If you choose to turn off AWS Backup features after they've been turned on, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the Backup Settings window, choose **Turn off**.
4. A confirmation screen will appear. Choose **Turn off features**.

If you can't turn the AWS Backup features on or off, your AWS admin may need to perform those actions.

On-demand backups

To create an on-demand backup of a DynamoDB table, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. Choose **Create backup**.
4. From the dropdown menu that appears, choose **Create an on-demand backup**.
5. To create a backup managed by AWS Backup with warm storage and other basic features, choose **Default Settings**. To create a backup that can be transitioned to cold storage, or to create a backup with DynamoDB features instead of AWS Backup, choose **Customize settings**.

If you want to create this backup with previous DynamoDB features instead, choose **Customize settings** and then choose **Backup with DynamoDB**.

6. When you have completed the settings, choose **Create backup**.

Scheduled backups

To schedule a backup, follow these steps.

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. From the dropdown menu that appears, choose **Schedule backups with AWS Backup**.
4. You will be taken to AWS Backup to create a backup plan.

Copying a backup of a DynamoDB table with AWS Backup

You can make a copy of a current backup. You can copy backups to multiple AWS accounts or AWS Regions on demand or automatically as part of a scheduled backup plan. You can also automate a sequence of cross-account and cross-Region copies for Amazon DynamoDB Encryption Client.

Cross-Region replication is especially valuable if you have business continuity or compliance requirements to store backups a minimum distance away from your production data.

Cross-account backups are useful for securely copying your backups to one or more AWS accounts in your organization for operational or security reasons. If your original backup is inadvertently deleted, you can copy the backup from its destination account to its source account, and then start the restore. Before you can do this, you must have two accounts that belong to the same organization in the Organizations service.

Copies inherit the source backup's configuration unless you specify otherwise, with one exception: if you specify that your new copy "Never" expire. With this setting, the new copy still inherits its source expiration date. If you want your new backup copy to be permanent, either set your source backups to never expire, or specify your new copy to expire 100 years after its creation.

 **Note**

If you're copying to another account, you must first have permission from that account.

To copy a backup, do the following:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. Select the check box next to the backup you want to copy.
 - If the backup you want to copy is grayed out, you must enable [advanced features with AWS Backup](#). Then create a new backup. You can now copy this new backup to other Regions and accounts, and copy any other new backups going forward.
4. Choose **Copy**.
5. If you want to copy the backup to another account or Region, select the check box next to **Copy the recovery point to another destination**. Then select whether you will to copy to another Region in your account, or to a different account in a different Region.

Note

To restore a backup to another Region or account, you must first copy the backup to that Region or account.

6. Select the desired vault the file will be copied into. You can also create a new backup vault if desired.
7. Choose **Copy backup**.

Restoring a backup of a DynamoDB table from AWS Backup

This section describes how to restore a backup of a DynamoDB table from AWS Backup.

Topics

- [Restoring a DynamoDB table from AWS Backup](#)
- [Restoring a DynamoDB table to another Region or account](#)

Restoring a DynamoDB table from AWS Backup

To restore your DynamoDB tables from AWS Backup, follow these steps:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>
2. In the navigation pane on the left side of the console, choose **Tables**.
3. Choose the **Backups** tab.
4. Select the check box next to the previous backup that you want to restore from.
5. Choose **Restore**. You will be taken to the **Restore table from backup** screen.
6. Enter the name for the newly restored table, the encryption that this new table will have, the key you want the restore to be encrypted with, and other options.
7. When you're finished, choose **Restore**.

Restoring a DynamoDB table to another Region or account

To restore a DynamoDB table to another Region or account, you will first need to copy the backup to that new Region or account. In order to copy to another account, that account must first grant

you permission. After you have copied your DynamoDB backup to the new Region or account, it can be restored with the process in the previous section.

Deleting a backup of a DynamoDB table with AWS Backup

This section describes how to delete a backup of a DynamoDB table with AWS Backup.

A DynamoDB backup created through AWS Backup features is stored in an AWS Backup vault.

In order to delete this kind of backup, do the following:

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. On the screen that follows, choose **Continue to AWS Backup**.

You will be taken to the AWS Backup console. To learn more on how to delete backups on the AWS Backup console, see [Deleting backups](#)

Usage notes

This section describes the technical differences between on-demand backups managed by AWS Backup and DynamoDB.

AWS Backup has some different workflows and behaviors than DynamoDB. These include:

Encryption - Backups created with the AWS Backup plan are stored in an encrypted vault with a key that is managed by the AWS Backup service. The vault has access control policies for additional security.

Backup ARN - The backup files created by AWS Backup will now have an AWS Backup ARN, which could impact the user permission model. Backup resource names (ARNs) will change from `arn:aws:dynamodb` to `arn:aws:backup`.

Deleting backups - Backups that are created with AWS Backup can only be deleted from the AWS Backup vault. You will not be able to delete AWS Backup files from the DynamoDB console.

Backup process - Unlike DynamoDB backups, backups made with AWS Backup are not instantaneous.

Billing - Backups of DynamoDB tables with AWS Backup features are billed from AWS Backup.

IAM roles - If you're managing access through IAM roles, you will also need to configure a new IAM role with these new permissions:

```
"dynamodb:StartAwsBackupJob",
"dynamodb:RestoreTableFromAwsBackup"
```

dynamodb:StartAwsBackupJob is needed for a successful backup with AWS Backup features, and dynamodb:RestoreTableFromAwsBackup is needed to restore from a backup made with AWS Backup features.

To see these permissions in a complete IAM policy, see Example 8 in [Using IAM](#).

Using DynamoDB backup and restore

Amazon DynamoDB supports stand-alone on-demand backup and restores features. Those features are available to you independent of whether you use AWS Backup.

You can use the DynamoDB on-demand backup capability to create full backups of your tables for long-term retention and archival for regulatory compliance needs. You can back up and restore your table data anytime with a single click on the AWS Management Console or with a single API call. Backup and restore actions run with zero impact on table performance or availability.

You can create table backups using the console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. For more information, see [Backing up a DynamoDB table](#).

For information about restoring a table from a backup, see [Restoring a DynamoDB table from a backup](#).

Backing up and restoring DynamoDB tables with DynamoDB: How it works

You can use the DynamoDB on-demand backup feature to create full backups of your Amazon DynamoDB tables. This feature is available independently from AWS backup. This section provides an overview of what happens during the DynamoDB backup and restore process.

Backups

When you create an on-demand backup with DynamoDB, a time marker of the request is cataloged. The backup is created asynchronously by applying all changes until the time of the

request to the last full table snapshot. DynamoDB backup requests are processed instantaneously and become available for restore within minutes.

 **Note**

Each time you create an on-demand backup, the entire table data is backed up. There is no limit to the number of on-demand backups that can be taken.

All backups in DynamoDB work without consuming any provisioned throughput on the table.

DynamoDB backups do not guarantee causal consistency across items; however, the skew between updates in a backup is usually much less than a second.

While a backup is in progress, you can't do the following:

- Pause or cancel the backup operation.
- Delete the source table of the backup.
- Disable backups on a table if a backup for that table is in progress.

If you don't want to create scheduling scripts and cleanup jobs, you can use AWS Backup to create backup plans with schedules and retention policies for your DynamoDB tables. AWS Backup runs the backups and deletes them when they expire. For more information, see the [AWS Backup Developer Guide](#).

In addition to AWS Backup, you can schedule periodic or future backups by using AWS Lambda functions. For more information, see the blog post [A serverless solution to schedule your Amazon DynamoDB On-Demand backup](#).

If you're using the console, any backups created using AWS Backup are listed on the **Backups** tab with the **Backup type** set to AWS.

 **Note**

You can't delete backups marked with a **Backup type** of AWS using the DynamoDB console. To manage these backups, use the AWS Backup console.

To learn how to perform a backup, see [Backing up a DynamoDB table](#).

Restores

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore from your DynamoDB backup, or you can configure the destination table settings. When you do a restore, you can change the following table settings:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

Important

When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units as the source table, as recorded at the time the backup was requested. The restore process also restores the local secondary indexes and the global secondary indexes.

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the backup resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data that you transfer out of the source Region and for restoring to a new table in the destination Region.

Restores can be faster and more cost-efficient if you choose to exclude some or all secondary indexes from being created on the new restored table.

You must manually set up the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings

- Deletion protection settings
- Point in time recovery (PITR) settings

You can only restore the entire table data to a new table from a backup. You can write to the restored table only after it becomes active.

 **Note**

You can't overwrite an existing table during a restore operation.

Service metrics show that 95 percent of customers' table restores complete in less than one hour. However, restore times are directly related to the configuration of your tables (such as the size of your tables and the number of underlying partitions) and other related variables. A best practice when planning for disaster recovery is to regularly document average restore completion times and establish how these times affect your overall Recovery Time Objective.

To learn how to perform a restore, see [Restoring a DynamoDB table from a backup](#).

You can use IAM policies for access control. For more information, see [Using IAM with DynamoDB backup and restore](#).

All backup and restore console and API actions are captured and recorded in AWS CloudTrail for logging, continuous monitoring, and auditing.

Backing up a DynamoDB table

This section describes how to use the Amazon DynamoDB console or the AWS Command Line Interface to back up a table.

Topics

- [Creating a table backup \(console\)](#)
- [Creating a table backup \(AWS CLI\)](#)

Creating a table backup (console)

Follow these steps to create a backup named MusicBackup for an existing Music table using the AWS Management Console.

To create a table backup

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. You can create a backup by doing one of the following:
 - On the **Backups** tab of the Music table, choose **Create backup**.
 - In the navigation pane on the left side of the console, choose **Backups**. Then choose **Create backup**.
3. Make sure that Music is the table name, and enter **MusicBackup** for the backup name. Then, choose **Create** to create the backup.

Create backup

Backup settings Info

Source table
Music

Backup name
This will be used to identify your backup.
 Between 3 and 255 characters in length. Only A-Z, a-z, 0-9, underscore characters, hyphens, and periods are allowed.

Cancel **Create backup**

Note

If you create backups using the **Backups** section in the navigation pane, the table isn't preselected for you. You have to manually choose the source table name for the backup.

While the backup is being created, the backup status is set to **Creating**. After the backup is complete, the backup status changes to **Available**.

	Name	Status	Creation Date	ARN
	MusicBackup	Available	August 23...	arn:aws:dynamodb:us-w...

Creating a table backup (AWS CLI)

Follow these steps to create a backup for an existing table Music using the AWS CLI.

To create a table backup

- Create a backup with the name MusicBackup for the Music table.

```
aws dynamodb create-backup --table-name Music \
--backup-name MusicBackup
```

While the backup is being created, the backup status is set to CREATING.

```
{
    "BackupDetails": {
        "BackupName": "MusicBackup",
        "BackupArn": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489602797149-73d8d5bc",
        "BackupStatus": "CREATING",
        "BackupCreationDateTime": 1489602797.149
    }
}
```

After the backup is complete, its BackupStatus should change to AVAILABLE. To confirm this, use the describe-backup command. You can get the input value of backup-arn from the output of the previous step or by using the list-backups command.

```
aws dynamodb describe-backup \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/01489173575360-
b308cd7d
```

To keep track of your backups, you can use the `list-backups` command. It lists all your backups that are in CREATING or AVAILABLE status.

```
aws dynamodb list-backups
```

The `list-backups` command and the `describe-backup` command are useful to check information about the source table of the backup.

Restoring a DynamoDB table from a backup

This section describes how to restore a table from a backup using the Amazon DynamoDB console or the AWS Command Line Interface (AWS CLI).

Note

If you want to use the AWS CLI, you must configure it first. For more information, see [Accessing DynamoDB](#).

Topics

- [Restoring a table from a backup \(console\)](#)
- [Restoring a table from a backup \(AWS CLI\)](#)

Restoring a table from a backup (console)

The following procedure shows how to restore the Music table by using the MusicBackup file that is created in the [Backing up a DynamoDB table](#) tutorial.

Note

This procedure assumes that the Music table no longer exists before restoring it using the MusicBackup file.

To restore a table from a backup

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.

2. In the navigation pane on the left side of the console, choose **Backups**.

3. In the list of backups, choose MusicBackup.

On-demand backups (1/1)					Info	C	Restore	Delete	Create backup	
<input type="text"/> Find backups by ARN or name						<	1	>		
<input checked="" type="checkbox"/>	Name	Table	Status	Creation t...	ARN					
<input checked="" type="checkbox"/>	MusicBackup	Music	Available	August 23, 2...	arn:aws:dynamodb:us-w...					

4. Choose **Restore**.

5. Enter **Music** as the new table name. Confirm the backup name and other backup details. Then choose **Restore table** to start the restore process.

Note

You can restore the table to the same AWS Region or to a different Region from where the backup resides. You can also exclude secondary indexes from being created on the new restored table. In addition, you can specify a different encryption mode.

Tables restored from backups are always created using the DynamoDB Standard table class.

Restore table from backup Info

Restoring a table from a backup will restore it as a new table.

Restore settings

Name of restored table

This name will identify your restored table.

Between 3 and 255 characters in length. Only A–Z, a–z, 0–9, underscore characters, hyphens, and periods allowed.

Secondary indexes

Restore the entire table

Your restored table will include all local and global secondary indexes.

Restore the table without secondary indexes

Your restored table will exclude all local and global secondary indexes. Restoring this way can be faster and more cost efficient.

Destination AWS Region

Same Region (Oregon)

Restore the table to the same Region as the original table.

Cross-Region

Restore the table to a different Region for greater redundancy but with higher data transfer costs.

▼ Encryption at rest - optional

All user data stored in Amazon DynamoDB is fully encrypted at rest. By default, Amazon DynamoDB manages the encryption key, and you are not charged any fee for using it.

Encryption key management Info

Owned by Amazon DynamoDB

The key is owned and managed by DynamoDB. You are not charged an additional fee for using this customer master key (CMK).

AWS managed CMK

The key is stored in your account and is managed by AWS Key Management Service (AWS KMS). AWS KMS charges apply.

Stored in your account, and owned and managed by you

Choose a key that is owned and managed by you, and stored in AWS KMS.

i The time it takes to restore a table from a backup can vary and is based on multiple variables. After your table is restored from the backup, you might need to reapply configuration settings. [Learn more](#) ↗

The table that is being restored is shown with the status **Creating**. After the restore process is finished, the status of the Music table changes to **Active**.

Restoring a table from a backup (AWS CLI)

Follow these steps to use the AWS CLI to restore the Music table using the MusicBackup that is created in the [Backing up a DynamoDB table](#) tutorial.

To restore a table from a backup

1. Confirm the backup that you want to restore by using the `list-backups` command. This example uses MusicBackup.

```
aws dynamodb list-backups
```

To get additional details for the backup, use the `describe-backup` command. You can get the input `backup-arn` from the previous step.

```
aws dynamodb describe-backup \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d
```

2. Restore the table from the backup. In this case, the MusicBackup restores the Music table to the same AWS Region.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d
```

3. Restore the table from the backup with custom table settings. In this case, the MusicBackup restores the Music table and specifies an encryption mode for the restored table.

Note

The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the `CreateTable` command. To learn more, see [Managing encrypted tables in DynamoDB](#).

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581080476474-e177ebe2 \
--sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can restore the table to a different AWS Region from where the backup resides.

 **Note**

- The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores in the same Region as the source table.
- When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see [Command line options](#) in the *AWS Command Line Interface User Guide*.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581080476474-e177ebe2 \
--sse-specification-override Enabled=true,SSEType=KMS
```

You can override the billing mode and the provisioned throughput for the restored table.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d \
--billing-mode-override PAY_PER_REQUEST
```

You can exclude some or all secondary indexes from being created on the restored table.

Note

Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the restored table.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01581081403719-db9c1f91 \
--global-secondary-index-override '[]' \
--sse-specification-override Enabled=true,SSEType=KMS
```

Note

The secondary indexes provided should match existing indexes. You cannot create new indexes at the time of restore.

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```
aws dynamodb restore-table-from-backup \
--target-table-name Music \
--backup-arn arn:aws:dynamodb:eu-west-1:123456789012:table/Music/
backup/01581082594992-303b6239 \
--billing-mode-override PROVISIONED \
--provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100 \
--global-secondary-index-override IndexName=singers-
index,KeySchema=[{"AttributeName=SingerName,KeyType=HASH"}],Projection="{ProjectionType=KEYS_"
 \
--sse-specification-override Enabled=true,SSEType=KMS
```

To verify the restore, use the `describe-table` command to describe the `Music` table.

```
aws dynamodb describe-table --table-name Music
```

The table that is being restored from the backup is shown with the status **Creating**. After the restore process is finished, the status of the Music table changes to **Active**.

Important

While a restore is in progress, don't modify or delete your IAM role policy; otherwise, unexpected behavior can result. For example, suppose that you removed write permissions for a table while that table is being restored. In this case, the underlying `RestoreTableFromBackup` operation would not be able to write any of the restored data to the table.

After the restore operation is complete, you can modify or delete your IAM role policy. IAM policies involving [source IP restrictions](#) for accessing the target restore table should have the [`aws:ViaAWSService`](#) key set to `false` to ensure that the restrictions apply only to requests made directly by a principal. Otherwise, the restore will be canceled.

If your backup is encrypted with an AWS managed key or a customer managed key, don't disable or delete the key while a restore is in progress, or the restore will fail.

After the restore operation is complete, you can change the encryption key for the restored table and disable or delete the old key.

Deleting a DynamoDB table backup

This section describes how to use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to delete an Amazon DynamoDB table backup.

Note

If you want to use the AWS CLI, you have to configure it first. For more information, see [Using the AWS CLI](#).

Topics

- [Deleting a table backup \(console\)](#)
- [Deleting a table backup \(AWS CLI\)](#)

Deleting a table backup (console)

The following procedure shows how to use the console to delete the MusicBackup that is created in the [Backing up a DynamoDB table](#) tutorial.

To delete a backup

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Backups**.
3. In the list of backups, choose MusicBackup.

The screenshot shows the 'On-demand backups' section of the AWS DynamoDB console. It displays one backup entry: 'MusicBackup' for the 'Music' table, which is currently 'Available'. The table has columns for Name, Table, Status, Creation time, and ARN. Buttons for 'Info', 'Restore', 'Delete', and 'Create backup' are visible at the top right. A search bar and pagination controls are also present.

Name	Table	Status	Creation t...	ARN
MusicBackup	Music	Available	August 23, 2...	arn:aws:dynamodb:us-w...

4. Choose **Delete**. Confirm that you want to delete the backup by typing **delete** and clicking **Delete**.

Deleting a table backup (AWS CLI)

The following example deletes a backup for an existing table Music table using the AWS CLI.

```
aws dynamodb delete-backup \
--backup-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489602797149-73d8d5bc
```

Using IAM with DynamoDB backup and restore

You can use AWS Identity and Access Management (IAM) to restrict Amazon DynamoDB backup and restore actions for some resources. The `CreateBackup` and `RestoreTableFromBackup` APIs operate on a per-table basis.

For more information about using IAM policies in DynamoDB, see [Identity-based policies for DynamoDB](#).

The following are examples of IAM policies that you can use to configure specific backup and restore functionality in DynamoDB.

Example 1: Allow the CreateBackup and RestoreTableFromBackup actions

The following IAM policy grants permissions to allow the CreateBackup and RestoreTableFromBackup DynamoDB actions on all tables:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:CreateBackup",  
                "dynamodb:RestoreTableFromBackup",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:GetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan",  
                "dynamodb:BatchWriteItem"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

Important

DynamoDB RestoreTableFromBackup permissions are necessary on the source backup, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

DynamoDB RestoreTableToPointInTime permissions are necessary on the source table, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

Example 2: Allow CreateBackup and deny RestoreTableFromBackup

The following IAM policy grants permissions for the CreateBackup action and denies the RestoreTableFromBackup action:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb>CreateBackup"],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Deny",  
            "Action": ["dynamodb:RestoreTableFromBackup"],  
            "Resource": "*"  
        }  
    ]  
}
```

Example 3: Allow ListBackups and deny CreateBackup and RestoreTableFromBackup

The following IAM policy grants permissions for the `ListBackups` action and denies the `CreateBackup` and `RestoreTableFromBackup` actions:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb>ListBackups"],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Deny",  
            "Action": [  
                "dynamodb>CreateBackup",  
                "dynamodb:RestoreTableFromBackup"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

Example 4: Allow ListBackups and deny DeleteBackup

The following IAM policy grants permissions for the `ListBackups` action and denies the `DeleteBackup` action:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": ["dynamodb>ListBackups"],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Deny",  
            "Action": ["dynamodb>DeleteBackup"],  
            "Resource": "*"  
        }  
    ]  
}
```

Example 5: Allow RestoreTableFromBackup and DescribeBackup for all resources and deny DeleteBackup for a specific backup

The following IAM policy grants permissions for the `RestoreTableFromBackup` and `DescribeBackup` actions and denies the `DeleteBackup` action for a specific backup resource:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb>DescribeBackup",  
                "dynamodb>RestoreTableFromBackup",  
            ],  
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/  
backup/01489173575360-b308cd7d"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
        }
```

```
        "dynamodb:PutItem",
        "dynamodb:UpdateItem",
        "dynamodb>DeleteItem",
        "dynamodb:GetItem",
        "dynamodb:Query",
        "dynamodb:Scan",
        "dynamodb:BatchWriteItem"
    ],
    "Resource": "*"
},
{
    "Effect": "Deny",
    "Action": [
        "dynamodb>DeleteBackup"
    ],
    "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/
backup/01489173575360-b308cd7d"
}
]
```

Important

DynamoDB RestoreTableFromBackup permissions are necessary on the source backup, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

DynamoDB RestoreTableToPointInTime permissions are necessary on the source table, and DynamoDB read and write permissions on the target table are necessary for restore functionality.

Example 6: Allow CreateBackup for a specific table

The following IAM policy grants permissions for the CreateBackup action on the Movies table only:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dynamodb>CreateBackup",
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Movies"
        }
    ]
}
```

```
        "Action": ["dynamodb>CreateBackup"],
        "Resource": [
            "arn:aws:dynamodb:us-east-1:123456789012:table/Movies"
        ]
    }
]
```

Example 7: Allow ListBackups

The following IAM policy grants permissions for the `ListBackups` action:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["dynamodb>ListBackups"],
            "Resource": "*"
        }
    ]
}
```

Important

You cannot grant permissions for the `ListBackups` action on a specific table.

Example 8: Allow access to AWS Backup features

You will need API permissions for the `StartAwsBackupJob` action for a successful backup with advanced features, and the `dynamodb:RestoreTableFromAwsBackup` action to successfully restore that backup.

The following IAM policy grants AWS Backup the permissions to trigger backups with advanced features and restores. Also note that if the tables are encrypted the policy will need access to the [AWS KMS key](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
{  
    "Sid": "DescribeQueryScanBooksTable",  
    "Effect": "Allow",  
    "Action": [  
        "dynamodb:StartAwsBackupJob",  
        "dynamodb:DescribeTable",  
        "dynamodb:Query",  
        "dynamodb:Scan"  
    ],  
    "Resource": "arn:aws:dynamodb:us-west-2:account-id:table/Books"  
},  
{  
    "Sid": "AllowRestoreFromAwsBackup",  
    "Effect": "Allow",  
    "Action": ["dynamodb:RestoreTableFromAwsBackup"],  
    "Resource": "*"  
},  
]  
}
```

Example 9: Deny RestoreTableToPointInTime for a Specific Source Table

The following IAM policy denies permissions for the `RestoreTableToPointInTime` action for a specific source table:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Action": [  
                "dynamodb:RestoreTableToPointInTime"  
            ],  
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music"  
        }  
    ]  
}
```

Example 10: Deny RestoreTableFromBackup for all Backups for a Specific Source Table

The following IAM policy denies permissions for the `RestoreTableToPointInTime` action for all backups for a specific source table:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Action": [  
                "dynamodb:RestoreTableFromBackup"  
            ],  
            "Resource": "arn:aws:dynamodb:us-east-1:123456789012:table/Music/backup/*"  
        }  
    ]  
}
```

Point-in-time recovery for DynamoDB

You can create on-demand backups of your Amazon DynamoDB tables, or you can enable continuous backups using point-in-time recovery. For more information about on-demand backups, see [Using On-Demand backup and restore for DynamoDB](#).

Point-in-time recovery helps protect your DynamoDB tables from accidental write or delete operations. With point-in-time recovery, you don't have to worry about creating, maintaining, or scheduling on-demand backups. For example, suppose that a test script writes accidentally to a production DynamoDB table. With point-in-time recovery, you can restore that table to any point in time during the last 35 days. After you enable point-in-time recovery, you can restore to any point in time from five minutes before the current time until 35 days ago. DynamoDB maintains incremental backups of your table.

In addition, point-in-time operations don't affect performance or API latencies. For more information, see [Point-in-time recovery: How it works](#).

You can restore a DynamoDB table to a point in time using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the DynamoDB API. The point-in-time recovery process restores to a new table. For more information, see [Restoring a DynamoDB table to a point in time](#).

The following video will give you an introductory look at the backup and restore concept and talk more about point-in-time recovery.

[Backup and restore](#)

For more information about AWS Region availability and pricing, see [Amazon DynamoDB pricing](#).

Topics

- [Point-in-time recovery: How it works](#)
- [Before you begin using point-in-time recovery](#)
- [Restoring a DynamoDB table to a point in time](#)

Point-in-time recovery: How it works

Amazon DynamoDB point-in-time recovery (PITR) provides automatic backups of your DynamoDB table data. This section provides an overview of how the process works in DynamoDB.

Enabling point-in-time recovery

You can enable point-in-time recovery using the AWS Management Console, AWS Command Line Interface (AWS CLI), or the DynamoDB API. When enabled, point-in-time recovery provides continuous backups until you explicitly turn it off. For more information, see [Restoring a DynamoDB table to a point in time](#).

After you enable point-in-time recovery, you can restore to any point in time within `EarliestRestorableDateTime` and `LatestRestorableDateTime`. `LatestRestorableDateTime` is typically five minutes before the current time.

 **Note**

The point-in-time recovery process always restores to a new table.

Restoring a table using point-in-time recovery

For `EarliestRestorableDateTime`, you can restore your table to any point in time during the last 35 days. The retention period is a fixed 35 days (5 calendar weeks) and can't be modified. Any number of users can run up to 50 concurrent restores (any type of restore) in a given account.

 **Important**

If you disable point-in-time recovery and later re-enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the `LatestRestorableDateTime`.

When you restore using point-in-time recovery, DynamoDB restores your table data to the state based on the selected date and time (day:hour:minute:second) to a new table.

You restore a table without consuming any provisioned throughput on the table. You can do a full table restore using point-in-time recovery, or you can configure the destination table settings. You can change the following table settings on the restored table:

- Global secondary indexes (GSIs)
- Local secondary indexes (LSIs)
- Billing mode
- Provisioned read and write capacity
- Encryption settings

Important

When you do a full table restore, the destination table is set with the same provisioned read capacity units and write capacity units that the source table had when the backup was requested. For example, suppose that a table's provisioned throughput was recently lowered to 50 read capacity units and 50 write capacity units. You then restore the table's state to three weeks ago, at which time its provisioned throughput was set to 100 read capacity units and 100 write capacity units. In this case, DynamoDB restores your table data to that point in time with the provisioned throughput from that time (100 read capacity units and 100 write capacity units).

You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.

Note

Cross-Region restore is not supported if the source or destination Region is Asia Pacific (Hong Kong) or Middle East (Bahrain).

Restores can be faster and more cost-efficient if you exclude some or all indexes from being created on the restored table.

You must manually set the following on the restored table:

- Auto scaling policies
- AWS Identity and Access Management (IAM) policies
- Amazon CloudWatch metrics and alarms
- Tags
- Stream settings
- Time to Live (TTL) settings
- Point-in-time recovery settings

The time it takes you to restore a table varies based on multiple factors. The point-in-time restore times are not always correlated directly to the size of the table. For more information, see [Restores](#).

Deleting a table with point-in-time recovery enabled

When you delete a table that has point-in-time recovery enabled, DynamoDB automatically creates a backup snapshot called a *system backup* and retains it for 35 days (at no additional cost). You can use the system backup to restore the deleted table to the state it was in just before deletion. All system backups follow a standard naming convention of *table-name\$DeletedTableBackup*.

Note

Once a table with point-in-time recovery enabled is deleted, you can use system restore to restore that table to a single point in time: the moment just before deletion. You do not have the capability to restore a deleted table to any other point in time in the past 35 days.

Before you begin using point-in-time recovery

Before you enable point-in-time recovery (PITR) on an Amazon DynamoDB table, consider the following:

- If you disable point-in-time recovery and later re-enable it on a table, you reset the start time for which you can recover that table. As a result, you can only immediately restore that table using the `LatestRestorableDateTime`.

- You can enable point-in-time recovery on each local replica of a global table. When you restore the table, the backup restores to an independent table that is not part of the global table. If you are using [Global Tables version 2019.11.21 \(Current\)](#) of global tables, you can create a new global table from the restored table. For more information, see [Global tables: How it works](#).
- You can also restore your DynamoDB table data across AWS Regions such that the restored table is created in a different Region from where the source table resides. You can do cross-Region restores between AWS commercial Regions, AWS China Regions, and AWS GovCloud (US) Regions. You pay only for the data you transfer out of the source Region and for restoring to a new table in the destination Region.
- AWS CloudTrail logs all console and API actions for point-in-time recovery to enable logging, continuous monitoring, and auditing. For more information, see [Logging DynamoDB operations by using AWS CloudTrail](#).

Restoring a DynamoDB table to a point in time

Amazon DynamoDB point-in-time recovery (PITR) provides continuous backups of your DynamoDB table data. You can restore a table to a point in time using the DynamoDB console or the AWS Command Line Interface (AWS CLI). The point-in-time recovery process restores to a new table.

If you want to use the AWS CLI, you must configure it first. For more information, see [Accessing DynamoDB](#).

Topics

- [Restoring a DynamoDB table to a point in time \(console\)](#)
- [Restoring a table to a point in time \(AWS CLI\)](#)

Restoring a DynamoDB table to a point in time (console)

The following example demonstrates how to use the DynamoDB console to restore an existing table named `Music` to a point in time.

Note

This procedure assumes that you have enabled point-in-time recovery. To enable it for the `Music` table, on the **Backups** tab, in the **Point-in-time recovery (PITR)** section, choose **Edit** and then check the box next to **Enable point-in-time-recovery**.

To restore a table to a point in time

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, choose **Tables**.
3. In the list of tables, choose the Music table.
4. On the **Backups** tab of the Music table, in the **Point-in-time recovery (PITR)** section, choose **Restore**.
5. For the new table name, enter **MusicMinutesAgo**.

 **Note**

You can restore the table to the same AWS Region or to a different Region from where the source table resides. You can also exclude secondary indexes from being created on the restored table. In addition, you can specify a different encryption mode.

6. To confirm the restorable time, set the restore date and time to **Earliest**. Then choose **Restore** to start the restore process.

The table that is being restored is shown with the status **Restoring**. After the restore process is finished, the status of the MusicMinutesAgo table changes to **Active**.

Restoring a table to a point in time (AWS CLI)

The following procedure shows how to use the AWS CLI to restore an existing table named Music to a point in time.

 **Note**

This procedure assumes that you have enabled point-in-time recovery. To enable it for the Music table, run the following command.

```
aws dynamodb update-continuous-backups \
    --table-name Music \
    --point-in-time-recovery-specification PointInTimeRecoveryEnabled=True
```

To restore a table to a point in time

1. Confirm that point-in-time recovery is enabled for the Music table by using the describe-continuous-backups command.

```
aws dynamodb describe-continuous-backups \
--table-name Music
```

Continuous backups (automatically enabled on table creation) and point-in-time recovery are enabled.

