What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides on-demand, scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 reduces hardware costs so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. You can add capacity (scale up) to handle compute-heavy tasks, such as monthly or yearly processes, or spikes in website traffic. When usage decreases, you can reduce capacity (scale down) again.

The following diagram shows a basic architecture of an Amazon EC2 instance deployed within an Amazon Virtual Private Cloud (VPC). In this example, the EC2 instance is within an Availability Zone in the Region. The EC2 instance is secured with a security group, which is a virtual firewall that controls incoming and outgoing traffic. A private key is stored on the local computer and a public key is stored on the instance. Both keys are specified as a key pair to prove the identity of the user. In this scenario, the instance is backed by an Amazon EBS volume. The VPC communicates with the internet using an internet gateway. For more information about Amazon VPC, see the [Amazon VPC User Guide](#).

Tip

This user guide provides information specific to running Linux-based instances on Amazon EC2. See the [EC2 User Guide for Windows Instances](#) for information to help you run Windows-based instances on EC2.

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see [PCI DSS Level 1](#).

If you are looking for technical guidance about Amazon EC2, try [AWS re:Post](#).

Features of Amazon EC2

Amazon EC2 provides the following high-level features:

Instances

Virtual servers.

Amazon Machine Images (AMIs)

Preconfigured templates for your instances that package the components you need for your server (including the operating system and additional software).

Instance types

Various configurations of CPU, memory, storage, networking capacity, and graphics hardware for your instances.

Key pairs

Secure login information for your instances. AWS stores the public key and you store the private key in a secure place.

Instance store volumes

Storage volumes for temporary data that is deleted when you stop, hibernate, or terminate your instance.

Amazon EBS volumes

Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS).

Regions, Availability Zones, Local Zones, AWS Outposts, and Wavelength Zones

Multiple physical locations for your resources, such as instances and Amazon EBS volumes.

Security groups

A virtual firewall that allows you to specify the protocols, ports, and source IP ranges that can reach your instances, and the destination IP ranges to which your instances can connect.

Elastic IP addresses

Static IPv4 addresses for dynamic cloud computing.

Tags

Metadata that you can create and assign to your Amazon EC2 resources.

Virtual private clouds (VPCs)

Virtual networks you can create that are logically isolated from the rest of the AWS Cloud. You can optionally connect these virtual networks to your own network.

For details about all of the features of Amazon EC2, see [Amazon EC2 features](#).

For options to run your website on AWS, see [Web Hosting](#).

Get started with Amazon EC2

The following topics can help you get started with Amazon EC2. After you set up to use EC2, you can walk through [Tutorial: Get started with Amazon EC2 Linux instances](#) to launch, connect to, and

clean up an instance. The remaining topics point to more information about the high-level features of EC2.

Related services

You can provision Amazon EC2 resources, such as instances and volumes, directly using Amazon EC2. In addition, you can provision EC2 resources using other AWS services, such as the following:

- [Amazon EC2 Auto Scaling](#)

Helps ensure you have the correct number of Amazon EC2 instances available to handle the load for your application.

- [AWS CloudFormation](#)

Helps you model and set up your AWS resources using templates.

- [AWS Elastic Beanstalk](#)

Deploy and manage applications in the AWS Cloud without having to understand the underlying infrastructure.

- [AWS OpsWorks](#)

Automate how servers are configured, deployed, and managed across your Amazon EC2 instances using Chef and Puppet.

- [EC2 Image Builder](#)

Automate the creation, management, and deployment of customized, secure, and up-to-date server images.

- [AWS Launch Wizard](#)

Size, configure, and deploy AWS resources for third-party applications without having to manually identify and provision individual AWS resources.

Additional related services

- [Amazon Lightsail](#)

To build websites or web applications, you can deploy and manage basic cloud resources using Amazon Lightsail. To compare the features of Amazon EC2 and Lightsail for your use case, see [Amazon Lightsail or Amazon EC2](#).

- [Elastic Load Balancing](#)

Automatically distribute incoming application traffic across multiple instances.

- [Amazon Relational Database Service \(Amazon RDS\)](#)

Set up, operate, and scale a managed relational database in the cloud. Although you can set up a database on an EC2 instance, Amazon RDS offers the advantage of handling your database management tasks, such as patching the software, backing up, and storing the backups.

- [Amazon Elastic Container Service \(Amazon ECS\)](#)

Deploy, manage, and scale containerized applications on a cluster of EC2 instances.

- [Amazon Elastic Kubernetes Service \(Amazon EKS\)](#)

Run your Kubernetes applications on AWS.

- [Amazon CloudWatch](#)

Monitor your instances and Amazon EBS volumes.

- [Amazon GuardDuty](#)

Detect potentially unauthorized or malicious use of your EC2 instances.

- [AWS Backup](#)

Automate backing up your Amazon EC2 instances and the Amazon EBS volumes attached to them.

Access Amazon EC2

You can create and manage your Amazon EC2 instances using the following interfaces:

Amazon EC2 console

A simple web interface to create and manage Amazon EC2 instances and resources. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting **EC2** from the console home page.

AWS Command Line Interface

Enables you to interact with AWS services using commands in your command-line shell. It is supported on Windows, Mac, and Linux. For more information about the AWS CLI , see [AWS Command Line Interface User Guide](#). You can find the Amazon EC2 commands in the [AWS CLI Command Reference](#).

AWS Tools for PowerShell

A set of PowerShell modules that are built on the functionality exposed by the AWS SDK for .NET. The Tools for PowerShell enable you to script operations on your AWS resources from the PowerShell command line. To get started, see the [AWS Tools for Windows PowerShell User Guide](#). You can find the cmdlets for Amazon EC2, in the [AWS Tools for PowerShell Cmdlet Reference](#).

AWS CloudFormation

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML format, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about supported resource types and properties for Amazon EC2, see [EC2 resource type reference](#) in the *AWS CloudFormation User Guide*.

Query API

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named Action. For more information about the API actions for Amazon EC2, see [Actions](#) in the *Amazon EC2 API Reference*.

AWS SDKs

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it easier for you to get started. For more information, see [Tools to Build on AWS](#).

Pricing for Amazon EC2

Amazon EC2 provides the following pricing options:

Free Tier

You can get started with Amazon EC2 for free. To explore the Free Tier options, see [AWS Free Tier](#).

On-Demand Instances

Pay for the instances that you use by the second, with a minimum of 60 seconds, with no long-term commitments or upfront payments.

Savings Plans

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

Reserved Instances

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

Spot Instances

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

Dedicated Hosts

Reduce costs by using a physical EC2 server that is fully dedicated for your use, either On-Demand or as part of a Savings Plan. You can use your existing server-bound software licenses and get help meeting compliance requirements.

On-Demand Capacity Reservations

Reserve compute capacity for your EC2 instances in a specific Availability Zone for any duration of time.

Per-second billing

Removes the cost of unused minutes and seconds from your bill.

For a complete list of charges and prices for Amazon EC2 and more information about the purchase models, see [Amazon EC2 pricing](#).

Estimates, billing, and cost optimization

To create estimates for your AWS use cases, use the [AWS Pricing Calculator](#).

To see your bill, go to the **Billing and Cost Management Dashboard** in the [AWS Billing and Cost Management console](#). Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see [AWS Billing and Cost Management User Guide](#).

If you have questions concerning AWS billing, accounts, and events, [contact AWS Support](#).

To calculate the cost of a sample provisioned environment, see [Cloud Economics Center](#). When calculating the cost of a provisioned environment, remember to include incidental costs such as snapshot storage for EBS volumes.

You can optimize the cost, security, and performance of your AWS environment using [AWS Trusted Advisor](#).

Set up to use Amazon EC2

Complete the tasks in this section to get set up for launching an Amazon EC2 instance for the first time:

1. [Sign up for an AWS account](#)
2. [Create an administrative user](#)
3. [Create a key pair](#)
4. [Create a security group](#)

When you are finished, you will be ready for the [Amazon EC2 Getting started](#) tutorial.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create an administrative user

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create an administrative user

1. Enable IAM Identity Center.

For instructions, see [Enabling AWS IAM Identity Center](#) in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to an administrative user.

For a tutorial about using the IAM Identity Center directory as your identity source, see [Configure user access with the default IAM Identity Center directory](#) in the *AWS IAM Identity Center User Guide*.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Create a key pair

AWS uses public-key cryptography to secure the login information for your instance. A Linux instance has no password; you use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your instance, then provide the private key when you log in using SSH.

If you haven't created a key pair already, you can create one by using the Amazon EC2 console. Note that if you plan to launch instances in multiple AWS Regions, you'll need to create a key pair in each Region. For more information about Regions, see [Regions and Zones](#).

To create your key pair

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Create key pair**.
4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
5. For **Key pair type**, choose either **RSA** or **ED25519**. Note that **ED25519** keys are not supported for Windows instances.
6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.
7. Choose **Create key pair**.
8. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is determined by the file format you chose. Save the private key file in a safe place.

 **Important**

This is the only chance for you to save the private key file.

9. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 key-pair-name.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see [Error: Unprotected private key file](#).

For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

Create a security group

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere.

Note that if you plan to launch instances in multiple AWS Regions, you'll need to create a security group in each Region. For more information about Regions, see [Regions and Zones](#).

Prerequisites

You'll need the public IPv4 address of your local computer. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address for you. Alternatively, you can use the search phrase "what is my IP address" in an internet browser, or use the following service: [Check IP](#). If you are connecting through an Internet service provider (ISP) or from behind a firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

You can create a custom security group using one of the following methods.

Console

To create a security group with least privilege

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the top navigation bar, select an AWS Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your key pair.
3. In the left navigation pane, choose **Security Groups**.
4. Choose **Create security group**.

5. For **Basic details**, do the following:
 - a. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `me_SG_uswest2`.
 - b. In the **VPC** list, select your default VPC for the Region.
6. For **Inbound rules**, create rules that allow specific traffic to reach your instance. For example, use the following rules for a web server that accepts HTTP and HTTPS traffic. For more examples, see [Security group rules for different use cases](#).
 - a. Choose **Add rule**. For **Type**, choose **HTTP**. For **Source**, choose **Anywhere-IPv4** to allow inbound HTTP traffic from any IPv4 address, or **Anywhere-IPv6** to allow inbound HTTP traffic from any IPv6 address.
 - b. Choose **Add rule**. For **Type**, choose **HTTPS**. For **Source**, choose **Anywhere-IPv4** to allow inbound HTTPS traffic from any IPv4 address, or **Anywhere-IPv6** to allow inbound HTTPS traffic from any IPv6 address.
 - c. Choose **Add rule**. For **Type**, choose **SSH**. For **Source**, do one of the following:
 - Choose **My IP** to automatically add the public IPv4 address of your local computer.
 - Choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix `/32`, for example, `203.0.113.25/32`. If your company or your router allocates addresses from a range, specify the entire range, such as `203.0.113.0/24`.

 **Warning**

For security reasons, do not choose **Anywhere-IPv4** or **Anywhere-IPv6** for **Source** with a rule for SSH. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. For **Outbound rules**, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

AWS CLI

When you use the AWS CLI to create a security group, an outbound rule that allows all outbound traffic is automatically added to the security group. An inbound rule isn't automatically added; you'll need to add it.

In this procedure, you'll combine the [create-security-group](#) and [authorize-security-group-ingress](#) AWS CLI commands to create the security group and add the inbound rule that allows the specified inbound traffic. An alternative to the following procedure is to run the commands separately, first creating a security group, and then adding an inbound rule to the security group.

To create a security group and add an inbound rule to the security group

Use the [create-security-group](#) and [authorize-security-group-ingress](#) AWS CLI commands as follows:

```
aws ec2 authorize-security-group-ingress \
--region us-west-2 \
--group-id $(aws ec2 create-security-group \
--group-name myname_SG_uswest2 \
--description "Security group description" \
--vpc-id vpc-12345678 \
--output text \
--region us-west-2) \
--ip-permissions \
IpProtocol=tcp,FromPort=80,ToPort=80,IpRanges='[{"CidrIp=0.0.0.0/0,Description="HTTP from anywhere"}]' \
IpProtocol=tcp,FromPort=443,ToPort=443,IpRanges='[{"CidrIp=0.0.0.0/0,Description="HTTPS from anywhere"}]' \
IpProtocol=tcp,FromPort=22,ToPort=22,IpRanges='[{"CidrIp=172.31.0.0/16,Description="SSH from private network"}]' \
IpProtocol=tcp,FromPort=22,ToPort=22,IpRanges='[{"CidrIp=203.0.113.25/32,Description="SSH from public IP"}]'
```

For:

- **--region** – Specify the Region in which to create the inbound rules.

- **--group-id** – Specify the `create-security-group` command and the following parameters to create the security group:
 - **--group-name** – Specify a name for the new security group. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `myname_SG_uswest2`.
 - **--description** – Specify a description that will help you know what traffic the security group allows.
 - **--vpc-id** – Specify your default VPC for the Region.
 - **--output** – Specify text as the output format for the command.
 - **--region** – Specify the Region in which to create the security group. It should be the same Region that you specified for the inbound rules.
- **--ip-permissions** – Specify the inbound rules to add to the security group. The rules in this example are for a web server that accepts HTTP and HTTPS traffic from anywhere, and that accepts SSH traffic from a private network (if your company or your router allocates addresses from a range) and a specified public IP address (such as the public IPv4 address of your computer or network in CIDR notation).

⚠ Warning

For security reasons, do not specify `0.0.0.0/0` for `CidrIp` with a rule for SSH. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

PowerShell

When you use the AWS Tools for Windows PowerShell to create a security group, an outbound rule that allows all outbound traffic is automatically added to the security group. An inbound rule isn't automatically added; you'll need to add it.

In this procedure, you'll combine the [New-EC2SecurityGroup](#) and [Grant-EC2SecurityGroupIngress](#) AWS Tools for Windows PowerShell commands to create the security group and add the inbound rule that allows the specified inbound traffic. An alternative to the following procedure is to run the commands separately, first creating a security group, and then adding an inbound rule to the security group.

To create a security group

Use the [New-EC2SecurityGroup](#) and [Grant-EC2SecurityGroupIngress](#) AWS Tools for Windows PowerShell commands as follows.

```
Import-Module AWS.Tools.EC2
New-EC2SecurityGroup -GroupName myname_SG_uswest2 -Description 'Security group description' -VpcId vpc-12345678 -Region us-west-2 | ` 
    Grant-EC2SecurityGroupIngress ` 
        -GroupName $_ ` 
        -Region us-west-2 ` 
        -IpPermission @(
            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 80;
                ToPort     = 80;
                Ipv4Ranges = @(@{CidrIp = '0.0.0.0/0'; Description = 'HTTP from anywhere'})
            }),
            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 443;
                ToPort     = 443;
                Ipv4Ranges = @(@{CidrIp = '0.0.0.0/0'; Description = 'HTTPS from anywhere'})
            }),
            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 3389;
                ToPort     = 3389;
                Ipv4Ranges = @(
                    @{CidrIp = '172.31.0.0/16'; Description = 'RDP from private network'},
                    @{CidrIp = '203.0.113.25/32'; Description = 'RDP from public IP'}
                )
            })
        )
    )
```

For the security group:

- **-GroupName** – Specify a name for the new security group. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `myname_SG_uswest2`.
- **-Description** – Specify a description that will help you know what traffic the security group allows.
- **-VpcId** – Specify your default VPC for the Region.
- **-Region** – Specify the Region in which to create the security group.

For the inbound rules:

- **-GroupName** – Specify `$_` to reference the security group you're creating.
- **-Region** – Specify the Region in which to create the inbound rules. It should be the same Region that you specified for the security group.
- **-IpPermission** – Specify the inbound rules to add to the security group. The rules in this example are for a web server that accepts HTTP and HTTPS traffic from anywhere, and that accepts RDP traffic from a private network (if your company or your router allocates addresses from a range) and a specified public IP address (such as the public IPv4 address of your computer or network in CIDR notation).

 **Warning**

For security reasons, do not specify `0.0.0.0/0` for `CidrIp` with a rule for RDP. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

For more information, see [Amazon EC2 security groups for Linux instances](#).

Tutorial: Get started with Amazon EC2 Linux instances

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You'll learn how to launch, connect to, and use a Linux instance. An *instance* is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

When you sign up for AWS, you can get started with Amazon EC2 using the [AWS Free Tier](#). If you created your AWS account less than 12 months ago, and have not already exceeded the Free Tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial because we help you select options that are within the Free Tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle.

Related tutorials

- If you'd prefer to launch a Windows instance, see this tutorial in the *Amazon EC2 User Guide for Windows Instances*: [Get started with Amazon EC2 Windows instances](#).