```
{
    "ContinuousBackupsDescription": {
        "PointInTimeRecoveryDescription": {
            "PointInTimeRecoveryStatus": "ENABLED",
            "EarliestRestorableDateTime": 1519257118.0,
            "LatestRestorableDateTime": 1520018653.01
        },
        "ContinuousBackupsStatus": "ENABLED"
    }
}
```

2. Restore the table to a point in time. In this case, the Music table is restored to the LatestRestorableDateTime (~5 minutes ago) to the same AWS Region.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-name Music \
--target-table-name MusicMinutesAgo \
--use-latest-restorable-time
```

Note

You can also restore to a specific point in time. To do this, run the command using the --restore-date-time argument, and specify a timestamp. You can specify any point in time during the last 35 days. For example, the following command restores the table to the EarliestRestorableDateTime.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-name Music \
--target-table-name MusicEarliestRestorableDateTime \
```

```
--no-use-latest-restorable-time \
--restore-date-time 1519257118.0
```

Specifying the `--no-use-latest-restorable-time` argument is optional when restoring to a specific point in time.

3. Restore the table to a point in time with custom table settings. In this case, the `Music` table is restored to the `LatestRestorableDateTime` (~5 minutes ago).

You can specify a different encryption mode for the restored table, as follows.

 **Note**

The `sse-specification-override` parameter takes the same values as the `sse-specification-override` parameter used in the `CreateTable` command. To learn more, see [Managing encrypted tables in DynamoDB](#).

```
aws dynamodb restore-table-to-point-in-time \
  --source-table-name Music \
  --target-table-name MusicMinutesAgo \
  --use-latest-restorable-time \
  --sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can restore the table to a different AWS Region from where the source table resides.

 **Note**

- The `sse-specification-override` parameter is mandatory for cross-Region restores but optional for restores to the same Region as the source table.
- The `source-table-arn` parameter must be provided for cross-Region restores.
- When performing a cross-Region restore from the command line, you must set the default AWS Region to the desired destination Region. To learn more, see [Command line options](#) in the *AWS Command Line Interface User Guide*.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-arn arn:aws:dynamodb:us-east-1:123456789012:table/Music \
--target-table-name MusicMinutesAgo \
--use-latest-restorable-time \
--sse-specification-override Enabled=true,SSEType=KMS,KMSMasterKeyId=abcd1234-
abcd-1234-a123-ab1234a1b234
```

You can override the billing mode and the provisioned throughput for the restored table.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-name Music \
--target-table-name MusicMinutesAgo \
--use-latest-restorable-time \
--billing-mode-override PAY_PER_REQUEST
```

You can exclude some or all secondary indexes from being created on the restored table.

 **Note**

Restores can be faster and more cost-efficient if you exclude some or all secondary indexes from being created on the new restored table.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-name Music \
--target-table-name MusicMinutesAgo \
--use-latest-restorable-time \
--global-secondary-index-override '[]'
```

You can use a combination of different overrides. For example, you can use a single global secondary index and change provisioned throughput at the same time, as follows.

```
aws dynamodb restore-table-to-point-in-time \
--source-table-name Music \
--target-table-name MusicMinutesAgo \
--billing-mode-override PROVISIONED \
--provisioned-throughput-override ReadCapacityUnits=100,WriteCapacityUnits=100 \
\
```

```
--global-secondary-index-override IndexName=singers-
index,KeySchema=[{"AttributeName=SingerName,KeyType=HASH"}],Projection="{ProjectionType=KEY
 \
--sse-specification-override Enabled=true,SSEType=KMS \
--use-latest-restorable-time
```

To verify the restore, use the `describe-table` command to describe the `MusicEarliestRestorableDateTime` table.

```
aws dynamodb describe-table --table-name MusicEarliestRestorableDateTime
```

The table that is being restored is shown with the status **Creating** and restore in progress as **true**. After the restore process is finished, the status of the `MusicEarliestRestorableDateTime` table changes to **Active**.

Important

While a restore is in progress, don't modify or delete the AWS Identity and Access Management (IAM) policies that grant the IAM entity (for example, user, group, or role) permission to perform the restore. Otherwise, unexpected behavior can result. For example, suppose that you remove write permissions for a table while that table is being restored. In this case, the underlying `RestoreTableToPointInTime` operation can't write any of the restored data to the table. IAM policies involving source IP restrictions for accessing the target restore table can similarly cause issues.

You can modify or delete permissions only after the restore operation is completed.

In-memory acceleration with DynamoDB Accelerator (DAX)

Amazon DynamoDB is designed for scale and performance. In most cases, the DynamoDB response times can be measured in single-digit milliseconds. However, there are certain use cases that require response times in microseconds. For these use cases, DynamoDB Accelerator (DAX) delivers fast response times for accessing eventually consistent data.

DAX is a DynamoDB-compatible caching service that enables you to benefit from fast in-memory performance for demanding applications. DAX addresses three core scenarios:

1. As an in-memory cache, DAX reduces the response times of eventually consistent read workloads by an order of magnitude from single-digit milliseconds to microseconds.
2. DAX reduces operational and application complexity by providing a managed service that is API-compatible with DynamoDB. Therefore, it requires only minimal functional changes to use with an existing application.
3. For read-heavy or bursty workloads, DAX provides increased throughput and potential operational cost savings by reducing the need to overprovision read capacity units. This is especially beneficial for applications that require repeated reads for individual keys.

DAX supports server-side encryption. With encryption at rest, the data persisted by DAX on disk will be encrypted. DAX writes data to disk as part of propagating changes from the primary node to read replicas. For more information, see [DAX encryption at rest](#).

DAX also supports encryption in transit, ensuring that all requests and responses between your application and the cluster are encrypted by transport level security (TLS), and connections to the cluster can be authenticated by verification of a cluster x509 certificate. For more information, see [DAX encryption in transit](#).

Use cases for DAX

DAX provides access to eventually consistent data from DynamoDB tables, with microsecond latency. A Multi-AZ DAX cluster can serve millions of requests per second.

DAX is ideal for the following types of applications:

- Applications that require the fastest possible response time for reads. Some examples include real-time bidding, social gaming, and trading applications. DAX delivers fast, in-memory read performance for these use cases.
- Applications that read a small number of items more frequently than others. For example, consider an ecommerce system that has a one-day sale on a popular product. During the sale, demand for that product (and its data in DynamoDB) would sharply increase, compared to all of the other products. To mitigate the impacts of a "hot" key and a non-uniform traffic distribution, you could offload the read activity to a DAX cache until the one-day sale is over.
- Applications that are read-intensive, but are also cost-sensitive. With DynamoDB, you provision the number of reads per second that your application requires. If read activity increases, you can increase your tables' provisioned read throughput (at an additional cost). Or, you can offload the activity from your application to a DAX cluster, and reduce the number of read capacity units that you need to purchase otherwise.

- Applications that require repeated reads against a large set of data. Such an application could potentially divert database resources from other applications. For example, a long-running analysis of regional weather data could temporarily consume all the read capacity in a DynamoDB table. This situation would negatively impact other applications that need to access the same data. With DAX, the weather analysis could be performed against cached data instead.

DAX is *not* ideal for the following types of applications:

- Applications that require strongly consistent reads (or that cannot tolerate eventually consistent reads).
- Applications that do not require microsecond response times for reads, or that do not need to offload repeated read activity from underlying tables.
- Applications that are write-intensive, or that do not perform much read activity.
- Applications that are already using a different caching solution with DynamoDB, and are using their own client-side logic for working with that caching solution.

DAX usage notes

- For a list of AWS Regions where DAX is available, see [Amazon DynamoDB pricing](#).
- DAX supports applications written in Go, Java, Node.js, Python, and .NET, using AWS-provided clients for those programming languages.
- DAX is only available for the EC2-VPC platform.
- The DAX cluster service role policy must allow the dynamodb:DescribeTable action in order to maintain metadata about the DynamoDB table.
- DAX clusters maintain metadata about the attribute names of items they store. That metadata is maintained indefinitely (even after the item has expired or been evicted from the cache). Applications that use an unbounded number of attribute names can, over time, cause memory exhaustion in the DAX cluster. This limitation applies only to top-level attribute names, not nested attribute names. Examples of problematic top-level attribute names include timestamps, UUIDs, and session IDs.

This limitation applies only to attribute names, not their values. Items like the following are not a problem.

{

```
"Id": 123,  
"Title": "Bicycle 123",  
"CreationDate": "2017-10-24T01:02:03+00:00"  
}
```

But items like the following are a problem if there are enough of them and they each have a different timestamp.

```
{  
    "Id": 123,  
    "Title": "Bicycle 123",  
    "2017-10-24T01:02:03+00:00": "created"  
}
```

DAX: How it works

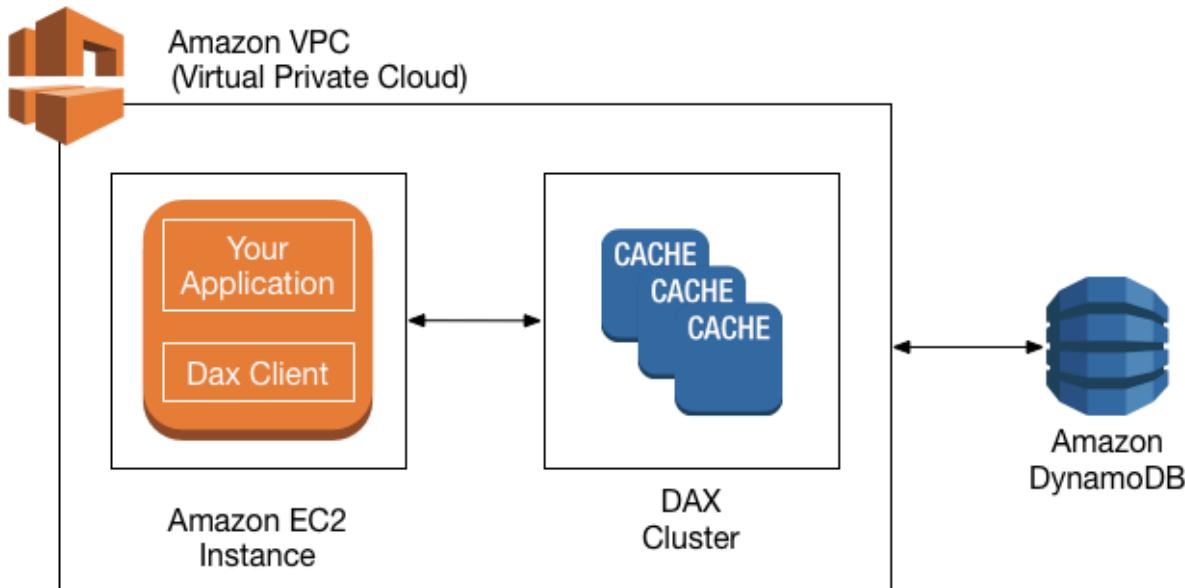

Amazon DynamoDB Accelerator (DAX) is designed to run within an Amazon Virtual Private Cloud (Amazon VPC) environment. The Amazon VPC service defines a virtual network that closely resembles a traditional data center. With a VPC, you have control over its IP address range, subnets, routing tables, network gateways, and security settings. You can launch a DAX cluster in your virtual network and control access to the cluster by using Amazon VPC security groups.

Note

If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. The VPC is ready for you to use immediately—without having to perform any additional configuration steps.

For more information, see [Default VPC and default subnets](#) in the *Amazon VPC User Guide*.

The following diagram shows a high-level overview of DAX.

To create a DAX cluster, you use the AWS Management Console. Unless you specify otherwise, your DAX cluster runs within your default VPC. To run your application, you launch an Amazon EC2 instance into your Amazon VPC. You then deploy your application (with the DAX client) on the EC2 instance.

At runtime, the DAX client directs all of your application's DynamoDB API requests to the DAX cluster. If DAX can process one of these API requests directly, it does so. Otherwise, it passes the request through to DynamoDB.

Finally, the DAX cluster returns the results to your application.

Topics

- [How DAX processes requests](#)
- [Item cache](#)
- [Query cache](#)

How DAX processes requests

A DAX cluster consists of one or more nodes. Each node runs its own instance of the DAX caching software. One of the nodes serves as the primary node for the cluster. Additional nodes (if present) serve as read replicas. For more information, see [Nodes](#).

Your application can access DAX by specifying the endpoint for the DAX cluster. The DAX client software works with the cluster endpoint to perform intelligent load balancing and routing.

Read operations

DAX can respond to the following API calls:

- `GetItem`
- `BatchGetItem`
- `Query`
- `Scan`

If the request specifies *eventually consistent reads* (the default behavior), it tries to read the item from DAX:

- If DAX has the item available (a *cache hit*), DAX returns the item to the application without accessing DynamoDB.
- If DAX does not have the item available (a *cache miss*), DAX passes the request through to DynamoDB. When it receives the response from DynamoDB, DAX returns the results to the application. But it also writes the results to the cache on the primary node.

 **Note**

If there are any read replicas in the cluster, DAX automatically keeps the replicas in sync with the primary node. For more information, see [Clusters](#).

If the request specifies *strongly consistent reads*, DAX passes the request through to DynamoDB. The results from DynamoDB are not cached in DAX. Instead, they are simply returned to the application.

Write operations

The following DAX API operations are considered "write-through":

- `BatchWriteItem`
- `UpdateItem`
- `DeleteItem`
- `PutItem`

With these operations, data is first written to the DynamoDB table, and then to the DAX cluster. The operation is successful only if the data is successfully written to *both* the table and to DAX.

Other operations

DAX does not recognize any DynamoDB operations for managing tables (such as `CreateTable`, `UpdateTable`, and so on). If your application needs to perform these operations, it must access DynamoDB directly rather than using DAX.

For detailed information about DAX and DynamoDB consistency, see [DAX and DynamoDB consistency models](#).

For information about how transactions work in DAX, see [Using transactional APIs in DynamoDB Accelerator \(DAX\)](#).

Request rate limiting

If the number of requests sent to DAX exceeds the capacity of a node, DAX limits the rate at which it accepts additional requests by returning a [ThrottlingException](#). DAX continuously evaluates your CPU utilization to determine the volume of requests it can process while maintaining a healthy cluster state.

You can monitor the [ThrottledRequestCount metric](#) that DAX publishes to Amazon CloudWatch. If you see these exceptions regularly, you should consider [scaling up your cluster](#).

Item cache

DAX maintains an *item cache* to store the results from `GetItem` and `BatchGetItem` operations. The items in the cache represent eventually consistent data from DynamoDB, and are stored by their primary key values.

When an application sends a `GetItem` or `BatchGetItem` request, DAX tries to read the items directly from the item cache using the specified key values. If the items are found (cache hit), DAX returns them to the application immediately. If the items are not found (cache miss), DAX sends the request to DynamoDB. DynamoDB processes the requests using eventually consistent reads and returns the items to DAX. DAX stores them in the item cache and then returns them to the application.

The item cache has a Time to Live (TTL) setting, which is 5 minutes by default. DAX assigns a timestamp to every item that it writes to the item cache. An item expires if it has remained in the cache for longer than the TTL setting. If you issue a `GetItem` request on an expired item, this is considered a cache miss, and DAX sends the `GetItem` request to DynamoDB.

Note

You can specify the TTL setting for the item cache when you create a new DAX cluster. For more information, see [Managing DAX clusters](#).

DAX also maintains a least recently used (LRU) list for the item cache. The LRU list tracks when an item was first written to the cache, and when the item was last read from the cache. If the item cache becomes full, DAX evicts older items (even if they haven't expired yet) to make room for new items. The LRU algorithm is always enabled for the item cache and is not user-configurable.

If you specify zero as the *item cache* TTL setting, items in the item cache will only be refreshed due to an LRU eviction or a ["write-through"](#) operation.

For detailed information about the consistency of the item cache in DAX, see [DAX item cache behavior](#).

Query cache

DAX also maintains a *query cache* to store the results from `Query` and `Scan` operations. The items in this cache represent result sets from queries and scans on DynamoDB tables. These result sets are stored by their parameter values.

When an application sends a `Query` or `Scan` request, DAX tries to read a matching result set from the query cache using the specified parameter values. If the result set is found (cache hit), DAX returns it to the application immediately. If the result set is not found (cache miss), DAX sends

the request to DynamoDB. DynamoDB processes the requests using eventually consistent reads and returns the result set to DAX. DAX stores it in the query cache and then returns it to the application.

 **Note**

You can specify the TTL setting for the query cache when you create a new DAX cluster. For more information, see [Managing DAX clusters](#).

DAX also maintains an LRU list for the query cache. The list tracks when a result set was first written to the cache, and when the result was last read from the cache. If the query cache becomes full, DAX evicts older result sets (even if they have not expired yet) to make room for new result sets. The LRU algorithm is always enabled for the query cache, and is not user-configurable.

If you specify zero as the *query cache* TTL setting, the query response will not be cached.

For detailed information about the consistency of the query cache in DAX, see [DAX query cache behavior](#).

DAX cluster components

An Amazon DynamoDB Accelerator (DAX) cluster consists of AWS infrastructure components. This section describes these components and how they work together.

- [Maintenance window](#)

Nodes

A *node* is the smallest building block of a DAX cluster. Each node runs an instance of the DAX software, and maintains a single replica of the cached data.

You can scale your DAX cluster in one of two ways:

- By adding more nodes to the cluster. This increases the overall read throughput of the cluster.
- By using a larger node type. Larger node types provide more capacity and can increase throughput. (You must create a new cluster with the new node type.)

Every node within a cluster is of the same node type and runs the same DAX caching software. For a list of available node types, see [Amazon DynamoDB pricing](#).

Clusters

A *cluster* is a logical grouping of one or more nodes that DAX manages as a unit. One of the nodes in the cluster is designated as the *primary* node, and the other nodes (if any) are *read replicas*.

The primary node is responsible for the following:

- Fulfilling application requests for cached data.
- Handling write operations to DynamoDB.
- Evicting data from the cache according to the cluster's eviction policy.

When changes are made to cached data on the primary node, DAX propagates the changes to all of the read replica nodes using replication logs. After the confirmation is received from all read replicas, DynamoDB deletes the replication logs from the primary node.

Read replicas are responsible for the following:

- Fulfilling application requests for cached data.
- Evicting data from the cache according to the cluster's eviction policy.

However, unlike the primary node, read replicas don't write to DynamoDB.

Read replicas serve two additional purposes:

- **Scalability.** If you have a large number of application clients that need to access DAX concurrently, you can add more replicas for read-scaling. DAX spreads the load evenly across all the nodes in the cluster. (Another way to increase throughput is to use larger cache node types.)
- **High availability.** In the event of a primary node failure, DAX automatically fails over to a read replica and designates it as the new primary. If a replica node fails, other nodes in the DAX cluster can still serve requests until the failed node can be recovered. For maximum fault tolerance, you should deploy read replicas in separate Availability Zones. This configuration ensures that your DAX cluster can continue to function, even if an entire Availability Zone becomes unavailable.

A DAX cluster can support up to 11 nodes per cluster (the primary node plus a maximum of 10 read replicas).

Important

For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in different Availability Zones. Three nodes are required for a DAX cluster to be fault-tolerant.

A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don't recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

Regions and availability zones

A DAX cluster in an AWS Region can only interact with DynamoDB tables that are in the same Region. For this reason, ensure that you launch your DAX cluster in the correct Region. If you have DynamoDB tables in other Regions, you must launch DAX clusters in those Regions too.

Each Region is designed to be completely isolated from the other Regions. Within each Region are multiple Availability Zones. By launching your nodes in different Availability Zones, you can achieve the greatest possible fault tolerance.

⚠ Important

Don't place all of your cluster's nodes in a single Availability Zone. In this configuration, your DAX cluster becomes unavailable if there is an Availability Zone failure.

For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in different Availability Zones. Three nodes are required for a DAX cluster to be fault-tolerant.

A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don't recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

Parameter groups

Parameter groups are used to manage runtime settings for DAX clusters. DAX has several parameters that you can use to optimize performance (such as defining a TTL policy for cached data). A parameter group is a named set of parameters that you can apply to a cluster. You can thereby ensure that all the nodes in that cluster are configured in exactly the same way.

Security groups

A DAX cluster runs in an Amazon Virtual Private Cloud (Amazon VPC) environment. This environment is a virtual network that is dedicated to your AWS account and is isolated from other VPCs. A *security group* acts as a virtual firewall for your VPC, allowing you to control inbound and outbound network traffic.

When you launch a cluster in your VPC, you add an *ingress* rule to your security group to allow incoming network traffic. The ingress rule specifies the protocol (TCP) and port number (8111) for your cluster. After you add this rule to your security group, the applications that are running within your VPC can access the DAX cluster.

Cluster ARN

Every DAX cluster is assigned an *Amazon Resource Name* (ARN). The ARN format is as follows.

```
arn:aws:dax:region:accountID:cache/clusterName
```

You use the cluster ARN in an IAM policy to define permissions for DAX API operations. For more information, see [DAX access control](#).

Cluster endpoint

Every DAX cluster provides a *cluster endpoint* for use by your application. By accessing the cluster using its endpoint, your application does not need to know the hostnames and port numbers of individual nodes in the cluster. Your application automatically "knows" all the nodes in the cluster, even if you add or remove read replicas.

The following is an example of a cluster endpoint in the us-east-1 region that is not configured to use encryption in transit.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

The following is an example of a cluster endpoint in the same region that is configured to use encryption in transit.

```
daxs://my-encrypted-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Node endpoints

Each of the individual nodes in a DAX cluster has its own hostname and port number. The following is an example of a *node endpoint*.

```
myDAXcluster-a.2cmrw1.clustercfg.dax.use1.cache.amazonaws.com:8111
```

Your application can access a node directly by using its endpoint. However, we recommend that you treat the DAX cluster as a single unit and access it using the cluster endpoint instead. The cluster endpoint insulates your application from having to maintain a list of nodes and keep that list up to date when you add or remove nodes from the cluster.

Subnet groups

Access to DAX cluster nodes is restricted to applications running on Amazon EC2 instances within an Amazon VPC environment. You can use *subnet groups* to grant cluster access from Amazon EC2 instances running on specific subnets. A subnet group is a collection of subnets (typically private) that you can designate for your clusters running in an Amazon VPC environment.

When you create a DAX cluster, you must specify a subnet group. DAX uses that subnet group to select a subnet and IP addresses within that subnet to associate with your nodes.

Events

DAX records significant events within your clusters, such as a failure to add a node, success in adding a node, or changes to security groups. By monitoring key events, you can know the current state of your clusters and, depending upon the event, be able to take corrective action. You can access these events using the AWS Management Console or the `DescribeEvents` action in the DAX management API.

You can also request that notifications be sent to a specific Amazon Simple Notification Service (Amazon SNS) topic. Then you will know immediately when an event occurs in your DAX cluster.

Maintenance window

Every cluster has a weekly maintenance window during which any system changes are applied. If you don't specify a preferred maintenance window when you create or modify a cache cluster, DAX assigns a 60-minute maintenance window on a randomly selected day of the week.

The 60-minute maintenance window is selected at random from an 8-hour block of time per AWS Region. The following table lists the time blocks for each Region from which the default maintenance windows are assigned.

Region code	Region name	Maintenance window
ap-northeast-1	Asia Pacific (Tokyo) Region	13:00–21:00 UTC
ap-southeast-1	Asia Pacific (Singapore) Region	14:00–22:00 UTC
ap-southeast-2	Asia Pacific (Sydney) Region	12:00–20:00 UTC
ap-south-1	Asia Pacific (Mumbai) Region	17:30–1:30 UTC
cn-northwest-1	China (Ningxia) Region	23:00–07:00 UTC
cn-north-1	China (Beijing) Region	14:00–22:00 UTC
eu-central-1	Europe (Frankfurt) Region	23:00–07:00 UTC
eu-west-1	Europe (Ireland) Region	22:00–06:00 UTC

Region code	Region name	Maintenance window
eu-west-2	Europe (London) Region	23:00–07:00 UTC
eu-west-3	Europe (Paris) Region	23:00–07:00 UTC
sa-east-1	South America (São Paulo) Region	01:00–09:00 UTC
us-east-1	US East (N. Virginia) Region	03:00–11:00 UTC
us-east-2	US East (Ohio) Region	23:00–07:00 UTC
us-west-1	US West (N. California) Region	06:00–14:00 UTC
us-west-2	US West (Oregon) Region	06:00–14:00 UTC

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. You can specify a time range of up to 24 hours in duration during which any maintenance activities that you request should occur.

Creating a DAX cluster

This section walks you through the first-time setup and usage of Amazon DynamoDB Accelerator (DAX) in your default Amazon Virtual Private Cloud (Amazon VPC) environment. You can create your first DAX cluster using either the AWS Command Line Interface (AWS CLI) or the AWS Management Console.

After you create your DAX cluster, you can access it from an Amazon EC2 instance running in the same VPC. You can then use your DAX cluster with an application program. For more information, see [Developing with the DynamoDB Accelerator \(DAX\) client](#).

Topics

- [Creating an IAM service role for DAX to access DynamoDB](#)
- [Creating a DAX cluster using the AWS CLI](#)
- [Creating a DAX cluster using the AWS Management Console](#)

Creating an IAM service role for DAX to access DynamoDB

For your DAX cluster to access DynamoDB tables on your behalf, you must create a *service role*. A service role is an AWS Identity and Access Management (IAM) role that authorizes an AWS service to act on your behalf. The service role allows DAX to access your DynamoDB tables, as if you were accessing those tables yourself. You must create the service role before you can create the DAX cluster.

If you are using the console, the workflow for creating a cluster checks for the presence of a pre-existing DAX service role. If none is found, the console creates a new service role for you. For more information, see [the section called “Step 2: Create a DAX cluster”](#).

If you are using the AWS CLI, you must specify a DAX service role that you have created previously. Otherwise, you need to create a new service role beforehand. For more information, see [Step 1: Create an IAM service role for DAX to access DynamoDB using the AWS CLI](#).

Permissions required to create a service role

The AWS managed AdministratorAccess policy provides all the permissions needed for creating a DAX cluster and a service role. If your user has AdministratorAccess attached, no further action is needed.

Otherwise, you must add the following permissions to your IAM policy so that your user can create the service role:

- `iam:CreateRole`
- `iam:CreatePolicy`
- `iam:AttachRolePolicy`
- `iam:PassRole`

Attach these permissions to the user who is trying to perform the action.

Note

The `iam:CreateRole`, `iam:CreatePolicy`, `iam:AttachRolePolicy`, and `iam:PassRole` permissions are not included in the AWS managed policies for DynamoDB. This is by design because these permissions provide the possibility of privilege escalation: That is, a user could use these permissions to create a new administrator policy and then

attach that policy to an existing role. For this reason, you (the administrator of your DAX cluster) must explicitly add these permissions to your policy.

Troubleshooting

If your user policy is missing the `iam:CreateRole`, `iam:CreatePolicy`, and `iam:AttachPolicy` permissions, you will get error messages. The following table lists these messages and describes how to correct the problems.

If you see this error message...	Do the following:
User: arn:aws:iam:: <i>accountID</i> :user/ <i>userName</i> is not authorized to perform: iam:CreateRole on resource: arn:aws:iam:: <i>accountID</i> :role/service-role/ <i>roleName</i>	Add <code>iam:CreateRole</code> to your user policy.
User: arn:aws:iam:: <i>accountID</i> :user/ <i>userName</i> is not authorized to perform: iam:CreatePolicy on resource: policy <i>policyName</i>	Add <code>iam:CreatePolicy</code> to your user policy.
User: arn:aws:iam:: <i>accountID</i> :user/ <i>userName</i> is not authorized to perform: iam:AttachRolePolicy on resource: role <i>daxServiceRole</i>	Add <code>iam:AttachRolePolicy</code> to your user policy.

For more information about the IAM policies required for DAX cluster administration, see [DAX access control](#).

Creating a DAX cluster using the AWS CLI

This section describes how to create an Amazon DynamoDB Accelerator (DAX) cluster using the AWS Command Line Interface (AWS CLI). If you haven't already done so, you must install and configure the AWS CLI. To do this, see the following instructions in the *AWS Command Line Interface User Guide*:

- [Installing the AWS CLI](#)
- [Configuring the AWS CLI](#)

A **Important**

To manage DAX clusters using the AWS CLI, install or upgrade to version 1.11.110 or higher.

All of the AWS CLI examples use the us-west-2 Region and fictitious account IDs.

Topics

- [Step 1: Create an IAM service role for DAX to access DynamoDB using the AWS CLI](#)
- [Step 2: Create a subnet group](#)
- [Step 3: Create a DAX cluster using the AWS CLI](#)
- [Step 4: Configure security group inbound rules using the AWS CLI](#)

Step 1: Create an IAM service role for DAX to access DynamoDB using the AWS CLI

Before you can create an Amazon DynamoDB Accelerator (DAX) cluster, you must create a service role for it. A *service role* is an AWS Identity and Access Management (IAM) role that authorizes an AWS service to act on your behalf. The service role allows DAX to access your DynamoDB tables as if you were accessing those tables yourself.

In this step, you create an IAM policy and then attach that policy to an IAM role. This enables you to assign the role to a DAX cluster so that it can perform DynamoDB operations on your behalf.

To create an IAM service role for DAX

1. Create a file named `service-trust-relationship.json` with the following contents.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {
```

```
        "Service": "dax.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
]
}
}
```

2. Create the service role.

```
aws iam create-role \
--role-name DAXServiceRoleForDynamoDBAccess \
--assume-role-policy-document file://service-trust-relationship.json
```

3. Create a file named `service-role-policy.json` with the following contents.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "dynamodb:DescribeTable",
                "dynamodb:PutItem",
                "dynamodb:GetItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:BatchGetItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem"
            ],
            "Effect": "Allow",
            "Resource": [
                "arn:aws:dynamodb:us-west-2:accountID:*"
            ]
        }
    ]
}
```

Replace **accountID** with your AWS account ID. To find your AWS account ID, in the upper-right corner of the console, choose your login ID. Your AWS account ID appears in the drop-down menu.

In the Amazon Resource Name (ARN) in the example, *accountID* must be a 12-digit number. Don't use hyphens or any other punctuation.

4. Create an IAM policy for the service role.

```
aws iam create-policy \
--policy-name DAXServicePolicyForDynamoDBAccess \
--policy-document file://service-role-policy.json
```

In the output, note the ARN for the policy that you created, as in the following example.

arn:aws:iam::123456789012:policy/DAXServicePolicyForDynamoDBAccess

5. Attach the policy to the service role. Replace *arn* in the following code with the actual role ARN from the previous step.

```
aws iam attach-role-policy \
--role-name DAXServiceRoleForDynamoDBAccess \
--policy-arn arn
```

Next, you specify a subnet group for your default VPC. A *subnet group* is a collection of one or more subnets within your VPC. See [Step 2: Create a subnet group](#).

Step 2: Create a subnet group

Follow this procedure to create a subnet group for your Amazon DynamoDB Accelerator (DAX) cluster using the AWS Command Line Interface (AWS CLI).

Note

If you already created a subnet group for your default VPC, you can skip this step.

DAX is designed to run within an Amazon Virtual Private Cloud environment (Amazon VPC). If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. For more information, see [Default VPC and default subnets](#) in the *Amazon VPC User Guide*.

To create a subnet group

1. To determine the identifier for your default VPC, enter the following command.

```
aws ec2 describe-vpcs
```

In the output, note the identifier for your default VPC, as in the following example.

vpc-12345678

2. Determine the subnet IDs associated with your default VPC. Replace *vpcID* with your actual VPC ID—for example, vpc-12345678.

```
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=vpcID" \
--query "Subnets[*].SubnetId"
```

In the output, note the subnet identifiers—for example, subnet-11111111.

3. Create the subnet group. Ensure that you specify at least one subnet ID in the --subnet-ids parameter.

```
aws dax create-subnet-group \
--subnet-group-name my-subnet-group \
--subnet-ids subnet-11111111 subnet-22222222 subnet-33333333 subnet-44444444
```

To create the cluster, see [Step 3: Create a DAX cluster using the AWS CLI](#).

Step 3: Create a DAX cluster using the AWS CLI

Follow this procedure to use the AWS Command Line Interface (AWS CLI) to create an Amazon DynamoDB Accelerator (DAX) cluster in your default Amazon VPC.

To create a DAX cluster

1. Get the Amazon Resource Name (ARN) for your service role.

```
aws iam get-role \
--role-name DAXServiceRoleForDynamoDBAccess \
--query "Role.Arn" --output text
```

In the output, note the service role ARN, as in the following example.

arn:aws:iam::123456789012:role/DAXServiceRoleForDynamoDBAccess

2. Create the DAX cluster. Replace *roleARN* with the ARN from the previous step.

```
aws dax create-cluster \
--cluster-name mydaxcluster \
--node-type dax.r4.large \
--replication-factor 3 \
--iam-role-arn roleARN \
--subnet-group my-subnet-group \
--sse-specification Enabled=true \
--region us-west-2
```

All of the nodes in the cluster are of type `dax.r4.large` (`--node-type`). There are three nodes (`--replication-factor`)—one primary node and two replicas.

 **Note**

Since `sudo` and `grep` are reserved keywords, you cannot create a DAX cluster with these words in the cluster name. For example, `sudo` and `sudocluster` are invalid cluster names.

To view the cluster status, enter the following command.

```
aws dax describe-clusters
```

The status is shown in the output—for example, "Status": "creating".

 **Note**

Creating the cluster takes several minutes. When the cluster is ready, its status changes to available. In the meantime, proceed to [Step 4: Configure security group inbound rules using the AWS CLI](#) and follow the instructions there.

Step 4: Configure security group inbound rules using the AWS CLI

The nodes in your Amazon DynamoDB Accelerator (DAX) cluster use the default security group for your Amazon VPC. For the default security group, you must authorize inbound traffic on TCP

port 8111 for unencrypted clusters or port 9111 for encrypted clusters. This allows Amazon EC2 instances in your Amazon VPC to access your DAX cluster.

Note

If you launched your DAX cluster with a different security group (other than default), you must perform this procedure for that group instead.

To configure security group inbound rules

1. To determine the default security group identifier, enter the following command. Replace *vpcID* with your actual VPC ID (from [Step 2: Create a subnet group](#)).

```
aws ec2 describe-security-groups \
--filters Name=vpc-id,Values=vpcID Name=group-name,Values=default \
--query "SecurityGroups[*].{GroupName:GroupName,GroupId:GroupId}"
```

In the output, note the security group identifier—for example, sg-01234567.

2. Then enter the following. Replace *sgID* with your actual security group identifier. Use port 8111 for unencrypted clusters and 9111 for encrypted clusters.

```
aws ec2 authorize-security-group-ingress \
--group-id sgID --protocol tcp --port 8111
```

Creating a DAX cluster using the AWS Management Console

This section describes how to create an Amazon DynamoDB Accelerator (DAX) cluster using the AWS Management Console.

Topics

- [Step 1: Create a subnet group using the AWS Management Console](#)
- [Step 2: Create a DAX cluster using the AWS Management Console](#)
- [Step 3: Configure security group inbound rules using the AWS Management Console](#)

Step 1: Create a subnet group using the AWS Management Console

Follow this procedure to create a subnet group for your Amazon DynamoDB Accelerator (DAX) cluster using the AWS Management Console.

 **Note**

If you already created a subnet group for your default VPC, you can skip this step.

DAX is designed to run within an Amazon Virtual Private Cloud (Amazon VPC) environment. If you created your AWS account after December 4, 2013, you already have a default VPC in each AWS Region. For more information, see [Default VPC and default subnets](#) in the *Amazon VPC User Guide*.

As part of the creation process for a DAX cluster, you must specify a *subnet group*. A subnet group is a collection of one or more subnets within your VPC. When you create your DAX cluster, the nodes are deployed to the subnets within the subnet group.

To create a subnet group

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, under **DAX**, choose **Subnet groups**.
3. Choose **Create subnet group**.
4. In the **Create subnet group** window, do the following:
 - a. **Name**—Enter a short name for the subnet group.
 - b. **Description**—Enter a description for the subnet group.
 - c. **VPC ID**—Choose the identifier for your Amazon VPC environment.
 - d. **Subnets**—Choose one or more subnets from the list.

 **Note**

The subnets are distributed among multiple Availability Zones. If you plan to create a multi-node DAX cluster (a primary node and one or more read replicas), we recommend that you choose multiple subnet IDs. Then DAX can deploy the cluster nodes into multiple Availability Zones. If an Availability Zone becomes

unavailable, DAX automatically fails over to a surviving Availability Zone. Your DAX cluster will continue to function without interruption.

When the settings are as you want them, choose **Create subnet group**.

To create the cluster, see [Step 2: Create a DAX cluster using the AWS Management Console](#).

Step 2: Create a DAX cluster using the AWS Management Console

Follow this procedure to create an Amazon DynamoDB Accelerator (DAX) cluster in your default Amazon VPC.

To create a DAX cluster

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, under **DAX**, choose **Clusters**.
3. Choose **Create cluster**.
4. In the **Create cluster** window, do the following:
 - a. **Cluster name**—Enter a short name for your DAX cluster.

 **Note**

Since sudo and grep are reserved keywords, you cannot create a DAX cluster with these words in the cluster name. For example, sudo and sudocluster are invalid cluster names.

- b. **Cluster description**—Enter a description for the cluster.
- c. **Node types**—Choose the node type for all of the nodes in the cluster.
- d. **Cluster size**—Choose the number of nodes in the cluster. A cluster consists of one primary node and up to nine read replicas.

 **Note**

If you want to create a single-node cluster, choose **1**. Your cluster will consist of one primary node.

If you want to create a multi-node cluster, choose a number between **3** (one primary and two read replicas) and **10** (one primary and nine read replicas).

 **Important**

For production usage, we strongly recommend using DAX with at least three nodes, where each node is placed in a different Availability Zone. Three nodes are required for a DAX cluster to be fault-tolerant.

A DAX cluster can be deployed with one or two nodes for development or test workloads. One- and two-node clusters are not fault-tolerant, and we don't recommend using fewer than three nodes for production use. If a one- or two-node cluster encounters software or hardware errors, the cluster can become unavailable or lose cached data.

- e. Choose **Next**.
- f. **Subnet group**—Select **Choose existing** and choose the subnet group that you created in [Step 1: Create a subnet group using the AWS Management Console](#).
- g. **Access control**—Choose the **default** security group.
- h. **Availability Zones (AZ)**—Choose **Automatic**.
- i. Choose next.
- j. **IAM service role for DynamoDB access**—Choose **Create new**, and enter the following information:
 - **IAM role name**—Enter a name for an IAM role, for example, `DAXServiceRole`. The console creates a new IAM role, and your DAX cluster assumes this role at runtime.
 - Select the box next to **Create policy**.
 - **IAM role policy**—Choose **Read/Write**. This allows the DAX cluster to perform read and write operations in DynamoDB.
 - **New IAM policy name**—This field will populate as you enter the IAM role name. You can also enter a name for an IAM policy, for example, `DAXServicePolicy`. The console creates a new IAM policy and attaches the policy to the IAM role.
 - **Access to DynamoDB tables**—Choose **All tables**.
- k. **Encryption**—Choose **Turn on encryption at rest** and **Turn on encryption in transit** For more information, see [DAX encryption at rest](#) and [DAX encryption in transit](#).

A separate service role for DAX to access Amazon EC2 is also required. DAX automatically creates this service role for you. For more information, see [Using service-linked roles for DAX](#).

5. When the settings are as you want them, choose **Next**.
6. **Parameter group**—Choose **Choose existing**.
7. **Maintenance window**—Choose **No preference** if you don't have a preference when software upgrades are applied, or choose **Specify time window** and provide the **Weekday**, **Time(UTC)** and **Start within (hours)** options to schedule your maintenance window.
8. **Tags**—Choose **Add new tag** to enter a key/value pair for tagging purposes.
9. Choose **Next**.

On the **Review and create** screen, you can review all of the settings. If you are ready to create the cluster, choose **Create cluster**.

On the **Clusters** screen, your DAX cluster will be listed with a status of **Creating**.

 **Note**

Creating the cluster takes several minutes. When the cluster is ready, its status changes to **Available**.

In the meantime, proceed to [Step 3: Configure security group inbound rules using the AWS Management Console](#) and follow the instructions there.

Step 3: Configure security group inbound rules using the AWS Management Console

Your Amazon DynamoDB Accelerator (DAX) cluster communicates via TCP port 8111 (for unencrypted clusters) or 9111 (for encrypted clusters), so you must authorize inbound traffic on that port. This allows Amazon EC2 instances in your Amazon VPC to access your DAX cluster.

 **Note**

If you launched your DAX cluster with a different security group (other than default), you must perform this procedure for that group instead.

To configure security group inbound rules

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Security Groups**.
3. Choose the **default** security group. On the **Actions** menu, choose **Edit inbound rules**.
4. Choose **Add Rule**, and enter the following information:
 - **Port Range**—Enter **8111** (if your cluster is unencrypted) or **9111** (if your cluster is encrypted).
 - **Source**—Leave this as **Custom**, and choose the search field to the right. A drop-down menu will be displayed. Choose the identifier for your default security group.
5. Choose **Save rules** to save your changes.
6. To update the name in the console, go to the **Name** property and choose the **Edit** option that is displayed.

DAX and DynamoDB consistency models

Amazon DynamoDB Accelerator (DAX) is a write-through caching service that is designed to simplify the process of adding a cache to DynamoDB tables. Because DAX operates separately from DynamoDB, it is important that you understand the consistency models of both DAX and DynamoDB to ensure that your applications behave as you expect.

In many use cases, the way that your application uses DAX affects the consistency of data within the DAX cluster, and the consistency of data between DAX and DynamoDB.

Topics

- [Consistency among DAX cluster nodes](#)
- [DAX item cache behavior](#)
- [DAX query cache behavior](#)
- [Strongly consistent and transactional reads](#)
- [Negative caching](#)
- [Strategies for writes](#)

Consistency among DAX cluster nodes

To achieve high availability for your application, we recommend that you provision your DAX cluster with at least three nodes. Then place those nodes in multiple Availability Zones within a Region.

When your DAX cluster is running, it replicates the data among all of the nodes in the cluster (assuming that you provisioned more than one node). Consider an application that performs a successful `UpdateItem` using DAX. This action causes the item cache in the primary node to be modified with the new value. That value is then replicated to all the other nodes in the cluster. This replication is eventually consistent and usually takes less than one second to complete.

In this scenario, it's possible for two clients to read the same key from the same DAX cluster but receive different values, depending on the node that each client accessed. The nodes are all consistent when the update has been fully replicated throughout all the nodes in the cluster. (This behavior is similar to the eventually consistent nature of DynamoDB.)

If you are building an application that uses DAX, that application should be designed so that it can tolerate eventually consistent data.

DAX item cache behavior

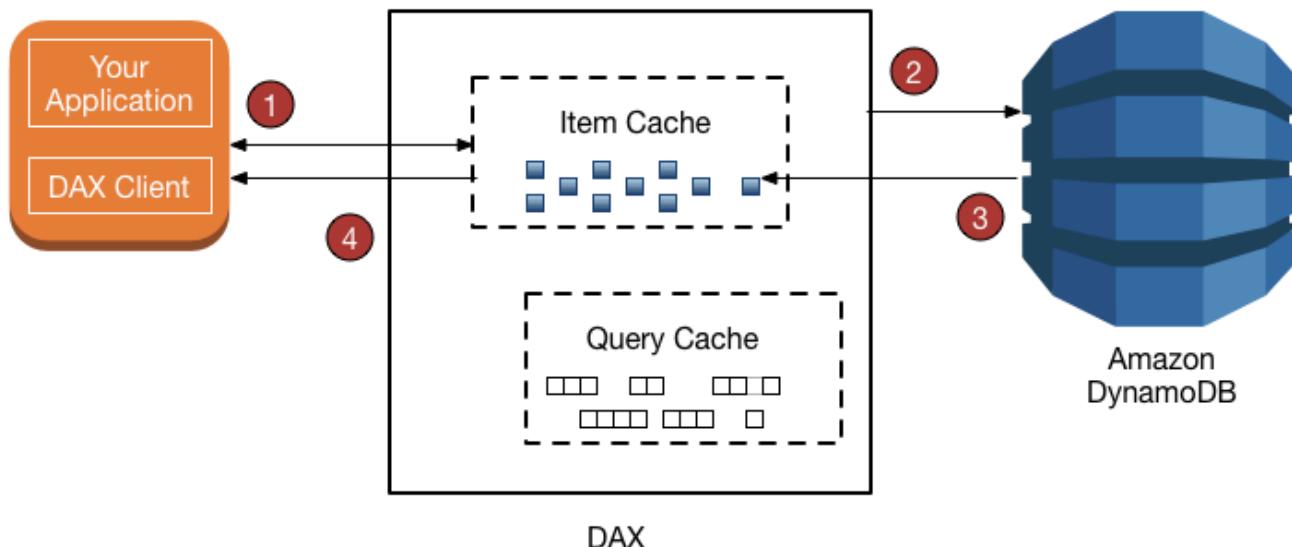

Every DAX cluster has two distinct caches—an *item* cache and a *query* cache. For more information, see [DAX: How it works](#).

This section addresses the consistency implications of reading from and writing to the DAX item cache.

Consistency of reads

With DynamoDB, the `GetItem` operation performs an eventually consistent read by default. Suppose that you use `UpdateItem` with the DynamoDB client. If you then try to read the same item immediately afterward, you might see the data as it appeared before the update. This is due to propagation delay across all the DynamoDB storage locations. Consistency is usually reached within seconds. So if you retry the read, you will likely see the updated item.

When you use `GetItem` with the DAX client, the operation (in this case, an eventually consistent read) proceeds as shown following.

1. The DAX client issues a `GetItem` request. DAX tries to read the requested item from the item cache. If the item is in the cache (*cache hit*), DAX returns it to the application.
2. If the item is not available (*cache miss*), DAX performs an eventually consistent `GetItem` operation against DynamoDB.
3. DynamoDB returns the requested item, and DAX stores it in the item cache.
4. DAX returns the item to the application.
5. (Not shown) If the DAX cluster contains more than one node, the item is replicated to all the other nodes in the cluster.

The item remains in the DAX item cache, subject to the Time to Live (TTL) setting and the least recently used (LRU) algorithm for the cache. For more information, see [DAX: How it works](#).

However, during this period, DAX doesn't re-read the item from DynamoDB. If someone else updates the item using a DynamoDB client, bypassing DAX entirely, a `GetItem` request using the DAX client yields different results from the same `GetItem` request using the DynamoDB client. In this scenario, DAX and DynamoDB hold inconsistent values for the same key until the TTL for the DAX item expires.

If an application modifies data in an underlying DynamoDB table, bypassing DAX, the application needs to anticipate and tolerate data inconsistencies that might arise.

Note

In addition to `GetItem`, the DAX client also supports `BatchGetItem` requests.

`BatchGetItem` is essentially a wrapper around one or more `GetItem` requests, so DAX treats each of these as an individual `GetItem` operation.

Consistency of writes

DAX is a write-through cache, which simplifies the process of keeping the DAX item cache consistent with the underlying DynamoDB tables.

The DAX client supports the same write API operations as DynamoDB (`PutItem`, `UpdateItem`, `DeleteItem`, `BatchWriteItem`, and `TransactWriteItems`). When you use these operations with the DAX client, the items are modified in both DAX and DynamoDB. DAX updates the items in its item cache, regardless of the TTL value for these items.

For example, suppose that you issue a `GetItem` request from the DAX client to read an item from the `ProductCatalog` table. (The partition key is `Id`, and there is no sort key.) You retrieve the item whose `Id` is `101`. The `QuantityOnHand` value for that item is `42`. DAX stores the item in its item cache with a specific TTL. For this example, assume that the TTL is `10` minutes. Then, `3` minutes later, another application uses the DAX client to update the same item so that its `QuantityOnHand` value is now `41`. Assuming that the item is not updated again, any subsequent reads of the same item during the next `10` minutes return the cached value for `QuantityOnHand` (`41`).

How DAX processes writes

DAX is intended for applications that require high-performance reads. As a write-through cache, DAX passes your writes through to DynamoDB synchronously, then automatically and asynchronously replicates resulting updates to your item cache across all nodes in the cluster. You don't need to manage cache invalidation logic because DAX handles it for you.

DAX supports the following write operations: `PutItem`, `UpdateItem`, `DeleteItem`, `BatchWriteItem`, and `TransactWriteItems`.

When you send a `PutItem`, `UpdateItem`, `DeleteItem`, or `BatchWriteItem` request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the write succeeded.
- DAX writes the item to its item cache.
- DAX returns success to the requester.

When you send a `TransactWriteItems` request to DAX, the following occurs:

- DAX sends the request to DynamoDB.
- DynamoDB replies to DAX, confirming that the transaction completed.
- DAX returns success to the requester.
- In the background, DAX makes a `TransactGetItems` request for each item in the `TransactWriteItems` request to store the item in the item cache. `TransactGetItems` is used to ensure [Serializable isolation](#).

If a write to DynamoDB fails for any reason, including throttling, the item is not cached in DAX. The exception for the failure is returned to the requester. This ensures that data is not written to the DAX cache unless it is first written successfully to DynamoDB.

 **Note**

Every write to DAX alters the state of the item cache. However, writes to the item cache don't affect the query cache. (The DAX item cache and query cache serve different purposes, and operate independently from one another.)

DAX query cache behavior

DAX caches the results from Query and Scan requests in its query cache. However, these results don't affect the item cache at all. When your application issues a Query or Scan request with DAX, the result set is saved in the query cache—not in the item cache. You can't "warm up" the item cache by performing a Scan operation because the item cache and query cache are separate entities.

Consistency of query-update-query

Updates to the item cache, or to the underlying DynamoDB table, do not invalidate or modify the results stored in the query cache.

To illustrate, consider the following scenario. An application is working with the DocumentRevisions table, which has DocId as its partition key and RevisionNumber as its sort key.

1. A client issues a Query for DocId 101, for all items with RevisionNumber greater than or equal to 5. DAX stores the result set in the query cache and returns the result set to the user.
2. The client issues a PutItem request for DocId 101 with a RevisionNumber value of 20.
3. The client issues the same Query as described in step 1 (DocId 101 and RevisionNumber >= 5).

In this scenario, the cached result set for the Query issued in step 3 is identical to the result set that was cached in step 1. The reason is that DAX does not invalidate Query or Scan result sets based on updates to individual items. The PutItem operation from step 2 is only reflected in the DAX query cache when the TTL for the Query expires.

Your application should consider the TTL value for the query cache and how long your application can tolerate inconsistent results between the query cache and the item cache.

Strongly consistent and transactional reads

To perform a strongly consistent GetItem, BatchGetItem, Query, or Scan request, you set the ConsistentRead parameter to true. DAX passes strongly consistent read requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it does not cache the results. DAX can't serve strongly consistent reads by itself because it's not tightly coupled to DynamoDB. For this reason, any subsequent reads from DAX would have to be eventually consistent reads. And any subsequent strongly consistent reads would have to be passed through to DynamoDB.

DAX handles TransactGetItems requests the same way it handles strongly consistent reads. DAX passes all TransactGetItems requests to DynamoDB. When it receives a response from DynamoDB, DAX returns the results to the client, but it doesn't cache the results.

Negative caching

DAX supports negative cache entries in both the item cache and the query cache. A *negative cache entry* occurs when DAX can't find requested items in an underlying DynamoDB table. Instead of generating an error, DAX caches an empty result and returns that result to the user.

For example, suppose that an application sends a `GetItem` request to a DAX cluster, and that there is no matching item in the DAX item cache. This causes DAX to read the corresponding item from the underlying DynamoDB table. If the item doesn't exist in DynamoDB, DAX stores an empty item in its item cache and returns the empty item to the application. Now suppose that the application sends another `GetItem` request for the same item. DAX finds the empty item in the item cache and returns it to the application immediately. It does not consult DynamoDB at all.

A negative cache entry remains in the DAX item cache until its item TTL has expired, its LRU is invoked, or the item is modified using `PutItem`, `UpdateItem`, or `DeleteItem`.

The DAX query cache handles negative cache results in a similar way. If an application performs a `Query` or `Scan`, and the DAX query cache doesn't contain a cached result, DAX sends the request to DynamoDB. If there are no matching items in the result set, DAX stores an empty result set in the query cache and returns the empty result set to the application. Subsequent `Query` or `Scan` requests yield the same (empty) result set, until the TTL for that result set has expired.

Strategies for writes

The write-through behavior of DAX is appropriate for many application patterns. However, there are some application patterns where a write-through model might not be appropriate.

For applications that are sensitive to latency, writing through DAX incurs an extra network hop. So a write to DAX is a little slower than a write directly to DynamoDB. If your application is sensitive to write latency, you can reduce the latency by writing directly to DynamoDB instead. For more information, see [Write-around](#).

For write-intensive applications (such as those that perform bulk data loading), you might not want to write all of the data through DAX because only a small percentage of that data is ever read by the application. When you write large amounts of data through DAX, it must invoke its LRU algorithm to make room in the cache for the new items to be read. This diminishes the effectiveness of DAX as a read cache.

When you write an item to DAX, the item cache state is altered to accommodate the new item. (For example, DAX might need to evict older data from the item cache to make room for the new item.)

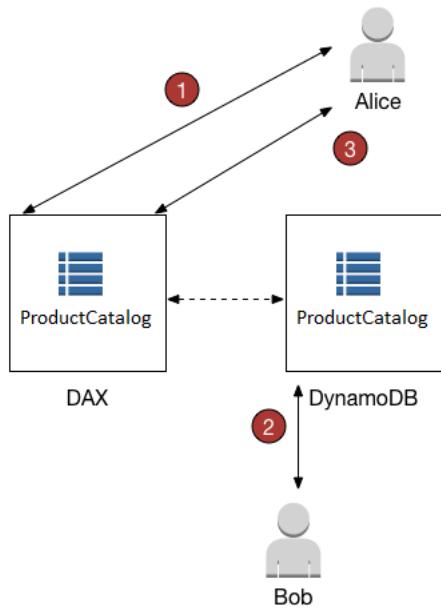

The new item remains in the item cache, subject to the cache's LRU algorithm and the TTL setting for the cache. As long as the item persists in the item cache, DAX doesn't re-read the item from DynamoDB.

Write-through

The DAX item cache implements a write-through policy. For more information, see [How DAX processes writes](#).

When you write an item, DAX ensures that the cached item is synchronized with the item as it exists in DynamoDB. This is helpful for applications that need to re-read an item immediately after writing it. However, if other applications write directly to a DynamoDB table, the item in the DAX item cache is no longer in sync with DynamoDB.

To illustrate, consider two users (Alice and Bob), who are working with the `ProductCatalog` table. Alice accesses the table using DAX, but Bob bypasses DAX and accesses the table directly in DynamoDB.

1. Alice updates an item in the `ProductCatalog` table. DAX forwards the request to DynamoDB, and the update succeeds. DAX then writes the item to its item cache and returns a successful response to Alice. From that point on, until the item is ultimately evicted from the cache, any user who reads the item from DAX sees the item with Alice's update.

2. A short time later, Bob updates the same ProductCatalog item that Alice wrote. However, Bob updates the item directly in DynamoDB. DAX does not automatically refresh its item cache in response to updates via DynamoDB. Therefore, DAX users don't see Bob's update.
3. Alice reads the item from DAX again. The item is in the item cache, so DAX returns it to Alice without accessing the DynamoDB table.

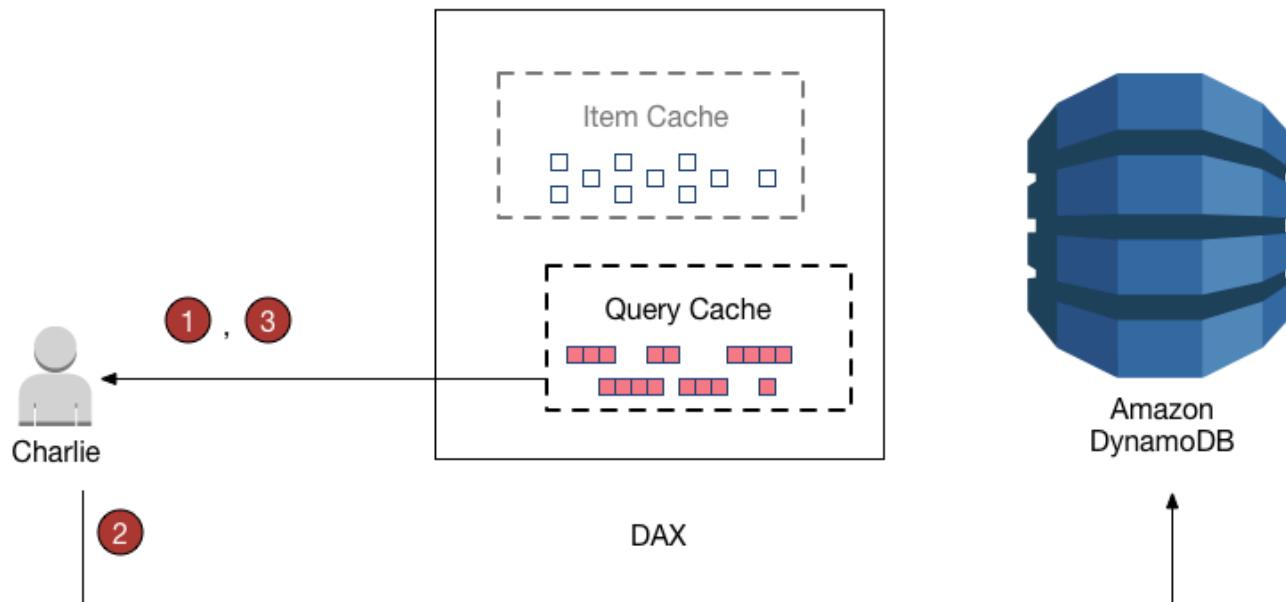

In this scenario, Alice and Bob see different representations of the same ProductCatalog item. This is the case until DAX evicts the item from the item cache, or until another user updates the same item again using DAX.

Write-around

If your application needs to write large quantities of data (such as a bulk data load), it might make sense to bypass DAX and write the data directly to DynamoDB. Such a *write-around* strategy reduces write latency. However, the item cache doesn't remain in sync with the data in DynamoDB.

If you decide to use a write-around strategy, remember that DAX populates its item cache whenever applications use the DAX client to read data. This can be advantageous in some cases because it ensures that only the most frequently read data is cached (as opposed to the most frequently written data).

For example, consider a user (Charlie) who wants to work with a different table, the GameScores table, using DAX. The partition key for GameScores is UserId, so all of Charlie's scores would have the same UserId.

1. Charlie wants to retrieve all of his scores, so he sends a Query to DAX. Assuming that this query has not been issued before, DAX forwards the query to DynamoDB for processing. It stores the results in the DAX query cache, and then returns the results to Charlie. The result set remains available in the query cache until it is evicted.
2. Now suppose that Charlie plays the Meteor Blasters game and achieves a high score. Charlie sends an UpdateItem request to DynamoDB, modifying an item in the GameScores table.
3. Finally, Charlie decides to rerun his earlier Query to retrieve all of his data from GameScores. Charlie does not see his high score for Meteor Blasters in the results. This is because the query results come from the query cache, not the item cache. The two caches are independent from one another, so a change in one cache does not affect the other cache.

DAX does not refresh result sets in the query cache with the most current data from DynamoDB. Each result set in the query cache is current as of the time that the Query or Scan operation was performed. Thus, Charlie's Query results don't reflect his PutItem operation. This is the case until DAX evicts the result set from the query cache.

Developing with the DynamoDB Accelerator (DAX) client

To use DAX from an application, you use the DAX client for your programming language. The DAX client is designed for minimal disruption to your existing Amazon DynamoDB applications—with only a few simple code modifications needed.

Note

DAX clients for various programming languages are available on the following site:

- <http://dax-sdk.s3-website-us-west-2.amazonaws.com>

This section demonstrates how to launch an Amazon EC2 instance in your default Amazon VPC, connect to the instance, and run a sample application. It also provides information about how to modify your existing application so that it can use your DAX cluster.

Topics

- [Tutorial: Running a sample application using DynamoDB Accelerator \(DAX\)](#)
- [Modifying an existing application to use DAX](#)

Tutorial: Running a sample application using DynamoDB Accelerator (DAX)

This tutorial demonstrates how to launch an Amazon EC2 instance in your default virtual private cloud (VPC), connect to the instance, and run a sample application that uses Amazon DynamoDB Accelerator (DAX).

Note

To complete this tutorial, you must have a DAX cluster running in your default VPC. If you haven't created a DAX cluster, see [Creating a DAX cluster](#) for instructions.

Topics

- [Step 1: Launch an Amazon EC2 instance](#)

- [Step 2: Create a user and policy](#)
- [Step 3: Configure an Amazon EC2 instance](#)
- [Step 4: Run a sample application](#)

Step 1: Launch an Amazon EC2 instance

When your Amazon DynamoDB Accelerator (DAX) cluster is available, you can launch an Amazon EC2 instance in your default Amazon VPC. You can then install and run DAX client software on that instance.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance**, and do the following:

Step 1: Choose an Amazon Machine Image (AMI)

1. In the list of AMIs, find the **Amazon Linux AMI**, and choose **Select**.

Step 2: Choose an Instance Type

1. In the list of instance types, choose **t2.micro**.
2. Choose **Next: Configure Instance Details**.

Step 3: Configure Instance Details

1. For **Network**, choose your default VPC.
2. Choose **Next: Add Storage**.

Step 4: Add Storage

1. Skip this step by choosing **Next: Add Tags**.

Step 5: Add Tags

1. Skip this step by choosing **Next: Configure Security Group**.

Step 6: Configure Security Group

1. Choose **Select an existing security group**.
2. In the list of security groups, choose **default**. This is the default security group for your VPC.
3. Choose **Next: Review and Launch**.

Step 7: Review Instance Launch

1. Choose **Launch**.
3. In the **Select an existing key pair or create a new key pair** window, do one of the following:
 - If you don't have an Amazon EC2 key pair, choose **Create a new key pair** and follow the instructions. You are asked to download a private key file (. pem file). You need this file later when you log in to your Amazon EC2 instance.
 - If you already have an existing Amazon EC2 key pair, go to **Select a key pair** and choose your key pair from the list. You must already have the private key file (. pem file) available in order to log in to your Amazon EC2 instance.
4. After configuring your key pair, choose **Launch Instances**.
5. In the console navigation pane, choose **EC2 Dashboard**, and then choose the instance that you launched. In the lower pane, on the **Description** tab, find the **Public DNS** for your instance, for example: ec2-11-22-33-44.us-west-2.compute.amazonaws.com. Make a note of this public DNS name because you need it for [Step 3: Configure an Amazon EC2 instance](#).

 **Note**

It takes a few minutes for your Amazon EC2 instance to become available. In the meantime, proceed to [Step 2: Create a user and policy](#) and follow the instructions there.

Step 2: Create a user and policy

In this step, you create a user with a policy that grants access to your Amazon DynamoDB Accelerator (DAX) cluster and to DynamoDB using AWS Identity and Access Management. You can then run applications that interact with your DAX cluster.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create an administrative user

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create an administrative user

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to an administrative user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.

- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane on the left, choose **Policies**.
If this is your first time choosing **Policies**, the **Welcome to Managed Policies** page appears. Choose **Get Started**.
3. At the top of the page, choose **Create policy**.
4. In the **Policy editor** section, choose the **JSON** option.
5. Enter or paste a JSON policy document. For details about the IAM policy language, see [IAM JSON policy reference](#).
6. Resolve any security warnings, errors, or general warnings generated during [policy validation](#), and then choose **Next**.

 **Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](#) in the *IAM User Guide*.

7. (Optional) When you create or edit a policy in the AWS Management Console, you can generate a JSON or YAML policy template that you can use in AWS CloudFormation templates.

To do this, in the **Policy editor** choose **Actions**, and then choose **Generate CloudFormation template**. To learn more about AWS CloudFormation, see [AWS Identity and Access Management resource type reference](#) in the *AWS CloudFormation User Guide*.