Contents

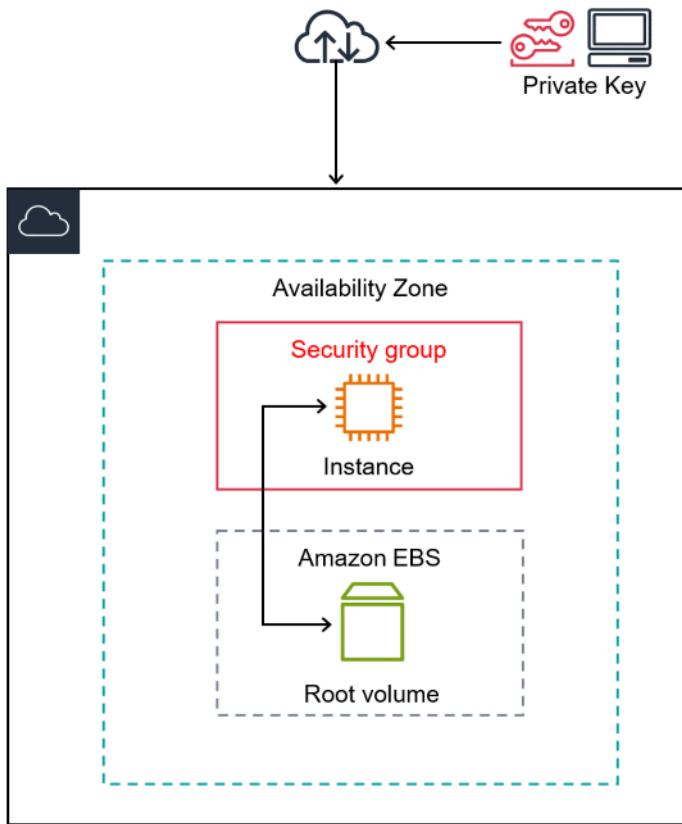

- [Overview](#)
- [Prerequisites](#)
- [Step 1: Launch an instance](#)
- [Step 2: Connect to your instance](#)
- [Step 3: Track your Free Tier usage](#)
- [Step 4: Clean up your instance](#)
- [Next steps](#)

Overview

The instance launched in this tutorial is an Amazon EBS-backed instance (meaning that the root volume is an EBS volume). You can either specify the Availability Zone in which your instance runs,

or let Amazon EC2 select an Availability Zone for you. Availability Zones are multiple, isolated locations within each AWS Region. You can think of an Availability Zone as an isolated data center.

When you launch your instance, you secure it by specifying a key pair (to prove your identity) and a security group (which acts as a virtual firewall to control ingoing and outgoing traffic). When you connect to your instance, you must provide the private key of the key pair that you specified when you launched your instance.

Prerequisites

Before you begin, be sure that you've completed the steps in [Set up to use Amazon EC2](#).

Step 1: Launch an instance

You can launch a Linux instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you quickly launch your first instance, so it doesn't cover all possible options. For information about advanced options, see [Launch an instance using the new launch instance wizard](#). For information about other ways to launch your instance, see [Launch your instance](#).

To launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the EC2 console dashboard, in the **Launch instance** box, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, do the following:
 - a. Choose **Quick Start**, and then choose Amazon Linux. This is the operating system (OS) for your instance.
 - b. From **Amazon Machine Image (AMI)**, select an HVM version of Amazon Linux 2. Notice that these AMIs are marked **Free Tier eligible**. An *Amazon Machine Image (AMI)* is a basic configuration that serves as a template for your instance.

 **Note**

AL2023 is the successor to Amazon Linux 2. For more information, see [Launching AL2023 using the Amazon EC2 console](#).

5. Under **Instance type**, from the **Instance type** list, you can select the hardware configuration for your instance. Choose the `t2.micro` instance type, which is selected by default. The `t2.micro` instance type is eligible for the Free Tier. In Regions where `t2.micro` is unavailable, you can use a `t3.micro` instance under the Free Tier. For more information, see [AWS Free Tier](#).
6. Under **Key pair (login)**, for **Key pair name**, choose the key pair that you created when getting set up.

 **Warning**

Do not choose **Proceed without a key pair (Not recommended)**. If you launch your instance without a key pair, then you can't connect to it.

7. Next to **Network settings**, choose **Edit**. For **Security group name**, you'll see that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select the security group that you created when getting set up using the following steps:
 - a. Choose **Select existing security group**.

- b. From **Common security groups**, choose your security group from the list of existing security groups.
8. Keep the default selections for the other configuration settings for your instance.
9. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.
10. A confirmation page lets you know that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console.
11. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch. When you launch an instance, its initial state is pending. After the instance starts, its state changes to running and it receives a public DNS name. If the **Public IPv4 DNS** column is hidden, choose the settings icon () in the top-right corner, toggle on **Public IPv4 DNS**, and choose **Confirm**.
12. It can take a few minutes for the instance to be ready for you to connect to it. Check that your instance has passed its status checks; you can view this information in the **Status check** column.

Step 2: Connect to your instance

There are several ways to connect to your Linux instance. For more information, see [Connect to your Linux instance](#).

 **Important**

You can't connect to your instance unless you launched it with a key pair for which you have the .pem file and you launched it with a security group that allows SSH access from your computer. If you can't connect to your instance, see [Troubleshoot connecting to your instance](#) for assistance.

Step 3: Track your Free Tier usage

You can use Amazon EC2 without incurring charges if you've been an AWS customer for less than 12 months and you stay within the Free Tier usage limits. It's important to track your Free Tier

usage to avoid billing surprises. If you exceed the Free Tier limits, you'll incur standard pay-as-go charges.

 **Note**

If you've been an AWS customer for more than 12 months, you're no longer eligible for Free Tier usage and you won't see the **EC2 Free Tier** box that is described in the following procedure.

To track your Free Tier usage

1. In the navigation pane, choose **EC2 Dashboard**.
2. Find the **EC2 Free Tier** box (at top right).

EC2 Free Tier [Info](#)

Offers for all AWS Regions.

3 EC2 free tier offers in use

End of month forecast

⚠ 2 offers forecasted to exceed free tier limit.

Exceeds free tier

⚠ 1 offers exceeded and is now pay-as-you-go pricing.

[View Global EC2 resources](#)

Offer usage (monthly)

Offer Type	Usage (%)	Remaining
Windows EC2 Instances	12%	662 hours remaining
Linux EC2 Instances	100%	⚠ Offer limit reached
Storage space on EBS	85%	4.59 GB remaining

[View all AWS Free Tier offers](#)

3. In the **EC2 Free Tier** box, check your Free Tier usage, as follows:

- Under **EC2 Free Tier offers in use**, take note of the warnings:
 - End of month forecast** – This warns that you will incur charges this month if you continue with your current usage pattern.
 - Exceeds Free Tier** – This warns that you've exceeded your Free Tier limits and you're already incurring charges.

- Under **Offer usage (monthly)**, take note of your usage of Linux instances, Windows instances, and EBS storage. The percentage indicates how much of your Free Tier limits you've used this month. If you're at 100%, you will incur charges for further use.

 **Note**

This information appears only after you've created an instance. However, usage information is not updated in real time; it's updated three times a day.

- To avoid incurring further charges, delete any resources that are either incurring charges now, or will incur charges if you exceed your Free Tier limit usage.
 - For the instructions to delete your instance, go to the next step in this tutorial.
 - To check if you have resources in other Regions that might be incurring charges, in the **EC2 Free Tier** box, choose **View Global EC2 resources** to open the **EC2 Global View**. For more information, see [Amazon EC2 Global View](#).
- To view your resource usage for all AWS services under the AWS Free Tier, at the bottom of the **EC2 Free Tier** box, choose **View all AWS Free Tier offers**. For more information, see [Using the AWS Free Tier](#) in the *AWS Billing User Guide*.

Step 4: Clean up your instance

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see [Next steps](#).

 **Important**

Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.

If you launched an instance that is not within the [AWS Free Tier](#), you'll stop incurring charges for that instance as soon as the instance status changes to shutting down or terminated. To keep your instance for later, but not incur charges, you can stop the instance now and then start it again later. For more information, see [Stop and start Amazon EC2 instances](#).

To terminate your instance

1. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
2. Choose **Instance state, Terminate instance**.
3. Choose **Terminate** when prompted for confirmation.

Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console for a short while, and then the entry is automatically deleted. You cannot remove the terminated instance from the console display yourself.

Next steps

After you start your instance, you might want to try some of the following exercises:

- Learn how to remotely manage your EC2 instance using the Run command. For more information, see [AWS Systems Manager Run Command](#) in the *AWS Systems Manager User Guide*.
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier. For more information, see [Tracking your AWS Free Tier usage](#) in the *AWS Billing User Guide*.
- Add an EBS volume. For more information, see [Create an Amazon EBS volume](#) in the *Amazon EBS User Guide*.
- Install the LAMP stack. For more information, see [Install LAMP on Amazon Linux 2](#).
- Learn about instance purchasing options. For more information, see [Instance purchasing options](#).
- Get advice about instance types. For more information, see [Get instance type recommendations for a new workload](#).

Best practices for Amazon EC2

To ensure the maximum benefit from Amazon EC2, we recommend that you perform the following best practices.

Security

- Manage access to AWS resources and APIs using identity federation with an identity provider and IAM roles whenever possible. For more information, see [Creating IAM policies](#) in the *IAM User Guide*.
- Implement the least permissive rules for your security group. For more information, see [Security group rules](#).
- Regularly patch, update, and secure the operating system and applications on your instance. For more information about updating AL2023, see [Updating AL2023](#) in the *AL2023 User Guide*. For more information about updating Amazon Linux 2 or the Amazon Linux AMI, see [Manage software on your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.
- Use Amazon Inspector to automatically discover and scan Amazon EC2 instances for software vulnerabilities and unintended network exposure. For more information, see the [Amazon Inspector User Guide](#).
- Use AWS Security Hub controls to monitor your Amazon EC2 resources against security best practices and security standards. For more information about using Security Hub, see [Amazon Elastic Compute Cloud controls](#) in the *AWS Security Hub User Guide*.

Storage

- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see [Storage for the root device](#).
- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see [Preserve data when an instance is terminated](#).
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.

- Encrypt EBS volumes and snapshots. For more information, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*.

Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see [Instance metadata and user data](#) and [Tag your Amazon EC2 resources](#).
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you'll need them. For more information, see [Amazon EC2 service quotas](#).
- Use AWS Trusted Advisor to inspect your AWS environment, and then make recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. For more information, see [AWS Trusted Advisor](#) in the *AWS Support User Guide*.

Backup and recovery

- Regularly back up your EBS volumes using [Amazon EBS snapshots](#), and create an [Amazon Machine Image \(AMI\)](#) from your instance to save the configuration as a template for launching future instances. For more information about AWS services that help achieve this use case, see [AWS Backup](#) and [Amazon Data Lifecycle Manager](#).
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see [Amazon EC2 instance IP addressing](#).
- Monitor and respond to events. For more information, see [Monitor Amazon EC2](#).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see [Elastic network interfaces](#). For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
- Regularly test the process of recovering your instances and Amazon EBS volumes to ensure data and services are restored successfully.

Networking

- Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.

Tutorials for Amazon EC2 instances running Linux

The following tutorials show you how to perform common tasks using EC2 instances running Linux. AWS provides Amazon Linux 2023, Amazon Linux 2, and the Amazon Linux AMI. Install LAMP on Amazon Linux 2

The following procedures help you install an Apache web server with PHP and [MariaDB](#) (a community-developed fork of MySQL) support on your Amazon Linux 2 instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important

If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux AMI, see [Install LAMP on Amazon Linux](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [AWS Docs - Install a LAMP Server - AL2](#) Automation document.

Tasks

- [Step 1: Prepare the LAMP server](#)
- [Step 2: Test your LAMP server](#)
- [Step 3: Secure the database server](#)
- [Step 4: \(Optional\) Install phpMyAdmin](#)
- [Troubleshoot](#)
- [Related topics](#)

Step 1: Prepare the LAMP server

Prerequisites

- This tutorial assumes that you have already launched a new instance using Amazon Linux 2, with a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance](#). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Authorize inbound traffic for your Linux instances](#).

- The following procedure installs the latest PHP version available on Amazon Linux 2, currently php8.2. If you plan to use PHP applications other than those described in this tutorial, you should check their compatibility with php8.2.

To prepare the LAMP server

- Connect to your instance.
- To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

The -y option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

- Install the mariadb10.5 Amazon Linux Extras repositories to get the latest version of the MariaDB package.

```
[ec2-user ~]$ sudo amazon-linux-extras install mariadb10.5
```

If you receive an error stating sudo: amazon-linux-extras: command not found, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

```
cat /etc/system-release
```

- Install the php8.2 Amazon Linux Extras repositories to get the latest version of the PHP package for Amazon Linux 2.

```
[ec2-user ~]$ sudo amazon-linux-extras install php8.2
```

- Now that your instance is current, you can install the Apache web server, MariaDB, and PHP software packages. Use the yum install command to install multiple software packages and all related dependencies at the same time

```
[ec2-user ~]$ sudo yum install -y httpd
```

You can view the current versions of these packages using the following command:

```
yum info package_name
```

6. Start the Apache web server.

```
[ec2-user ~]$ sudo systemctl start httpd
```

7. Use the **systemctl** command to configure the Apache web server to start at each system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd
```

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

8. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a **launch-wizard-N** security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. Choose **Instances** and select your instance.
 - c. On the **Security** tab, view the inbound rules. You should see the following rule:

Port range	Protocol	Source
22	tcp	0.0.0.0/0

 **Warning**

Using **0.0.0.0/0** allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

- d. Choose the link for the security group. Using the procedures in [Add rules to a security group](#), add a new inbound security rule with the following values:
 - **Type:** HTTP

- **Protocol:** TCP
 - **Port Range:** 80
 - **Source:** Custom
9. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. If there is no content in `/var/www/html`, you should see the Apache test page. You can get the public DNS for your instance using the Amazon EC2 console (check the **Public DNS** column; if this column is hidden, choose **Show/Hide Columns** (the gear-shaped icon) and choose **Public DNS**).

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group](#).

Important

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Test Page

This page is used to test the proper operation of the Apache HTTP server after it has been installed. If you can read this page, it means that the Apache HTTP server installed at this site is working properly.

If you are a member of the general public:

The fact that you are seeing this page indicates that the website you just visited is either experiencing problems, or is undergoing routine maintenance.

If you would like to let the administrators of this website know that you've seen this page instead of the page you expected, you should send them e-mail. In general, mail sent to the name "webmaster" and directed to the website's domain should reach the appropriate person.

For example, if you experienced problems while visiting www.example.com, you should send e-mail to "webmaster@example.com".

If you are the website administrator:

You may now add content to the directory `/var/www/html/`. Note that until you do so, people visiting your website will see this page, and not your content. To prevent this page from ever being used, follow the instructions in the file `/etc/httpd/conf.d/welcome.conf`.

You are free to use the image below on web sites powered by the Apache HTTP Server:

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.

To allow the `ec2-user` account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the apache group, to give the apache group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions

1. Add your user (in this case, `ec2-user`) to the apache group.

```
[ec2-user ~]$ sudo usermod -a -G apache ec2-user
```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
 - a. Log out (use the `exit` command or close the terminal window):

```
[ec2-user ~]$ exit
```

- b. To verify your membership in the apache group, reconnect to your instance, and then run the following command:

```
[ec2-user ~]$ groups  
ec2-user adm wheel apache systemd-journal
```

3. Change the group ownership of `/var/www` and its contents to the apache group.

```
[ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of `/var/www` and its subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www && find /var/www -type d -exec sudo chmod 2775 {} \;
```

5. To add group write permissions, recursively change the file permissions of `/var/www` and its subdirectories:

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, `ec2-user` (and any future members of the `apache` group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

To secure your web server (Optional)

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see [Configure SSL/TLS on Amazon Linux 2](#).

Step 2: Test your LAMP server

If your server is installed and running, and your file permissions are set correctly, your `ec2-user` account should be able to create a PHP file in the `/var/www/html` directory that is available from the internet.

To test your LAMP server

1. Create a PHP file in the Apache document root.

```
[ec2-user ~]$ echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in [To set file permissions](#).

2. In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page:

If you do not see this page, verify that the `/var/www/html/phpinfo.php` file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command.

```
[ec2-user ~]$ sudo yum list installed httpd mariadb-server php-mysqlnd
```

If any of the required packages are not listed in your output, install them with the **sudo yum install package** command. Also verify that the `php7.2` and `lamp-mariadb10.2-php7.2` extras are enabled in the output of the **amazon-linux-extras** command.