8. When you are finished adding permissions to the policy, choose **Next**.
9. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.
10. (Optional) Add metadata to the policy by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#) in the *IAM User Guide*.
11. Choose **Create policy** to save your new policy.

Policy document – Copy and paste the following document to create the JSON policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "dax:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "*"  
            ]  
        },  
        {  
            "Action": [  
                "dynamodb:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "*"  
            ]  
        }  
    ]  
}
```

Step 3: Configure an Amazon EC2 instance

When your Amazon EC2 instance is available, you can log in to the instance and prepare it for use.

Note

The following steps assume that you are connecting to your Amazon EC2 instance from a computer running Linux. For other ways to connect, see [Connect to Your Linux Instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

To configure the EC2 instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. Use the ssh command to log in to your Amazon EC2 instance, as shown in the following example.

```
ssh -i my-keypair.pem ec2-user@public-dns-name
```

You need to specify your private key file (. pem file) and the public DNS name of your instance. (See [Step 1: Launch an Amazon EC2 instance](#).)

The login ID is ec2-user. No password is required.

3. After you log in to your EC2 instance, configure your AWS credentials as shown following. Enter your AWS access key ID and secret key (from [Step 2: Create a user and policy](#)), and set the default Region name to your current Region. (In the following example, the default Region name is us-west-2.)

```
aws configure
```

```
AWS Access Key ID [None]: AKIAIOSFODNN7EXAMPLE
```

```
AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRficiYEXAMPLEKEY
```

```
Default region name [None]: us-west-2
```

```
Default output format [None]:
```

After launching and configuring your Amazon EC2 instance, you can test the functionality of DAX using one of the available sample applications. For more information, see [Step 4: Run a sample application](#).

Step 4: Run a sample application

To help you test Amazon DynamoDB Accelerator (DAX) functionality, you can run one of the available sample applications on your Amazon EC2 instance.

Topics

- [DAX SDK for Go](#)
- [Java and DAX](#)
- [.NET and DAX](#)
- [Node.js and DAX](#)
- [Python and DAX](#)

DAX SDK for Go

Follow this procedure to run the Amazon DynamoDB Accelerator (DAX) SDK for Go sample application on your Amazon EC2 instance.

To run the SDK for Go sample for DAX

1. Set up the SDK for Go on your Amazon EC2 instance:

- a. Install the Go programming language (Golang).

```
sudo yum install -y golang
```

- b. Test that Golang is installed and running correctly.

```
go version
```

A message like this should appear.

```
go version go1.15.5 linux/amd64
```

The remaining instructions rely on module support, which became the default with Go version 1.13.

2. Install the sample Golang application.

```
go get github.com/aws-samples/aws-dax-go-sample
```

3. Run the following Golang programs. The first program creates a DynamoDB table named TryDaxGoTable. The second program writes data to the table.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -service dynamodb -command create-table
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -service dynamodb -command put-item
```

4. Run the following Golang programs.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -service dynamodb -command get-item
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -service dynamodb -command query
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -service dynamodb -command scan
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now, run the programs again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{  
    "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",  
    "Port": 8111,  
    "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"  
}
```

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go  
-service dax -command get-item -endpoint my-cluster.16fzcv.dax-clusters.us-  
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go  
-service dax -command query -endpoint my-cluster.16fzcv.dax-clusters.us-  
east-1.amazonaws.com:8111
```

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go  
-service dax -command scan -endpoint my-cluster.16fzcv.dax-clusters.us-  
east-1.amazonaws.com:8111
```

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

6. Run the following Golang program to delete TryDaxGoTable.

```
go run ~/go/pkg/mod/github.com/aws-samples/aws-dax-go-sample@v1.0.2/try_dax.go -  
service dynamodb -command delete-table
```

Java and DAX

DAX SDK for Java 2.x is compatible with [AWS SDK for Java 2.x](#). It's built on top of Java 8+ and includes support for non-blocking I/O. For information about using DAX with AWS SDK for Java 1.x, see [Using DAX with AWS SDK for Java 1.x](#)

Using the client as a Maven dependency

Follow these steps to use the client for the DAX SDK for Java in your application as a dependency.

1. Download and install Apache Maven. For more information, see [Downloading Apache Maven](#) and [Installing Apache Maven](#).
2. Add the client Maven dependency to your application's Project Object Model (POM) file. In this example, replace `x.x.x` with the actual version number of the client.

```
<!--Dependency:-->  
<dependencies>  
    <dependency>
```

```
<groupId>software.amazon.dax</groupId>
<artifactId>amazon-dax-client</artifactId>
<version>x.x.x</version>
</dependency>
</dependencies>
```

TryDax sample code

After you've set up your workspace and added the DAX SDK as a dependency, copy [TryDax.java](#) into your project.

Run the code using this command.

```
java -cp classpath TryDax
```

You should see output similar to the following.

```
Creating a DynamoDB client
```

```
Attempting to create table; please wait...
Successfully created table. Table status: ACTIVE
Writing data to the table...
Writing 10 items for partition key: 1
Writing 10 items for partition key: 2
Writing 10 items for partition key: 3
...
```

```
Running GetItem and Query tests...
First iteration of each test will result in cache misses
Next iterations are cache hits
```

```
GetItem test - partition key 1-100 and sort keys 1-10
Total time: 4390.240 ms - Avg time: 4.390 ms
Total time: 3097.089 ms - Avg time: 3.097 ms
Total time: 3273.463 ms - Avg time: 3.273 ms
Total time: 3353.739 ms - Avg time: 3.354 ms
Total time: 3533.314 ms - Avg time: 3.533 ms
Query test - partition key 1-100 and sort keys between 2 and 9
Total time: 475.868 ms - Avg time: 4.759 ms
Total time: 423.333 ms - Avg time: 4.233 ms
Total time: 460.271 ms - Avg time: 4.603 ms
Total time: 397.859 ms - Avg time: 3.979 ms
```

```
Total time: 466.644 ms - Avg time: 4.666 ms
```

```
Attempting to delete table; please wait...
Successfully deleted table.
```

Take note of the timing information—the number of milliseconds required for the GetItem and Query tests. In this case, you ran the program against the DynamoDB endpoint. Now you'll run the program again, this time against your DAX cluster.

To determine the endpoint of your DAX cluster, choose one of the following:

- In the DynamoDB console, select your DAX cluster. The cluster endpoint is shown in the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- Using the AWS CLI, enter the following command:

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint address, port, and URL are shown in the output, as in the following example.

```
{
  "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",
  "Port": 8111,
  "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"
}
```

Now run the program again, but this time, specify the cluster endpoint URL as a command line parameter.

```
java -cp classpath TryDax dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the output and take note of the timing information. The elapsed times for GetItem and Query should be significantly lower with DAX than with DynamoDB.

SDK metrics

With DAX SDK for Java 2.x, you can collect metrics about the service clients in your application and analyze the output in Amazon CloudWatch. See [Enabling SDK metrics](#) for more information.

 **Note**

The DAX SDK for Java only collects `ApiCallSuccessful` and `ApiCallDuration` metrics.

TryDax.java

```

                client.queryPaginator(QueryRequest.builder()
                    .tableName(tableName)
                    .keyConditionExpression("pk = :pkval and sk between :skval1
and :skval2")
                    .expressionAttributeValues(Map.of(":pkval", attr(ipk),
":skval1", attr(sk1), ":skval2", attr(sk2)))
                    .build()).items().subscribe((item) -> {
                }).get();
            } catch (Exception e) {
                System.err.println("Unable to query table:");
                e.printStackTrace();
            }
        }
        endTime = System.nanoTime();
        printTime(startTime, endTime, pk);
    }
}

private static void printTime(long startTime, long endTime, int iterations) {
    System.out.format("\tTotal time: %.3f ms - ", (endTime - startTime) /
(1000000.0));
```

```
        System.out.format("Avg time: %.3f ms\n", (endTime - startTime) / (iterations *  
1000000.0));  
    }  
}
```

.NET and DAX

Follow these steps to run the .NET sample on your Amazon EC2 instance.

Note

This tutorial uses the .NET 6 SDK, but will work with the .NET Core SDK also. It shows how you can run a program in your default Amazon VPC to access your Amazon DynamoDB Accelerator (DAX) cluster. If you prefer, you can use the AWS Toolkit for Visual Studio to write a .NET application and deploy it into your VPC.

For more information, see [Creating and Deploying Elastic Beanstalk Applications in .NET Using AWS Toolkit for Visual Studio](#) in the *AWS Elastic Beanstalk Developer Guide*.

To run the .NET sample for DAX

1. Go to the [Microsoft Downloads page](#) and download the latest .NET 6 (or .NET Core) SDK for Linux. The downloaded file is dotnet-sdk-**N.N.N**-linux-x64.tar.gz.
2. Extract the SDK files.

```
mkdir dotnet  
tar zxvf dotnet-sdk-N.N.N-linux-x64.tar.gz -C dotnet
```

Replace **N.N.N** with the actual version number of the .NET SDK (for example: 6.0.100).

3. Verify the installation.

```
alias dotnet=$HOME/dotnet/dotnet  
dotnet --version
```

This should print the version number of the .NET SDK.

Note

Instead of the version number, you might receive the following error:

error: libunwind.so.8: cannot open shared object file: No such file or directory
To resolve the error, install the libunwind package.

```
sudo yum install -y libunwind
```

After you do this, you should be able to run the dotnet --version command without any errors.

4. Create a new .NET project.

```
dotnet new console -o myApp
```

This requires a few minutes to perform a one-time-only setup. When it is complete, run the sample project.

```
dotnet run --project myApp
```

You should receive the following message: Hello World!

5. The myApp/myApp.csproj file contains metadata about your project. To use the DAX client in your application, modify the file so that it looks like the following.

```
<Project Sdk="Microsoft.NET.Sdk">
  <PropertyGroup>
    <OutputType>Exe</OutputType>
    <TargetFramework>net6.0</TargetFramework>
  </PropertyGroup>
  <ItemGroup>
    <PackageReference Include="AWSSDK.DAX.Client" Version="*" />
  </ItemGroup>
</Project>
```

6. Download the sample program source code (.zip file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

7. Now run the sample programs, one at a time. For each program, copy its contents into the `myApp/Program.cs`, and then run the `MyApp` project.

Run the following .NET programs. The first program creates a DynamoDB table named `TryDaxTable`. The second program writes data to the table.

```
cp TryDax/dotNet/01-CreateTable.cs myApp/Program.cs  
dotnet run --project MyApp
```

```
cp TryDax/dotNet/02-Write-Data.cs myApp/Program.cs  
dotnet run --project MyApp
```

8. Next, run some programs to perform `GetItem`, `Query`, and `Scan` operations on your DAX cluster. To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{  
    "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",  
    "Port": 8111,  
    "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"  
}
```

Now run the following programs, specifying your cluster endpoint as a command line parameter. (Replace the sample endpoint with your actual DAX cluster endpoint.)

```
cp TryDax/dotNet/03-GetItem-Test.cs myApp/Program.cs
```

```
dotnet run --project myApp dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com

cp TryDax/dotNet/04-Query-Test.cs myApp/Program.cs
dotnet run --project myApp dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com

cp TryDax/dotNet/05-Scan-Test.cs myApp/Program.cs
dotnet run --project myApp dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

9. Run the following .NET program to delete TryDaxTable.

```
cp TryDax/dotNet/06-DeleteTable.cs myApp/Program.cs
dotnet run --project myApp
```

For more information about these programs, see the following sections:

- [01-CreateTable.cs](#)
- [02-Write-Data.cs](#)
- [03-GetItem-Test.cs](#)
- [04-Query-Test.cs](#)
- [05-Scan-Test.cs](#)
- [06-DeleteTable.cs](#)

01-CreateTable.cs

The `01-CreateTable.cs` program creates a table (TryDaxTable). The remaining .NET programs in this section depend on this table.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;
```

```
namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();

            var tableName = "TryDaxTable";

            var request = new CreateTableRequest()
            {
                TableName = tableName,
                KeySchema = new List<KeySchemaElement>()
                {
                    new KeySchemaElement{ AttributeName = "pk",KeyType = "HASH" },
                    new KeySchemaElement{ AttributeName = "sk",KeyType = "RANGE" }
                },
                AttributeDefinitions = new List<AttributeDefinition>() {
                    new AttributeDefinition{ AttributeName = "pk",AttributeType = "N" },
                    new AttributeDefinition{ AttributeName = "sk",AttributeType = "N" }
                },
                ProvisionedThroughput = new ProvisionedThroughput()
                {
                    ReadCapacityUnits = 10,
                    WriteCapacityUnits = 10
                }
            };
            var response = await client.CreateTableAsync(request);

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

02-Write-Data.cs

The 02-Write-Data.cs program writes test data to TryDaxTable.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DynamoDBv2;
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();

            var tableName = "TryDaxTable";

            string someData = new string('X', 1000);
            var pkmax = 10;
            var skmax = 10;

            for (var ipk = 1; ipk <= pkmax; ipk++)
            {
                Console.WriteLine($"Writing {skmax} items for partition key: {ipk}");
                for (var isk = 1; isk <= skmax; isk++)
                {
                    var request = new PutItemRequest()
                    {
                        TableName = tableName,
                        Item = new Dictionary<string, AttributeValue>()
                        {
                            { "pk", new AttributeValue{N = ipk.ToString()} },
                            { "sk", new AttributeValue{N = isk.ToString()} },
                            { "someData", new AttributeValue{S = someData} }
                        }
                    };
                    var response = await client.PutItemAsync(request);
                }
            }

            Console.WriteLine("Hit <enter> to continue...");
            Console.ReadLine();
        }
    }
}
```

```
}
```

03-GetItem-Test.cs

The `03-GetItem-Test.cs` program performs `GetItem` operations on `TryDaxTable`.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.DAX;
using Amazon.DynamoDbv2.Model;
using Amazon.Runtime;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            string endpointUri = args[0];
            Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");

            var clientConfig = new DaxClientConfig(endpointUri)
            {
                AwsCredentials = FallbackCredentialsFactory.GetCredentials()
            };
            var client = new ClusterDaxClient(clientConfig);

            var tableName = "TryDaxTable";

            var pk = 1;
            var sk = 10;
            var iterations = 5;

            var startTime = System.DateTime.Now;

            for (var i = 0; i < iterations; i++)
            {
                for (var ipk = 1; ipk <= pk; ipk++)
                {
                    for (var isk = 1; isk <= sk; isk++)
                    {
```

```
var request = new GetItemRequest()
{
    TableName = tableName,
    Key = new Dictionary<string, AttributeValue>() {
        {"pk", new AttributeValue {N = ipk.ToString()} },
        {"sk", new AttributeValue {N = isk.ToString()} }
    }
};

var response = await client.GetItemAsync(request);
Console.WriteLine($"GetItem succeeded for pk: {ipk},sk: {isk}");
```

```
}
```

```
}
```

```
}
```

```
}
```

```
}

var endTime = DateTime.Now;
TimeSpan timeSpan = endTime - startTime;
Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}
milliseconds");

Console.WriteLine("Hit <enter> to continue...");
Console.ReadLine();
}
```

```
}
```

```
}
```

04-Query-Test.cs

The 04-Query-Test.cs program performs Query operations on TryDaxTable.

```
using System;
using System.Collections.Generic;
using System.Threading.Tasks;
using Amazon.Runtime;
using Amazon.DAX;
using Amazon.DynamoDBv2.Model;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
```

```
{  
    string endpointUri = args[0];  
    Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");  
  
    var clientConfig = new DaxClientConfig(endpointUri)  
    {  
        AwsCredentials = FallbackCredentialsFactory.GetCredentials()  
    };  
    var client = new ClusterDaxClient(clientConfig);  
  
    var tableName = "TryDaxTable";  
  
    var pk = 5;  
    var sk1 = 2;  
    var sk2 = 9;  
    var iterations = 5;  
  
    var startTime = DateTime.Now;  
  
    for (var i = 0; i < iterations; i++)  
    {  
        var request = new QueryRequest()  
        {  
            TableName = tableName,  
            KeyConditionExpression = "pk = :pkval and sk between :skval1  
and :skval2",  
            ExpressionAttributeValues = new Dictionary<string,  
AttributeValue>() {  
                {"":pkval", new AttributeValue {N = pk.ToString()} },  
                {"":skval1", new AttributeValue {N = sk1.ToString()} },  
                {"":skval2", new AttributeValue {N = sk2.ToString()} }  
            }  
        };  
        var response = await client.QueryAsync(request);  
        Console.WriteLine($"{i}: Query succeeded");  
  
    }  
  
    var endTime = DateTime.Now;  
    TimeSpan timeSpan = endTime - startTime;  
    Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}  
milliseconds");  
}
```

```
        Console.WriteLine("Hit <enter> to continue...");  
        Console.ReadLine();  
    }  
}  
}
```

05-Scan-Test.cs

The `05-Scan-Test.cs` program performs Scan operations on TryDaxTable.

```
using System;  
using System.Threading.Tasks;  
using Amazon.Runtime;  
using Amazon.DAX;  
using Amazon.DynamoDBv2.Model;  
  
namespace ClientTest  
{  
    class Program  
    {  
        public static async Task Main(string[] args)  
        {  
            string endpointUri = args[0];  
            Console.WriteLine($"Using DAX client - endpointUri={endpointUri}");  
  
            var clientConfig = new DaxClientConfig(endpointUri)  
            {  
                AwsCredentials = FallbackCredentialsFactory.GetCredentials()  
            };  
            var client = new ClusterDaxClient(clientConfig);  
  
            var tableName = "TryDaxTable";  
  
            var iterations = 5;  
  
            var startTime = DateTime.Now;  
  
            for (var i = 0; i < iterations; i++)  
            {  
                var request = new ScanRequest()  
                {  
                    TableName = tableName  
                };  
                var response = await client.ScanAsync(request);  
                var items = response.Items;  
                if (items != null)  
                {  
                    foreach (var item in items)  
                    {  
                        var id = item["id"];  
                        var name = item["name"];  
                        var age = item["age"];  
                        var email = item["email"];  
                        Console.WriteLine($"ID: {id}, Name: {name}, Age: {age}, Email: {email}");  
                    }  
                }  
            }  
        }  
    }  
}
```

```
    };

    var response = await client.ScanAsync(request);
    Console.WriteLine($"[{i}]: Scan succeeded");
}

var endTime = DateTime.Now;
TimeSpan timeSpan = endTime - startTime;
Console.WriteLine($"Total time: {timeSpan.TotalMilliseconds}
milliseconds");

Console.WriteLine("Hit <enter> to continue...");
Console.ReadLine();
}
}

}
```

06-DeleteTable.cs

The 06-DeleteTable.cs program deletes TryDaxTable. Run this program after you have finished testing.

```
using System;
using System.Threading.Tasks;
using Amazon.DynamoDBv2.Model;
using Amazon.DynamoDBv2;

namespace ClientTest
{
    class Program
    {
        public static async Task Main(string[] args)
        {
            AmazonDynamoDBClient client = new AmazonDynamoDBClient();

            var tableName = "TryDaxTable";

            var request = new DeleteTableRequest()
            {
                TableName = tableName
            };
        }
    }
}
```

```
        var response = await client.DeleteTableAsync(request);

        Console.WriteLine("Hit <enter> to continue...");
        Console.ReadLine();
    }
}
```

Node.js and DAX

Follow these steps to run the Node.js sample application on your Amazon EC2 instance.

To run the Node.js sample for DAX

1. Set up Node.js on your Amazon EC2 instance, as follows:

- a. Install node version manager (nvm).

```
curl -o- https://raw.githubusercontent.com/nvm-sh/nvm/v0.35.3/install.sh | bash
```

- b. Use nvm to install Node.js.

```
nvm install 12.16.3
```

- c. Test that Node.js is installed and running correctly.

```
node -e "console.log('Running Node.js ' + process.version)"
```

This should display the following message.

Running Node.js v12.16.3

2. Install the DAX Node.js client using the node package manager (npm).

```
npm install amazon-dax-client
```

3. Download the sample program source code (.zip file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

- Run the following Node.js programs. The first program creates an Amazon DynamoDB table named TryDaxTable. The second program writes data to the table.

```
node 01-create-table.js  
node 02-write-data.js
```

- Run the following Node.js programs.

```
node 03-getitem-test.js  
node 04-query-test.js  
node 05-scan-test.js
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

- In the previous step, you ran the programs against the DynamoDB endpoint. Run the programs again, but this time, the GetItem, Query and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following.

- Using the DynamoDB console**—Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- Using the AWS CLI**—Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in the following example.

```
{  
    "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",  
    "Port": 8111,  
    "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"
```

{}

Now run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
node 03-getitem-test.js dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com  
node 04-query-test.js dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com  
node 05-scan-test.js dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

7. Run the following Node.js program to delete TryDaxTable.

```
node 06-delete-table
```

For more information about these programs, see the following sections:

- [01-create-table.js](#)
- [02-write-data.js](#)
- [03-getitem-test.js](#)
- [04-query-test.js](#)
- [05-scan-test.js](#)
- [06-delete-table.js](#)

01-create-table.js

The `01-create-table.js` program creates a table (TryDaxTable). The remaining Node.js programs in this section depend on this table.

```
const AmazonDaxClient = require("amazon-dax-client");  
var AWS = require("aws-sdk");  
  
var region = "us-west-2";  
  
AWS.config.update({
```

```
    region: region,
});

var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
  KeySchema: [
    { AttributeName: "pk", KeyType: "HASH" }, //Partition key
    { AttributeName: "sk", KeyType: "RANGE" } //Sort key
  ],
  AttributeDefinitions: [
    { AttributeName: "pk", AttributeType: "N" },
    { AttributeName: "sk", AttributeType: "N" },
  ],
  ProvisionedThroughput: {
    ReadCapacityUnits: 10,
    WriteCapacityUnits: 10,
  },
};

dynamodb.createTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to create table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
    console.log(
      "Created table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

02-write-data.js

The `02-write-data.js` program writes test data to `TryDaxTable`.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");
```

```
var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();

var tableName = "TryDaxTable";

var someData = "X".repeat(1000);
var pkmax = 10;
var skmax = 10;

for (var ipk = 1; ipk <= pkmax; ipk++) {
  for (var isk = 1; isk <= skmax; isk++) {
    var params = {
      TableName: tableName,
      Item: {
        pk: ipk,
        sk: isk,
        someData: someData,
      },
    };
    //put item
    ddbClient.put(params, function (err, data) {
      if (err) {
        console.error("Unable to write data: ", JSON.stringify(err, null, 2));
      } else {
        console.log("PutItem succeeded");
      }
    });
  }
}
```

03-getitem-test.js

The `03-getitem-test.js` program performs GetItem operations on TryDaxTable.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 1;
var sk = 10;
var iterations = 5;

for (var i = 0; i < iterations; i++) {
  var startTime = new Date().getTime();

  for (var ipk = 1; ipk <= pk; ipk++) {
    for (var isk = 1; isk <= sk; isk++) {
      var params = {
        TableName: tableName,
        Key: {
          pk: ipk,
          sk: isk,
        },
      };

      client.get(params, function (err, data) {
        if (err) {
          console.error(
            `Error performing GET on item ${ipk}#${isk}: ${err.message}`
          );
        } else {
          console.log(`Item ${ipk}#${isk} retrieved successfully`);
        }
      });
    }
  }
}
```

```
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
    );
} else {
    // GetItem succeeded
}
});
}

var endTime = new Date().getTime();
console.log(
"\tTotal time: ",
endTime - startTime,
"ms - Avg time: ",
(endTime - startTime) / iterations,
"ms"
);
}
```

04-query-test.js

The `04-query-test.js` program performs Query operations on TryDaxTable.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}
```

```
var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var pk = 5;
var sk1 = 2;
var sk2 = 9;
var iterations = 5;

var params = {
    TableName: tableName,
    KeyConditionExpression: "pk = :pkval and sk between :skval1 and :skval2",
    ExpressionAttributeValues: {
        ":pkval": pk,
        ":skval1": sk1,
        ":skval2": sk2,
    },
};

for (var i = 0; i < iterations; i++) {
    var startTime = new Date().getTime();

    client.query(params, function (err, data) {
        if (err) {
            console.error(
                "Unable to read item. Error JSON:",
                JSON.stringify(err, null, 2)
            );
        } else {
            // Query succeeded
        }
    });
}

var endTime = new Date().getTime();
console.log(
    "\tTotal time: ",
    endTime - startTime,
    "ms - Avg time: ",
    (endTime - startTime) / iterations,
    "ms"
);
}
```

05-scan-test.js

The `05-scan-test.js` program performs Scan operations on TryDaxTable.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var ddbClient = new AWS.DynamoDB.DocumentClient();
var daxClient = null;

if (process.argv.length > 2) {
  var dax = new AmazonDaxClient({
    endpoints: [process.argv[2]],
    region: region,
  });
  daxClient = new AWS.DynamoDB.DocumentClient({ service: dax });
}

var client = daxClient != null ? daxClient : ddbClient;
var tableName = "TryDaxTable";

var iterations = 5;

var params = {
  TableName: tableName,
};

var startTime = new Date().getTime();
for (var i = 0; i < iterations; i++) {
  client.scan(params, function (err, data) {
    if (err) {
      console.error(
        "Unable to read item. Error JSON:",
        JSON.stringify(err, null, 2)
      );
    } else {
      // Scan succeeded
    }
  });
}
```

```
}

var endTime = new Date().getTime();
console.log(
  "\tTotal time: ",
  endTime - startTime,
  "ms - Avg time: ",
  (endTime - startTime) / iterations,
  "ms"
);
}
```

06-delete-table.js

The `06-delete-table.js` program deletes `TryDaxTable`. Run this program after you have finished testing.

```
const AmazonDaxClient = require("amazon-dax-client");
var AWS = require("aws-sdk");

var region = "us-west-2";

AWS.config.update({
  region: region,
});

var dynamodb = new AWS.DynamoDB(); //low-level client

var tableName = "TryDaxTable";

var params = {
  TableName: tableName,
};

dynamodb.deleteTable(params, function (err, data) {
  if (err) {
    console.error(
      "Unable to delete table. Error JSON:",
      JSON.stringify(err, null, 2)
    );
  } else {
    console.log(
      "Deleted table. Table description JSON:",
      JSON.stringify(data, null, 2)
    );
  }
});
```

```
    JSON.stringify(data, null, 2)
);
}
});
```

Python and DAX

Follow this procedure to run the Python sample application on your Amazon EC2 instance.

To run the Python sample for DAX

1. Install the DAX Python client using the pip utility.

```
pip install amazon-dax-client
```

2. Download the sample program source code (.zip file).

```
wget http://docs.aws.amazon.com/amazondynamodb/latest/developerguide/samples/TryDax.zip
```

When the download is complete, extract the source files.

```
unzip TryDax.zip
```

3. Run the following Python programs. The first program creates an Amazon DynamoDB table named TryDaxTable. The second program writes data to the table.

```
python 01-create-table.py
python 02-write-data.py
```

4. Run the following Python programs.

```
python 03-getitem-test.py
python 04-query-test.py
python 05-scan-test.py
```

Take note of the timing information—the number of milliseconds required for the GetItem, Query, and Scan tests.

5. In the previous step, you ran the programs against the DynamoDB endpoint. Now run the programs again, but this time, the GetItem, Query, and Scan operations are processed by your DAX cluster.

To determine the endpoint for your DAX cluster, choose one of the following:

- **Using the DynamoDB console** — Choose your DAX cluster. The cluster endpoint is shown on the console, as in the following example.

```
dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

- **Using the AWS CLI** — Enter the following command.

```
aws dax describe-clusters --query "Clusters[*].ClusterDiscoveryEndpoint"
```

The cluster endpoint is shown in the output, as in this example.

```
{  
    "Address": "my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com",  
    "Port": 8111,  
    "URL": "dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com"  
}
```

Run the programs again, but this time, specify the cluster endpoint as a command line parameter.

```
python 03-getitem-test.py dax://my-cluster.16fzcv.dax-clusters.us-  
east-1.amazonaws.com  
python 04-query-test.py dax://my-cluster.16fzcv.dax-clusters.us-  
east-1.amazonaws.com  
python 05-scan-test.py dax://my-cluster.16fzcv.dax-clusters.us-east-1.amazonaws.com
```

Look at the rest of the output, and take note of the timing information. The elapsed times for GetItem, Query, and Scan should be significantly lower with DAX than with DynamoDB.

6. Run the following Python program to delete TryDaxTable.

```
python 06-delete-table.py
```

For more information about these programs, see the following sections:

- [01-create-table.py](#)
- [02-write-data.py](#)
- [03-getitem-test.py](#)
- [04-query-test.py](#)
- [05-scan-test.py](#)
- [06-delete-table.py](#)

01-create-table.py

The `01-create-table.py` program creates a table (`TryDaxTable`). The remaining Python programs in this section depend on this table.

```
import boto3

def create_dax_table(dyn_resource=None):
    """
    Creates a DynamoDB table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The newly created table.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table_name = "TryDaxTable"
    params = {
        "TableName": table_name,
        "KeySchema": [
            {"AttributeName": "partition_key", "KeyType": "HASH"},
            {"AttributeName": "sort_key", "KeyType": "RANGE"},
        ],
        "AttributeDefinitions": [
            {"AttributeName": "partition_key", "AttributeType": "N"},
            {"AttributeName": "sort_key", "AttributeType": "N"},
        ],
        "ProvisionedThroughput": {"ReadCapacityUnits": 10, "WriteCapacityUnits": 10},
    }
    table = dyn_resource.create_table(**params)
```

```
print(f"Creating {table_name}...")
table.wait_until_exists()
return table

if __name__ == "__main__":
    dax_table = create_dax_table()
    print(f"Created table.")
```

02-write-data.py

The `02-write-data.py` program writes test data to TryDaxTable.

```
import boto3

def write_data_to_dax_table(key_count, item_size, dyn_resource=None):
    """
    Writes test data to the demonstration table.

    :param key_count: The number of partition and sort keys to use to populate the
                      table. The total number of items is key_count * key_count.
    :param item_size: The size of non-key data for each test item.
    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    some_data = "X" * item_size

    for partition_key in range(1, key_count + 1):
        for sort_key in range(1, key_count + 1):
            table.put_item(
                Item={
                    "partition_key": partition_key,
                    "sort_key": sort_key,
                    "some_data": some_data,
                }
            )
            print(f"Put item ({partition_key}, {sort_key}) succeeded.")

    if __name__ == "__main__":
```

```
write_key_count = 10
write_item_size = 1000
print(
    f"Writing {write_key_count}*{write_key_count} items to the table. "
    f"Each item is {write_item_size} characters."
)
write_data_to_dax_table(write_key_count, write_item_size)
```

03-getitem-test.py

The `03-getitem-test.py` program performs GetItem operations on TryDaxTable. This example is given for the Region eu-west-1.

```
import argparse
import sys
import time
import amazondax
import boto3

def get_item_test(key_count, iterations, dyn_resource=None):
    """
    Gets items from the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param key_count: The number of items to get from the table in each iteration.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource('dynamodb')

    table = dyn_resource.Table('TryDaxTable')
    start = time.perf_counter()
    for _ in range(iterations):
        for partition_key in range(1, key_count + 1):
            for sort_key in range(1, key_count + 1):
                table.get_item(Key={
                    'partition_key': partition_key,
                    'sort_key': sort_key
                })
```

```
        })
        print('..', end='')
        sys.stdout.flush()

print()
end = time.perf_counter()
return start, end

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument(
        'endpoint_url', nargs='?',
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.")
args = parser.parse_args()

test_key_count = 10
test_iterations = 50
if args.endpoint_url:
    print(f"Getting each item from the table {test_iterations} times, "
          f"using the DAX client.")
    # Use a with statement so the DAX client closes the cluster after completion.
    with amazonadax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url,
region_name='eu-west-1') as dax:
        test_start, test_end = get_item_test(
            test_key_count, test_iterations, dyn_resource=dax)
else:
    print(f"Getting each item from the table {test_iterations} times, "
          f"using the Boto3 client.")
    test_start, test_end = get_item_test(
        test_key_count, test_iterations)
print(f"Total time: {test_end - test_start:.4f} sec. Average time: "
      f"{{(test_end - test_start) / test_iterations}}")
```

04-query-test.py

The `04-query-test.py` program performs Query operations on TryDaxTable.

```
import argparse
import time
import sys
import amazonadax
import boto3
from boto3.dynamodb.conditions import Key
```

```
def query_test(partition_key, sort_keys, iterations, dyn_resource=None):
    """
    Queries the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param partition_key: The partition key value to use in the query. The query
                          returns items that have partition keys equal to this value.
    :param sort_keys: The range of sort key values for the query. The query returns
                      items that have sort key values between these two values.
    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """

    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    key_condition_expression = Key("partition_key").eq(partition_key) & Key(
        "sort_key"
    ).between(*sort_keys)

    start = time.perf_counter()
    for _ in range(iterations):
        table.query(KeyConditionExpression=key_condition_expression)
        print(".", end="")
        sys.stdout.flush()
    print()
    end = time.perf_counter()
    return start, end

if __name__ == "__main__":
    # pylint: disable=not-context-manager
    parser = argparse.ArgumentParser()
    parser.add_argument(
        "endpoint_url",
        nargs="?",
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.",
    )
    args = parser.parse_args()
```

```
test_partition_key = 5
test_sort_keys = (2, 9)
test_iterations = 100
if args.endpoint_url:
    print(f"Querying the table {test_iterations} times, using the DAX client.")
    # Use a with statement so the DAX client closes the cluster after completion.
    with amazonadax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url) as dax:
        test_start, test_end = query_test(
            test_partition_key, test_sort_keys, test_iterations, dyn_resource=dax
        )
else:
    print(f"Querying the table {test_iterations} times, using the Boto3 client.")
    test_start, test_end = query_test(
        test_partition_key, test_sort_keys, test_iterations
    )

print(
    f"Total time: {test_end - test_start:.4f} sec. Average time: "
    f"{(test_end - test_start)/test_iterations}."
)
```

05-scan-test.py

The `05-scan-test.py` program performs Scan operations on TryDaxTable.

```
import argparse
import time
import sys
import amazonadax
import boto3

def scan_test(iterations, dyn_resource=None):
    """
    Scans the table a specified number of times. The time before the
    first iteration and the time after the last iteration are both captured
    and reported.

    :param iterations: The number of iterations to run.
    :param dyn_resource: Either a Boto3 or DAX resource.
    :return: The start and end times of the test.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")
```

```
table = dyn_resource.Table("TryDaxTable")
start = time.perf_counter()
for _ in range(iterations):
    table.scan()
    print(".", end="")
    sys.stdout.flush()
print()
end = time.perf_counter()
return start, end

if __name__ == "__main__":
    # pylint: disable=not-context-manager
    parser = argparse.ArgumentParser()
    parser.add_argument(
        "endpoint_url",
        nargs="?",
        help="When specified, the DAX cluster endpoint. Otherwise, DAX is not used.",
    )
    args = parser.parse_args()

    test_iterations = 100
    if args.endpoint_url:
        print(f"Scanning the table {test_iterations} times, using the DAX client.")
        # Use a with statement so the DAX client closes the cluster after completion.
        with amazondax.AmazonDaxClient.resource(endpoint_url=args.endpoint_url) as dax:
            test_start, test_end = scan_test(test_iterations, dyn_resource=dax)
    else:
        print(f"Scanning the table {test_iterations} times, using the Boto3 client.")
        test_start, test_end = scan_test(test_iterations)
    print(
        f"Total time: {test_end - test_start:.4f} sec. Average time: "
        f"{{(test_end - test_start)/test_iterations}}."
    )
```

06-delete-table.py

The `06-delete-table.py` program deletes `TryDaxTable`. Run this program after you have finished testing Amazon DynamoDB Accelerator (DAX) functionality.

```
import boto3
```

```
def delete_dax_table(dyn_resource=None):
    """
    Deletes the demonstration table.

    :param dyn_resource: Either a Boto3 or DAX resource.
    """
    if dyn_resource is None:
        dyn_resource = boto3.resource("dynamodb")

    table = dyn_resource.Table("TryDaxTable")
    table.delete()

    print(f"Deleting {table.name}...")
    table.wait_until_not_exists()

if __name__ == "__main__":
    delete_dax_table()
    print("Table deleted!")
```

Modifying an existing application to use DAX

If you already have a Java application that uses Amazon DynamoDB, you can modify it so that it can access your DynamoDB Accelerator (DAX) cluster. You don't have to rewrite the entire application because the DAX Java client is similar to the DynamoDB low-level client included in the AWS SDK for Java 2.x. See [Working with items in DynamoDB](#) for details.

 **Note**

This example uses AWS SDK for Java 2.x. For the legacy SDK for Java 1.x version, see [Modifying an existing SDK for Java 1.x application to use DAX](#).

To modify your program, replace the DynamoDB client with a DAX client.

```
Region region = Region.US_EAST_1;

// Create an asynchronous DynamoDB client
DynamoDbAsyncClient client = DynamoDbAsyncClient.builder()
    .region(region)
    .build();
```

```
// Create an asynchronous DAX client
DynamoDbAsyncClient client = ClusterDaxAsyncClient.builder()
    .overrideConfiguration(Configuration.builder()
        .url(<cluster url>) // for example, "dax://my-cluster.16fzcv.dax-
clusters.us-east-1.amazonaws.com"
        .region(region)
        .addMetricPublisher(cloudWatchMetricsPub) // optionally enable SDK
metric collection
    .build())
    .build();
```

You can also use the high-level library that is part of the AWS SDK for Java 2.x, replacing the DynamoDB client with a DAX client.

```
Region region = Region.US_EAST_1;
DynamoDbAsyncClient dax = ClusterDaxAsyncClient.builder()
    .overrideConfiguration(Configuration.builder()
        .url(<cluster url>) // for example, "dax://my-cluster.16fzcv.dax-
clusters.us-east-1.amazonaws.com"
        .region(region)
    .build())
    .build();

DynamoDbEnhancedClient enhancedClient = DynamoDbEnhancedClient.builder()
    .dynamoDbClient(dax)
    .build();
```

For more information, see [Mapping items in DynamoDB tables](#).

Managing DAX clusters

This section addresses some of the common management tasks for Amazon DynamoDB Accelerator (DAX) clusters.

Topics

- [IAM permissions for managing a DAX cluster](#)
- [Scaling a DAX cluster](#)
- [Customizing DAX cluster settings](#)
- [Configuring TTL settings](#)

- [Tagging support for DAX](#)
- [AWS CloudTrail integration](#)
- [Deleting a DAX cluster](#)

IAM permissions for managing a DAX cluster

When you administer a DAX cluster using the AWS Management Console or the AWS Command Line Interface (AWS CLI), we strongly recommend that you narrow the scope of actions that users can perform. By doing so, you help mitigate risk while following the principle of least privilege.

The following discussion focuses on access control for the DAX management APIs. For more information, see [Amazon DynamoDB accelerator](#) in the *Amazon DynamoDB API Reference*.

Note

For more detailed information about managing AWS Identity and Access Management (IAM) permissions, see the following:

- IAM and creating DAX clusters: [Creating a DAX cluster](#).
- IAM and DAX data plane operations: [DAX access control](#).

For the DAX management APIs, you can't scope API actions to a specific resource. The `Resource` element must be set to `"*"`. This is different from DAX data plane API operations, such as `GetItem`, `Query`, and `Scan`. Data plane operations are exposed through the DAX client, and those operations *can* be scoped to specific resources.

To illustrate, consider the following IAM policy document.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "dax:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"  
            ]  
        }  
    ]  
}
```

```
        ]
    }
]
}
```

Suppose that the intent of this policy is to allow DAX management API calls for the cluster `DAXCluster01`— and only that cluster.

Now suppose that a user issues the following AWS CLI command.

```
aws dax describe-clusters
```

This command fails with a Not Authorized exception because the underlying `DescribeClusters` API call can't be scoped to a specific cluster. Even though the policy is syntactically valid, the command fails because the `Resource` element must be set to `"*"`. However, if the user runs a program that sends DAX data plane calls (such as `GetItem` or `Query`) to `DAXCluster01`, those calls *do* succeed. This is because DAX data plane APIs can be scoped to specific resources (in this case, `DAXCluster01`).

If you want to write a single comprehensive IAM policy to encompass both DAX management APIs and DAX data plane APIs, we suggest that you include two distinct statements in the policy document. One of these statements should address the DAX data plane APIs, while the other statement addresses the DAX management APIs.

The following example policy shows this approach. Note how the `DAXDataAPIs` statement is scoped to the `DAXCluster01` resource, but the resource for `DAXManagementAPIs` must be `"*"`. The actions shown in each statement are for illustration only. You can customize them as needed for your application.

```

Scaling a DAX cluster

There are two options available for scaling a DAX cluster. The first option is *horizontal scaling*, where you add read replicas to the cluster. The second option is *vertical scaling*, where you select

different node types. For advice on how to approach choosing an appropriate cluster size and node type for your application, see [DAX cluster sizing guide](#).

Horizontal scaling

With horizontal scaling, you can improve throughput for read operations by adding more read replicas to the cluster. A single DAX cluster supports up to 10 read replicas, and you can add or remove replicas while the cluster is running.

The following AWS CLI examples show how to increase or decrease the number of nodes. The `--new-replication-factor` argument specifies the total number of nodes in the cluster. One of the nodes is the primary node, and the other nodes are read replicas.

```
aws dax increase-replication-factor \
--cluster-name MyNewCluster \
--new-replication-factor 5
```

```
aws dax decrease-replication-factor \
--cluster-name MyNewCluster \
--new-replication-factor 3
```

Note

The cluster status changes to `modifying` when you modify the replication factor. The status changes to `available` when the modification is complete.

Vertical scaling

If you have a large working set of data, your application might benefit from using larger node types. Larger nodes can enable the cluster to store more data in memory, reducing cache misses and improving overall application performance of the application. (All of the nodes in a DAX cluster must be of the same type.)

If your DAX cluster has a high rate of write operations or cache misses, your application might also benefit from using larger node types. Write operations and cache misses consume resources on the cluster's primary node. Therefore, using larger node types might increase the performance of the primary node and thereby allow a higher throughput for these types of operations.

You can't modify the node types on a running DAX cluster. Instead, you must create a new cluster with the desired node type. For a list of supported node types, see [Nodes](#).

You can create a new DAX cluster using the AWS Management Console, [AWS CloudFormation](#), the AWS CLI, or the [AWS SDK](#). (For the AWS CLI, use the `--node-type` parameter to specify the node type.)

Customizing DAX cluster settings

When you create a DAX cluster, the following default settings are used:

- Automatic cache eviction enabled with Time to Live (TTL) of 5 minutes
- No preference for Availability Zones
- No preference for maintenance windows
- Notifications disabled

For new clusters, you can customize the settings at creation time. To do this in the AWS Management Console, clear **Use default settings** to modify the following settings:

- **Network and Security**—Allows you to run individual DAX cluster nodes in different Availability Zones within the current AWS Region. If you choose **No Preference**, the nodes are distributed among Availability Zones automatically.
- **Parameter Group**—A named set of parameters that are applied to every node in the cluster. You can use a parameter group to specify cache TTL behavior. You can change the value of any given parameter within a parameter group (except default parameter group `default.dax.1.0`) at any time.
- **Maintenance Window**—A weekly time period during which software upgrades and patches are applied to the nodes in the cluster. You can choose the start day, start time, and duration of the maintenance window. If you choose **No Preference**, the maintenance window is selected at random from an 8-hour block of time per Region. For more information, see [Maintenance window](#).

 **Note**

Parameter Group and **Maintenance Window** can also be changed at any time on a running cluster.

When a maintenance event occurs, DAX can notify you using Amazon Simple Notification Service (Amazon SNS). To configure notifications, choose an option from the **Topic for SNS notification** selector. You can create a new Amazon SNS topic, or use an existing topic.

For more information about setting up and subscribing to an Amazon SNS topic, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

Configuring TTL settings

DAX maintains two caches for data that it reads from DynamoDB:

- **Item cache**—For items retrieved using GetItem or BatchGetItem.
- **Query cache**—For result sets retrieved using Query or Scan.

For more information, see [Item cache](#) and [Query cache](#).

The default TTL for each of these caches is 5 minutes. If you want to use different TTL settings, you can launch a DAX cluster using a custom parameter group. To do this on the console, choose **DAX | Parameter groups** in the navigation pane.

You can also perform these tasks using the AWS CLI. The following example shows how to launch a new DAX cluster using a custom parameter group. In this example, the item cache TTL is set to 10 minutes, and the query cache TTL is set to 3 minutes.

1. Create a new parameter group.

```
aws dax create-parameter-group \
--parameter-group-name custom-ttl
```

2. Set the item cache TTL to 10 minutes (600000 milliseconds).

```
aws dax update-parameter-group \
--parameter-group-name custom-ttl \
--parameter-name-values "ParameterName=record-ttl-millis,ParameterValue=600000"
```

3. Set the query cache TTL to 3 minutes (180000 milliseconds).

```
aws dax update-parameter-group \
--parameter-group-name custom-ttl \
--parameter-name-values "ParameterName=query-ttl-millis,ParameterValue=180000"
```

4. Verify that the parameters have been set correctly.

```
aws dax describe-parameters --parameter-group-name custom-ttl \
    --query "Parameters[*].[ParameterName,Description,ParameterValue]"
```

You can now launch a new DAX cluster with this parameter group.

```
aws dax create-cluster \
    --cluster-name MyNewCluster \
    --node-type dax.r3.large \
    --replication-factor 3 \
    --iam-role-arn arn:aws:iam::123456789012:role/DAXServiceRole \
    --parameter-group custom-ttl
```

 **Note**

You can't modify a parameter group that is being used by a running DAX instance.

Tagging support for DAX

Many AWS services, including DynamoDB, support *tagging*—the ability to label resources with user-defined names. You can assign tags to DAX clusters, allowing you to quickly identify all of your AWS resources that have the same tag, or to categorize your AWS bills by the tags you assign.

For more information, see [Adding tags and labels to resources](#).

Using the AWS Management Console

To manage DAX cluster tags

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, under **DAX**, choose **Clusters**.
3. Choose the cluster that you want to work with.
4. Choose the **Tags** tab. You can add, list, edit, or delete your tags here.

When the settings are as you want them, choose **Apply Changes**.

Using the AWS CLI

When you use the AWS CLI to manage DAX cluster tags, you must first determine the Amazon Resource Name (ARN) for the cluster. The following example shows how to determine the ARN for a cluster named MyDAXCluster.

```
aws dax describe-clusters \
--cluster-name MyDAXCluster \
--query "Clusters[*].ClusterArn"
```

In the output, the ARN will look similar to this: arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster

The following example shows how to tag the cluster.

```
aws dax tag-resource \
--resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster \
--tags="Key=ClusterUsage,Value=prod"
```

List all the tags for a cluster.

```
aws dax list-tags \
--resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster
```

To remove a tag, specify its key.

```
aws dax untag-resource \
--resource-name arn:aws:dax:us-west-2:123456789012:cache/MyDAXCluster \
--tag-keys ClusterUsage
```

AWS CloudTrail integration

DAX is integrated with AWS CloudTrail, allowing you to audit DAX cluster activities. You can use CloudTrail logs to view all the changes that have been made at the cluster level. You can also see changes to cluster components such as nodes, subnet groups, and parameter groups. For more information, see [Logging DynamoDB operations by using AWS CloudTrail](#).

Deleting a DAX cluster

If you are no longer using a DAX cluster, you should delete it to avoid being charged for unused resources.

You can delete a DAX cluster using the console or the AWS CLI. The following is an example.

```
aws dax delete-cluster --cluster-name mydaxcluster
```

Monitoring DAX

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon DynamoDB Accelerator (DAX) and your AWS solutions. You should collect monitoring data from all parts of your AWS solution so that you can more easily debug a multi-point failure, if one occurs.

Before you start monitoring DAX, you should create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

Topics

- [Monitoring tools](#)
- [Monitoring with Amazon CloudWatch](#)
- [Logging DAX operations using AWS CloudTrail](#)

Monitoring tools

AWS provides tools that you can use to monitor Amazon DynamoDB Accelerator (DAX). You can configure some of these tools to do the monitoring for you, and some require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Topics

- [Automated monitoring tools](#)
- [Manual monitoring tools](#)

Automated monitoring tools

You can use the following automated monitoring tools to watch DAX and report when something is wrong:

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring with Amazon CloudWatch](#).
- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see [Monitoring Log Files](#) in the *Amazon CloudWatch User Guide*.
- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see [What Is Amazon CloudWatch Events](#) in the *Amazon CloudWatch User Guide*.
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Working with CloudTrail Log Files](#) in the *AWS CloudTrail User Guide*.

Manual monitoring tools

Another important part of monitoring DAX involves manually monitoring those items that the CloudWatch alarms don't cover. The DAX, CloudWatch, Trusted Advisor, and other AWS Management Console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on DAX.

- The DAX dashboard shows the following:
 - Service health

- The CloudWatch home page shows the following:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all of your AWS resource metrics.
- Create and edit alarms to be notified of problems.

Monitoring with Amazon CloudWatch

You can monitor Amazon DynamoDB Accelerator (DAX) using Amazon CloudWatch, which collects and processes raw data from DAX into readable, near real-time metrics. These statistics are recorded for a period of two weeks. You can then access historical information for a better perspective on how your web application or service is performing. By default, DAX metric data is sent to CloudWatch automatically. For more information, see [What Is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

How do I use DAX metrics?

The metrics reported by DAX provide information that you can analyze in different ways. The following list shows some common uses for the metrics. These are suggestions to get you started, and not a comprehensive list.

How Can I?	Relevant Metrics
Determine if any system errors occurred	Monitor <code>FaultRequestCount</code> to determine if any requests resulted in an HTTP 500 (server error) code. This can indicate a DAX internal service error or an HTTP 500 in the underlying table's SystemErrors metric .
Determine if any user errors occurred	Monitor <code>ErrorRequestCount</code> to determine if any requests resulted in an HTTP 400 (client error) code. If you see the error count growing, you might want to investigate and make sure you are sending correct client requests.
Determine if any cache misses occurred	Monitor <code>ItemCacheMisses</code> to determine the number of times an item was not found in the cache, and <code>QueryCacheMisses</code> and <code>ScanCacheMisses</code> to determine the number of times a query or scan result was not found in the cache.
Monitor cache hit rates	<p>Use CloudWatch Metric Math to define a cache hit rate metric using math expressions.</p> <p>For example, for the item cache, you can use the expression $m1/\text{SUM}([m1, m2]) * 100$, where $m1$ is the <code>ItemCacheHits</code> metric and $m2$ is the <code>ItemCacheMisses</code> metric for your cluster. For the query and scan caches, you can follow the same pattern using the corresponding query and scan cache metric.</p>

Viewing DAX metrics and dimensions

When you interact with Amazon DynamoDB, it sends metrics and dimensions to Amazon CloudWatch. You can use the following procedures to view the metrics for DynamoDB Accelerator (DAX).

To view metrics (console)

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

2. In the navigation pane, choose **Metrics**.
3. Select the **DAX** namespace.

To view metrics (AWS CLI)

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace "AWS/DAX"
```

DAX metrics and dimensions

The following sections contain the metrics and dimensions that DAX sends to CloudWatch.

DAX Metrics

The following metrics are available from DAX. DAX sends metrics to CloudWatch only when they have a non-zero value.

Note

CloudWatch aggregates the following DAX metrics at one-minute intervals:

- CPUUtilization
- CacheMemoryUtilization
- NetworkBytesIn
- NetworkBytesOut
- NetworkPacketsIn
- NetworkPacketsOut
- GetItemRequestCount
- BatchGetItemRequestCount
- BatchWriteItemRequestCount
- DeleteItemRequestCount
- PutItemRequestCount
- UpdateItemRequestCount
- TransactWriteItemsCount

- TransactItemCount
- ItemCacheHits
- ItemCacheMisses
- QueryCacheHits
- QueryCacheMisses
- ScanCacheHits
- ScanCacheMisses
- TotalRequestCount
- ErrorRequestCount
- FaultRequestCount
- FailedRequestCount
- QueryRequestCount
- ScanRequestCount
- ClientConnections
- EstimatedDbSize
- EvictedSize
- CPUCreditUsage
- CPUCreditBalance
- CPUSurplusCreditBalance
- CPUSurplusCreditsCharged

Not all statistics, such as Average or Sum, are applicable for every metric. However, all of these values are available through the DAX console, or by using the CloudWatch console, AWS CLI, or AWS SDKs for all metrics. In the following table, each metric has a list of valid statistics that are applicable to that metric.

Metric	Description
CPUUtilization	The percentage of CPU utilization of the node or cluster.

Metric	Description
	<p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average
CacheMemoryUtilization	<p>The percentage of available cache memory that is in use by the item cache and query cache on the node or cluster. Cached data starts to be evicted prior to memory utilization reaching 100% (see EvictedSize metric). If CacheMemoryUtilization reaches 100% on any node, write requests will be throttled and you should consider switching to a cluster with a larger node type.</p> <p>Units: Percent</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average
NetworkBytesIn	<p>The number of bytes received on all network interfaces by the node or cluster.</p> <p>Units: Bytes</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average

Metric	Description
NetworkBytesOut	<p>The number of bytes sent out on all network interfaces by the node or cluster. This metric identifies the volume of outgoing traffic in terms of the number of bytes on a single node or cluster.</p> <p>Units: Bytes</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average
NetworkPacketsIn	<p>The number of packets received on all network interfaces by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average
NetworkPacketsOut	<p>The number of packets sent out on all network interfaces by the node or cluster. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average

Metric	Description
GetItemRequestCount	<p>The number of <code>.GetItem</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
BatchGetItemRequestCount	<p>The number of <code>BatchGetItem</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
BatchWriteItemRequestCount	<p>The number of <code>BatchWriteItem</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
DeleteItemRequestCount	<p>The number of <code>DeleteItem</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
PutItemRequestCount	<p>The number of PutItem requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
UpdateItemRequestCount	<p>The number of UpdateItem requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
TransactWriteItemCount	<p>The number of <code>TransactWriteItems</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
TransactGetItemCount	<p>The number of <code>TransactGetItems</code> requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
ItemCacheHits	<p>The number of times an item was returned from the cache by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
ItemCacheMisses	<p>The number of times an item was not in the node or cluster cache, and had to be retrieved from DynamoDB.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
QueryCacheHits	<p>The number of times a query result was returned from the node or cluster cache.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
QueryCacheMisses	<p>The number of times a query result was not in the node or cluster cache, and had to be retrieved from DynamoDB.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
ScanCacheHits	<p>The number of times a scan result was returned from the node or cluster cache.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
ScanCacheMisses	<p>The number of times a scan result was not in the node or cluster cache, and had to be retrieved from DynamoDB.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
TotalRequestCount	<p>Total number of requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
ErrorRequestCount	<p>Total number of requests that resulted in a user error reported by the node or cluster. Requests that were throttled by the node or cluster are included.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
ThrottledRequestCount	<p>Total number of requests throttled by the node or cluster. Requests that were throttled by DynamoDB are not included, and can be monitored using DynamoDB Metrics.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
FaultRequestCount	<p>Total number of requests that resulted in an internal error reported by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
FailedRequestCount	<p>Total number of requests that resulted in an error reported by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
QueryRequestCount	<p>The number of query requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
ScanRequestCount	<p>The number of scan requests handled by the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
ClientConnections	<p>The number of simultaneous connections made by clients to the node or cluster.</p> <p>Units: Count</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum
EstimatedDbSize	<p>An approximation of the amount of data cached in the item cache and the query cache by the node or cluster.</p> <p>Units: Bytes</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average

Metric	Description
EvictedSize	<p>The amount of data that was evicted by the node or cluster to make room for newly requested data. If the miss rate goes up, and you see this metric also growing, it probably means that your working set has increased. You should consider switching to a cluster with a larger node type.</p> <p>Units: Bytes</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• Sum
CPUCreditUsage	<p>The number of CPU credits spent by the node for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</p> <p>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average.</p> <p>Units: Credits (vCPU-minutes)</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
CPUCreditBalance	<p>The number of earned CPU credits that a node has accrued since it was launched or started.</p> <p>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the DAX node size. After the limit is reached, any new credits that are earned are discarded.</p> <p>The credits in the CPUCreditBalance are available for the node to spend to burst beyond its baseline CPU utilization.</p> <p>Units: Credits (vCPU-minutes)</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
CPUSurplusCreditBalance	<p>The number of surplus credits that have been spent by a DAX node when its CPUCreditBalance value is zero.</p> <p>The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the node can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge.</p> <p>Units: Credits (vCPU-minutes)</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

Metric	Description
CPUSurplusCreditsCharged	<p>The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.</p> <p>Spent surplus credits are charged when the spent surplus credits exceed the maximum number of credits that the node can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour or when the node is terminated.</p> <p>Units: Credits (vCPU-minutes)</p> <p>Valid Statistics:</p> <ul style="list-style-type: none">• Minimum• Maximum• Average• SampleCount• Sum

 **Note**

The CPUCreditUsage, CPUCreditBalance, CPUSurplusCreditBalance, and CPUSurplusCreditsCharged metrics are available only for T3 nodes.

Dimensions for DAX Metrics

The metrics for DAX are qualified by the values for the account, cluster ID, or cluster ID and node ID combination. You can use the CloudWatch console to retrieve DAX data along any of the dimensions in the following table.

Dimension	Description
Account	Provides aggregated statistics across all nodes in an account.
ClusterId	Limits the data to a cluster.
ClusterId, NodeId	Limits the data to a node within a cluster.

Creating CloudWatch alarms to monitor DAX

You can create an Amazon CloudWatch alarm that sends an Amazon Simple Notification Service (Amazon SNS) message when the alarm changes state. An alarm watches a single metric over a time period that you specify. It performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification that is sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

How can I be notified of query cache misses?

1. Create an Amazon SNS topic, `arn:aws:sns:us-west-2:522194210714:QueryMissAlarm`.

For more information, see [Set Up Amazon Simple Notification Service](#) in the *Amazon CloudWatch User Guide*.

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
--alarm-name QueryCacheMissesAlarm \
--alarm-description "Alarm over query cache misses" \
--namespace AWS/DAX \
```

```
--metric-name QueryCacheMisses \
--dimensions Name=ClusterID,Value=myCluster \
--statistic Sum \
--threshold 8 \
--comparison-operator GreaterThanOrEqualToThreshold \
--period 60 \
--evaluation-periods 1 \
--alarm-actions arn:aws:sns:us-west-2:522194210714:QueryMissAlarm
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name QueryCacheMissesAlarm --state-reason
"initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name QueryCacheMissesAlarm --state-reason
"initializing" --state-value ALARM
```

Note

You can increase or decrease the threshold to one that makes sense for your application. You can also use [CloudWatch Metric Math](#) to define a cache miss rate metric and set an alarm over that metric.

How can I be notified if requests cause any internal error in the cluster?

1. Create an Amazon SNS topic, arn:aws:sns:us-west-2:123456789012:notify-on-system-errors.

For more information, see [Set Up Amazon Simple Notification Service](#) in the *Amazon CloudWatch User Guide*.

2. Create the alarm.

```
aws cloudwatch put-metric-alarm \
--alarm-name FaultRequestCountAlarm \
--alarm-description "Alarm when a request causes an internal error" \
--namespace AWS/DAX \
--metric-name FaultRequestCount \
--dimensions Name=ClusterID,Value=myCluster \
```

```
--statistic Sum \
--threshold 0 \
--comparison-operator GreaterThanThreshold \
--period 60 \
--unit Count \
--evaluation-periods 1 \
--alarm-actions arn:aws:sns:us-east-1:123456789012:notify-on-system-errors
```

3. Test the alarm.

```
aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason
"initializing" --state-value OK
```

```
aws cloudwatch set-alarm-state --alarm-name FaultRequestCountAlarm --state-reason
"initializing" --state-value ALARM
```

Production monitoring

You should establish a baseline for normal DAX performance in your environment, by measuring performance at various times and under different load conditions. As you monitor DAX, you should consider storing historical monitoring data. This stored data gives you a baseline from which to compare current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline, you should, at minimum, monitor the following items both during load testing and in production.

- CPU utilization and throttled requests, so that you can determine whether you might need to use a larger node type in your cluster. The CPU utilization of your cluster is available through the `CPUUtilization` CloudWatch metric.
- Operation latency (as measure on the client side) should remain consistent within your application's latency requirements.
- Error rates should remain low, as seen from the `ErrorRequestCount`, `FaultRequestCount`, and `FailedRequestCount` CloudWatch metrics.
- Network bytes consumption, so that you can determine whether you will need to use more nodes or a larger node type in your cluster. `NetworkBytesIn` and `NetworkBytesOut` metrics are available in CloudWatch, and you should compare them against your instances available baseline bandwidth as documented [here](#).

Note

The Amazon EC2 documented available baseline bandwidth is in Gigabits per second (Gbps), whereas the NetworkBytesIn and NetworkBytesOut metrics are in Gigabytes per minute (GBpm). To convert Gbps to GBpm and measure utilization, please multiply the baseline bandwidth by 7.5.

- Cache memory utilization and evicted size, so that you can determine whether the cluster's node type has sufficient memory to hold your working set, and if not, switch to a larger node type.

Note

In case of a large number of cache misses and writes, cache memory utilization can increase up to 100% and may cause availability downtime.

- Client connections, so that you can monitor for any unexplained spikes in connections to the cluster.

Logging DAX operations using AWS CloudTrail

Amazon DynamoDB Accelerator (DAX) is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in DAX.

To learn more about DAX and CloudTrail, see the DynamoDB Accelerator (DAX) section in [Logging DynamoDB operations by using AWS CloudTrail](#).

DAX T3/T2 burstable instances

DAX allows you to choose between fixed performance instances (such as R4 and R5) and burstable performance instances (such as T2 and T3). Burstable performance instances provide a baseline level of CPU performance with the ability to burst above the baseline when needed.

Baseline performance and the ability to burst above it are governed by CPU credits. Burstable performance instances accumulate CPU credits continuously, at a rate determined by the instance size, when the workload is below the baseline threshold. These credits may then be consumed when the workload increases. A CPU credit provides the performance of a full CPU core for one minute.

Many workloads don't need consistently high levels of CPU, but benefit significantly from having full access to very fast CPUs when they need them. Burstable performance instances are engineered specifically for these use cases. If you need consistently high CPU performance for your database, we recommend you use fixed performance instances.

DAX T2 instance family

DAX T2 instances are burstable general-purpose performance instances that provide a baseline level of CPU performance with the ability to burst above the baseline. T2 instances are a good choice for test and development workloads which need price predictability. DAX T2 instances are configured for standard mode, which means that if the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level. For more information on standard mode, refer to [Standard mode for burstable performance instances](#) in the Amazon EC2 User Guide for Linux Instances.

DAX T3 instance family

DAX T3 instances are the next generation burstable general-purpose instance type, providing a baseline level of CPU performance with the ability to burst CPU usage at any time for as long as required. T3 instances offer a balance of compute, memory, and network resources and are ideal for workloads with moderate CPU usage that experience temporary spikes in use. DAX T3 instances are configured for unlimited mode, which means they can burst beyond the baseline over a 24-hour window for an additional charge. For more information on unlimited mode, refer to [Unlimited mode for burstable performance instances](#) in the Amazon EC2 User Guide for Linux Instances.

DAX T3 instances can sustain high CPU performance for as long as a workload requires it. For most general-purpose workloads, T3 instances will provide ample performance without any additional charges. The hourly T3 instance price automatically covers all interim spikes in usage when the average CPU utilization of a T3 instance is at or less than the baseline over a 24-hour window.

For example, a `dax.t3.small` instance receives credits continuously at a rate of 24 CPU credits per hour. This capability provides baseline performance equivalent to 20% of a CPU core ($20\% \times 60 \text{ minutes} = 12 \text{ minutes}$). If the instance does not use the credits it receives, they are stored in its CPU credit balance up to a maximum of 576 CPU credits. When the `t3.small` instance needs to burst to more than 20% of a core, it draws from its CPU credit balance to handle this surge automatically.

While DAX T2 instances are restricted to baseline performance once the CPU credit balance is drawn down to zero, DAX T3 instances can burst above the baseline even when their CPU credit

balance is zero. For the vast majority of workloads, where the average CPU utilization is at or below the baseline performance, the basic hourly price for t3.small covers all CPU bursts. If the instance happens to run at an average 25% CPU utilization (5% above baseline) over a period of 24 hours after its CPU credit balance is drawn to zero, it will be charged an additional 11.52 cents (9.6 cents/vCPU-hour × 1 vCPU × 5% × 24 hours). See [Amazon DynamoDB Pricing](#) for pricing details.

DAX access control

DynamoDB Accelerator (DAX) is designed to work together with DynamoDB, to seamlessly add a caching layer to your applications. However, DAX and DynamoDB have separate access control mechanisms. Both services use AWS Identity and Access Management (IAM) to implement their respective security policies, but the security models for DAX and DynamoDB are different.

We highly recommend that you understand both security models, so that you can implement proper security measures for your applications that use DAX.

This section describes the access control mechanisms provided by DAX and provides sample IAM policies that you can tailor to your needs.

With DynamoDB, you can create IAM policies that limit the actions a user can perform on individual DynamoDB resources. For example, you can create a user role that only allows the user to perform read-only actions on a particular DynamoDB table. (For more information, see [Identity and Access Management for Amazon DynamoDB](#).) By comparison, the DAX security model focuses on cluster security, and the ability of the cluster to perform DynamoDB API actions on your behalf.

Warning

If you are currently using IAM roles and policies to restrict access to DynamoDB tables data, then the use of DAX can **subvert** those policies. For example, a user could have access to a DynamoDB table via DAX but not have explicit access to the same table accessing DynamoDB directly. For more information, see [Identity and Access Management for Amazon DynamoDB](#).

DAX does not enforce user-level separation on data in DynamoDB. Instead, users inherit the permissions of the DAX cluster's IAM policy when they access that cluster. Thus, when accessing DynamoDB tables via DAX, the only access controls that are in effect are the permissions in the DAX cluster's IAM policy. No other permissions are recognized.

If you require isolation, we recommend that you create additional DAX clusters and scope the IAM policy for each cluster accordingly. For example, you could create multiple DAX clusters and allow each cluster to access only a single table.

IAM service role for DAX

When you create a DAX cluster, you must associate the cluster with an IAM role. This is known as the *service role* for the cluster.

Suppose that you wanted to create a new DAX cluster named *DAXCluster01*. You could create a service role named *DAXServiceRole*, and associate the role with *DAXCluster01*. The policy for *DAXServiceRole* would define the DynamoDB actions that *DAXCluster01* could perform, on behalf of the users who interact with *DAXCluster01*.

When you create a service role, you must specify a trust relationship between *DAXServiceRole* and the DAX service itself. A trust relationship determines which entities can assume a role and make use of its permissions. The following is an example trust relationship document for *DAXServiceRole*:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "dax.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

This trust relationship allows a DAX cluster to assume *DAXServiceRole* and perform DynamoDB API calls on your behalf.

The DynamoDB API actions that are allowed are described in an IAM policy document, which you attach to *DAXServiceRole*. The following is an example policy document.