3. Delete the `phpinfo.php` file. Although this can be useful information, it should not be broadcast to the internet for security reasons.

```
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at `/var/www/html`, you should be able to view that content at the public DNS address for your instance.

Step 3: Secure the database server

The default installation of the MariaDB server has several features that are great for testing and development, but they should be disabled or removed for production servers. The **mysql_secure_installation** command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MariaDB server, we recommend performing this procedure.

To secure the MariaDB server

1. Start the MariaDB server.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

2. Run **mysql_secure_installation**.

```
[ec2-user ~]$ sudo mysql_secure_installation
```

- a. When prompted, type a password for the root account.

- i. Type the current root password. By default, the root account does not have a password set. Press Enter.
- ii. Type **Y** to set a password, and type a secure password twice. For more information about creating a secure password, see <https://identitysafe.norton.com/password-generator/>. Make sure to store this password in a safe place.

Setting a root password for MariaDB is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.

- b. Type **Y** to remove the anonymous user accounts.
 - c. Type **Y** to disable the remote root login.
 - d. Type **Y** to remove the test database.
 - e. Type **Y** to reload the privilege tables and save your changes.
3. (Optional) If you do not plan to use the MariaDB server right away, stop it. You can restart it when you need it again.

```
[ec2-user ~]$ sudo systemctl stop mariadb
```

4. (Optional) If you want the MariaDB server to start at every boot, type the following command.

```
[ec2-user ~]$ sudo systemctl enable mariadb
```

Step 4: (Optional) Install phpMyAdmin

[phpMyAdmin](#) is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

Important

We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see [Securing your phpMyAdmin installation](#). For general information about securing a web server on an EC2 instance, see [Configure SSL/TLS on Amazon Linux 2](#).

To install phpMyAdmin

1. Install the required dependencies.

```
[ec2-user ~]$ sudo yum install php-mbstring php-xml -y
```

2. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

3. Restart php-fpm.

```
[ec2-user ~]$ sudo systemctl restart php-fpm
```

4. Navigate to the Apache document root at /var/www/html.

```
[ec2-user ~]$ cd /var/www/html
```

5. Select a source package for the latest phpMyAdmin release from <https://www.phpmyadmin.net/downloads>. To download the file directly to your instance, copy the link and paste it into a `wget` command, as in this example:

```
[ec2-user html]$ wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it with the following command.

```
[ec2-user html]$ mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz -C phpMyAdmin --strip-components 1
```

7. Delete the `phpMyAdmin-latest-all-languages.tar.gz` tarball.

```
[ec2-user html]$ rm phpMyAdmin-latest-all-languages.tar.gz
```

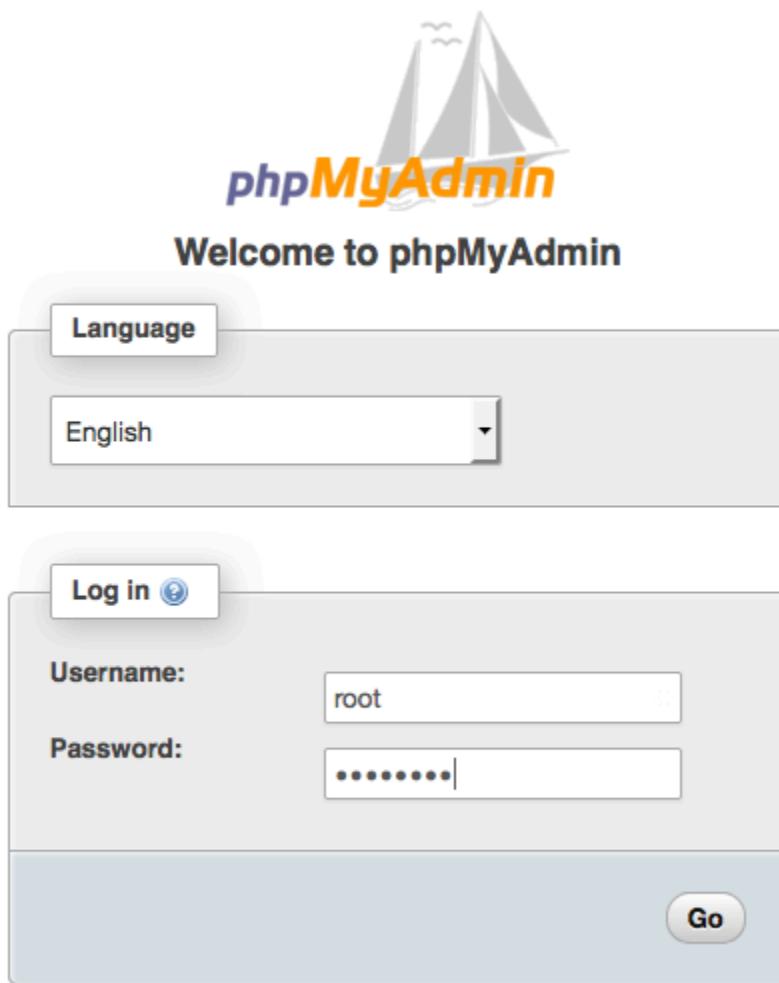

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:

10. Log in to your phpMyAdmin installation with the `root` user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. We suggest that you begin by manually creating the configuration file, as follows:

- a. To start with a minimal configuration file, use your favorite text editor to create a new file, and then copy the contents of `config.sample.inc.php` into it.
- b. Save the file as `config.inc.php` in the phpMyAdmin directory that contains `index.php`.
- c. Refer to post-file creation instructions in the [Using the Setup script](#) section of the phpMyAdmin installation instructions for any additional setup.

For information about using phpMyAdmin, see the [phpMyAdmin User Guide](#).

Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the **httpd** process is not running, repeat the steps described in [To prepare the LAMP server](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80.

For more information, see [Add rules to a security group](#).

I can't connect to my server using HTTPS

Perform the following checks to see if your Apache web server is configured to support HTTPS.

- **Is the web server correctly configured?**

After you install Apache, the server is configured for HTTP traffic. To support HTTPS, enable TLS on the server and install an SSL certificate. For information, see [Configure SSL/TLS on Amazon Linux 2](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTPS traffic on port 443. For more information, see [Add rules to a security group](#).

Install LAMP on Amazon Linux

The following procedures help you install an Apache web server with PHP and MySQL support on your Amazon Linux instance (sometimes called a LAMP web server or LAMP stack). You can use this server to host a static website or deploy a dynamic PHP application that reads and writes information to a database.

Important

If you are trying to set up a LAMP web server on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this tutorial will not work. For Amazon Linux 2, see [Install LAMP on Amazon Linux 2](#). For Ubuntu, see the following Ubuntu community documentation: [ApacheMySQLPHP](#). For other distributions, see their specific documentation.

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [AWS Docs - Install a LAMP Server - AL](#) Automation document.

Tasks

- [Step 1: Prepare the LAMP server](#)
- [Step 2: Test your LAMP server](#)
- [Step 3: Secure the database server](#)
- [Step 4: \(Optional\) Install phpMyAdmin](#)
- [Troubleshoot](#)
- [Related topics](#)

Step 1: Prepare the LAMP server

Prerequisites

This tutorial assumes that you have already launched a new instance using the Amazon Linux AMI, with a public DNS name that is reachable from the internet. For more information, see [Step 1: Launch an instance](#). You must also have configured your security group to allow SSH (port 22), HTTP (port 80), and HTTPS (port 443) connections. For more information about these prerequisites, see [Authorize inbound traffic for your Linux instances](#).

To install and start the LAMP web server with the Amazon Linux AMI

1. [Connect to your instance](#).
2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, you can install the Apache web server, MySQL, and PHP software packages.

Important

Some applications may not be compatible with the following recommended software environment. Before installing these packages, check whether your LAMP applications

are compatible with them. If there is a problem, you may need to install an alternative environment. For more information, see [The application software I want to run on my server is incompatible with the installed PHP version or other software](#)

Use the **yum install** command to install multiple software packages and all related dependencies at the same time.

```
[ec2-user ~]$ sudo yum install -y httpd24 php72 mysql57-server php72-mysqlnd
```

If you receive the error No package *package-name* available, then your instance was not launched with the Amazon Linux AMI (perhaps you are using Amazon Linux 2 instead). You can view your version of Amazon Linux with the following command.

```
cat /etc/system-release
```

4. Start the Apache web server.

```
[ec2-user ~]$ sudo service httpd start
Starting httpd: [ OK ]
```

5. Use the **chkconfig** command to configure the Apache web server to start at each system boot.

```
[ec2-user ~]$ sudo chkconfig httpd on
```

The **chkconfig** command does not provide any confirmation message when you successfully use it to enable a service.

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ chkconfig --list httpd
httpd           0:off   1:off   2:on    3:on    4:on    5:on    6:off
```

Here, **httpd** is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

6. Add a security rule to allow inbound HTTP (port 80) connections to your instance if you have not already done so. By default, a **launch-wizard-N** security group was set up for your instance during initialization. This group contains a single rule to allow SSH connections.

- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
- b. Choose **Instances** and select your instance.
- c. On the **Security** tab, view the inbound rules. You should see the following rule:

Port range	Protocol	Source
22	tcp	0.0.0.0/0

 **Warning**

Using `0.0.0.0/0` allows all IPv4 addresses to access your instance using SSH. This is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, you authorize only a specific IP address or range of addresses to access your instance.

- d. Choose the link for the security group. Using the procedures in [Add rules to a security group](#), add a new inbound security rule with the following values:
 - **Type:** HTTP
 - **Protocol:** TCP
 - **Port Range:** 80
 - **Source:** Custom
7. Test your web server. In a web browser, type the public DNS address (or the public IP address) of your instance. You can get the public DNS address for your instance using the Amazon EC2 console. If there is no content in `/var/www/html`, you should see the Apache test page. When you add content to the document root, your content appears at the public DNS address of your instance instead of the test page.

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group](#).

If you are not using Amazon Linux, you may also need to configure the firewall on your instance to allow these connections. For more information about how to configure the firewall, see the documentation for your specific distribution.

Apache **httpd** serves files that are kept in a directory called the Apache document root. The Amazon Linux Apache document root is `/var/www/html`, which by default is owned by root.

```
[ec2-user ~]$ ls -l /var/www
total 16
drwxr-xr-x 2 root root 4096 Jul 12 01:00 cgi-bin
drwxr-xr-x 3 root root 4096 Aug 7 00:02 error
drwxr-xr-x 2 root root 4096 Jan 6 2012 html
drwxr-xr-x 3 root root 4096 Aug 7 00:02 icons
drwxr-xr-x 2 root root 4096 Aug 7 21:17 noindex
```

To allow the ec2-user account to manipulate files in this directory, you must modify the ownership and permissions of the directory. There are many ways to accomplish this task. In this tutorial, you add ec2-user to the apache group, to give the apache group ownership of the /var/www directory and assign write permissions to the group.

To set file permissions

1. Add your user (in this case, ec2-user) to the apache group.

```
[ec2-user ~]$ sudo usermod -a -G apache ec2-user
```

2. Log out and then log back in again to pick up the new group, and then verify your membership.
 - a. Log out (use the **exit** command or close the terminal window):

```
[ec2-user ~]$ exit
```
 - b. To verify your membership in the apache group, reconnect to your instance, and then run the following command:

```
[ec2-user ~]$ groups
ec2-user wheel apache
```

3. Change the group ownership of /var/www and its contents to the apache group.

```
[ec2-user ~]$ sudo chown -R ec2-user:apache /var/www
```

4. To add group write permissions and to set the group ID on future subdirectories, change the directory permissions of /var/www and its subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www
```

```
[ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} \;
```

- To add group write permissions, recursively change the file permissions of /var/www and its subdirectories:

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, ec2-user (and any future members of the apache group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

(Optional) Secure your web server

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of webpages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption.

For information about enabling HTTPS on your server, see [Configure SSL/TLS on Amazon Linux](#).

Step 2: Test your LAMP server

If your server is installed and running, and your file permissions are set correctly, your ec2-user account should be able to create a PHP file in the /var/www/html directory that is available from the internet.

To test your LAMP web server

- Create a PHP file in the Apache document root.

```
[ec2-user ~]$ echo "<?php phpinfo(); ?>" > /var/www/html/phpinfo.php
```

If you get a "Permission denied" error when trying to run this command, try logging out and logging back in again to pick up the proper group permissions that you configured in [Step 1: Prepare the LAMP server](#).

- In a web browser, type the URL of the file that you just created. This URL is the public DNS address of your instance followed by a forward slash and the file name. For example:

<http://my.public.dns.amazonaws.com/phpinfo.php>

You should see the PHP information page:

If you do not see this page, verify that the `/var/www/html/phpinfo.php` file was created properly in the previous step. You can also verify that all of the required packages were installed with the following command. The package versions in the second column do not need to match this example output.

```
[ec2-user ~]$ sudo yum list installed httpd24 php72 mysql57-server php72-mysqlnd
Loaded plugins: priorities, update-motd, upgrade-helper

updates
```

If any of the required packages are not listed in your output, install them using the `sudo yum install package` command.

3. Delete the `phpinfo.php` file. Although this can be useful information, it should not be broadcast to the internet for security reasons.

```
[ec2-user ~]$ rm /var/www/html/phpinfo.php
```

Step 3: Secure the database server

The default installation of the MySQL server has several features that are great for testing and development, but they should be disabled or removed for production servers. The `mysql_secure_installation` command walks you through the process of setting a root password and removing the insecure features from your installation. Even if you are not planning on using the MySQL server, we recommend performing this procedure.

To secure the database server

1. Start the MySQL server.

```
[ec2-user ~]$ sudo service mysqld start
Initializing MySQL database:
...
PLEASE REMEMBER TO SET A PASSWORD FOR THE MySQL root USER !
...
Starting mysqld: [ OK ]
```

2. Run `mysql_secure_installation`.

```
[ec2-user ~]$ sudo mysql_secure_installation
```

- a. When prompted, type a password for the root account.
 - i. Type the current root password. By default, the root account does not have a password set. Press Enter.
 - ii. Type **Y** to set a password, and type a secure password twice. For more information about creating a secure password, see <https://identitysafe.norton.com/password-generator/>. Make sure to store this password in a safe place.

Setting a root password for MySQL is only the most basic measure for securing your database. When you build or install a database-driven application, you typically create a database service user for that application and avoid using the root account for anything but database administration.

- b. Type **Y** to remove the anonymous user accounts.
 - c. Type **Y** to disable the remote root login.
 - d. Type **Y** to remove the test database.
 - e. Type **Y** to reload the privilege tables and save your changes.
3. (Optional) If you do not plan to use the MySQL server right away, stop it. You can restart it when you need it again.

```
[ec2-user ~]$ sudo service mysqld stop  
Stopping mysqld: [ OK ]
```

4. (Optional) If you want the MySQL server to start at every boot, type the following command.

```
[ec2-user ~]$ sudo chkconfig mysqld on
```

You should now have a fully functional LAMP web server. If you add content to the Apache document root at /var/www/html, you should be able to view that content at the public DNS address for your instance.

Step 4: (Optional) Install phpMyAdmin

To install phpMyAdmin

[phpMyAdmin](#) is a web-based database management tool that you can use to view and edit the MySQL databases on your EC2 instance. Follow the steps below to install and configure phpMyAdmin on your Amazon Linux instance.

Important

We do not recommend using phpMyAdmin to access a LAMP server unless you have enabled SSL/TLS in Apache; otherwise, your database administrator password and other data are transmitted insecurely across the internet. For security recommendations from the developers, see [Securing your phpMyAdmin installation](#).

Note

The Amazon Linux package management system does not currently support the automatic installation of phpMyAdmin in a PHP 7 environment. This tutorial describes how to install phpMyAdmin manually.

1. Log in to your EC2 instance using SSH.
2. Install the required dependencies.

```
[ec2-user ~]$ sudo yum install php72-mbstring.x86_64 -y
```

3. Restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
Stopping httpd:                                     [  OK  ]
Starting httpd:                                     [  OK  ]
```

4. Navigate to the Apache document root at /var/www/html.

```
[ec2-user ~]$ cd /var/www/html
[ec2-user html]$
```

5. Select a source package for the latest phpMyAdmin release from <https://www.phpmyadmin.net/downloads>. To download the file directly to your instance, copy the link and paste it into a `wget` command, as in this example:

```
[ec2-user html]$ wget https://www.phpmyadmin.net/downloads/phpMyAdmin-latest-all-languages.tar.gz
```

6. Create a phpMyAdmin folder and extract the package into it using the following command.

```
[ec2-user html]$ mkdir phpMyAdmin && tar -xvzf phpMyAdmin-latest-all-languages.tar.gz -C phpMyAdmin --strip-components 1
```

7. Delete the `phpMyAdmin-latest-all-languages.tar.gz` tarball.

```
[ec2-user html]$ rm phpMyAdmin-latest-all-languages.tar.gz
```

8. (Optional) If the MySQL server is not running, start it now.

```
[ec2-user ~]$ sudo service mysqld start
```

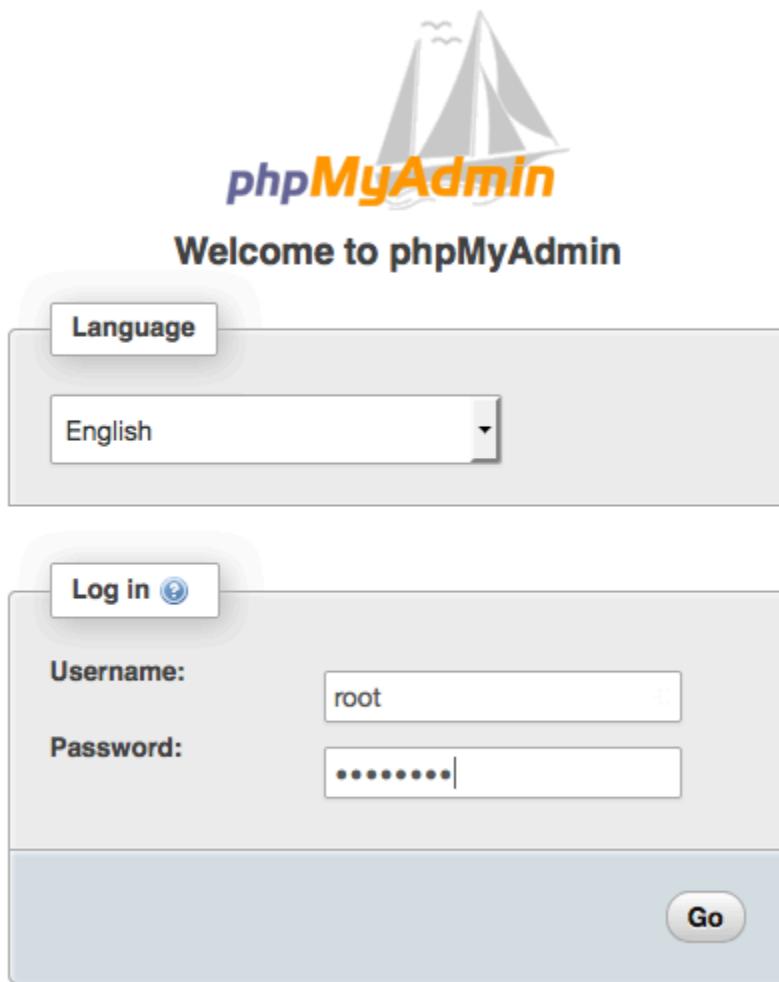

```
Starting mysqld:
```

```
[ OK ]
```

9. In a web browser, type the URL of your phpMyAdmin installation. This URL is the public DNS address (or the public IP address) of your instance followed by a forward slash and the name of your installation directory. For example:

```
http://my.public.dns.amazonaws.com/phpMyAdmin
```

You should see the phpMyAdmin login page:

10. Log in to your phpMyAdmin installation with the `root` user name and the MySQL root password you created earlier.

Your installation must still be configured before you put it into service. To configure phpMyAdmin, you can [manually create a configuration file](#), [use the setup console](#), or combine both approaches.

For information about using phpMyAdmin, see the [phpMyAdmin User Guide](#).

Troubleshoot

This section offers suggestions for resolving common problems you may encounter while setting up a new LAMP server.

I can't connect to my server using a web browser.

Perform the following checks to see if your Apache web server is running and accessible.

- **Is the web server running?**

You can verify that **httpd** is on by running the following command:

```
[ec2-user ~]$ chkconfig --list httpd  
httpd           0:off    1:off    2:on     3:on     4:on     5:on     6:off
```

Here, **httpd** is on in runlevels 2, 3, 4, and 5 (which is what you want to see).

If the **httpd** process is not running, repeat the steps described in [Step 1: Prepare the LAMP server](#).

- **Is the firewall correctly configured?**

Verify that the security group for the instance contains a rule to allow HTTP traffic on port 80. For more information, see [Add rules to a security group](#).

The application software I want to run on my server is incompatible with the installed PHP version or other software

This tutorial recommends installing the most up-to-date versions of Apache HTTP Server, PHP, and MySQL. Before installing an additional LAMP application, check its requirements to confirm that it is compatible with your installed environment. If the latest version of PHP is not supported, it is possible (and entirely safe) to downgrade to an earlier supported configuration. You can also

install more than one version of PHP in parallel, which solves certain compatibility problems with a minimum of effort. For information about configuring a preference among multiple installed PHP versions, see [Amazon Linux AMI 2016.09 Release Notes](#).

How to downgrade

The well-tested previous version of this tutorial called for the following core LAMP packages:

- httpd24
- php56
- mysql55-server
- php56-mysqlnd

If you have already installed the latest packages as recommended at the start of this tutorial, you must first uninstall these packages and other dependencies as follows:

```
[ec2-user ~]$ sudo yum remove -y httpd24 php72 mysql57-server php72-mysqlnd perl-DBD-MySQL57
```

Next, install the replacement environment:

```
[ec2-user ~]$ sudo yum install -y httpd24 php56 mysql55-server php56-mysqlnd
```

If you decide later to upgrade to the recommended environment, you must first remove the customized packages and dependencies:

```
[ec2-user ~]$ sudo yum remove -y httpd24 php56 mysql55-server php56-mysqlnd perl-DBD-MySQL56
```

Now you can install the latest packages, as described earlier.

Configure SSL/TLS

This section includes tutorials that show you how to configure SSL/TLS on web server running on an Amazon EC2 instance.

Configure SSL/TLS on Amazon Linux 2

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with Amazon Linux 2 and

Apache web server. This tutorial assumes that you are not using a load balancer. If you are using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from [AWS Certificate Manager](#) instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. Amazon Linux 2 disables server-side support for all versions of SSL by default. [Security standards bodies](#) consider TLS 1.0 to be unsafe. TLS 1.0 and TLS 1.1 were formally [deprecated](#) in March 2021. This tutorial contains guidance based exclusively on enabling TLS 1.2. TLS 1.3 was finalized in 2018 and is available in Amazon Linux 2 as long as the underlying TLS library (OpenSSL in this tutorial) is supported and enabled. [Clients must support TLS 1.2 or later by June 28, 2023](#). For more information about the updated encryption standards, see [RFC 7568](#) and [RFC 8446](#).

This tutorial refers to modern web encryption simply as TLS.

Important

These procedures are intended for use with Amazon Linux 2. We also assume that you are starting with a new Amazon EC2 instance. If you are trying to set up an EC2 instance running a different distribution, or an instance running an old version of Amazon Linux 2, some procedures in this tutorial might not work. For the Amazon Linux AMI, see [Configure SSL/TLS on Amazon Linux](#). For Ubuntu, see the following community documentation: [Open SSL on Ubuntu](#). For Red Hat Enterprise Linux, see the following: [Setting up the Apache HTTP Web Server](#). For other distributions, see their specific documentation.

Note

Alternatively, you can use AWS Certificate Manager (ACM) for AWS Nitro enclaves, which is an enclave application that allows you to use public and private SSL/TLS certificates with your web applications and servers running on Amazon EC2 instances with AWS Nitro Enclaves. Nitro Enclaves is an Amazon EC2 capability that enables creation of isolated compute environments to protect and securely process highly sensitive data, such as SSL/TLS certificates and private keys.

ACM for Nitro Enclaves works with **nginx** running on your Amazon EC2 Linux instance to create private keys, to distribute certificates and private keys, and to manage certificate renewals.

To use ACM for Nitro Enclaves, you must use an enclave-enabled Linux instance.

For more information, see [What is AWS Nitro Enclaves?](#) and [AWS Certificate Manager for Nitro Enclaves](#) in the *AWS Nitro Enclaves User Guide*.

- [Prerequisites](#)
- [Step 1: Enable TLS on the server](#)
- [Step 2: Obtain a CA-signed certificate](#)
- [Step 3: Test and harden the security configuration](#)
- [Troubleshoot](#)

Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed Amazon Linux 2 instance. For more information, see [Step 1: Launch an instance](#).
- Configure your security groups to allow your instance to accept connections on the following TCP ports:
 - SSH (port 22)
 - HTTP (port 80)
 - HTTPS (port 443)

For more information, see [Authorize inbound traffic for your Linux instances](#).

- Install the Apache web server. For step-by-step instructions, see [Tutorial: Install a LAMP Web Server on Amazon Linux 2](#). Only the `httpd` package and its dependencies are needed, so you can ignore the instructions involving PHP and MariaDB.
- To identify and authenticate websites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public website, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use [Amazon Route 53](#).

Step 1: Enable TLS on the server

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [automation document](#).

This procedure takes you through the process of setting up TLS on Amazon Linux 2 with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site are greeted by security warnings.

To enable TLS on a server

1. [Connect to your instance](#) and confirm that Apache is running.

```
[ec2-user ~]$ sudo systemctl is-enabled httpd
```

If the returned value is not "enabled," start Apache and set it to start each time the system boots.

```
[ec2-user ~]$ sudo systemctl start httpd && sudo systemctl enable httpd
```

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure that you have the latest security updates and bug fixes.

Note

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, add TLS support by installing the Apache module mod_ssl.

```
[ec2-user ~]$ sudo yum install -y mod_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

- /etc/httpd/conf.d/ssl.conf

The configuration file for mod_ssl. It contains *directives* telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

- /etc/pki/tls/certs/make-dummy-cert

A script to generate a self-signed X.509 certificate and private key for your server host. This certificate is useful for testing that Apache is properly set up to use TLS. Because it offers no proof of identity, it should not be used in production. If used in production, it triggers warnings in Web browsers.

4. Run the script to generate a self-signed dummy certificate and key for testing.

```
[ec2-user ~]$ cd /etc/pki/tls/certs  
sudo ./make-dummy-cert localhost.crt
```

This generates a new file `localhost.crt` in the `/etc/pki/tls/certs/` directory. The specified file name matches the default that is assigned in the **SSLCertificateFile** directive in `/etc/httpd/conf.d/ssl.conf`.

This file contains both a self-signed certificate and the certificate's private key. Apache requires the certificate and key to be in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in the following abbreviated example.

```

-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function. For example, you can call a certificate `cert.crt`, `cert.pem`, or any other file name, so long as the related directive in the `ssl.conf` file uses the same name.

 **Note**

When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

5. Open the `/etc/httpd/conf.d/ssl.conf` file using your favorite text editor (such as **vim** or **nano**) as root user and comment out the following line, because the self-signed dummy certificate also contains the key. If you do not comment out this line before you complete the next step, the Apache service fails to start.

```
SSLCertificateKeyFile /etc/pki/tls/private/localhost.key
```

6. Restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

Note

Make sure that TCP port 443 is accessible on your EC2 instance, as previously described.

7. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by entering the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix **https://**.

Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings. Override the warnings and proceed to the site.

If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now encrypted.

Note

To prevent site visitors from encountering warning screens, you must obtain a trusted, CA-signed certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical. A CA promises, at a minimum, to validate a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically

tied to the public key. When a browser connects to a web server over HTTPS, the server presents a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a *chain of trust* consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the [Let's Encrypt](#) project, which also supports the automation of the certificate creation and renewal process. For more information about using a Let's Encrypt certificate, see [Get Certbot](#).

If you plan to offer commercial-grade services, [AWS Certificate Manager](#) is a good option.

Underlying the host certificate is the key. As of 2019, [government](#) and [industry](#) groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents, through 2030. The default modulus size generated by OpenSSL in Amazon Linux 2 is 2048 bits, which is suitable for use in a CA-signed certificate. In the following procedure, an optional step provided for those who want a customized key, for example, one with a larger modulus or using a different encryption algorithm.

Important

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

To obtain a CA-signed certificate

1. [Connect to your instance](#) and navigate to `/etc/pki/tls/private/`. This is the directory where you store the server's private key for TLS. If you prefer to use an existing host key to generate the CSR, skip to Step 3.
2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys works with your web server, but they vary in the degree and type of security that they implement.
 - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key
```

- **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
```

- **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, `custom.key`, is a 4096-bit RSA private key encrypted with the AES-128 cipher.

 **Important**

Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

```
[ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out  
custom.key 4096
```

- **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

```
[ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
```

The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, [according to NIST](#).

 **Note**

Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as shown in the following example.

```
[ec2-user ~]$ sudo chown root:root custom.key  
[ec2-user ~]$ sudo chmod 600 custom.key  
[ec2-user ~]$ ls -al custom.key
```

The preceding commands yield the following result.

```
-rw----- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key. The following example uses **custom.key**.

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

Name	Description	Example
Country Name	The two-letter ISO abbreviation for your country.	US (=United States)
State or Province Name	The name of the state or province where your organization is located. This name cannot be abbreviated.	Washington
Locality Name	The location of your organization, such as a city.	Seattle
Organization Name	The full legal name of your organization. Do not abbreviate your organization name.	Example Corporation

Name	Description	Example
Organizational Unit Name	Additional organizational information, if any.	Example Dept
Common Name	This value must exactly match the web address that you expect users to enter into a browser. Usually, this means a domain name with a prefixed hostname or alias in the form www.example.com . In testing with a self-signed certificate and no DNS resolution, the common name may consist of the hostname alone. CAs also offer more expensive certificates that accept wild-card names such as *.example.com .	www.example.com
Email Address	The server administrator's email address.	someone@example.com

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file **csr.pem** contains your public key, your digital signature of your public key, and the metadata that you entered.

- Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If **www.example.com** is the common name, then **example.com** would be a good SAN, and vice versa. A visitor to your site entering either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA's chain of trust.

Note

Your CA might send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a `.pem` or `.crt` file extension. If you are uncertain which file to use, open the files with a text editor and find the one containing one or more blocks beginning with the following line.

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following line.

```
- - - - -END CERTIFICATE - - - - -
```

You can also test the file at the command line as shown in the following.

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with `.p7b`, `.p7c`, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the `/etc/pki/tls/certs` directory.

Note

There are several ways to upload your new certificate to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, `vi`, `nano`, or `notepad`) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [`sudo`] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the `/etc/pki/tls/certs` directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (owner=root, group=root, read/write for owner only). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root custom.crt  
[ec2-user certs]$ sudo chmod 600 custom.crt  
[ec2-user certs]$ ls -al custom.crt
```

These commands should yield the following result.

```
-rw----- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The following example shows the commands to use.

```
[ec2-user certs]$ sudo chown root:root intermediate.crt  
[ec2-user certs]$ sudo chmod 644 intermediate.crt  
[ec2-user certs]$ ls -al intermediate.crt
```

These commands should yield the following result.

```
-rw-r--r-- root root intermediate.crt
```

6. Place the private key that you used to create the CSR in the `/etc/pki/tls/private/` directory.

 **Note**

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the `/etc/pki/tls/private` directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux 2 defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user private]$ sudo chown root:root custom.key  
[ec2-user private]$ sudo chmod 600 custom.key  
[ec2-user private]$ ls -al custom.key
```

These commands should yield the following result.

```
-rw----- root root custom.key
```

7. Edit `/etc/httpd/conf.d/ssl.conf` to reflect your new certificate and key files.

- Provide the path and file name of the CA-signed host certificate in Apache's `SSLCertificateFile` directive:

```
SSLCertificateFile /etc/pki/tls/certs/custom.crt
```

- If you received an intermediate certificate file (`intermediate.crt` in this example), provide its path and file name using Apache's `SSLCACertificateFile` directive:

```
SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
```

Note

Some CAs combine the host certificate and the intermediate certificates in a single file, making the `SSLCACertificateFile` directive unnecessary. Consult the instructions provided by your CA.

- Provide the path and file name of the private key (`custom.key` in this example) in Apache's `SSLCertificateKeyFile` directive:

```
SSLCertificateKeyFile /etc/pki/tls/private/custom.key
```

8. Save `/etc/httpd/conf.d/ssl.conf` and restart Apache.