```
{  
    "Version": "2012-10-17",
```

```
"Statement": [  
    {  
        "Sid": "DaxAccessPolicy",  
        "Effect": "Allow",  
        "Action": [  
            "dynamodb:DescribeTable",  
            "dynamodb:PutItem",  
            "dynamodb:GetItem",  
            "dynamodb:UpdateItem",  
            "dynamodb:DeleteItem",  
            "dynamodb:Query",  
            "dynamodb:Scan",  
            "dynamodb:BatchGetItem",  
            "dynamodb:BatchWriteItem",  
            "dynamodb:ConditionCheckItem"  
        ],  
        "Resource": [  
            "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        ]  
    }  
]
```

This policy allows DAX to perform necessary DynamoDB API actions on a DynamoDB table. The dynamodb:DescribeTable action is required for DAX to maintain metadata about the table, and the others are read and write actions performed on items in the table. The table, named Books, is in the us-west-2 Region and is owned by AWS account ID 123456789012.

 **Note**

DAX supports mechanisms to prevent the confused deputy problem during cross-Service access. For more information, see [The confused deputy problem](#) in the *IAM User Guide*.

IAM policy to allow DAX cluster access

After you create a DAX cluster, you need to grant permissions to a user so that the user can access the DAX cluster.

For example, suppose that you want to grant access to *DAXCluster01* to a user named Alice. You would first create an IAM policy (*AliceAccessPolicy*) that defines the DAX clusters and DAX API

actions that the recipient can access. You would then confer access by attaching this policy to user Alice.

The following policy document gives the recipient full access on *DAXCluster01*.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "dax:*"  
            ],  
            "Effect": "Allow",  
            "Resource": [  
                "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"  
            ]  
        }  
    ]  
}
```

The policy document allows access to the DAX cluster, but it does not grant any DynamoDB permissions. (The DynamoDB permissions are conferred by the DAX service role.)

For user Alice, you would first create `AliceAccessPolicy` with the policy document shown previously. You would then attach the policy to Alice.

 **Note**

Instead of attaching the policy to a user, you could attach it to an IAM role. That way, all of the users who assume that role would have the permissions that you defined in the policy.

The user policy, together with the DAX service role, determine the DynamoDB resources and API actions that the recipient can access via DAX.

Case study: Accessing DynamoDB and DAX

The following scenario can help further your understanding of IAM policies for use with DAX. (This scenario is referred to throughout the rest of this section.) The following diagram shows a high-level overview of the scenario.

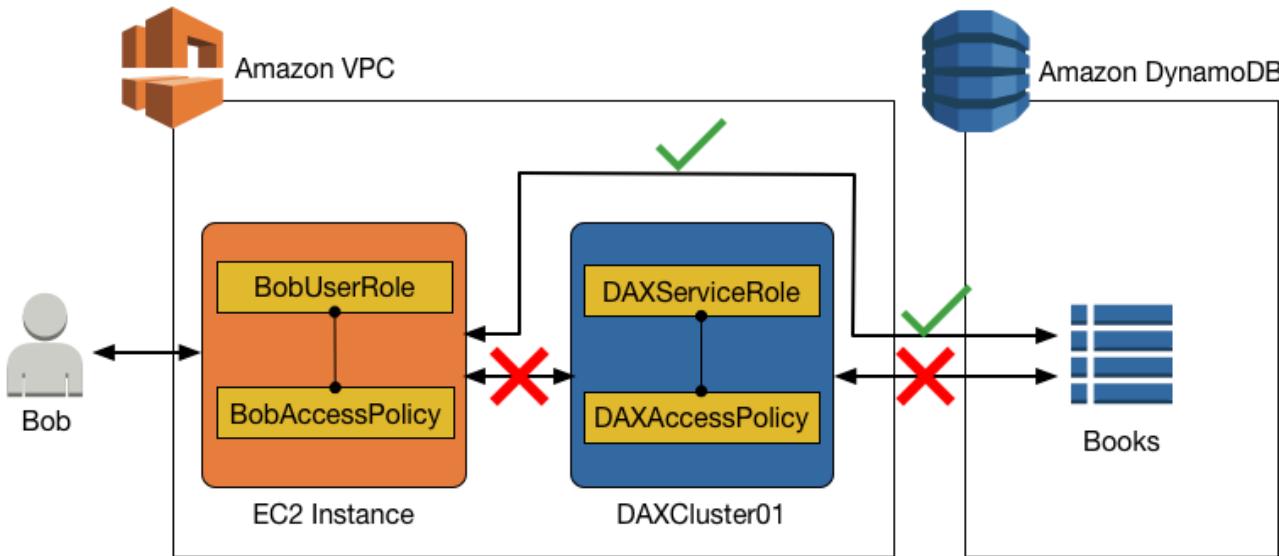

In this scenario, there are the following entities:

- A user (Bob).
- An IAM role (BobUserRole). Bob assumes this role at runtime.
- An IAM policy (BobAccessPolicy). This policy is attached to BobUserRole. BobAccessPolicy defines the DynamoDB and DAX resources that BobUserRole is allowed to access.
- A DAX cluster (DAXCluster01).
- An IAM service role (DAXServiceRole). This role allows DAXCluster01 to access DynamoDB.
- An IAM policy (DAXAccessPolicy). This policy is attached to DAXServiceRole. DAXAccessPolicy defines the DynamoDB APIs and resources that DAXCluster01 is allowed to access.
- A DynamoDB table (Books).

The combination of policy statements in BobAccessPolicy and DAXAccessPolicy determine what Bob can do with the Books table. For example, Bob might be able to access Books directly (using the DynamoDB endpoint), indirectly (using the DAX cluster), or both. Bob might also be able to read data from Books, write data to Books, or both.

Access to DynamoDB, but no access with DAX

It is possible to allow direct access to a DynamoDB table, while preventing indirect access using a DAX cluster. For direct access to DynamoDB, the permissions for BobUserRole are determined by BobAccessPolicy (which is attached to the role).

Read-only access to DynamoDB (only)

Bob can access DynamoDB with BobUserRole. The IAM policy attached to this role (BobAccessPolicy) determines the DynamoDB tables that BobUserRole can access, and what APIs that BobUserRole can invoke.

Consider the following policy document for BobAccessPolicy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DynamoDBAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan"  
            ]  
        }  
    ]  
}
```

```
        "dynamodb:Scan"
    ],
    "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
}
]
```

When this document is attached to BobAccessPolicy, it allows BobUserRole to access the DynamoDB endpoint and perform read-only operations on the Books table.

DAX does not appear in this policy, so access via DAX is denied.

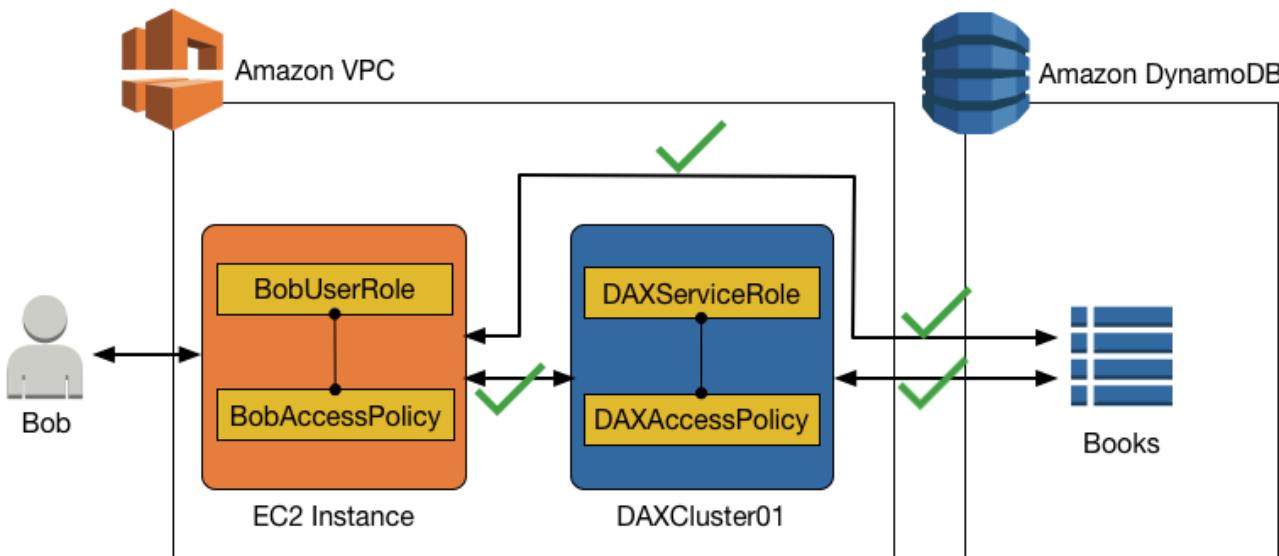

Read/write access to DynamoDB (only)

If BobUserRole requires read/write access to DynamoDB, the following policy would work.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

Again, DAX does not appear in this policy, so access via DAX is denied.

Access to DynamoDB and to DAX

To allow access to a DAX cluster, you must include DAX-specific actions in an IAM policy.

The following DAX-specific actions correspond to their similarly named counterparts in the DynamoDB API:

- `dax:GetItem`
- `dax:BatchGetItem`
- `dax:Query`
- `dax:Scan`
- `dax:PutItem`
- `dax:UpdateItem`
- `dax:DeleteItem`
- `dax:BatchWriteItem`
- `dax:ConditionCheckItem`

The same is true for the `dax:EnclosingOperation` condition key.

Read-only access to DynamoDB and read-only access to DAX

Suppose that Bob requires read-only access to the Books table, from DynamoDB and from DAX. The following policy (attached to BobUserRole) confers this access.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DAXAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dax:GetItem",  
                "dax:BatchGetItem",  
                "dax:Query",  
                "dax:Scan"  
            ],  
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"  
        },  
        {  
            "Sid": "DynamoDBAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        }  
    ]  
}
```

The policy has a statement for DAX access (DAXAccessStmt) and another statement for DynamoDBaccess (DynamoDBAccessStmt). These statements allow Bob to send GetItem, BatchGetItem, Query, and Scan requests to DAXCluster01.

However, the service role for DAXCluster01 would also require read-only access to the Books table in DynamoDB. The following IAM policy, attached to DAXServiceRole, would fulfill this requirement.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Sid": "DynamoDBAccessStmt",
        "Effect": "Allow",
        "Action": [
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:Scan"
        ],
        "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
    }
]
```

Read/write access to DynamoDB and read-only with DAX

For a given user role, you can provide read/write access to a DynamoDB table, while also allowing read-only access via DAX.

For Bob, the IAM policy for BobUserRole would need to allow DynamoDB read and write actions on the Books table, while also supporting read-only actions via DAXCluster01.

The following example policy document for BobUserRole confers this access.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DAXAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan"
            ],
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
        },
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",

```

```
        "Action": [
            "dynamodb:GetItem",
            "dynamodb:BatchGetItem",
            "dynamodb:Query",
            "dynamodb:Scan",
            "dynamodb:PutItem",
            "dynamodb:UpdateItem",
            "dynamodb:DeleteItem",
            "dynamodb:BatchWriteItem",
            "dynamodb:DescribeTable",
            "dynamodb:ConditionCheckItem"
        ],
        "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
    }
]
}
```

In addition, DAXServiceRole would require an IAM policy that allows DAXCluster01 to perform read-only actions on the Books table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:DescribeTable"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

Read/write access to DynamoDB and read/write access to DAX

Now suppose that Bob required read/write access to the Books table, directly from DynamoDB or indirectly from DAXCluster01. The following policy document, attached to BobAccessPolicy, confers this access.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DAXAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dax:GetItem",  
                "dax:BatchGetItem",  
                "dax:Query",  
                "dax:Scan",  
                "dax:PutItem",  
                "dax:UpdateItem",  
                "dax:DeleteItem",  
                "dax:BatchWriteItem",  
                "dax:ConditionCheckItem"  
            ],  
            "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"  
        },  
        {  
            "Sid": "DynamoDBAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem",  
                "dynamodb:DescribeTable",  
                "dynamodb:ConditionCheckItem"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        }  
    ]  
}
```

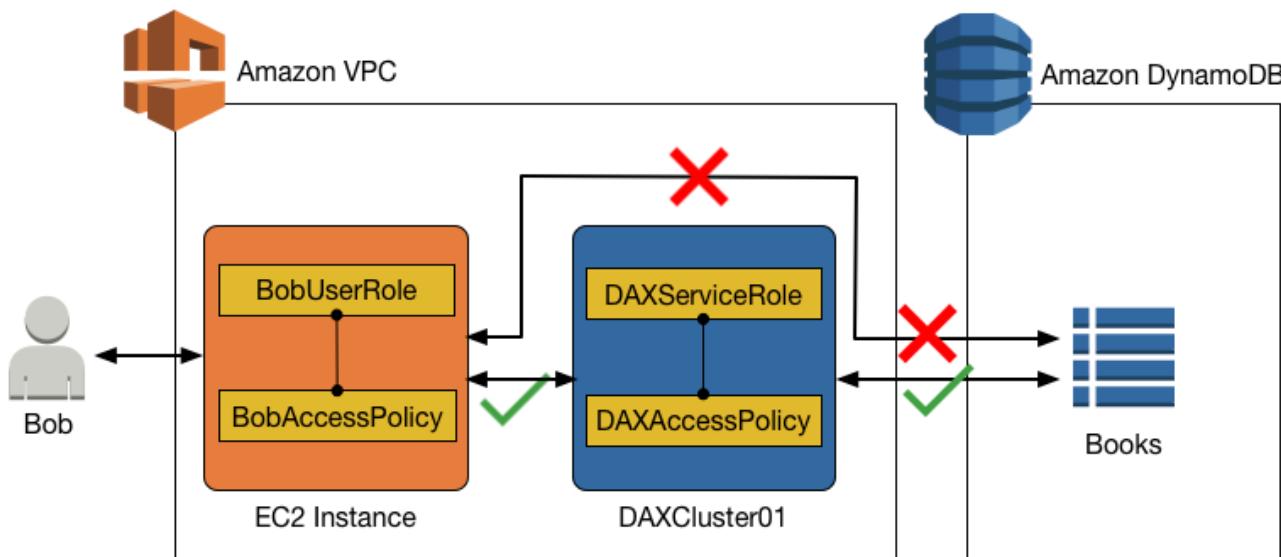

}

In addition, DAXServiceRole would require an IAM policy that allows DAXCluster01 to perform read/write actions on the Books table.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DynamoDBAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dynamodb:GetItem",  
                "dynamodb:BatchGetItem",  
                "dynamodb:Query",  
                "dynamodb:Scan",  
                "dynamodb:PutItem",  
                "dynamodb:UpdateItem",  
                "dynamodb:DeleteItem",  
                "dynamodb:BatchWriteItem",  
                "dynamodb:DescribeTable"  
            ],  
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"  
        }  
    ]  
}
```

Access to DynamoDB via DAX, but no direct access to DynamoDB

In this scenario, Bob can access the Books table via DAX, but he does not have direct access to the Books table in DynamoDB. Thus, when Bob gains access to DAX, he also gains access to a DynamoDB table that he otherwise might not be able to access. When you configure an IAM policy for the DAX service role, remember that any user that is given access to the DAX cluster via the user access policy gains access to the tables specified in that policy. In this case, BobAccessPolicy gains access to the tables specified in DAXAccessPolicy.

If you are currently using IAM roles and policies to restrict access to DynamoDB tables and data, using DAX can subvert those policies. In the following policy, Bob has access to a DynamoDB table via DAX but does not have explicit direct access to the same table in DynamoDB.

The following policy document (BobAccessPolicy), attached to BobUserRole, would confer this access.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "DAXAccessStmt",  
            "Effect": "Allow",  
            "Action": [  
                "dax:GetItem",  
                "dax:BatchGetItem",  
                "dax:Query",  
                "dax:Scan",  
                "dax:PutItem",  
                "dax:UpdateItem",  
                "dax:DeleteItem",  
                "dax:BatchWriteItem",  
                "dax:ConditionCheckItem"  
            ],  
            "Resource": "arn:aws:dynamodb:region:account-id:table/Books"  
        }  
    ]}
```

```
        "Resource": "arn:aws:dax:us-west-2:123456789012:cache/DAXCluster01"
    }
]
}
```

In this access policy, there are no permissions to access DynamoDB directly.

Together with BobAccessPolicy, the following DAXAccessPolicy gives BobUserRole access to the DynamoDB table Books even though BobUserRole cannot directly access the Books table.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBAccessStmt",
            "Effect": "Allow",
            "Action": [
                "dynamodb:GetItem",
                "dynamodb:BatchGetItem",
                "dynamodb:Query",
                "dynamodb:Scan",
                "dynamodb:PutItem",
                "dynamodb:UpdateItem",
                "dynamodb:DeleteItem",
                "dynamodb:BatchWriteItem",
                "dynamodb:DescribeTable",
                "dynamodb:ConditionCheckItem"
            ],
            "Resource": "arn:aws:dynamodb:us-west-2:123456789012:table/Books"
        }
    ]
}
```

As this example shows, when you configure access control for the user access policy and the DAX cluster access policy, you must fully understand the end-to-end access to ensure that the principle of least privilege is observed. Also ensure that giving a user access to a DAX cluster does not subvert previously established access control policies.

DAX encryption at rest

Amazon DynamoDB Accelerator (DAX) encryption at rest provides an additional layer of data protection by helping secure your data from unauthorized access to the underlying storage.

Organizational policies, industry or government regulations, and compliance requirements might require the use of encryption at rest to protect your data. You can use encryption to increase the data security of your applications that are deployed in the cloud.

With encryption at rest, the data persisted by DAX on disk is encrypted using 256-bit Advanced Encryption Standard, also known as AES-256 encryption. DAX writes data to disk as part of propagating changes from the primary node to read replicas.

DAX encryption at rest automatically integrates with AWS Key Management Service (AWS KMS) for managing the single service default key that is used to encrypt your clusters. If a service default key doesn't exist when you create your encrypted DAX cluster, AWS KMS automatically creates a new AWS managed key for you. This key is used with encrypted clusters that are created in the future. AWS KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud.

After your data is encrypted, DAX handles the decryption of your data transparently with minimal impact on performance. You don't need to modify your applications to use encryption.

 **Note**

DAX does not call AWS KMS for every single DAX operation. DAX only uses the key at the cluster launch. Even if access is revoked, DAX can still access the data until the cluster is shut down. Customer-specified AWS KMS keys are not supported.

DAX encryption at rest is available for the following cluster node types.

Family	Node type
Memory-optimized (R4 and R5)	dax.r4.large
	dax.r4.xlarge
	dax.r4.2xlarge
	dax.r4.4xlarge
	dax.r4.8xlarge
	dax.r4.16xlarge

Family	Node type
	dax.r5.large
	dax.r5.xlarge
	dax.r5.2xlarge
	dax.r5.4xlarge
	dax.r5.8xlarge
	dax.r5.12xlarge
	dax.r5.16xlarge
	dax.r5.24xlarge
General purpose (T2)	dax.t2.small
	dax.t2.medium
General purpose (T3)	dax.t3.small
	dax.t3.medium

Important

DAX encryption at rest is not supported for dax.r3.* node types.

You cannot enable or disable encryption at rest after a cluster has been created. You must re-create the cluster to enable encryption at rest if it was not enabled at creation.

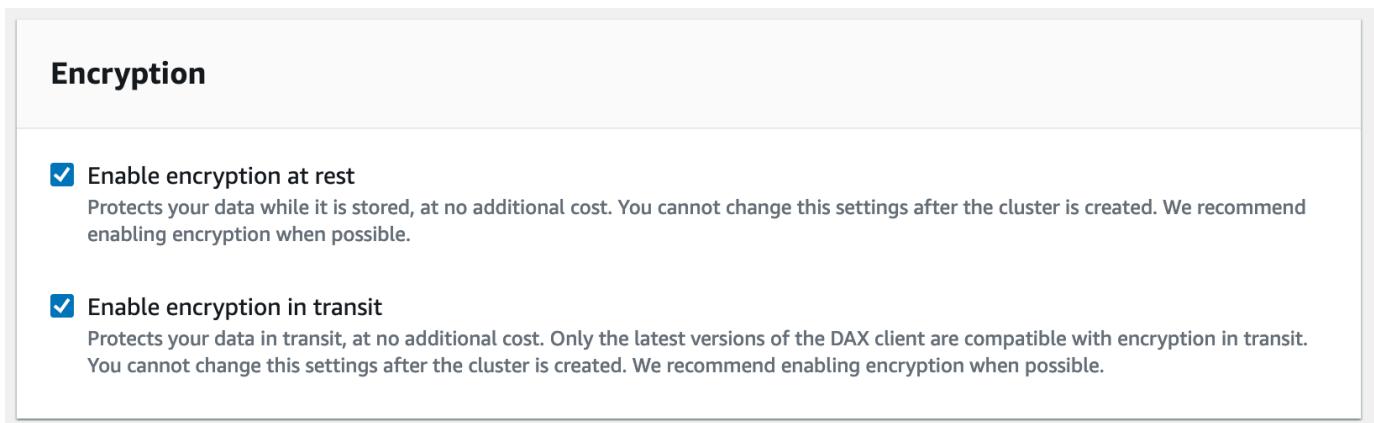

DAX encryption at rest is offered at no additional cost (AWS KMS encryption key usage charges apply). For information about pricing, see [Amazon DynamoDB pricing](#).

Enabling encryption at rest using the AWS Management Console

Follow these steps to enable DAX encryption at rest on a table using the console.

To enable DAX encryption at rest

1. Sign in to the AWS Management Console and open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane on the left side of the console, under **DAX**, choose **Clusters**.
3. Choose **Create cluster**.
4. For **Cluster name**, enter a short name for your cluster. Choose the **node type** for all of the nodes in the cluster, and for the cluster size, use **3 nodes**.
5. In **Encryption**, make sure that **Enable encryption** is selected.

6. After choosing the IAM role, subnet group, security groups, and cluster settings, choose **Launch cluster**.

To confirm that the cluster is encrypted, check the cluster details under the **Clusters** pane. Encryption should be **ENABLED**.

DAX encryption in transit

Amazon DynamoDB Accelerator (DAX) supports encryption in transit of data between your application and your DAX cluster, enabling you to use DAX in applications with stringent encryption requirements.

Regardless of whether or not you choose encryption in transit, traffic between your application and your DAX cluster remains in your Amazon VPC. This traffic is routed to Elastic Network Interfaces with private IPs in your VPC that are attached to the nodes of your cluster. With your VPC as the trust boundary, you have significant control over the security of your data through the use of standard tools like security groups, subnet segmentation with Network ACLs, and VPC flow

tracing. DAX encryption in transit adds to this baseline level of confidentiality, ensuring that all requests and responses between the application and the cluster are encrypted by transport level security (TLS), and connections to the cluster can be authenticated by verification of a cluster x509 certificate. Data written to disk by DAX can also be encrypted if you choose [encryption at rest](#) when creating your DAX cluster.

Using encryption in transit with DAX is easy. Simply select this option when creating a new cluster, and use a recent version of any of the [DAX clients](#) in your application. Clusters that use encryption in transit do not support unencrypted traffic, so there is no chance to misconfigure your application and bypass encryption. The DAX client will use the cluster's x509 certificate to authenticate the identity of the cluster when it establishes connections, ensuring that your DAX requests go where intended. All methods of creating DAX clusters support encryption in transit: the AWS Management Console, AWS CLI, all SDKs, and AWS CloudFormation.

Encryption in transit cannot be enabled on an existing DAX cluster. To use encryption in transit in an existing DAX application, create a new cluster with encryption in transit enabled, shift your application's traffic to it, then delete the old cluster.

Using service-linked IAM roles for DAX

Amazon DynamoDB Accelerator (DAX) uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to DAX. Service-linked roles are predefined by DAX and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up DAX easier because you don't have to manually add the necessary permissions. DAX defines the permissions of its service-linked roles, and unless defined otherwise, only DAX can assume its roles. The defined permissions include the trust policy and the permissions policy. That permissions policy can't be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your DAX resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) in the *IAM User Guide*. Look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** link to view the service-linked role documentation for that service.

Topics

- [Service-linked role permissions for DAX](#)
- [Creating a service-linked role for DAX](#)
- [Editing a service-linked role for DAX](#)
- [Deleting a service-linked role for DAX](#)

Service-linked role permissions for DAX

DAX uses the service-linked role named `AWSServiceRoleForDAX`. This role allows DAX to call services on behalf of your DAX cluster.

Important

The `AWSServiceRoleForDAX` service-linked role makes it easier for you to set up and maintain a DAX cluster. However, you must still grant each cluster access to DynamoDB before you can use it. For more information, see [DAX access control](#).

The `AWSServiceRoleForDAX` service-linked role trusts the following services to assume the role:

- `dax.amazonaws.com`

The role permissions policy allows DAX to complete the following actions on the specified resources:

- Actions on `ec2`:
 - `AuthorizeSecurityGroupIngress`
 - `CreateNetworkInterface`
 - `CreateSecurityGroup`
 - `DeleteNetworkInterface`
 - `DeleteSecurityGroup`
 - `DescribeAvailabilityZones`
 - `DescribeNetworkInterfaces`
 - `DescribeSecurityGroups`
 - `DescribeSubnets`

- `DescribeVpcs`
- `ModifyNetworkInterfaceAttribute`
- `RevokeSecurityGroupIngress`

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

To allow an IAM entity to create `AWSServiceRoleForDAX` service-linked roles

Add the following policy statement to the permissions for that IAM entity.

```
{  
    "Effect": "Allow",  
    "Action": [  
        "iam:CreateServiceLinkedRole"  
    ],  
    "Resource": "*",  
    "Condition": {"StringLike": {"iam:AWSServiceName": "dax.amazonaws.com"}}  
}
```

Creating a service-linked role for DAX

You don't need to manually create a service-linked role. When you create a cluster, DAX creates the service-linked role for you.

Important

If you were using the DAX service before February 28, 2018, when it began supporting service-linked roles, DAX created the `AWSServiceRoleForDAX` role in your account. For more information, see [A New Role Appeared in My AWS Account](#) in the *IAM User Guide*.

If you delete this service-linked role and then need to create it again, you can use the same process to re-create the role in your account. When you create an instance or a cluster, DAX creates the service-linked role for you again.

Editing a service-linked role for DAX

DAX does not allow you to edit the `AWSServiceRoleForDAX` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Deleting a service-linked role for DAX

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DAX clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the AWS Management Console and open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the `AWSServiceRoleForDAX` role.
3. On the **Summary** page for the selected role, choose the **Access Advisor** tab.
4. On the **Access Advisor** tab, review recent activity for the service-linked role.

Note

If you are unsure whether DAX is using the `AWSServiceRoleForDAX` role, you can try to delete the role. If the service is using the role, the deletion fails, and you can view the Regions where the role is being used. If the role is being used, you must delete your DAX clusters before you can delete the role. You can't revoke the session for a service-linked role.

If you want to remove the `AWSServiceRoleForDAX` role, you must first delete all of your DAX clusters.

Deleting all of your DAX clusters

Use one of these procedures to delete each of your DAX clusters.

To delete a DAX cluster (console)

1. Open the DynamoDB console at <https://console.aws.amazon.com/dynamodb/>.
2. In the navigation pane, under **DAX**, choose **Clusters**.
3. Choose **Actions**, and then choose **Delete**.
4. In the **Delete cluster confirmation** box, choose **Delete**.

To delete a DAX cluster (AWS CLI)

See [delete-cluster](#) in the *AWS CLI Command Reference*.

To delete a DAX cluster (API)

See [DeleteCluster](#) in the *Amazon DynamoDB API Reference*.

Deleting the service-linked role

To manually delete the service-linked role using IAM

Use the IAM console, the IAM CLI, or the IAM API to delete the `AWSServiceRoleForDAX` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Accessing DAX across AWS accounts

Imagine that you have a DynamoDB Accelerator (DAX) cluster running in one AWS account (account A), and the DAX cluster needs to be accessible from an Amazon Elastic Compute Cloud (Amazon EC2) instance in another AWS account (account B). In this tutorial, you accomplish this by launching an EC2 instance in account B with an IAM role from account B. You then use temporary security credentials from the EC2 instance to assume an IAM role from account A. Finally, you use the temporary security credentials from assuming the IAM role in account A to make application calls over an Amazon VPC peering connection to the DAX cluster in account A. In order to perform these tasks you will need administrative access in both AWS accounts.

⚠️ Important

It is not possible to have a DAX cluster access a DynamoDB table from a different account.

Topics

- [Set up IAM](#)
- [Set up a VPC](#)
- [Modify the DAX client to allow cross-account access](#)

Set up IAM

1. Create a text file named `AssumeDaxRoleTrust.json` with the following content, which allows Amazon EC2 to work on your behalf.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "ec2.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}
```

2. In account B, create a role that Amazon EC2 can use when launching instances.