```
[ec2-user ~]$ sudo systemctl restart httpd
```

9. Test your server by entering your domain name into a browser URL bar with the prefix `https://`. Your browser should load the test page over HTTPS without generating errors.

Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as [Qualys SSL Labs](#), which performs a free and thorough analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see [how Qualys formulates its scores](#).

Important

Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the [Qualys SSL Labs](#) site, enter the fully qualified domain name of your server, in the form `www.example.com`. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. The following table summarizes the report for a domain with settings identical to the default Apache configuration on Amazon Linux 2, and with a default Certbot certificate.

Overall rating	B
Certificate	100%
Protocol support	95%
Key exchange	70%
Cipher strength	90%

Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems, listed here in order of severity:

- x The RC4 cipher is supported for use by certain older browsers.** A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several [serious weaknesses](#). Unless you have very good reasons to support legacy browsers, you should disable this.
- x Old TLS versions are supported.** The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.
- x Forward secrecy is not fully supported.** [Forward secrecy](#) is a feature of algorithms that encrypt using temporary (ephemeral) session keys derived from the private key. This means in practice that attackers cannot decrypt HTTPS data even if they possess a web server's long-term private key.

To correct and future-proof the TLS configuration

1. Open the configuration file /etc/httpd/conf.d/ssl.conf in a text editor and comment out the following line by entering "#" at the beginning of the line.

```
#SSLProtocol all -SSLv3
```

2. Add the following directive:

```
#SSLProtocol all -SSLv3  
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

This directive explicitly disables SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive conveys more clearly, to a human reader, what the server is configured to do.

Note

Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. In the configuration file `/etc/httpd/conf.d/ssl.conf`, find the section with the **SSLCipherSuite** directive and comment out the existing line by entering "#" at the beginning of the line.

```
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```
2. Specify explicit cipher suites and a cipher order that prioritizes forward secrecy and avoids insecure ciphers. The **SSLCipherSuite** directive used here is based on output from the [Mozilla SSL Configuration Generator](#), which tailors a TLS configuration to the specific software running on your server. (For more information, see Mozilla's useful resource [Security/Server Side TLS](#).) First determine your Apache and OpenSSL versions by using the output from the following commands.

```
[ec2-user ~]$ yum list installed | grep httpd
```

```
[ec2-user ~]$ yum list installed | grep openssl
```

For example, if the returned information is Apache 2.4.34 and OpenSSL 1.0.2, we enter this into the generator. If you choose the "modern" compatibility model, this creates an **SSLCipherSuite** directive that aggressively enforces security but still works for most browsers. If your software doesn't support the modern configuration, you can update your software or choose the "intermediate" configuration instead.

```
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-ECDSA-CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:  
ECDHE-ECDSA-AES256-SHA384:ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256
```

The selected ciphers have *ECDHE* in their names, an abbreviation for *Elliptic Curve Diffie-Hellman Ephemeral*. The term *ephemeral* indicates forward secrecy. As a by-product, these ciphers do not support RC4.

We recommend that you use an explicit list of ciphers instead of relying on defaults or terse directives whose content isn't visible.

Copy the generated directive into /etc/httpd/conf.d/ssl.conf.

 **Note**

Though shown here on several lines for readability, the directive must be on a single line when copied to /etc/httpd/conf.d/ssl.conf, with only a colon (no spaces) between cipher names.

- Finally, uncomment the following line by removing the "#" at the beginning of the line.

```
#SSLHonorCipherOrder on
```

This directive forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strong secure connection before falling back to allowed ciphers with lesser security.

After completing both of these procedures, save the changes to /etc/httpd/conf.d/ssl.conf and restart Apache.

If you test the domain again on [Qualys SSL Labs](#), you should see that the RC4 vulnerability and other warnings are gone and the summary looks something like the following.

Overall rating	A
Certificate	100%
Protocol support	100%
Key exchange	90%
Cipher strength	90%

Each update to OpenSSL introduces new ciphers and removes support for old ones. Keep your EC2 Amazon Linux 2 instance up-to-date, watch for security announcements from [OpenSSL](#), and be alert to reports of new security exploits in the technical press.

Troubleshoot

- **My Apache webserver doesn't start unless I enter a password**

This is expected behavior if you installed an encrypted, password-protected, private server key.

You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/  
[ec2-user private]$ sudo cp custom.key custom.key.bak  
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out  
  custom.key.nocrypt  
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key  
[ec2-user private]$ sudo chown root:root custom.key  
[ec2-user private]$ sudo chmod 600 custom.key  
[ec2-user private]$ sudo systemctl restart httpd
```

Apache should now start without prompting you for a password.

- **I get errors when I run `sudo yum install -y mod_ssl`.**

When you are installing the required packages for SSL, you may see errors similar to the following.

```
Error: httpd24-tools conflicts with httpd-tools-2.2.34-1.16.amzn1.x86_64  
Error: httpd24 conflicts with httpd-2.2.34-1.16.amzn1.x86_64
```

This typically means that your EC2 instance is not running Amazon Linux 2. This tutorial only supports instances freshly created from an official Amazon Linux 2 AMI.

Configure SSL/TLS on Amazon Linux

Secure Sockets Layer/Transport Layer Security (SSL/TLS) creates an encrypted channel between a web server and web client that protects data in transit from being eavesdropped on. This tutorial explains how to add support manually for SSL/TLS on an EC2 instance with the Amazon Linux AMI and Apache web server. This tutorial assumes that you are not using a load balancer. If you are

using Elastic Load Balancing, you can choose to configure SSL offload on the load balancer, using a certificate from [AWS Certificate Manager](#) instead.

For historical reasons, web encryption is often referred to simply as SSL. While web browsers still support SSL, its successor protocol TLS is less vulnerable to attack. The Amazon Linux AMI disables server-side support for all versions of SSL by default. [Security standards bodies](#) consider TLS 1.0 to be unsafe. TLS 1.0 and TLS 1.1 were formally [deprecated](#) in March 2021. This tutorial contains guidance based exclusively on enabling TLS 1.2. TLS 1.3 was finalized in 2018 and is available in Amazon Linux 2 as long as the underlying TLS library (OpenSSL in this tutorial) is supported and enabled. [Clients must support TLS 1.2 or later by June 28, 2023](#). For more information about the updated encryption standards, see [RFC 7568](#) and [RFC 8446](#).

This tutorial refers to modern web encryption simply as TLS.

Important

These procedures are intended for use with the Amazon Linux AMI. If you are trying to set up a LAMP web server on an instance with a different distribution, some procedures in this tutorial might not work for you. For Amazon Linux 2, see [Configure SSL/TLS on Amazon Linux 2](#). For Ubuntu, see the following community documentation: [Open SSL on Ubuntu](#). For Red Hat Enterprise Linux, see the following: [Setting up the Apache HTTP Web Server](#). For other distributions, see their specific documentation.

Note

Alternatively, you can use AWS Certificate Manager (ACM) for AWS Nitro enclaves, which is an enclave application that allows you to use public and private SSL/TLS certificates with your web applications and servers running on Amazon EC2 instances with AWS Nitro Enclaves. Nitro Enclaves is an Amazon EC2 capability that enables creation of isolated compute environments to protect and securely process highly sensitive data, such as SSL/TLS certificates and private keys.

ACM for Nitro Enclaves works with **nginx** running on your Amazon EC2 Linux instance to create private keys, to distribute certificates and private keys, and to manage certificate renewals.

To use ACM for Nitro Enclaves, you must use an enclave-enabled Linux instance.

For more information, see [What is AWS Nitro Enclaves?](#) and [AWS Certificate Manager for Nitro Enclaves](#) in the *AWS Nitro Enclaves User Guide*.

- [Prerequisites](#)
- [Step 1: Enable TLS on the server](#)
- [Step 2: Obtain a CA-signed certificate](#)
- [Step 3: Test and harden the security configuration](#)
- [Troubleshoot](#)

Prerequisites

Before you begin this tutorial, complete the following steps:

- Launch an EBS-backed instance using the Amazon Linux AMI. For more information, see [Step 1: Launch an instance](#).
- Configure your security group to allow your instance to accept connections on the following TCP ports:
 - SSH (port 22)
 - HTTP (port 80)
 - HTTPS (port 443)

For more information, see [Authorize inbound traffic for your Linux instances](#).

- Install Apache web server. For step-by-step instructions, see [Tutorial: Installing a LAMP Web Server on Amazon Linux](#). Only the http24 package and its dependencies are needed; you can ignore the instructions involving PHP and MySQL.
- To identify and authenticate web sites, the TLS public key infrastructure (PKI) relies on the Domain Name System (DNS). To use your EC2 instance to host a public web site, you need to register a domain name for your web server or transfer an existing domain name to your Amazon EC2 host. Numerous third-party domain registration and DNS hosting services are available for this, or you can use [Amazon Route 53](#).

Step 1: Enable TLS on the server

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager instead of the following tasks, run the [automation document](#).

This procedure takes you through the process of setting up TLS on Amazon Linux with a self-signed digital certificate.

Note

A self-signed certificate is acceptable for testing but not production. If you expose your self-signed certificate to the internet, visitors to your site receive security warnings.

To enable TLS on a server

1. [Connect to your instance](#) and confirm that Apache is running.

```
[ec2-user ~]$ sudo service httpd status
```

If necessary, start Apache.

```
[ec2-user ~]$ sudo service httpd start
```

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes, but it is important to make sure you have the latest security updates and bug fixes.

Note

The `-y` option installs the updates without asking for confirmation. If you would like to examine the updates before installing, you can omit this option.

```
[ec2-user ~]$ sudo yum update -y
```

3. Now that your instance is current, add TLS support by installing the Apache module `mod_ssl`:

```
[ec2-user ~]$ sudo yum install -y mod_ssl
```

Your instance now has the following files that you use to configure your secure server and create a certificate for testing:

/etc/httpd/conf.d/ssl.conf

The configuration file for mod_ssl. It contains "directives" telling Apache where to find encryption keys and certificates, the TLS protocol versions to allow, and the encryption ciphers to accept.

/etc/pki/tls/private/localhost.key

An automatically generated, 2048-bit RSA private key for your Amazon EC2 host. During installation, OpenSSL used this key to generate a self-signed host certificate, and you can also use this key to generate a certificate signing request (CSR) to submit to a certificate authority (CA).

/etc/pki/tls/certs/localhost.crt

An automatically generated, self-signed X.509 certificate for your server host. This certificate is useful for testing that Apache is properly set up to use TLS.

The .key and .crt files are both in PEM format, which consists of Base64-encoded ASCII characters framed by "BEGIN" and "END" lines, as in this abbreviated example of a certificate:

```
-----BEGIN CERTIFICATE-----
MIIEazCCA10gAwIBAgICWxQwDQYJKoZIhvcNAQELBQAwgbExCzAJBgNVBAYTAi0t
MRIwEAYDVQQIDA1Tb211U3RhGUxETAPBgNVBAcMCFNvbWVDaXR5MRkwFwYDVQQK
DBBTb211T3JnYW5pemF0aW9uMR8wHQYDVQQLDBTb211T3JnYW5pemF0aW9uYWxV
bm10MRkwFwYDVQQDDBpcC0xNzItMzEtMjAtMjM2MSQwIgYJKoZIhvcNAQkBFhVv
...
z5rRUE/XzxRLBZ0oWZpNWTXJkQ3uFYH6s/sBwtHpKKZMz0vDedREjNKAvk4ws6F0
WanXWehT6FiSZvB4sTEXXJN2jdw8g+sHGnZ8zC0sclknYhHrCVD2vnBlZJKSzvak
3ZazhBxtQSukFMOnWPP2a0DMMFGYUH0d0BQE8sBJxg==
-----END CERTIFICATE-----
```

The file names and extensions are a convenience and have no effect on function; you can call a certificate cert.crt, cert.pem, or any other file name, so long as the related directive in the ssl.conf file uses the same name.

Note

When you replace the default TLS files with your own customized files, be sure that they are in PEM format.

4. Restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
```

5. Your Apache web server should now support HTTPS (secure HTTP) over port 443. Test it by typing the IP address or fully qualified domain name of your EC2 instance into a browser URL bar with the prefix **https://**. Because you are connecting to a site with a self-signed, untrusted host certificate, your browser may display a series of security warnings.

Override the warnings and proceed to the site. If the default Apache test page opens, it means that you have successfully configured TLS on your server. All data passing between the browser and server is now safely encrypted.

To prevent site visitors from encountering warning screens, you need to obtain a certificate that not only encrypts, but also publicly authenticates you as the owner of the site.

Step 2: Obtain a CA-signed certificate

You can use the following process to obtain a CA-signed certificate:

- Generate a certificate signing request (CSR) from a private key
- Submit the CSR to a certificate authority (CA)
- Obtain a signed host certificate
- Configure Apache to use the certificate

A self-signed TLS X.509 host certificate is cryptologically identical to a CA-signed certificate. The difference is social, not mathematical; a CA promises to validate, at a minimum, a domain's ownership before issuing a certificate to an applicant. Each web browser contains a list of CAs trusted by the browser vendor to do this. An X.509 certificate consists primarily of a public key that corresponds to your private server key, and a signature by the CA that is cryptographically tied to the public key. When a browser connects to a web server over HTTPS, the server presents

a certificate for the browser to check against its list of trusted CAs. If the signer is on the list, or accessible through a chain of trust consisting of other trusted signers, the browser negotiates a fast encrypted data channel with the server and loads the page.

Certificates generally cost money because of the labor involved in validating the requests, so it pays to shop around. A few CAs offer basic-level certificates free of charge. The most notable of these CAs is the [Let's Encrypt](#) project, which also supports the automation of the certificate creation and renewal process. For more information about using a Let's Encrypt certificate, see [Get Certbot](#).

If you plan to offer commercial-grade services, [AWS Certificate Manager](#) is a good option.

Underlying the host certificate is the key. As of 2017, [government](#) and [industry](#) groups recommend using a minimum key (modulus) size of 2048 bits for RSA keys intended to protect documents through 2030. The default modulus size generated by OpenSSL in Amazon Linux is 2048 bits, which means that the existing auto-generated key is suitable for use in a CA-signed certificate. An alternative procedure is described below for those who desire a customized key, for instance, one with a larger modulus or using a different encryption algorithm.

These instructions for acquiring a CA-signed host certificate do not work unless you own a registered and hosted DNS domain.

To obtain a CA-signed certificate

1. [Connect to your instance](#) and navigate to `/etc/pki/tls/private/`. This is the directory where the server's private key for TLS is stored. If you prefer to use your existing host key to generate the CSR, skip to Step 3.
2. (Optional) Generate a new private key. Here are some examples of key configurations. Any of the resulting keys work with your web server, but they vary in how (and how much) security they implement.
 - **Example 1:** Create a default RSA host key. The resulting file, `custom.key`, is a 2048-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key
```
 - **Example 2:** Create a stronger RSA key with a bigger modulus. The resulting file, `custom.key`, is a 4096-bit RSA private key.

```
[ec2-user ~]$ sudo openssl genrsa -out custom.key 4096
```

- **Example 3:** Create a 4096-bit encrypted RSA key with password protection. The resulting file, **custom.key**, is a 4096-bit RSA private key encrypted with the AES-128 cipher.

 **Important**

Encrypting the key provides greater security, but because an encrypted key requires a password, services depending on it cannot be auto-started. Each time you use this key, you must supply the password (in the preceding example, "abcde12345") over an SSH connection.

```
[ec2-user ~]$ sudo openssl genrsa -aes128 -passout pass:abcde12345 -out  
custom.key 4096
```

- **Example 4:** Create a key using a non-RSA cipher. RSA cryptography can be relatively slow because of the size of its public keys, which are based on the product of two large prime numbers. However, it is possible to create keys for TLS that use non-RSA ciphers. Keys based on the mathematics of elliptic curves are smaller and computationally faster when delivering an equivalent level of security.

```
[ec2-user ~]$ sudo openssl ecparam -name prime256v1 -out custom.key -genkey
```

The result is a 256-bit elliptic curve private key using prime256v1, a "named curve" that OpenSSL supports. Its cryptographic strength is slightly greater than a 2048-bit RSA key, [according to NIST](#).

 **Note**

Not all CAs provide the same level of support for elliptic-curve-based keys as for RSA keys.

Make sure that the new private key has highly restrictive ownership and permissions (owner=root, group=root, read/write for owner only). The commands would be as follows:

```
[ec2-user ~]$ sudo chown root.root custom.key  
[ec2-user ~]$ sudo chmod 600 custom.key  
[ec2-user ~]$ ls -al custom.key
```

The commands above should yield the following result:

```
-rw----- root root custom.key
```

After you have created and configured a satisfactory key, you can create a CSR.

3. Create a CSR using your preferred key; the example below uses **custom.key**:

```
[ec2-user ~]$ sudo openssl req -new -key custom.key -out csr.pem
```

OpenSSL opens a dialog and prompts you for the information shown in the following table. All of the fields except **Common Name** are optional for a basic, domain-validated host certificate.

Name	Description	Example
Country Name	The two-letter ISO abbreviation for your country.	US (=United States)
State or Province Name	The name of the state or province where your organization is located. This name cannot be abbreviated.	Washington
Locality Name	The location of your organization, such as a city.	Seattle
Organization Name	The full legal name of your organization. Do not abbreviate your organization name.	Example Corporation
Organizational Unit Name	Additional organizational information, if any.	Example Dept
Common Name	This value must exactly match the web address that you expect users to type into	www.example.com

Name	Description	Example
	a browser. Usually, this means a domain name with a prefixed host name or alias in the form www.example.com . In testing with a self-signed certificate and no DNS resolution, the common name may consist of the host name alone. CAs also offer more expensive certificates that accept wild-card names such as *.example.com .	
Email Address	The server administrator's email address.	someone@example.com

Finally, OpenSSL prompts you for an optional challenge password. This password applies only to the CSR and to transactions between you and your CA, so follow the CA's recommendations about this and the other optional field, optional company name. The CSR challenge password has no effect on server operation.

The resulting file **csr.pem** contains your public key, your digital signature of your public key, and the metadata that you entered.

- Submit the CSR to a CA. This usually consists of opening your CSR file in a text editor and copying the contents into a web form. At this time, you may be asked to supply one or more subject alternate names (SANs) to be placed on the certificate. If **www.example.com** is the common name, then **example.com** would be a good SAN, and vice versa. A visitor to your site typing in either of these names would see an error-free connection. If your CA web form allows it, include the common name in the list of SANs. Some CAs include it automatically.

After your request has been approved, you receive a new host certificate signed by the CA. You might also be instructed to download an *intermediate certificate* file that contains additional certificates needed to complete the CA's chain of trust.

Note

Your CA may send you files in multiple formats intended for various purposes. For this tutorial, you should only use a certificate file in PEM format, which is usually (but not always) marked with a **.pem** or **.crt** extension. If you are uncertain which file to

use, open the files with a text editor and find the one containing one or more blocks beginning with the following:

```
- - - - -BEGIN CERTIFICATE - - - - -
```

The file should also end with the following:

```
- - - - -END CERTIFICATE - - - - -
```

You can also test a file at the command line as follows:

```
[ec2-user certs]$ openssl x509 -in certificate.crt -text
```

Verify that these lines appear in the file. Do not use files ending with .p7b, .p7c, or similar file extensions.

5. Place the new CA-signed certificate and any intermediate certificates in the /etc/pki/tls/certs directory.

Note

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (for example, vi, nano, or notepad) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] permissions when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/certs directory, use the following commands to verify that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only).

```
[ec2-user certs]$ sudo chown root.root custom.crt
[ec2-user certs]$ sudo chmod 600 custom.crt
[ec2-user certs]$ ls -al custom.crt
```

The commands above should yield the following result:

```
-rw----- root root custom.crt
```

The permissions for the intermediate certificate file are less stringent (owner=root, group=root, owner can write, group can read, world can read). The commands would be:

```
[ec2-user certs]$ sudo chown root.root intermediate.crt
[ec2-user certs]$ sudo chmod 644 intermediate.crt
[ec2-user certs]$ ls -al intermediate.crt
```

The commands above should yield the following result:

```
-rw-r--r-- root root intermediate.crt
```

6. If you used a custom key to create your CSR and the resulting host certificate, remove or rename the old key from the /etc/pki/tls/private/ directory, and then install the new key there.

 **Note**

There are several ways to upload your custom key to your EC2 instance, but the most straightforward and informative way is to open a text editor (vi, nano, notepad, etc.) on both your local computer and your instance, and then copy and paste the file contents between them. You need root [sudo] privileges when performing these operations on the EC2 instance. This way, you can see immediately if there are any permission or path problems. Be careful, however, not to add any additional lines while copying the contents, or to change them in any way.

From inside the /etc/pki/tls/private directory, check that the file ownership, group, and permission settings match the highly restrictive Amazon Linux defaults (owner=root, group=root, read/write for owner only). The commands would be as follows:

```
[ec2-user private]$ sudo chown root.root custom.key
[ec2-user private]$ sudo chmod 600 custom.key
[ec2-user private]$ ls -al custom.key
```

The commands above should yield the following result:

```
-rw----- root root custom.key
```

7. Edit /etc/httpd/conf.d/ssl.conf to reflect your new certificate and key files.

- a. Provide the path and file name of the CA-signed host certificate in Apache's SSLCertificateFile directive:

```
SSLCertificateFile /etc/pki/tls/certs/custom.crt
```

- b. If you received an intermediate certificate file (intermediate.crt in this example), provide its path and file name using Apache's SSLCACertificateFile directive:

```
SSLCACertificateFile /etc/pki/tls/certs/intermediate.crt
```

 **Note**

Some CAs combine the host certificate and the intermediate certificates in a single file, making this directive unnecessary. Consult the instructions provided by your CA.

- c. Provide the path and file name of the private key in Apache's SSLCertificateKeyFile directive:

```
SSLCertificateKeyFile /etc/pki/tls/private/custom.key
```

8. Save /etc/httpd/conf.d/ssl.conf and restart Apache.

```
[ec2-user ~]$ sudo service httpd restart
```

9. Test your server by entering your domain name into a browser URL bar with the prefix https://. Your browser should load the test page over HTTPS without generating errors.

Step 3: Test and harden the security configuration

After your TLS is operational and exposed to the public, you should test how secure it really is. This is easy to do using online services such as [Qualys SSL Labs](#), which performs a free and thorough

analysis of your security setup. Based on the results, you may decide to harden the default security configuration by controlling which protocols you accept, which ciphers you prefer, and which you exclude. For more information, see [how Qualys formulates its scores](#).

Important

Real-world testing is crucial to the security of your server. Small configuration errors may lead to serious security breaches and loss of data. Because recommended security practices change constantly in response to research and emerging threats, periodic security audits are essential to good server administration.

On the [Qualys SSL Labs](#) site, type the fully qualified domain name of your server, in the form **www.example.com**. After about two minutes, you receive a grade (from A to F) for your site and a detailed breakdown of the findings. Though the overview shows that the configuration is mostly sound, the detailed report flags several potential problems. For example:

- ✗ **The RC4 cipher is supported for use by certain older browsers.** A cipher is the mathematical core of an encryption algorithm. RC4, a fast cipher used to encrypt TLS data-streams, is known to have several [serious weaknesses](#). Unless you have very good reasons to support legacy browsers, you should disable this.
- ✗ **Old TLS versions are supported.** The configuration supports TLS 1.0 (already deprecated) and TLS 1.1 (on a path to deprecation). Only TLS 1.2 has been recommended since 2018.

To correct the TLS configuration

1. Open the configuration file `/etc/httpd/conf.d/ssl.conf` in a text editor and comment out the following lines by typing "#" at the beginning of each:

```
#SSLProtocol all -SSLv3  
#SSLProxyProtocol all -SSLv3
```

2. Add the following directives:

```
SSLProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2  
SSLProxyProtocol -SSLv2 -SSLv3 -TLSv1 -TLSv1.1 +TLSv1.2
```

These directives explicitly disable SSL versions 2 and 3, as well as TLS versions 1.0 and 1.1. The server now refuses to accept encrypted connections with clients using anything except TLS 1.2. The verbose wording in the directive communicates more clearly, to a human reader, what the server is configured to do.

 **Note**

Disabling TLS versions 1.0 and 1.1 in this manner blocks a small percentage of outdated web browsers from accessing your site.

To modify the list of allowed ciphers

1. Open the configuration file `/etc/httpd/conf.d/ssl.conf` and find the section with commented-out examples for configuring **SSLCipherSuite** and **SSLProxyCipherSuite**.

```
#SSLCipherSuite HIGH:MEDIUM:!aNULL:!MD5  
#SSLProxyCipherSuite HIGH:MEDIUM:!aNULL:!MD5
```

Leave these as they are, and below them add the following directives:

 **Note**

Though shown here on several lines for readability, each of these two directives must be on a single line without spaces between the cipher names.

```
SSLCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-SHA384:ECDHE-  
ECDSA-CHACHA20-POLY1305:  
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-  
SHA256:ECDHE-ECDSA-AES256-SHA384:  
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:  
aNULL:!eNULL:!EXPORT:!DES:  
!RC4:!MD5:!PSK:!aECDH:!EDH-DSS-DES-CBC3-SHA:!EDH-RSA-DES-CBC3-SHA:!KRB5-DES-CBC3-  
SHA
```

```
SSLProxyCipherSuite ECDHE-ECDSA-AES256-GCM-SHA384:ECDHE-RSA-AES256-GCM-  
SHA384:ECDHE-ECDSA-CHACHA20-POLY1305:
```

```
ECDHE-RSA-CHACHA20-POLY1305:ECDHE-ECDSA-AES128-GCM-SHA256:ECDHE-RSA-AES128-GCM-SHA256:ECDHE-ECDSA-AES256-SHA384:  
ECDHE-RSA-AES256-SHA384:ECDHE-ECDSA-AES128-SHA256:ECDHE-RSA-AES128-SHA256:AES:  
aNULL:!eNULL:!EXPORT:!DES:  
!RC4:!MD5:!PSK:!aECDH:!EDH-DSS-DES-CBC3-SHA:!EDH-RSA-DES-CBC3-SHA:!KRB5-DES-CBC3-SHA
```

These ciphers are a subset of the much longer list of supported ciphers in OpenSSL. They were selected and ordered according to the following criteria:

- Support for forward secrecy
- Strength
- Speed
- Specific ciphers before cipher families
- Allowed ciphers before denied ciphers

The high-ranking ciphers have *ECDHE* in their names, for *Elliptic Curve Diffie-Hellman Ephemeral*; the *ephemeral* indicates forward secrecy. Also, RC4 is now among the forbidden ciphers near the end.

We recommend that you use an explicit list of ciphers instead relying on defaults or terse directives whose content isn't visible. The cipher list shown here is just one of many possible lists; for instance, you might want to optimize a list for speed rather than forward secrecy.

If you anticipate a need to support older clients, you can allow the DES-CBC3-SHA cipher suite.

Each update to OpenSSL introduces new ciphers and deprecates old ones. Keep your EC2 Amazon Linux instance up to date, watch for security announcements from [OpenSSL](#), and be alert to reports of new security exploits in the technical press.

2. Uncomment the following line by removing the "#":

```
#SSLHonorCipherOrder on
```

This command forces the server to prefer high-ranking ciphers, including (in this case) those that support forward secrecy. With this directive turned on, the server tries to establish a strongly secure connection before falling back to allowed ciphers with lesser security.

3. Restart Apache. If you test the domain again on [Qualys SSL Labs](#), you should see that the RC4 vulnerability is gone.

Troubleshoot

- **My Apache webserver won't start unless I enter a password**

This is expected behavior if you installed an encrypted, password-protected, private server key.

You can remove the encryption and password requirement from the key. Assuming that you have a private encrypted RSA key called `custom.key` in the default directory, and that the password on it is `abcde12345`, run the following commands on your EC2 instance to generate an unencrypted version of the key.

```
[ec2-user ~]$ cd /etc/pki/tls/private/  
[ec2-user private]$ sudo cp custom.key custom.key.bak  
[ec2-user private]$ sudo openssl rsa -in custom.key -passin pass:abcde12345 -out  
  custom.key.nocrypt  
[ec2-user private]$ sudo mv custom.key.nocrypt custom.key  
[ec2-user private]$ sudo chown root.root custom.key  
[ec2-user private]$ sudo chmod 600 custom.key  
[ec2-user private]$ sudo service httpd restart
```

Apache should now start without prompting you for a password.

Host a WordPress blog

This section includes tutorials that show you how to install, configure, and secure a WordPress blog on an Amazon EC2 instance.

 **Note**

For the AL2023 WordPress tutorial, see [Tutorial: Host a WordPress blog on AL2023](#) in the *Amazon Linux 2023 User Guide*.

Host a WordPress blog on

- [Host a WordPress blog on Amazon Linux 2](#)

Host a WordPress blog on Amazon Linux 2

The following procedures will help you install, configure, and secure a WordPress blog on your Amazon Linux 2 instance. This tutorial is a good introduction to using Amazon EC2 in that you have full control over a web server that hosts your WordPress blog, which is not typical with a traditional hosting service.

You are responsible for updating the software packages and maintaining security patches for your server. For a more automated WordPress installation that does not require direct interaction with the web server configuration, the AWS CloudFormation service provides a WordPress template that can also get you started quickly. For more information, see [Get started in the AWS CloudFormation User Guide](#). If you'd prefer to host your WordPress blog on a Windows instance, see [Deploy a WordPress blog on your Amazon EC2 Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*. If you need a high-availability solution with a decoupled database, see [Deploying a high-availability WordPress website](#) in the *AWS Elastic Beanstalk Developer Guide*.

Important

These procedures are intended for use with Amazon Linux 2. For more information about other distributions, see their specific documentation. Many steps in this tutorial do not work on Ubuntu instances. For help installing WordPress on an Ubuntu instance, see [WordPress in the Ubuntu documentation](#). You can also use [CodeDeploy](#) to accomplish this task on Amazon Linux, macOS, or Unix systems.

Topics

- [Prerequisites](#)
- [Install WordPress](#)
- [Next steps](#)
- [Help! My public DNS name changed and now my blog is broken](#)

Prerequisites

This tutorial assumes that you have launched an Amazon Linux 2 instance with a functional web server with PHP and database (either MySQL or MariaDB) support by following all of the steps in [Install LAMP on Amazon Linux](#) for [Install LAMP on Amazon Linux 2](#) for Amazon Linux 2. This tutorial also has steps for configuring a security group to allow HTTP and HTTPS traffic, as well as

several steps to ensure that file permissions are set properly for your web server. For information about adding rules to your security group, see [Add rules to a security group](#).

We strongly recommend that you associate an Elastic IP address (EIP) to the instance you are using to host a WordPress blog. This prevents the public DNS address for your instance from changing and breaking your installation. If you own a domain name and you want to use it for your blog, you can update the DNS record for the domain name to point to your EIP address (for help with this, contact your domain name registrar). You can have one EIP address associated with a running instance at no charge. For more information, see [Elastic IP addresses](#).

If you don't already have a domain name for your blog, you can register a domain name with Route 53 and associate your instance's EIP address with your domain name. For more information, see [Registering domain names using Amazon Route 53](#) in the *Amazon Route 53 Developer Guide*.

Install WordPress

Option: Complete this tutorial using automation

To complete this tutorial using AWS Systems Manager Automation instead of the following tasks, run the [automation document](#).

Connect to your instance, and download the WordPress installation package.

To download and unzip the WordPress installation package

1. Download the latest WordPress installation package with the `wget` command. The following command should always download the latest release.

```
[ec2-user ~]$ wget https://wordpress.org/latest.tar.gz
```

2. Unzip and unarchive the installation package. The installation folder is unzipped to a folder called `wordpress`.

```
[ec2-user ~]$ tar -xzf latest.tar.gz
```

To create a database user and database for your WordPress installation

Your WordPress installation needs to store information, such as blog posts and user comments, in a database. This procedure helps you create your blog's database and a user that is authorized to read and save information to it.

1. Start the database server.

- [ec2-user ~]\$ **sudo systemctl start mariadb**

2. Log in to the database server as the `root` user. Enter your database `root` password when prompted; this may be different than your `root` system password, or it might even be empty if you have not secured your database server.

If you have not secured your database server yet, it is important that you do so. For more information, see [To secure the MariaDB server](#) (Amazon Linux 2).

```
[ec2-user ~]$ mysql -u root -p
```

3. Create a user and password for your MySQL database. Your WordPress installation uses these values to communicate with your MySQL database.

Make sure that you create a strong password for your user. Do not use the single quote character (') in your password, because this will break the preceding command. For more information about creating a secure password, go to <http://www.pctools.com/guides/password/>. Do not reuse an existing password, and make sure to store this password in a safe place.

Enter the following command, substituting a unique user name and password.

```
CREATE USER 'wordpress-user'@'localhost' IDENTIFIED BY 'your_strong_password';
```

4. Create your database. Give your database a descriptive, meaningful name, such as `wordpress-db`.

 **Note**

The punctuation marks surrounding the database name in the command below are called backticks. The backtick (`) key is usually located above the Tab key on a standard keyboard. Backticks are not always required, but they allow you to use otherwise illegal characters, such as hyphens, in database names.

```
CREATE DATABASE `wordpress-db`;
```

5. Grant full privileges for your database to the WordPress user that you created earlier.

```
GRANT ALL PRIVILEGES ON `wordpress-db`.* TO "wordpress-user"@"localhost";
```

- Flush the database privileges to pick up all of your changes.

```
FLUSH PRIVILEGES;
```

- Exit the mysql client.

```
exit
```

To create and edit the wp-config.php file

The WordPress installation folder contains a sample configuration file called wp-config-sample.php. In this procedure, you copy this file and edit it to fit your specific configuration.