```
aws iam create-role \  
  --role-name AssumeDaxRole \  
  --assume-role-policy-document file://AssumeDaxRoleTrust.json
```

3. Create a text file named `AssumeDaxRolePolicy.json` with the following content, which allows code running on the EC2 instance in account B to assume an IAM role in account A. Replace `accountA` with the actual ID of account A.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": "sts:AssumeRole",
        "Resource": "arn:aws:iam::accountA:role/DaxCrossAccountRole"
    }
]
```

4. Add that policy to the role you just created.

```
aws iam put-role-policy \
--role-name AssumeDaxRole \
--policy-name AssumeDaxRolePolicy \
--policy-document file://AssumeDaxRolePolicy.json
```

5. Create an instance profile to allow instances to use the role.

```
aws iam create-instance-profile \
--instance-profile-name AssumeDaxInstanceProfile
```

6. Associate the role with the instance profile.

```
aws iam add-role-to-instance-profile \
--instance-profile-name AssumeDaxInstanceProfile \
--role-name AssumeDaxRole
```

7. Create a text file named DaxCrossAccountRoleTrust.json with the following content, which allows account B to assume an account A role. Replace *accountB* with the actual ID of account B.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::accountB:role/AssumeDaxRole"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

```
}
```

8. In account A, create the role that account B can assume.

```
aws iam create-role \
--role-name DaxCrossAccountRole \
--assume-role-policy-document file://DaxCrossAccountRoleTrust.json
```

9. Create a text file named `DaxCrossAccountPolicy.json` that allows access to the DAX cluster. Replace `dax-cluster-arn` with the correct Amazon Resource Name (ARN) of your DAX cluster.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "dax:GetItem",
                "dax:BatchGetItem",
                "dax:Query",
                "dax:Scan",
                "dax:PutItem",
                "dax:UpdateItem",
                "dax:DeleteItem",
                "dax:BatchWriteItem",
                "dax:ConditionCheckItem"
            ],
            "Resource": "dax-cluster-arn"
        }
    ]
}
```

10. In account A, add the policy to the role.

```
aws iam put-role-policy \
--role-name DaxCrossAccountRole \
--policy-name DaxCrossAccountPolicy \
--policy-document file://DaxCrossAccountPolicy.json
```

Set up a VPC

1. Find the subnet group of account A's DAX cluster. Replace *cluster-name* with the name of the DAX cluster that account B must access.

```
aws dax describe-clusters \
--cluster-name cluster-name
--query 'Clusters[0].SubnetGroup'
```

2. Using that *subnet-group*, find the cluster's VPC.

```
aws dax describe-subnet-groups \
--subnet-group-name subnet-group \
--query 'SubnetGroups[0].VpcId'
```

3. Using that *vpc-id*, find the VPC's CIDR.

```
aws ec2 describe-vpcs \
--vpc vpc-id \
--query 'Vpcs[0].CidrBlock'
```

4. From account B, create a VPC using a different, non-overlapping CIDR than the one found in the previous step. Then, create at least one subnet. You can use either the [VPC creation wizard](#) in the AWS Management Console or the [AWS CLI](#).
5. From account B, request a peering connection to the account A VPC as described in [Creating and accepting a VPC peering connection](#). From account A, accept the connection.
6. From account B, find the new VPC's routing table. Replace *vpc-id* with the ID of the VPC you created in account B.

```
aws ec2 describe-route-tables \
--filters 'Name=vpc-id,Values=vpc-id' \
--query 'RouteTables[0].RouteTableId'
```

7. Add a route to send traffic destined for account A's CIDR to the VPC peering connection. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
aws ec2 create-route \
--route-table-id accountB-route-table-id \
--destination-cidr accountA-vpc-cidr \
```

```
--vpc-peering-connection-id peering-connection-id
```

8. From account A, find the DAX cluster's route table using the *vpc-id* you found previously.

```
aws ec2 describe-route-tables \  
--filters 'Name=vpc-id, Values=accountA-vpc-id' \  
--query 'RouteTables[0].RouteTableId'
```

9. From account A, add a route to send traffic destined for account B's CIDR to the VPC peering connection. Replace each *user input placeholder* with the correct values for your accounts.

```
aws ec2 create-route \  
--route-table-id accountA-route-table-id \  
--destination-cidr accountB-vpc-cidr \  
--vpc-peering-connection-id peering-connection-id
```

10. From account B, launch an EC2 instance in the VPC that you created earlier. Give it the `AssumeDaxInstanceProfile`. You can use either the [launch wizard](#) in the AWS Management Console or the [AWS CLI](#). Take note of the instance's security group.
11. From account A, find the security group used by the DAX cluster. Remember to replace *cluster-name* with the name of your DAX cluster.

```
aws dax describe-clusters \  
--cluster-name cluster-name \  
--query 'Clusters[0].SecurityGroups[0].SecurityGroupIdentifier'
```

12. Update the DAX cluster's security group to allow inbound traffic from the security group of the EC2 instance you created in account B. Remember to replace the *user input placeholders* with the correct values for your accounts.

```
aws ec2 authorize-security-group-ingress \  
--group-id accountA-security-group-id \  
--protocol tcp \  
--port 8111 \  
--source-group accountB-security-group-id \  
--group-owner accountB-id
```

At this point, an application on account B's EC2 instance is able to use the instance profile to assume the `arn:aws:iam::accountA-id:role/DaxCrossAccountRole` role and use the DAX cluster.

Modify the DAX client to allow cross-account access

Note

AWS Security Token Service (AWS STS) credentials are temporary credentials. Some clients handle refreshing automatically, while others require additional logic to refresh the credentials. We recommend that you follow the guidance of the appropriate documentation.

Java

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the [Java and DAX tutorial](#).

1. Add the following imports.

```
import com.amazonaws.auth.STSShareRoleSessionCredentialsProvider;
import com.amazonaws.services.securitytoken.AWSSecurityTokenService;
import
com.amazonaws.services.securitytoken.AWSSecurityTokenServiceClientBuilder;
```

2. Get a credentials provider from AWS STS and create a DAX client object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
AWSSecurityTokenService awsSecurityTokenService =
AWSSecurityTokenServiceClientBuilder
    .standard()
    .withRegion(region)
    .build();

STSShareRoleSessionCredentialsProvider credentials = new
STSShareRoleSessionCredentialsProvider.Builder("arn:aws:iam::accountA:role/
RoleName", "TryDax")
    .withStsClient(awsSecurityTokenService)
    .build();
```

```
DynamoDB client = AmazonDaxClientBuilder.standard()
    .withRegion(region)
    .withEndpointConfiguration(dax_endpoint)
    .withCredentials(credentials)
    .build();
```

.NET

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the [.NET and DAX tutorial](#).

1. Add the [AWSSDK.SecurityToken](#) NuGet package to the solution.

```
<PackageReference Include="AWSSDK.SecurityToken" Version="latest version" />
```

2. Use the `SecurityToken` and `SecurityToken.Model` packages.

```
using Amazon.SecurityToken;
using Amazon.SecurityToken.Model;
```

3. Get temporary credentials from `AmazonSimpleTokenService` and create a `ClusterDaxClient` object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
IAmazonSecurityTokenService sts = new AmazonSecurityTokenServiceClient();

var assumeRoleResponse = sts.AssumeRole(new AssumeRoleRequest
{
    RoleArn = "arn:aws:iam::accountA:role/RoleName",
    RoleSessionName = "TryDax"
});

Credentials credentials = assumeRoleResponse.Credentials;

var clientConfig = new DaxClientConfig(dax_endpoint, port)
{
    AwsCredentials = assumeRoleResponse.Credentials
};
```

```
var client = new ClusterDaxClient(clientConfig);
```

Go

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find [working code examples on GitHub](#).

1. Import the AWS STS and session packages.

```
import (
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/sts"
    "github.com/aws/aws-sdk-go/aws/credentials/stscreds"
)
```

2. Get temporary credentials from AmazonSimpleTokenService and create a DAX client object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
sess, err := session.NewSession(&aws.Config{
    Region: aws.String(region)},
)
if err != nil {
    return nil, err
}

stsClient := sts.New(sess)
arp := &stscreds.AssumeRoleProvider{
    Duration:      900 * time.Second,
    ExpiryWindow: 10 * time.Second,
    RoleARN:       "arn:aws:iam::accountA:role/role_name",
    Client:        stsClient,
    RoleSessionName: "session_name",
}
cfg := dax.DefaultConfig()

cfg.HostPorts = []string{dax_endpoint}
cfg.Region = region
cfg.Credentials = credentials.NewCredentials(arp)
daxClient := dax.New(cfg)
```

Python

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the [Python and DAX](#) tutorial.

1. Import boto3.

```
import boto3
```

2. Get temporary credentials from sts and create an AmazonDaxClient object. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
sts = boto3.client('sts')
stsresponse =
    sts.assume_role(RoleArn='arn:aws:iam::accountA:role/
RoleName',RoleSessionName='tryDax')
credentials = botocore.session.get_session()['Credentials']

dax = amazondax.AmazonDaxClient(session, region_name=region,
endpoints=[dax_endpoint], aws_access_key_id=credentials['AccessKeyId'],
aws_secret_access_key=credentials['SecretAccessKey'],
aws_session_token=credentials['SessionToken'])
client = dax
```

Node.js

This section helps you modify your existing DAX client code to allow cross-account DAX access. If you don't have DAX client code already, you can find working code examples in the [Node.js and DAX](#) tutorial. Remember to replace each *user input placeholder* with the correct values for your accounts.

```
const AmazonDaxClient = require('amazon-dax-client');
const AWS = require('aws-sdk');
const region = 'region';
const endpoints = [daxEndpoint1, ...];

const getCredentials = async() => {
  return new Promise((resolve, reject) => {
    const sts = new AWS.STS();
    const roleParams = {
```

```
        RoleArn: 'arn:aws:iam::accountA:role/RoleName',
        RoleSessionName: 'tryDax',
    );
    sts.assumeRole(roleParams, (err, session) => {
        if(err) {
            reject(err);
        } else {
            resolve({
                accessKeyId: session.Credentials.AccessKeyId,
                secretAccessKey: session.Credentials.SecretAccessKey,
                sessionToken: session.Credentials.SessionToken,
            });
        }
    });
});
};

const createDaxClient = async() => {
    const credentials = await getCredentials();
    const daxClient = new AmazonDaxClient({endpoints: endpoints, region: region,
accessKeyId: credentials.accessKeyId, secretAccessKey: credentials.secretAccessKey,
sessionToken: credentials.sessionToken});
    return new AWS.DynamoDB.DocumentClient({service: daxClient});
};

createDaxClient().then((client) => {
    client.get(...);
    ...
}).catch((error) => {
    console.log('Caught an error: ' + error);
});
```

DAX cluster sizing guide

This guide provides advice for choosing an appropriate Amazon DynamoDB Accelerator (DAX) cluster size and node type for your application. These instructions guide you through the steps of estimating your application's DAX traffic, selecting a cluster configuration, and testing it.

If you have an existing DAX cluster and want to evaluate whether it has the appropriate number and size of nodes, please refer to [Scaling a DAX cluster](#).

Topics

- [Overview](#)
- [Estimating traffic](#)
- [Load testing](#)

Overview

It's important to scale your DAX cluster appropriately for your workload, whether you're creating a new cluster or maintaining an existing cluster. As time goes on and your application's workload changes, you should periodically revisit your scaling decisions to make sure that they are still appropriate.

The process typically follows these steps:

1. **Estimating traffic.** In this step, you make predictions about the volume of traffic that your application will send to DAX, the nature of the traffic (read vs. write operations), and the expected cache hit rate.
2. **Load testing.** In this step, you create a cluster and send traffic to it mirroring your estimates from the previous step. Repeat this step until you find a suitable cluster configuration.
3. **Production monitoring.** While your application is using DAX in production, you should [monitor the cluster](#) to continuously validate that it is still scaled correctly as your workload changes over time.

Estimating traffic

There are three main factors that characterize a typical DAX workload:

- Cache hit rate
- [Read capacity units](#) (RCUs) per second
- [Write capacity units](#) (WCUs) per second

Estimating cache hit rate

If you already have a DAX cluster, you can use the `ItemCacheHits` and `ItemCacheMisses` [Amazon CloudWatch metrics](#) to determine the cache hit rate. The cache hit rate is equal to $\text{ItemCacheHits} / (\text{ItemCacheHits} + \text{ItemCacheMisses})$. If your workload includes `Query` or `Scan` operations, you should also look at the `QueryCacheHits`, `QueryCacheMisses`,

ScanCacheHits, and ScanCacheMisses metrics. Cache hit rates vary from one application to another and are heavily influenced by the cluster's Time to Live (TTL) setting. Typical hit rates for applications using DAX are 85–95 percent.

Estimating read and write capacity units

If you already have DynamoDB tables for your application, look at the ConsumedReadCapacityUnits and ConsumedWriteCapacityUnits [CloudWatch metrics](#). Use the Sum statistic and divide by the number of seconds in the period.

If you also already have a DAX cluster, remember that the DynamoDB ConsumedReadCapacityUnits metric only accounts for cache misses. So, to get an idea of the read capacity units per second handled by your DAX cluster, divide the number by your cache miss rate (that is, 1 - cache hit rate).

If you don't already have a DynamoDB table, see the documentation about [read capacity units](#) and [write capacity units](#) to estimate your traffic based on your application's estimated request rate, items accessed per request, and item size.

When making traffic estimates, plan for future growth and for expected and unexpected peaks to ensure that your cluster has enough headroom for traffic increases.

Load testing

The next step after estimating traffic is to test the cluster configuration under load.

1. For your initial load test, we recommend that you start with the dax.r4.large node type, the lowest-cost fixed performance, memory-optimized node type.
2. A fault-tolerant cluster requires at least three nodes, spread across three Availability Zones. In this case, if an Availability Zone becomes unavailable, the effective number of Availability Zones is reduced by one-third. For your initial load test, we recommend that you start with a two-node cluster, which simulates the failure of one Availability Zone in a three-node cluster.
3. Drive sustained traffic (as estimated in the previous step) to your test cluster for the duration of the load test.
4. Monitor the performance of the cluster during the load test.

Ideally, the traffic profile that you drive during the load test should be as similar as possible to your application's real traffic. This includes the distribution of operations (for example, 70 percent

GetItem, 25 percent Query, and 5 percent PutItem), the request rate for each operation, the number of items accessed per request, and the distribution of item sizes. To achieve a cache hit rate similar to your application's expected cache hit rate, pay close attention to the distribution of keys in your test traffic.

Note

Be careful when load testing T2 node types (dax.t2.small and dax.t2.medium). T2 node types provide [burstable CPU performance](#) that varies over time depending on the node's CPU credit balance. A DAX cluster running on T2 nodes might appear to be operating normally, but if any node is bursting above the [baseline performance](#) of its instance, the node is spending its accrued CPU credit balance. When the credit balance runs low, [performance is gradually lowered](#) to the baseline performance level.

[Monitor your DAX cluster](#) during the load test to determine whether the node type that you're using for the load test is the right node type for you. In addition, during a load test, you should monitor your request rate and cache hit rate to ensure that your test infrastructure is actually driving the amount of traffic you intend.

You should pay attention to network bytes consumption of your selected cluster instance type. Exceeding the available baseline bandwidth for an Amazon EC2 instance indicates that your cluster may not sustain your application's workload, and needs to be scaled.

If load testing indicates that the selected cluster configuration can't sustain your application's workload, you should [switch to a larger node type](#), especially if you see high CPU utilization on the primary node in the cluster, high eviction rates, or high cache memory utilization. If hit rates are consistently high, and the ratio of read to write traffic is high, you may want to consider [adding more nodes to your cluster](#). Refer to [Scaling a DAX cluster](#) for additional guidance on when to use a larger node type (vertical scaling) or add more nodes (horizontal scaling).

You should repeat your load test after making changes to your cluster configuration.

DAX API reference

For more information about Amazon DynamoDB Accelerator (DAX) APIs, see [Amazon DynamoDB accelerator](#) in the Amazon DynamoDB API Reference.

Data modeling for DynamoDB tables

Before we dive into data modeling, it's important to understand some DynamoDB fundamentals. DynamoDB is a key-value NoSQL database which allows flexible schema. The set of data attributes apart from the key attributes for each item can be either uniform or discrete. The DynamoDB key schema is in the form of either a simple primary key where a partition key uniquely identifies an item, or in the form of a composite primary key where a combination of a partition key and sort key uniquely defines an item. The partition key is hashed to determine the physical location of data and retrieve it. Therefore, it is important to choose a high cardinality and horizontally scalable attribute as a partition key to ensure even distribution of data. The sort key attribute is optional in the key schema and having a sort key enables modelling one-to-many relationships and creating item collections in DynamoDB. Sort keys are also referred to as range keys—they are used to sort items in an item collection and also allow flexible range-based operations.

For more details and best practices on DynamoDB key schema, you can refer to the following:

- [the section called “Partitions and data distribution”](#)
- [the section called “Partition key design”](#)
- [the section called “Sort key design”](#)
- [Choosing the right DynamoDB partition key](#)

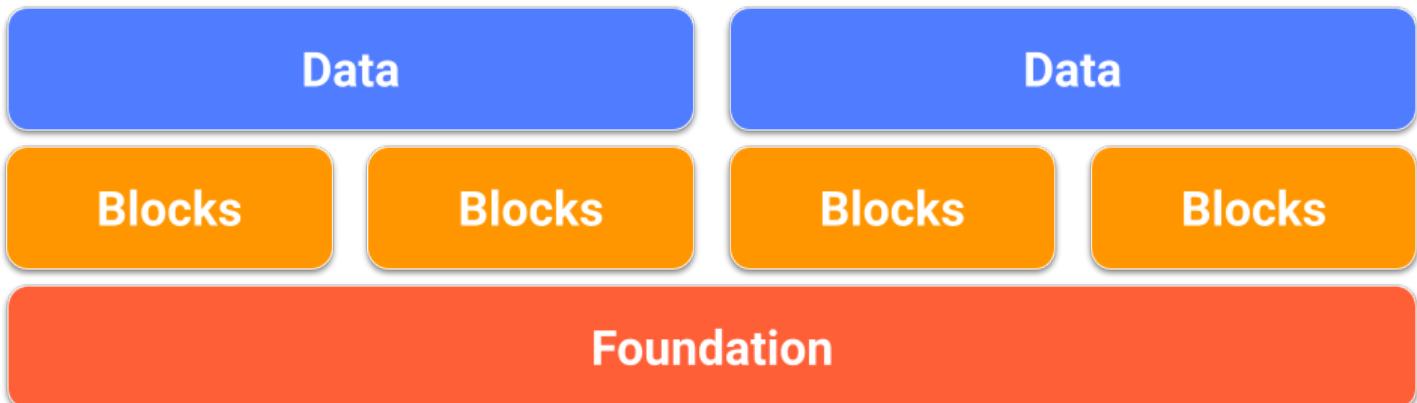

Secondary indexes are often needed to support additional query patterns in DynamoDB. Secondary indexes are shadow tables where the same data is organised via a different key schema compared to the base table. A local secondary index (LSI) shares the same partition key as the base table and allows having an alternate sort key allowing it to share the base table's capacity. A global secondary index (GSI) can have a different partition key as well as a different sort key attribute than the base table which means throughput management for a GSI is independent of the base table.

For more details on secondary indexes and best practices, you can refer to the following:

- [the section called “Working with indexes”](#)
- [the section called “Secondary indexes”](#)

Let's now look at data modeling a little closer. The process of designing a flexible and highly-optimized schema on DynamoDB, or any NoSQL database for that matter, can be a challenging

skill to learn. The goal of this module is to help you develop a mental flowchart for designing a schema that will take you from use case into production. We will start with an introduction to the foundational choice of any design, single table versus multiple table design. Then we will review the multitude of design patterns (building blocks) that can be used to achieve various organizational or performance results for your application. Finally, we are including a variety of complete schema design packages for different use cases and industries.

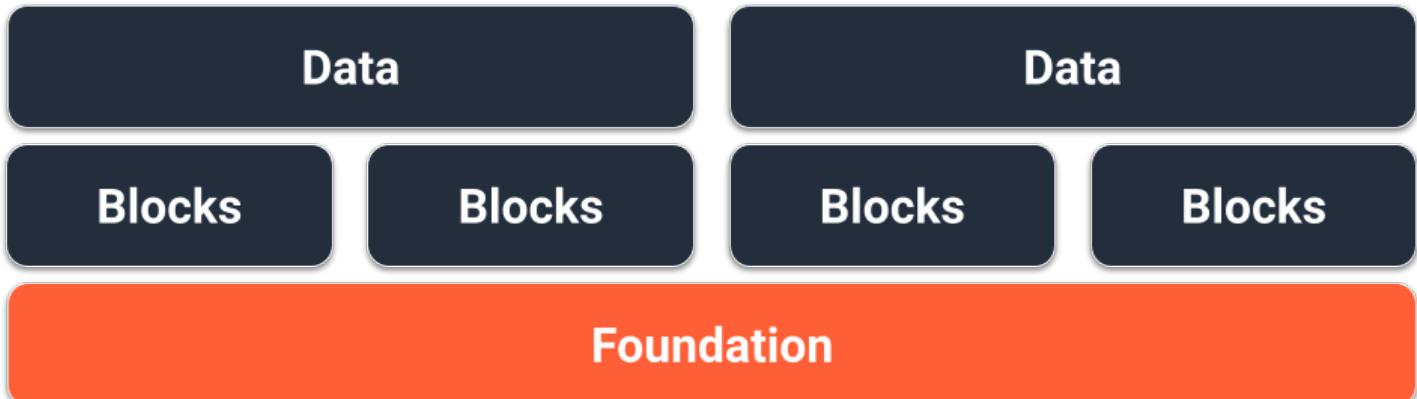

Topics

- [Data Modeling foundations in DynamoDB](#)
- [Data modeling building blocks in DynamoDB](#)
- [Data modeling schema design packages in DynamoDB](#)

Data Modeling foundations in DynamoDB

This section covers the foundation layer by examining the two types of table design: single table and multiple table.

Single table design foundation

One choice for the foundation of our DynamoDB schema is **single table design**. Single table design is a pattern that allows you to store multiple types (entities) of data in a single DynamoDB table. It aims to optimize data access patterns, improve performance, and reduce costs by eliminating the need for maintaining multiple tables and complex relationships between them. This is possible because DynamoDB stores items with the same partition key (known as an item collection) on the same partition(s) as each other. In this design, different types of data are stored as items in the same table, and each item is identified by a unique sort key.

Primary key		Attributes	
Partition key: PK	Sort key: SK		
UserID	Address#USA#CA#LA#90029	data	GSI-SK
		"Street Address"	Default
	Cart#ACTIVE#Coffee	data	GSI-SK
		CoffeeSKU	2019-11-27T103324
	Cart#ACTIVE#Spice	data	GSI-SK
		SpiceSKU	2019-11-28T091245
	Cart#SAVED#Cocoa	data	GSI-SK
		CocoaSKU	2019-11-28T125642
	OrderHistory#OrderUID	data	GSI-SK
		{Order:DataMap}	2019-10-08T132612
	ProfileName	data	
		"Paul Atreides"	
	Store#StoreUID	data	GSI-SK
		Los Angeles	Active

Advantages

- Data locality to support queries for multiple entity types in a single database call
- Reduces overall financial and latency costs of reads:
 - A single query for two items totalling less than 4KB is 0.5 RCU eventually consistent
 - Two queries for two items totalling less than 4KB is 1 RCU eventually consistent (0.5 RCU each)
 - The time to return two separate database calls will average higher than a single call

- Reduces the number of tables to manage:
 - Permissions do not need to be maintained across multiple IAM roles or policies
 - Capacity management for the table is averaged across all entities, usually resulting in a more predictable consumption pattern
 - Monitoring requires fewer alarms
 - Customer Managed Encryption Keys only need to be rotated on one table
- Smooths traffic to the table:
 - By aggregating multiple usage patterns to the same table, the overall usage tends to be smoother (the way a stock index's performance tends to be smoother than any individual stock) which works better for achieving higher utilization with provisioned mode tables

Disadvantages

- Learning curve can be steep due to paradoxical design compared to relational databases
- Data requirements must be consistent across all entity types
 - Backups are all or nothing so if some data is not mission critical, consider keeping it in a separate table
 - Table encryption is shared across all items. For multi-tenant applications with individual tenant encryption requirements, client side encryption would be required
 - Tables with a mix of historical data and operational data will not see as much of a benefit from enabling the Infrequent Access Storage Class. For more information, see [Table classes](#)
- All changed data will be propagated to DynamoDB Streams even if only a subset of entities need to be processed.
 - Thanks to Lambda event filters, this will not affect your bill when using Lambda, but will be an added cost when using the Kinesis Consumer Library
- When using GraphQL, single table design will be more difficult to implement
- When using higher-level SDK clients like Java's [DynamoDBMapper](#) or [Enhanced Client](#), it can be more difficult to process results because items in the same response may be associated with different classes

When to use

Single table design is the recommended design pattern for DynamoDB unless your use case would be impacted heavily by one of the above disadvantages. For most customers, the long term benefits outweigh the short term challenges of designing their tables this way.

Multiple table design foundation

The second choice for the foundation of our DynamoDB schema is multiple table design. Multiple table design is a pattern that is more like a traditional database design where you store a single type(entity) of data in each DynamoDB table. Data within each table will still be organized by partition key so performance within a single entity type will be optimized for scalability and performance, but queries across multiple tables must be done independently.

The screenshot shows the AWS DynamoDB Visualizer interface with two tables displayed:

Forum Table:

Primary key		Attributes			
Partition key: ForumName					
Amazon DynamoDB	Category	Threads	Messages	VIEWS	
	Amazon Web Services	2	4	1000	
Amazon Simple Notification Service	Category	Threads	Messages	VIEWS	
	Amazon Web Services	5	5	1200	
Amazon Simple Queue Service	Category	Threads	Messages	VIEWS	
	Amazon Web Services	9	6	1300	

Thread Table:

Primary key		Attributes			
Partition key: ForumName	Sort key: Subject				
Amazon DynamoDB	On-demand and transactions	Message	LastPostedBy	Replies	VIEWS
		DynamoDB on-demand and transactions now available in the AWS GovCloud (US) Regions	john@example.com	3	99
	Tagging tables	Message	LastPostedBy	Replies	VIEWS
		DynamoDB now supports tagging tables when you create them in the AWS GovCloud (US) Regions	carlos@example.com	5	30

Advantages

- Simpler to design for those who aren't used to working with single table design
- Easier implementation of GraphQL resolvers due to each resolver mapping to a single entity(table)

- Allows for unique data requirements across different entity types:
 - Backups can be made for the individual tables that are mission critical
 - Table encryption can be managed for each table. For multi-tenant applications with individual tenant encryption requirements, separate tenant tables make it possible for each customer to have their own encryption key
 - Infrequent Access Storage Class can be enabled on just the tables with historical data to realize the full cost savings benefit. For more information, see [Table classes](#)
- Each table will have its own change data stream allowing for a dedicated Lambda function to be designed for each type of item rather than a single monolithic processor

Disadvantages

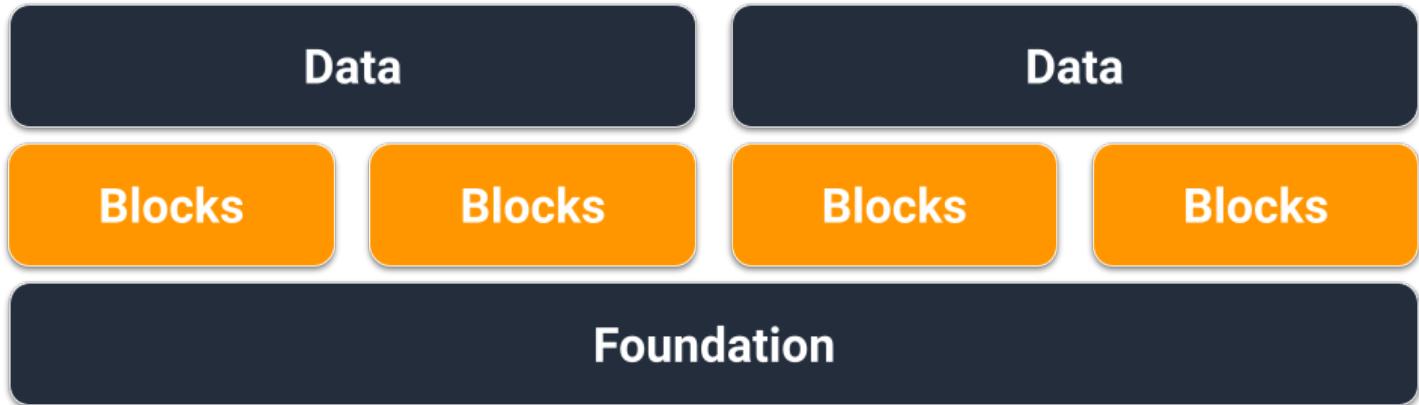

- For access patterns that require data across multiple tables, multiple reads from DynamoDB will be required and data may need to be processed/joined on the client code.
- Operations and monitoring of multiple tables requires more CloudWatch alarms and each table must be scaled independently
- Each table's permissions will need to be managed separately. The addition of tables in the future will require a change to any necessary IAM roles or policies

When to use

If your application's access patterns do not have the need to query multiple entities or tables together, then multiple table design is a good and sufficient approach.

Data modeling building blocks in DynamoDB

This section covers the building block layer to give you design patterns you can use in your application.

Topics

- [Composite sort key building block](#)
- [Multi-tenancy building block](#)
- [Sparse index building block](#)
- [Time to live building block](#)
- [Time to live for archival building block](#)
- [Vertical partitioning building block](#)
- [Write sharding building block](#)

Composite sort key building block

When people think of NoSQL, they may also think of it as non-relational. Ultimately, there is no reason relationships cannot be placed into a DynamoDB schema, they just look different than relational databases and their foreign keys. One of the most critical patterns we can use to develop a logical hierarchy of our data in DynamoDB is a composite sort key. The most common style for designing one is with each layer of the hierarchy (parent layer > child layer > grandchild layer) separated by a hashtag. For example, PARENT#CHILD#GRANDCHILD#ETC.

Primary key	
Partition key: PK	Sort key: SK
UserID	CART#ACTIVE#Apples
	CART#ACTIVE#Bananas
	CART#SAVED#Oranges
	CART#SAVED#Pears
	WISH#VEGGIES#Carrots

While a partition key in DynamoDB always requires the exact value to query for data, we can apply a partial condition to the sort key from left to right similar to traversing a binary tree.

In the example above, we have an e-Commerce store with a Shopping Cart that needs to be maintained across user sessions. Whenever the user logs in, they may want to see the entire Shopping Cart including items saved for later. But when they enter the checkout, only items in the active cart should be loaded for purchase. Since both of these KeyConditions explicitly ask for CART sort keys, the additional wishlist data is simply ignored by DynamoDB at read time. While both saved and active items are a part of the same cart, we need to treat them differently in different parts of the application, so applying a KeyCondition to the prefix of the sort key is the most optimized way of retrieving only the data needed for each part of the application.

Key features of this building block

- Related items are stored locally to each other for effective data access
- Using KeyCondition expressions, subsets of the hierarchy can be selectively retrieved meaning there are no wasted RCUs
- Different parts of the application can store their items under a specific prefix preventing overwritten items or conflicting writes

Multi-tenancy building block

Many customers use DynamoDB to host data for their multi-tenant applications. For these scenarios, we want to design the schema in a way that keeps all data from a single tenant in its own logical partition of the table. This leverages the concept of an Item Collection, which is a

term for all items in a DynamoDB table with the same partition key. For more information on how DynamoDB approaches multitenancy, see [Multitenancy on DynamoDB](#).