- Copy the wp-config-sample.php file to a file called wp-config.php. This creates a new configuration file and keeps the original sample file intact as a backup.

```
[ec2-user ~]$ cp wordpress/wp-config-sample.php wordpress/wp-config.php
```

- Edit the wp-config.php file with your favorite text editor (such as **nano** or **vim**) and enter values for your installation. If you do not have a favorite text editor, nano is suitable for beginners.

```
[ec2-user ~]$ nano wordpress/wp-config.php
```

- Find the line that defines DB_NAME and change database_name_here to the database name that you created in [Step 4 of To create a database user and database for your WordPress installation.](#)

```
define('DB_NAME', 'wordpress-db');
```

- Find the line that defines DB_USER and change username_here to the database user that you created in [Step 3 of To create a database user and database for your WordPress installation.](#)

```
define('DB_USER', 'wordpress-user');
```

- c. Find the line that defines DB_PASSWORD and change password_here to the strong password that you created in [Step 3](#) of [To create a database user and database for your WordPress installation](#).

```
define('DB_PASSWORD', 'your_strong_password');
```

- d. Find the section called Authentication Unique Keys and Salts. These KEY and SALT values provide a layer of encryption to the browser cookies that WordPress users store on their local machines. Basically, adding long, random values here makes your site more secure. Visit <https://api.wordpress.org/secret-key/1.1/salt/> to randomly generate a set of key values that you can copy and paste into your wp-config.php file. To paste text into a PuTTY terminal, place the cursor where you want to paste the text and right-click your mouse inside the PuTTY terminal.

For more information about security keys, go to <https://wordpress.org/support/article/editing-wp-config-php/#security-keys>.

 **Note**

The values below are for example purposes only; do not use these values for your installation.

```
define('AUTH_KEY', '#U$$+[RXN8:b^L 0(WU_+ c+WFKI~c]o]-bHw+)/Aj[wTwSiZ<Qb[mghExcRh-');
define('SECURE_AUTH_KEY', 'Zsz._P=l/|y.Lq)Xj1kwS1y5NJ76E6EJ.AV0pCKZZB,*~*r ?60P$eJT@;+(ndLg');
define('LOGGED_IN_KEY', 'ju}qwre3V*+8f_z0WF?{L1GsQ]Ye@2Jh^,8x>)Y |;(^[Iw]Pi+LG#A4R?7N`YB3');
define('NONCE_KEY', 'P(g62HeZxEes|LnI^i=H,[XwK9I&[2s|:?0N}VJM%?;v2v]v+;+^9eXUahg@::Cj');
define('AUTH_SALT', 'C$DpB4Hj[JK:?:ql`sRVa:{:7yShy(9A@5wg+`JJVb1fk%-Bx*M4(qc[Qg%JT!h');
define('SECURE_AUTH_SALT', 'd!uRu#]+q#[f$Z?Z9uFPG.${+S{n~1M%&%@~gL>U>NV<zpD-@2-Es7Q10-bp28EKv');
define('LOGGED_IN_SALT', 'j{00P*owZf)kVD+FVLn-~ >. |Y%Ug4#I^*LVd9QeZ^&XmK|e(76mic+&W&+^0P/');
define('NONCE_SALT', '-97r*V/cgxLmp?Zy4zUU4r99QQ_rGs2LTd%P;|_e1ts)8_B/, .6[=UK<J_y9?JWG');
```

- e. Save the file and exit your text editor.

To install your WordPress files under the Apache document root

- Now that you've unzipped the installation folder, created a MySQL database and user, and customized the WordPress configuration file, you are ready to copy your installation files to your web server document root so you can run the installation script that completes your installation. The location of these files depends on whether you want your WordPress blog to be available at the actual root of your web server (for example, *my.public.dns.amazonaws.com*) or in a subdirectory or folder under the root (for example, *my.public.dns.amazonaws.com/blog*).
 - If you want WordPress to run at your document root, copy the contents of the `wordpress` installation directory (but not the directory itself) as follows:

```
[ec2-user ~]$ cp -r wordpress/* /var/www/html/
```

- If you want WordPress to run in an alternative directory under the document root, first create that directory, and then copy the files to it. In this example, WordPress will run from the directory `blog`:

```
[ec2-user ~]$ mkdir /var/www/html/blog  
[ec2-user ~]$ cp -r wordpress/* /var/www/html/blog/
```

Important

For security purposes, if you are not moving on to the next procedure immediately, stop the Apache web server (`httpd`) now. After you move your installation under the Apache document root, the WordPress installation script is unprotected and an attacker could gain access to your blog if the Apache web server were running. To stop the Apache web server, enter the command `sudo systemctl stop httpd`. If you are moving on to the next procedure, you do not need to stop the Apache web server.

To allow WordPress to use permalinks

WordPress permalinks need to use Apache .htaccess files to work properly, but this is not enabled by default on Amazon Linux. Use this procedure to allow all overrides in the Apache document root.

1. Open the httpd.conf file with your favorite text editor (such as **nano** or **vim**). If you do not have a favorite text editor, nano is suitable for beginners.

```
[ec2-user ~]$ sudo vim /etc/httpd/conf/httpd.conf
```

2. Find the section that starts with <Directory "/var/www/html">.

```
<Directory "/var/www/html">
#
# Possible values for the Options directive are "None", "All",
# or any combination of:
#   Indexes Includes FollowSymLinks SymLinksifOwnerMatch ExecCGI MultiViews
#
# Note that "MultiViews" must be named *explicitly* --- "Options All"
# doesn't give it to you.
#
# The Options directive is both complicated and important. Please see
# http://httpd.apache.org/docs/2.4/mod/core.html#options
# for more information.
#
Options Indexes FollowSymLinks

#
# AllowOverride controls what directives may be placed in .htaccess files.
# It can be "All", "None", or any combination of the keywords:
#   Options FileInfo AuthConfig Limit
#
AllowOverride None

#
# Controls who can get stuff from this server.
#
Require all granted
</Directory>
```

3. Change the AllowOverride None line in the above section to read AllowOverride **All**.

Note

There are multiple `AllowOverride` lines in this file; be sure you change the line in the `<Directory "/var/www/html">` section.

`AllowOverride All`

4. Save the file and exit your text editor.

To install the PHP graphics drawing library on Amazon Linux 2

The GD library for PHP enables you to modify images. Install this library if you need to crop the header image for your blog. The version of phpMyAdmin that you install might require a specific minimum version of this library (for example, version 7.2).

Use the following command to install the PHP graphics drawing library on Amazon Linux 2. For example, if you installed php7.2 from amazon-linux-extras as part of installing the LAMP stack, this command installs version 7.2 of the PHP graphics drawing library.

```
[ec2-user ~]$ sudo yum install php-gd
```

To verify the installed version, use the following command:

```
[ec2-user ~]$ sudo yum list installed php-gd
```

The following is example output:

php-gd.x86_64	7.2.30-1.amzn2	@amzn2extra-php7.2
---------------	----------------	--------------------

To fix file permissions for the Apache web server

Some of the available features in WordPress require write access to the Apache document root (such as uploading media through the Administration screens). If you have not already done so, apply the following group memberships and permissions (as described in greater detail in the [LAMP web server tutorial](#)).

1. Grant file ownership of /var/www and its contents to the apache user.

```
[ec2-user ~]$ sudo chown -R apache /var/www
```

2. Grant group ownership of /var/www and its contents to the apache group.

```
[ec2-user ~]$ sudo chgrp -R apache /var/www
```

3. Change the directory permissions of /var/www and its subdirectories to add group write permissions and to set the group ID on future subdirectories.

```
[ec2-user ~]$ sudo chmod 2775 /var/www  
[ec2-user ~]$ find /var/www -type d -exec sudo chmod 2775 {} \;
```

4. Recursively change the file permissions of /var/www and its subdirectories.

```
[ec2-user ~]$ find /var/www -type f -exec sudo chmod 0644 {} \;
```

 **Note**

If you intend to also use WordPress as an FTP server, you'll need more permissive Group settings here. Please review the recommended [steps and security settings in WordPress](#) to accomplish this.

5. Restart the Apache web server to pick up the new group and permissions.

- ```
[ec2-user ~]$ sudo systemctl restart httpd
```

## Run the WordPress installation script with Amazon Linux 2

You are ready to install WordPress. The commands that you use depend on the operating system. The commands in this procedure are for use with Amazon Linux 2.

1. Use the **systemctl** command to ensure that the httpd and database services start at every system boot.

```
[ec2-user ~]$ sudo systemctl enable httpd && sudo systemctl enable mariadb
```

2. Verify that the database server is running.

```
[ec2-user ~]$ sudo systemctl status mariadb
```

If the database service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start mariadb
```

- Verify that your Apache web server (httpd) is running.

```
[ec2-user ~]$ sudo systemctl status httpd
```

If the httpd service is not running, start it.

```
[ec2-user ~]$ sudo systemctl start httpd
```

- In a web browser, type the URL of your WordPress blog (either the public DNS address for your instance, or that address followed by the blog folder). You should see the WordPress installation script. Provide the information required by the WordPress installation. Choose **Install WordPress** to complete the installation. For more information, see [Step 5: Run the Install Script](#) on the WordPress website.

## Next steps

After you have tested your WordPress blog, consider updating its configuration.

### Use a custom domain name

If you have a domain name associated with your EC2 instance's EIP address, you can configure your blog to use that name instead of the EC2 public DNS address. For more information, see [Changing The Site URL](#) on the WordPress website.

### Configure your blog

You can configure your blog to use different [themes](#) and [plugins](#) to offer a more personalized experience for your readers. However, sometimes the installation process can backfire, causing you to lose your entire blog. We strongly recommend that you create a backup Amazon Machine Image (AMI) of your instance before attempting to install any themes or plugins so you can restore your blog if anything goes wrong during installation. For more information, see [Create your own AMI](#).

### Increase capacity

If your WordPress blog becomes popular and you need more compute power or storage, consider the following steps:

- Expand the storage space on your instance. For more information, see [Amazon EBS Elastic Volumes](#) in the *Amazon EBS User Guide*.
- Move your MySQL database to [Amazon RDS](#) to take advantage of the service's ability to scale easily.

## Improve network performance of your internet traffic

If you expect your blog to drive traffic from users located around the world, consider [AWS Global Accelerator](#). Global Accelerator helps you achieve lower latency by improving internet traffic performance between your users' client devices and your WordPress application running on AWS. Global Accelerator uses the [AWS global network](#) to direct traffic to a healthy application endpoint in the AWS Region that is closest to the client.

## Help! My public DNS name changed and now my blog is broken

Your WordPress installation is automatically configured using the public DNS address for your EC2 instance. If you stop and restart the instance, the public DNS address changes (unless it is associated with an Elastic IP address) and your blog will not work anymore because it references resources at an address that no longer exists (or is assigned to another EC2 instance). A more detailed description of the problem and several possible solutions are outlined in <https://wordpress.org/support/article/changing-the-site-url/>.

If this has happened to your WordPress installation, you may be able to recover your blog with the procedure below, which uses the `wp-cli` command line interface for WordPress.

### To change your WordPress site URL with the wp-cli

1. Connect to your EC2 instance with SSH.

2. Note the old site URL and the new site URL for your instance. The old site URL is likely the public DNS name for your EC2 instance when you installed WordPress. The new site URL is the current public DNS name for your EC2 instance. If you are not sure of your old site URL, you can use **curl** to find it with the following command.

```
[ec2-user ~]$ curl localhost | grep wp-content
```

You should see references to your old public DNS name in the output, which will look like this (old site URL in red):

```
<script type='text/javascript' src='http://ec2-52-8-139-223.us-west-1.compute.amazonaws.com/wp-content/themes/twentyfifteen/js/functions.js?ver=20150330'></script>
```

3. Download the **wp-cli** with the following command.

```
[ec2-user ~]$ curl -O https://raw.githubusercontent.com/wp-cli/builds/gh-pages/phar/wp-cli.phar
```

4. Search and replace the old site URL in your WordPress installation with the following command. Substitute the old and new site URLs for your EC2 instance and the path to your WordPress installation (usually /var/www/html or /var/www/html/blog).