Primary key		Attributes
Partition key: PK	Sort key: SK	
UserOne	PhotoID1	ImageURL https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
	PhotoID2	ImageURL https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserTwo	PhotoID3	ImageURL https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
	PhotoID4	ImageURL https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]
UserThree	PhotoID5	ImageURL https://s3.amazonaws.com/[BUCKET-NAME]/[FILE-NAME].[FILE-TYPE]

For this example, we are running a photo hosting site with potentially thousands of users. Each user will only upload photos to their own profile initially, but by default we will not allow a user to see the photos of any other user. An additional level of isolation would ideally be added to the authorization of each user's call to your API to ensure they are only requesting data from their own partition, but at the schema level, unique partition keys is adequate.

Key features of this building block

- The amount of data read by any one user or tenant can only be as much as the total amount of items in their partition
- Removal of a tenant's data due to an account closure or compliance request can be done tactfully and cheaply. Simply run a query where the partition key equals their tenant ID, then execute a `DeleteItem` operation for each primary key returned

Note

Designed with multi-tenancy in mind, you can use different encryption key providers across a single table to safely isolate data. [AWS Database Encryption SDK](#) for Amazon DynamoDB enables you to include client-side encryption in your DynamoDB workloads. You can perform attribute-level encryption, enabling you to encrypt specific attribute values

before storing them in your DynamoDB table and search on encrypted attributes without decrypting the entire database beforehand.

Sparse index building block

Sometimes an access pattern requires looking for items that match a rare item or an item that receives a status (which requires an escalated response). Rather than regularly query across the entire dataset for these items, we can leverage the fact that **global secondary indexes (GSI)** are sparsely loaded with data. This means that only items in the base table that have the attributes defined in the index will be replicated to the index.

Primary key		Attributes

			EscalatedTo
			Sara

Primary key		Attributes	
Partition key: EscalatedTo	Sort key: State#Date	DeviceID	Operator
Sara	WARNING4#2020-04-27T16:15:00	d#11223	Sue

In this example, we see an IOT use case where each device in the field is reporting back a status on a regular basis. For the majority of the reports we expect the device to report everything is okay, but on occasion there can be a fault and it must be escalated to a repair technician. For reports with an escalation, the attribute EscalatedTo is added the item, but is not present otherwise. The GSI in this example is partitioned by EscalatedTo and since the GSI brings over keys from the base table we can still see which DeviceID reported the fault and at what time.

While reads are cheaper than writes in DynamoDB, sparse indexes are a very powerful tool for use cases where instances of a specific type of item is rare but reads to find them are common.

Key features of this building block

- Write and storage costs for the sparse GSI only apply to items that match the key pattern, so the cost of the GSI can be substantially less than other GSIs that have all items replicated to them
- A composite sort key can still be used to further narrow down the items that match the desired query, for instance, a timestamp could be used for the sort key to only view faults reported in the last X minutes (SK > 5 minutes ago, ScanIndexForward: False)

Time to live building block

Most data have some duration of time for which it can be considered worth keeping in a primary datastore. To facilitate data aging out from DynamoDB, it has a feature called **time to live (TTL)**. The [TTL](#) feature allows you to define a specific attribute at the table level that needs monitoring for items with an epoch timestamp (that's in the past). This allows you to delete expired records from the table for free.

 **Note**

If you are using [Global Tables version 2019.11.21 \(Current\)](#) of global tables and you also use the [Time to Live](#) feature, DynamoDB replicates TTL deletes to all replica tables. The initial TTL delete does not consume write capacity in the Region in which the TTL expiry occurs. However, the replicated TTL delete to the replica table(s) consumes replicated write capacity in each of the replica Regions and applicable charges will apply.

UserID	2030-06-30T12:12:12	TTL	Message
		1909570332	Hello
	2030-06-30T12:17:22	TTL	Message
		1909570647	DynamoDB
	2030-06-30T12:22:27	TTL	Message
		1909570947	TTL

In this example, we have an application designed to let a user create messages that are short-lived. When a message is created in DynamoDB, the TTL attribute is set to a date seven days in the future by the application code. In roughly seven days, DynamoDB will see that the epoch timestamp of these items is in the past and delete them.

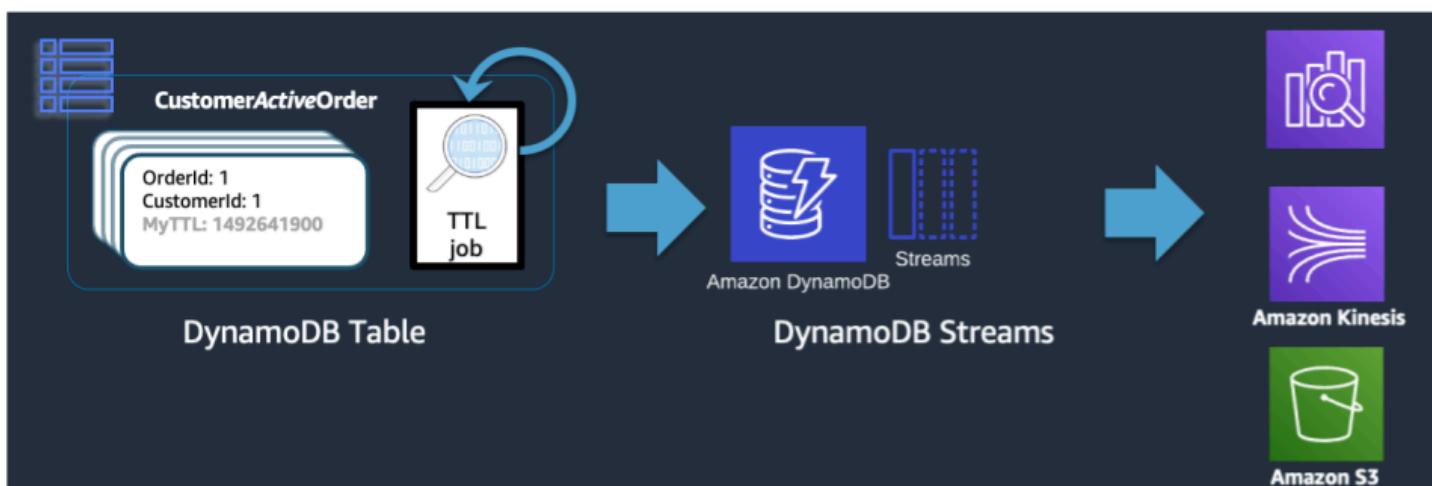

Since the deletes done by TTL are free, it is strongly recommended to use this feature to remove historical data from the table. This will reduce the overall storage bill each month and will likely reduce the costs of user reads since there will be less data to be retrieved by their queries. While TTL is enabled at the table level, it is up to you which items or entities to create a TTL attribute for and how far into the future to set the epoch timestamp to.

Key features of this building block

- TTL deletes are run behind the scenes with no impact to your table performance
- TTL is an asynchronous process that runs roughly every six hours, but can take over 48 hours for an expired record to be deleted
 - Do not rely on TTL deletes for use cases like lock records or state management if stale data must be cleaned up in less than 48 hours
- You can name the TTL attribute a valid attribute name, but the value must be a number type

Time to live for archival building block

While TTL is an effective tool for deleting older data from DynamoDB, many use cases require an archive of the data be kept for a longer period of time than the primary datastore. In this instance, we can leverage TTL's timed deletion of records to push expired records into a long-term datastore.

When a TTL delete is done by DynamoDB, it is still pushed into the DynamoDB Stream as a Delete event. When DynamoDB TTL is the one who performs the delete though, there is an attribute on the stream record of `principal:dynamodb`. Using a Lambda subscriber to the DynamoDB Stream, we can apply an event-filter for only the DynamoDB principal attribute and know that any records that match that filter are to be pushed to an archival store like S3 Glacier.

Key features of this building block

- Once the low-latency reads of DynamoDB are no longer needed for the historical items, migrating them to a colder storage service like S3 Glacier can reduce storage costs significantly while meeting the data compliance needs of your use case
- If the data is persisted into Amazon S3, cost-efficient analytics tools like Amazon Athena or Redshift Spectrum can be used to perform historical analysis of the data

Vertical partitioning building block

Users familiar with a document model database will be familiar with the idea of storing all related data within a single JSON document. While DynamoDB supports JSON data types, it does not support executing KeyConditions on nested JSON. Since KeyConditions are what dictate how much data is read from disk and effectively how many RCUs a query consumes, this can result in inefficiencies at scale. To better optimize the writes and reads of DynamoDB, we recommend breaking apart the document's individual entities into individual DynamoDB items, also referred to as **vertical partitioning**.

```
{  
    "UserProfile" : {  
        "FirstName": "Paul",  
        "LastName": "Atreides",  
        "DateJoined": "1965-08-01"},  
    "Store" : {  
        "store_id": "STOREUID",  
        "city": "Los Angeles",  
        "zip_code": "90029"}  
    "ShoppingCart" : [  
        {"Spice":  
            { "SKU": "SpicesSKU",  
                "CategoryID": "FictionalSpice",  
                "DateAdded": "2019-06-11"}},  
        {"EspressoBeans":  
            { "SKU": "CaffeineSKU",  
                "CategoryID": "FOODANDDRINK",  
                "DateAdded": "2019-06-10"}}],  
    "ShippingAddress" : {  
        "street_address": "1234 Arrakis Dr",  
        "city": "Los Angeles",  
        "zip_code": "90029",  
        "status": "default"}  
    "OrderHistory#OrderUID" : {  
        "ProductA": "SKU_A",  
        "ProductB": "SKU_B",  
        "DateOrdered": "2018-09-28"}  
}
```

Primary key		Attributes

Vertical partitioning, as shown above, is a key example of single table design in action but can also be implemented across multiple tables if desired. Since DynamoDB bills writes in 1KB increments, you should ideally partition the document in a way that results in items under 1KB.

Key features of this building block

- A hierarchy of data relationships is maintained via sort key prefixes so the singular document structure could be rebuilt client-side if needed
- Singular components of the data structure can be updated independently resulting in small item updates being only 1 WCU
- By using the sort key `BeginsWith`, the application can retrieve similar data in a single query, aggregating read costs for reduced total cost/latency
- Large documents can easily be larger than the 400 KB individual item size limit in DynamoDB and vertical partitioning helps work around this limit

Write sharding building block

One of the very few hard limits DynamoDB has in place is the restriction of how much throughput a single physical partition can maintain per second (not necessarily a single partition key). These limits are presently:

- 1000 WCU (or 1000 <=1KB items written per second) and 3000 RCU (or 3000 <=4KB reads per second) *strongly consistent* or
- 6000 <=4KB reads per second *eventually consistent*

In the event requests against the table exceed either of these limits, an error is sent back to the client SDK of `ThroughputExceededException`, more commonly referred to as throttling. Use cases that require read operations beyond that limit will mostly be served best by placing a read cache in front of DynamoDB, but write operations require a schema level design known as **write sharding**.

Primary Key	Attributes	
Partition Key: Candidate		
CandidateA#1	Vote-Counter	Last-Update
	10238	2019-09-30T11:35:53
CandidateA#2	Vote-Counter	Last-Update
	8452	2019-09-30T11:35:53
CandidateA#3	Vote-Counter	Last-Update
	9148	2019-09-30T11:35:53
CandidateA#4	Vote-Counter	Last-Update
	11092	2019-09-30T11:35:53

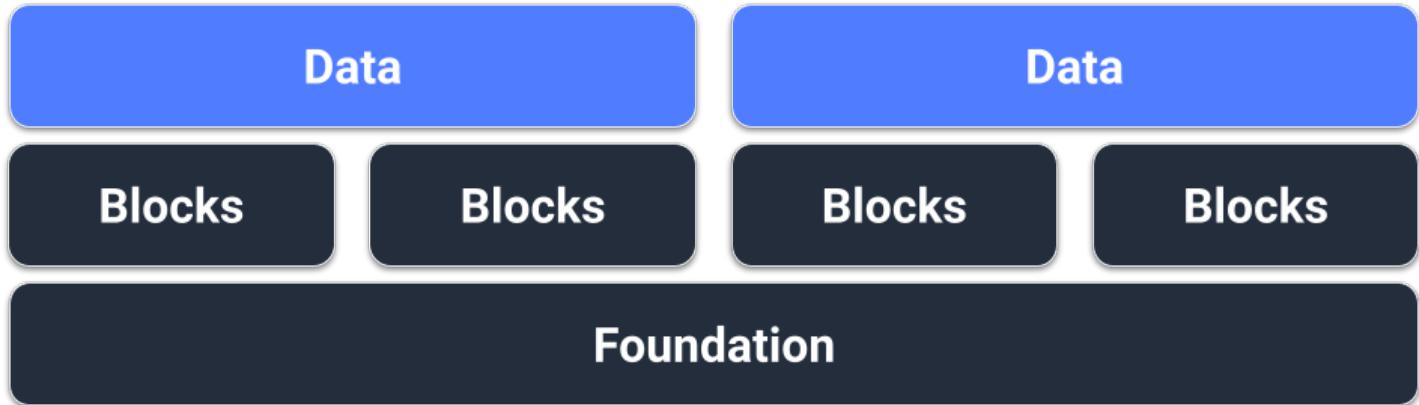

To solve this problem, we'll append a random integer onto the end of the partition key for each contestant in the application's `UpdateItem` code. The range of the random integer generator will need to have an upper bound matching or exceeding the expected amount of writes per second for a given contestant divided by 1000. To support 20,000 votes per second, it would look like `rand(0,19)`. Now that the data is stored under separate logical partitions, it must be combined back together at read time. Since vote totals doesn't need to be real time, a Lambda function scheduled to read all vote partitions every X minutes could perform occasional aggregation for each contestant and write it back to a single vote total record for live reads.

Key features of this building block

- For use cases with extremely high write throughput for a given partition key that cannot be avoided, write operations can be artificially spread across multiple DynamoDB partitions
- GSI with a low cardinality partition key should also utilize this pattern since throttling on a GSI will apply backpressure to write operations on the base table

Data modeling schema design packages in DynamoDB

This section covers the data layer to go over different examples you can use in your DynamoDB table design. Each example will go over their use case, access patterns, how to achieve the access patterns, and then what the final schema will look like.

Prerequisites

Before we attempt to design our schema for DynamoDB, we must first gather some prerequisite data on the use case the schema needs to support. Unlike relational databases, DynamoDB is sharded by default, meaning that the data will live on multiple servers behind the scenes so designing for data locality is important. We'll need to put together the following list for each schema design:

- List of entities (ER Diagram)
- Estimated volumes and throughput for each entity
- Access patterns that need to be supported (queries and writes)
- Data retention requirements

Topics

Social network schema design in DynamoDB

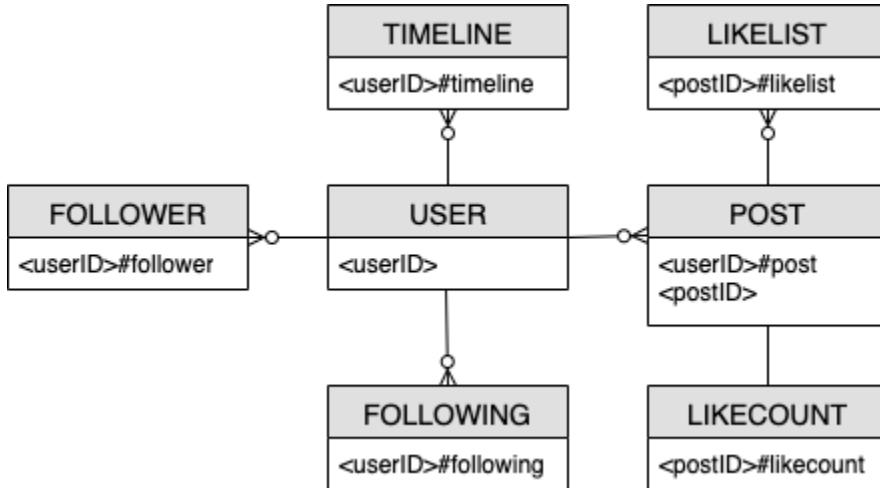

Social network business use case

This use case talks about using DynamoDB as a social network. A social network is an online service that lets different users interact with each other. The social network we'll design will let the user see a timeline consisting of their posts, their followers, who they are following, and the posts written by who they are following. The access patterns for this schema design are:

- Get user information for a given userID
- Get follower list for a given userID
- Get following list for a given userID
- Get post list for a given userID
- Get user list who likes the post for a given postID
- Get the like count for a given postID
- Get the timeline for a given userID

Social network entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the social network schema design.

Social network access patterns

These are the access patterns we'll be considering for the social network schema design.

- `getUserInfoByUserID`

- `getFollowerListByUserID`
- `getFollowingListByUserID`
- `getPostListByUserID`
- `getUserLikesByPostID`
- `getLikeCountByPostID`
- `getTimelineByUserID`

Social network schema design evolution

DynamoDB is a NoSQL database, so it does not allow you to perform a join - an operation that combines data from multiple databases. Customers unfamiliar with DynamoDB might apply relational database management system (RDBMS) design philosophies (such as creating a table for each entity) to DynamoDB when they do not need to. The purpose of DynamoDB's single-table design is to write data in a pre-joined form according to the application's access pattern, and then immediately use the data without additional computation. For more information, see [Single-table vs. multi-table design in DynamoDB](#).

Now, let's step through how we'll evolve our schema design to address all the access patterns.

Step 1: Address access pattern 1 (`getUserInfoByUserID`)

To get a given user's information, we'll need to [Query](#) the base table with a key condition of `PK=<userID>`. The query operation lets you paginate the results, which can be useful when a user has many followers. For more information on Query, see [Query operations in DynamoDB](#).

In our example, we track two types of data for our user: their "count" and their "info." A user's "count" reflects how many followers they have, how many users they are following, and how many posts they've created. A user's "info" reflects their personal information such as their name.

We see these two kinds of data represented by the two items below. The item that has "count" in its sort key (SK) is more likely to change than the item with "info." DynamoDB considers the size of the item as it appears before and after the update and the provisioned throughput consumed will reflect the larger of these item sizes. So even if you update just a subset of the item's attributes, [UpdateItem](#) will still consume the full amount of provisioned throughput (the larger of the before and after item sizes). You can get the items via a single Query operation and use `UpdateItem` to add or subtract from existing numeric attributes.

Primary key		Attributes			
Partition key: PK	Sort key: SK	follower#	following#	post#	
u#12345	"count"	3000000000	971	4945	
		hyuklee	My name is Hyuk Lee	s3://....	...
	"info"	name	content	imageUrl	etc
		hyuklee			

Step 2: Address access pattern 2 (getFollowerListByUserID)

To get a list of users who are following a given user, we'll need to Query the base table with a key condition of `PK=<userID>#follower`.

Primary key		Attributes			
Partition key: PK	Sort key: SK	follower#	following#	post#	
u#12345	"count"	3000000000	971	4945	
		hyuklee	My name is Hyuk Lee	s3://....	...
	"info"	name	content	imageUrl	etc
		hyuklee			
u#12345#follower	u#23456 u#34567 u#45678				

Step 3: Address access pattern 3 (getFollowingListByUserID)

To get a list of users a given user is following, we'll need to Query the base table with a key condition of `PK=<userID>#following`. You can then use a [TransactWriteItems](#) operation group up several requests together and do the following:

- Add User A to User B's follower list, and then increment User B's follower count by one
- Add User B to User A's follower list, and then increment User A's follower count by one

Primary key		Attributes			
Partition key: PK	Sort key: SK	follower#	following#	post#	
u#12345	"count"	3000000000	971	4945	
		hyuklee	My name is Hyuk Lee	s3://....	etc
	"info"	u#23456			
		u#34567			
u#12345#follower	u#45678				
	u#56789				
	u#67890				
	u#78912				
u#12345#following	u#23456				
	u#34567				
	u#45678				
	u#56789				
u#12345#post	u#67890				
	u#78912				

Step 4: Address access pattern 4 (getPostListByUserID)

To get a list of posts created by a given user, we'll need to Query the base table with a key condition of `PK=<userID>#post`. One important thing to note here is that a user's postIDs must be incremental: the second postID value must be greater than the first postID value (since users want to see their posts in a sorted manner). You can do this by generating postIDs based on a time value like a Universally Unique Lexicographically Sortable Identifier (ULID).

Primary key		Attributes			
Partition key: PK	Sort key: SK	follower#	following#	post#	
u#12345	"count"	3000000000	971	4945	
		hyuklee	My name is Hyuk Lee	s3://....	etc
	"info"	u#23456			
		u#34567			
u#12345#follower	u#45678				
	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
	p#12345	content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	

Step 5: Address access pattern 5 (getUserLikesByPostID)

To get a list of users who liked a given user's post, we'll need to Query the base table with a key condition of `PK=<postID>#likelist`. This approach is the same pattern that we used for retrieving the follower and following lists in access pattern 2 (`getFollowerListByUserID`) and access pattern 3 (`getFollowingListByUserID`).

Primary key		Attributes			
Partition key: PK	Sort key: SK				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				

Step 6: Address access pattern 6 (`getLikeCountByPostID`)

To get a count of likes for a given post, we'll need to perform a [GetItem](#) operation on the base table with a key condition of `PK=<postID>#likecount`. This access pattern can cause throttling issues whenever a user with many followers (such as a celebrity) creates a post since throttling occurs when a partition's throughput exceeds 1000 WCU per second. This problem is not a result of DynamoDB, it just appears in DynamoDB since it's at the end of the software stack.

You should evaluate whether it's really essential for all users to view the like count simultaneously or if it can happen gradually over time. In general, a post's like count doesn't need to be immediately 100% accurate. You can implement this strategy by putting a queue between your application and DynamoDB to have the updates happen periodically.

Primary key		Attributes			
Partition key: PK	Sort key: SK	follower#	following#	post#	
u#12345	"count"	3000000000	971	4945	
		hyuklee	My name is Hyuk Lee	s3://....	etc
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				
p#12345#likecount	"count"	etc			
		100			

Step 7: Address access pattern 7 (getTimelineByUserID)

To get the timeline for a given user, we'll need to perform a Query operation on the base table with a key condition of `PK=<userID>#timeline`. Let's consider a scenario where a user's followers need to view their post synchronously. Every time a user writes a post, their follower list is read and their userID and postID are slowly entered into the timeline key of all its followers. Then, when your application starts, you can read the timeline key with the Query operation and fill the timeline screen with a combination of userID and postID using the [BatchGetItem](#) operation for any new items. You cannot read the timeline with an API call, but this is a more cost effective solution if the posts could be edited frequently.

The timeline is a place that shows recent posts, so we'll need a way to clean up the old ones. Instead of using WCU to delete them, you can use DynamoDB's [TTL](#) feature to do it for free.

Primary key		Attributes			
Partition key: PK	Sort key: SK				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
u#12345#follower	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#following	u#23456				
	u#34567				
	u#45678				
u#12345#post	u#56789				
	u#67890				
	u#78912				
p#12345#likelist	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likecount	u#23456				
	u#34567				
	u#45678				
p#12345#timeline	"count"	etc			
		100			
	p#34567#u#56789	ttl			
		1571827560			
	p#45678#u#67890	ttl			
		1571827560			
	p#56789#u#78901	ttl			
		1571827560			

All access patterns and how the schema design addresses them are summarized in the table below:

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getUserInfoByUserID	Base table	Query	PK=<userID>		

Access pattern	Base table/ GSI/LSI	Operation	Partition key value	Sort key value	Other conditions/ filters
getFollow erListByU serID	Base table	Query	PK=<userl D>#follower		
getFollow ingListBy UserID	Base table	Query	PK=<userl D>#following		
getPostLi stByUserID	Base table	Query	PK=<userl D>#post		
getUserLi kesByPostID	Base table	Query	PK=<postl D>#likelist		
getLikeCo untByPostID	Base table	GetItem	PK=<postl D>#likecount		
getTimeli neByUserID	Base table	Query	PK=<userl D>#timeline		

Social network final schema

Here is the final schema design. To download this schema design as a JSON file, see [DynamoDB Examples](#) on GitHub.

Base table:

Primary key		Attributes			
Partition key: PK	Sort key: SK				
u#12345	"count"	follower#	following#	post#	
		3000000000	971	4945	
	"info"	name	content	imageUrl	etc
		hyuklee	My name is Hyuk Lee	s3://....	...
u#12345#follower	u#23456				
	u#34567				
	u#45678				
u#12345#following	u#56789				
	u#67890				
	u#78912				
u#12345#post	p#12345	content	imageUrl	timestamp	
		content for a post	s3://....	1571827560	
	p#23456	content	imageUrl	timestamp	
		content for a post	s3://....	1571827561	
p#12345#likelist	u#23456				
	u#34567				
	u#45678				
p#12345#likecount	"count"	etc			
		100			
u#12345#timeline	p#34567#u#56789	ttl			
		1571827560			
	p#45678#u#67890	ttl			
		1571827560			
	p#56789#u#78901	ttl			
		1571827560			

Using NoSQL Workbench with this schema design

You can import this final schema into [NoSQL Workbench](#), a visual tool that provides data modeling, data visualization, and query development features for DynamoDB, to further explore and edit your new project. Follow these steps to get started:

1. Download NoSQL Workbench. For more information, see [the section called “Download”](#).
2. Download the JSON schema file listed above, which is already in the NoSQL Workbench model format.
3. Import the JSON schema file into NoSQL Workbench. For more information, see [the section called “Importing an existing model”](#).

4. Once you've imported into NOSQL Workbench, you can edit the data model. For more information, see [the section called "Editing an existing model"](#).
5. To visualize your data model, add sample data, or import sample data from a CSV file, use the [Data Visualizer](#) feature of NoSQL Workbench.

Gaming profile schema design in DynamoDB

Gaming profile business use case

This use case talks about using DynamoDB to store player profiles for a gaming system. Users (in this case, players) need to create profiles before they can interact with many modern games, especially online ones. Gaming profiles typically include the following:

- Basic information such as their user name
- Game data such as items and equipment
- Game records such as tasks and activities
- Social information such as friend lists

To meet the fine-grained data query access requirements for this application, the primary keys (partition key and sort key) will use generic names (PK and SK) so they can be overloaded with various types of values as we will see below.

The access patterns for this schema design are:

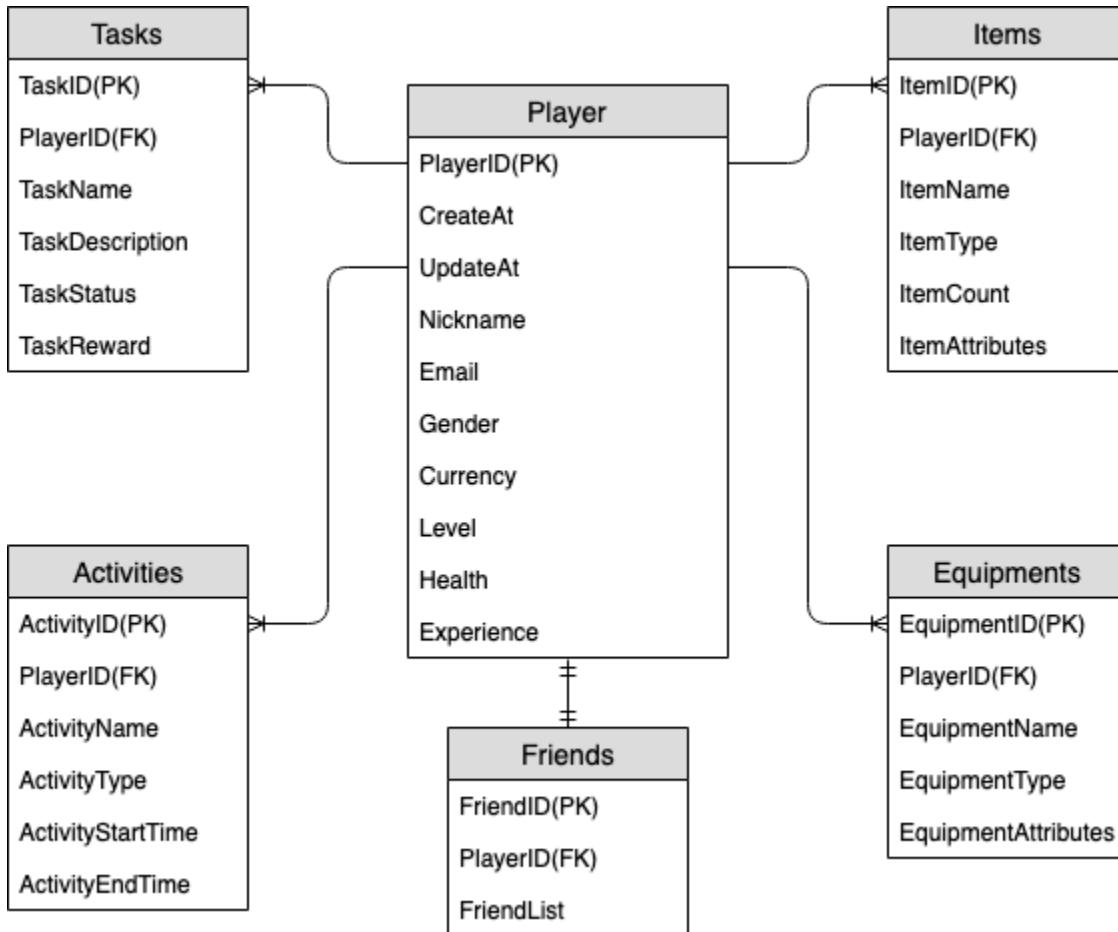

- Get a user's friend list
- Get all of a player's information
- Get a user's item list
- Get a specific item from the user's item list
- Update a user's character
- Update the item count for a user

The size of the gaming profile will vary in different games. [Compressing large attribute values](#) can let them fit within item limits in DynamoDB and reduce costs. The throughput management strategy would depend various on factors such as: number of players, number of games played

per second, and seasonality of the workload. Typically for a newly launched game, the number of players and the level of popularity are unknown so we will start with the [on-demand throughput mode](#).

Gaming profile entity relationship diagram

This is the entity relationship diagram (ERD) we'll be using for the gaming profile schema design.

Gaming profile access patterns

These are the access patterns we'll be considering for the social network schema design.

- getPlayerFriends
- getPlayerAllProfile
- getPlayerAllItems
- getPlayerSpecificItem
- updateCharacterAttributes

- updateItemCount

Gaming profile schema design evolution

From the above ERD, we can see that this is a one-to-many relationship type of data modeling. In DynamoDB, one-to-many data models can be organized into item collections, which is different from traditional relational databases where multiple tables are created and linked through foreign keys. An [item collections](#) is a group of items that share the same partition key value but have different sort key values. Within an item collection, each item has a unique sort key value that distinguishes it from other items. With this in mind, let's use the following pattern for HASH and RANGE values for each entity type.

To begin, we use generic names like PK and SK to store different types of entities in the same table to make the model future-proof. For better readability, we can include prefixes to denote the type of data or include an arbitrary attribute called Entity_type or Type. In the current example, we use a string starting with player to store player_ID as the PK; use entity_name# as the prefix of SK, and add a Type attribute to indicate which entity type this piece of data is. This allows us to support storing more entity types in the future, and use advanced technologies such as GSI Overloading and Sparse GSI to meet more access patterns.

Let's start implementing the access patterns. Access patterns such as adding players and adding equipment can be realized through the [PutItem](#) operation, so we can ignore them. In this document, we'll focus on the typical access patterns listed above.

Step 1: Address access pattern 1 (getPlayerFriends)

We address access pattern 1 (getPlayerFriends) with this step. In our current design, friendship is simple and the number of friends in the game is small. For simplicity's sake, we use a list data type to store friend lists (1:1 modeling). In this design, we use [GetItem](#) to satisfy this access pattern. In the GetItem operation, we explicitly provide the partition key and sort key value to get a specific item.

However, if a game has a large number of friends, and the relationships between them are complex (such as friendships being bi-directional with both an invite and accept component) it would be necessary to use a many-to-many relationship to store each friend individually, in order to scale to an unlimited friend list size. And if the friendship change involves operating on multiple items at the same time, DynamoDB transactions can be used to group multiple actions together and submit them as a single all-or-nothing [TransactWriteItems](#) or [TransactGetItems](#) operation.