```
[ec2-user ~]$ php wp-cli.phar search-replace 'old_site_url' 'new_site_url' --path=/path/to/wordpress/installation --skip-columns=guid
```

5. In a web browser, enter the new site URL of your WordPress blog to verify that the site is working properly again. If it is not, see <https://wordpress.org/support/article/changing-the-site-url/> and <https://wordpress.org/support/article/how-to-install-wordpress/#common-installation-problems> for more information.

# Amazon Machine Images (AMI)

An Amazon Machine Image (AMI) is a supported and maintained image provided by AWS that provides the information required to launch an instance. You must specify an AMI when you launch an instance. You can launch multiple instances from a single AMI when you require multiple instances with the same configuration. You can use different AMIs to launch instances when you require instances with different configurations.

An AMI includes the following:

- One or more Amazon Elastic Block Store (Amazon EBS) snapshots, or, for instance-store-backed AMIs, a template for the root volume of the instance (for example, an operating system, an application server, and applications).
- Launch permissions that control which AWS accounts can use the AMI to launch instances.
- A block device mapping that specifies the volumes to attach to the instance when it's launched.

- [AMI quotas](#)

## Use an AMI

The following diagram summarizes the AMI lifecycle. After you create and register an AMI, you can use it to launch new instances. (You can also launch instances from an AMI if the AMI owner grants you launch permissions.) You can copy an AMI within the same AWS Region or to different AWS Regions. When you no longer require an AMI, you can deregister it.

You can search for an AMI that meets the criteria for your instance. You can search for AMIs provided by AWS or AMIs provided by the community. For more information, see [AMI types](#) and [Find a Linux AMI](#).

After you launch an instance from an AMI, you can connect to it. When you are connected to an instance, you can use it just like you use any other server. For information about launching, connecting, and using your instance, see [Tutorial: Get started with Amazon EC2 Linux instances](#).

## Create your own AMI

You can launch an instance from an existing AMI, customize the instance (for example, [install software](#) on the instance), and then save this updated configuration as a custom AMI. Instances launched from this new custom AMI include the customizations that you made when you created the AMI.

The root storage device of the instance determines the process you follow to create an AMI. The root volume of an instance is either an Amazon Elastic Block Store (Amazon EBS) volume or an

instance store volume. For more information about the root device volume, see [Amazon EC2 instance root volume](#).

- To create an Amazon EBS-backed AMI, see [Create an Amazon EBS-backed Linux AMI](#).
- To create an instance store-backed AMI, see [Create an instance store-backed Linux AMI](#).

To help categorize and manage your AMIs, you can assign custom *tags* to them. For more information, see [Tag your Amazon EC2 resources](#).

## Buy, share, and sell AMIs

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see [Shared AMIs](#).

You can purchase AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users. For more information about buying or selling AMIs, see [Paid AMIs](#).

## Deregister your AMI

You can deregister an AMI when you have finished with it. After you deregister an AMI, it can't be used to launch new instances. Existing instances launched from the AMI are not affected. For more information, see [Deregister your AMI](#).

## AL2023 and Amazon Linux 2

The latest release of Amazon Linux, AL2023, is optimized for Amazon EC2 and is provided at no additional cost to Amazon EC2 users. The features of AL2023 include a predictable release cadence, frequent updates, and long-term support.

For more information about AL2023 features and launching an AL2023 AMI, see:

- [AL2023 Features](#)
- [Get started with AL2023](#)

Amazon Linux 2 provides a stable, secure, and high performance execution environment for applications running on Amazon EC2. For information about Amazon Linux 2 EOL, see [Amazon Linux 2 FAQs](#).

### Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

## AMI types

You can select an AMI to use based on the following characteristics:

- Region (see [Regions and Zones](#))
- Operating system
- Architecture (32-bit or 64-bit)
- [Launch permissions](#)
- [Storage for the root device](#)

## Launch permissions

The owner of an AMI determines its availability by specifying launch permissions. Launch permissions fall into the following categories.

| Launch permission | Description                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------|
| public            | The owner grants launch permissions to all AWS accounts.                                                    |
| explicit          | The owner grants launch permissions to specific AWS accounts, organizations, or organizational units (OUs). |
| implicit          | The owner has implicit launch permissions for an AMI.                                                       |

Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see [Shared AMIs](#). Developers can charge for their AMIs. For more information, see [Paid AMIs](#).

## Storage for the root device

All AMIs are categorized as either *backed by Amazon EBS* or *backed by instance store*.

- Amazon EBS-backed AMI – The root device for an instance launched from the AMI is an Amazon Elastic Block Store (Amazon EBS) volume created from an Amazon EBS snapshot.
- Amazon instance store-backed AMI – The root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

For more information, see [Amazon EC2 instance root volume](#).

The following table summarizes the important differences when using the two types of AMIs.

| Characteristic               | Amazon EBS-backed AMI                                                                                                                               | Amazon instance store-backed AMI                                                  |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Boot time for an instance    | Usually less than 1 minute                                                                                                                          | Usually less than 5 minutes                                                       |
| Size limit for a root device | 64 TiB**                                                                                                                                            | 10 GiB                                                                            |
| Root device volume           | EBS volume                                                                                                                                          | Instance store volume                                                             |
| Data persistence             | By default, the root volume is deleted when the instance terminates.* Data on any other EBS volumes persists after instance termination by default. | Data on any instance store volumes persists only during the life of the instance. |
| Modifications                |                                                                                                                                                     |                                                                                   |

| Characteristic        | Amazon EBS-backed AMI                                                                                                    | Amazon instance store-backed AMI                                     |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
|                       | The instance type, kernel, RAM disk, and user data can be changed while the instance is stopped.                         | Instance attributes are fixed for the life of an instance.           |
| Charges               | You're charged for instance usage, EBS volume usage, and storing your AMI as an EBS snapshot.                            | You're charged for instance usage and storing your AMI in Amazon S3. |
| AMI creation/bundling | Uses a single command/call                                                                                               | Requires installation and use of AMI tools                           |
| Stopped state         | Can be in a stopped state. Even when the instance is stopped and not running, the root volume is persisted in Amazon EBS | Cannot be in a stopped state; instances are running or terminated    |

\* By default, EBS root volumes have the `DeleteOnTermination` flag set to `true`. For information about how to change this flag so that the volume persists after termination, see [Change the root volume to persist](#).

\*\* Supported with io2 EBS Block Express only. For more information, see [Provisioned IOPS SSD Block Express volumes](#) in the *Amazon EBS User Guide*.

## Determine the root device type of your AMI

### To determine the root device type of an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and select the AMI.
3. On the **Details** tab, check the value of **Root device type** as follows:

- `ebs` – This is an EBS-backed AMI.
- `instance store` – This is an instance store-backed AMI.

## To determine the root device type of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [describe-images](#) (AWS CLI)
- [Get-EC2Image](#) (AWS Tools for Windows PowerShell)

## Stopped state

You can stop an instance that has an EBS volume for its root device, but you can't stop an instance that has an instance store volume for its root device.

Stopping causes the instance to stop running (its status goes from `running` to `stopping` to `stopped`). A stopped instance persists in Amazon EBS, which allows it to be restarted. Stopping is different from terminating; you can't restart a terminated instance. Because instances with an instance store volume for the root device can't be stopped, they're either running or terminated. For more information about what happens and what you can do while an instance is stopped, see [Stop and start Amazon EC2 instances](#).

## Default data storage and persistence

Instances that have an instance store volume for the root device automatically have instance store available (the root volume contains the root partition and you can store additional data). You can add persistent storage to your instance by attaching one or more EBS volumes. Any data on an instance store volume is deleted when the instance fails or terminates. For more information, see [Instance store volume and data lifetime](#).

Instances that have Amazon EBS for the root device automatically have an EBS volume attached. The volume appears in your list of volumes like any other. With most instance types, instances that have an EBS volume for the root device don't have instance store volumes by default. You can add instance store volumes or additional EBS volumes using a block device mapping. For more information, see [Block device mappings](#).

## Boot times

Instances launched from an Amazon EBS-backed AMI launch faster than instances launched from an instance store-backed AMI. When you launch an instance from an instance store-backed AMI, all the parts have to be retrieved from Amazon S3 before the instance is available. With an Amazon EBS-backed AMI, only the parts required to boot the instance need to be retrieved from the snapshot before the instance is available. However, the performance of an instance that uses an EBS volume for its root device is slower for a short time while the remaining parts are retrieved from the snapshot and loaded into the volume. When you stop and restart the instance, it launches quickly, because the state is stored in an EBS volume.

## AMI creation

To create Linux AMIs backed by instance store, you must create an AMI from your instance on the instance itself using the Amazon EC2 AMI tools.

AMI creation is much easier for AMIs backed by Amazon EBS. The `CreateImage` API action creates your Amazon EBS-backed AMI and registers it. There's also a button in the AWS Management Console that lets you create an AMI from a running instance. For more information, see [Create an Amazon EBS-backed Linux AMI](#).

## How you're charged

With AMIs backed by instance store, you're charged for instance usage and storing your AMI in Amazon S3. With AMIs backed by Amazon EBS, you're charged for instance usage, EBS volume storage and usage, and storing your AMI as an EBS snapshot.

With Amazon EC2 instance store-backed AMIs, each time you customize an AMI and create a new one, all of the parts are stored in Amazon S3 for each AMI. So, the storage footprint for each customized AMI is the full size of the AMI. For Amazon EBS-backed AMIs, each time you customize an AMI and create a new one, only the changes are stored. So, the storage footprint for subsequent AMIs that you customize after the first is much smaller, resulting in lower AMI storage charges.

When an instance with an EBS volume for its root device is stopped, you're not charged for instance usage; however, you're still charged for volume storage. As soon as you start your instance, we charge a minimum of one minute for usage. After one minute, we charge only for the seconds used. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage. We charge you for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

# Linux AMI virtualization types

Linux Amazon Machine Images use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance.

For the best performance, we recommend that you use current generation instance types and HVM AMIs when you launch your instances. For more information about current generation instance types, see [Amazon EC2 Instance Types](#). If you are using previous generation instance types and would like to upgrade, see [Upgrade Paths](#) and [Change the instance type](#).

The following table compares HVM and PV AMIs.

|             | HVM                                                                                                                                                                                                                                                                                                                                                                                                                                                   | PV                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest. | PV AMIs boot with a special boot loader called PV-GRUB, which starts the boot cycle and then chain loads the kernel specified in the menu.1st file on your image. Paravirtual guests can run on host hardware that does not have explicit support for virtualization. Historically, PV guests had better performance than HVM guests in many cases, but because of enhancements in HVM virtualization and the availability of PV drivers for HVM AMIs, this is no longer true. For more information about PV-GRUB and its use in Amazon EC2, see <a href="#">User provided kernels</a> . |

| Support for hardware extensions | <p>Yes. Unlike PV guests, HVM guests can take advantage of hardware extensions that provide fast access to the underlying hardware on the host system. For more information on CPU virtualization extensions available in Amazon EC2, see <a href="#">Intel Virtualization Technology</a> on the Intel website. HVM AMIs are required to take advantage of enhanced networking and GPU processing. In order to pass through instructions to specialized network and GPU devices, the OS needs to be able to have access to the native hardware platform; HVM virtualization provides this access. For more information, see <a href="#">Enhanced networking on Linux</a>.</p> | <p>No, they cannot take advantage of special hardware extensions such as enhanced networking or GPU processing.</p>                                            |

## PV on HVM

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so operating systems that cannot be ported to run in a paravirtualized environment can still see performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same, or better, performance than paravirtual guests.

## Boot modes

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

In Amazon EC2, two variants of the boot mode software are supported: Unified Extensible Firmware Interface (UEFI) and Legacy BIOS.

### Possible boot mode parameters on an AMI

An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`. The AMI boot mode parameter is optional. For AMIs with no boot mode parameter, the instances launched from these AMIs use the default boot mode value of the instance type.

## Purpose of the AMI boot mode parameter

The AMI boot mode parameter signals to Amazon EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to `uefi`, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch will be unsuccessful.

## UEFI Preferred boot mode parameter

You can create AMIs that support both UEFI and Legacy BIOS by using the `uefi-preferred` boot mode parameter. When the boot mode parameter is set to `uefi-preferred`, and if the instance type supports UEFI, the instance is launched on UEFI. If the instance type does not support UEFI, the instance is launched on Legacy BIOS.

### Warning

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

## Default boot modes for instance types

- Graviton instance types: UEFI
- Intel and AMD instance types: Legacy BIOS

## Running Intel and AMD instances types on UEFI

[Most Intel and AMD instance types](#) can run on both UEFI and Legacy BIOS. To use UEFI, you must select an AMI with the boot mode parameter set either to `uefi` or `uefi-preferred`, and the operating system contained in the AMI must be configured to support UEFI.

## Limitations

UEFI boot is not supported in Local Zones, Wavelength Zones, or with AWS Outposts.

## Considerations

Consider the following when launching an instance:

- The boot mode of the instance is determined by the configuration of the AMI, the operating system contained in it, and the instance type, illustrated by the following image:

The following table shows that the boot mode of an instance (indicated by the **Resulting instance boot mode** column) is determined by a combination of the boot mode parameter of the AMI (column 1), the boot mode configuration of the operating system contained in the AMI (column 2), and the boot mode support of the instance type (column 3).

| AMI boot mode parameter      | Operating system boot mode configuration | Instance type boot mode support | Resulting instance boot mode |
|------------------------------|------------------------------------------|---------------------------------|------------------------------|
| UEFI                         | UEFI                                     | UEFI                            | UEFI                         |
| Legacy BIOS                  | Legacy BIOS                              | Legacy BIOS                     | Legacy BIOS                  |

## To see the available instance types for Linux that support UEFI in a specific Region

The available instance types vary by AWS Region. To see the available instance types that support UEFI in a Region, use the [describe-instance-types](#) command with the --region parameter. If you omit the --region parameter, your [default Region](#) is used in the request. Include the --filters parameter to scope the results to the instance types that support UEFI and the --query parameter to scope the output to the value of InstanceType.

### AWS CLI

```
$ aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi --query "InstanceTypes[*].[InstanceType]" --output text | sort

a1.2xlarge
a1.4xlarge
a1.large
a1.medium
a1.metal
a1.xlarge
c5.12xlarge
...
```

## PowerShell

```
PS C:\> Get-EC2InstanceType | `
Where-Object {$_.SupportedBootModes -Contains "uefi"} | `
Sort-Object InstanceType | `
Format-Table InstanceType -GroupBy CurrentGeneration

CurrentGeneration: False

InstanceType

...
```

### To see the available instance types for Linux that support UEFI Secure Boot and persist non-volatile variables in a specific Region

Currently, bare metal instances do not support UEFI Secure Boot and non-volatile variables. Use the [describe-instance-types](#) command as described in the preceding example, but filter out the bare metal instances by including the Name=bare-metal,Values=false filter. For information about UEFI Secure Boot, see [UEFI Secure Boot](#).

## AWS CLI

```
$ aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi
Name=bare-metal,Values=false --query "InstanceTypes[*].[InstanceType]" --output
text | sort

a1.2xlarge
a1.4xlarge
a1.large
a1.medium
...
```

## PowerShell

```
PS C:\> Get-EC2InstanceType |
Where-Object {`
 $_.SupportedBootModes -Contains "uefi" -and `
 $_.BareMetal -eq $False
} | `
Sort-Object InstanceType | `
Format-Table InstanceType, SupportedBootModes, BareMetal,
@{Name="SupportedArchitectures";
Expression={$_.ProcessorInfo.SupportedArchitectures}}

InstanceType SupportedBootModes BareMetal SupportedArchitectures

## Requirements for launching an instance on UEFI

To launch an instance in UEFI boot mode, you must select an instance type that supports UEFI, and configure the AMI and the operating system for UEFI, as follows:

## Instance type

When launching an instance, you must select an instance type that supports UEFI. For more information, see [Determine the supported boot modes of an instance type](#).

### AMI

When launching an instance, you must select an AMI that is configured for UEFI. The AMI must be configured as follows:

- **Operating system** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the instance launch will fail. For more information, see [Determine the boot mode of the operating system](#).
- **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to `uefi` or `uefi-preferred`. For more information, see [Determine the boot mode parameter of an AMI](#).

AWS only provides Linux AMIs that are configured to support UEFI for Graviton-based instance types. To use Linux on other UEFI instance types, you must [configure the AMI](#), import the AMI through [VM Import/Export](#), or import the AMI through [CloudEndure](#).

For the supported Windows AMIs, see [Requirements for launching an instance on UEFI](#) in the *Amazon EC2 User Guide for Windows Instances*.

## Determine the boot mode parameter of an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`.

Some AMIs don't have a boot mode parameter. When an AMI has no boot mode parameter, the instances launched from the AMI use the default value of the instance type, which is `uefi` on Graviton, and `legacy-bios` on Intel and AMD instance types.

### Console

#### To determine the boot mode parameter of an AMI (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select the AMI.
3. Inspect the **Boot mode** field.

- A value of **uefi** indicates that the AMI supports UEFI.
- A value of **uefi-preferred** indicates that the AMI supports both UEFI and Legacy BIOS.
- If there is no value, the instances launched from the AMI use the default value of the instance type.

## To determine the boot mode parameter of an AMI when launching an instance (console)

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the **Boot mode** field. For more information, see [Application and OS Images \(Amazon Machine Image\)](#).

AWS CLI

## To determine the boot mode parameter of an AMI (AWS CLI)

Use the [describe-images](#) operation to determine the boot mode of an AMI.

```
$ aws ec2 describe-images --region us-east-1 --image-id ami-0abcdef1234567890

{
 "Images": [
 {
 ...
 },
 {
 "EnaSupport": true,
 "Hypervisor": "xen",
 "ImageOwnerAlias": "amazon",
 "Name": "UEFI_Boot_Mode_Enabled-Windows_Server-2016-English-Full-Base-2020.09.30",
 "RootDeviceName": "/dev/sda1",
 "RootDeviceType": "ebs",
 "SriovNetSupport": "simple",
 "VirtualizationType": "hvm",
 "BootMode": "uefi"
 }
]
}
```

In the output, the **BootMode** field indicates the boot mode of the AMI. A value of **uefi** indicates that the AMI supports UEFI. A value of **uefi-preferred** indicates that the AMI

supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

## PowerShell

### To determine the boot mode parameter of an AMI (Tools for PowerShell)

Use the [Get-EC2Image](#) Cmdlet to determine the boot mode of an AMI.

```
PS C:\> Get-EC2Image -Region us-east-1 -ImageId ami-0abcdef1234567890 | Format-List
Name, BootMode, TpmSupport
```

```
Name : TPM-Windows_Server-2016-English-Full-Base-2023.05.10
BootMode : uefi
TpmSupport : v2.0
```

In the output, the BootMode field indicates the boot mode of the AMI. A value of uefi indicates that the AMI supports UEFI. A value of uefi-preferred indicates that the AMI supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

## Determine the supported boot modes of an instance type

You can use the AWS CLI or the Tools for PowerShell to determine the supported boot modes of an instance type.

### To determine the supported boot modes of an instance type

You can use the following methods to determine the supported boot modes of an instance type.

#### AWS CLI

You can use the [describe-instance-types](#) command to determine the supported boot modes of an instance type. By including the --query parameter, you can filter the output. In this example, the output is filtered to return only the supported boot modes.

The following example shows that m5.2xlarge supports both UEFI and Legacy BIOS boot modes.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types m5.2xlarge --
query "InstanceTypes[*].SupportedBootModes"
```

Expected output:

```
[
 [
 "legacy-bios",
 "uefi"
]
]
```

The following example shows that t2.xlarge supports only Legacy BIOS.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types t2.xlarge --
query "InstanceTypes[*].SupportedBootModes"
```

Expected output:

```
[
 [
 "legacy-bios"
]
]
```

## PowerShell

You can use the [Get-EC2InstanceType](#) (Tools for PowerShell) Cmdlet to determine the supported boot modes of an instance type.

The following example shows that m5.2xlarge supports both UEFI and Legacy BIOS boot modes.

```
Get-EC2InstanceType -Region us-east-1 -InstanceType m5.2xlarge | Format-List
InstanceType, SupportedBootModes
```

Expected output:

```
InstanceType : m5.2xlarge
SupportedBootModes : {legacy-bios, uefi}
```

The following example shows that t2.xlarge supports only Legacy BIOS.

```
Get-EC2InstanceType -Region us-east-1 -InstanceType t2.xlarge | Format-List
InstanceType, SupportedBootModes
```

Expected output:

```
InstanceType : t2.xlarge
SupportedBootModes : {legacy-bios}
```

## Determine the boot mode of an instance

The boot mode of an instance is displayed in the **Boot mode** field in the Amazon EC2 console, and by the `currentInstanceBootMode` parameter in the AWS CLI.

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:

- An AMI with a boot mode parameter of `uefi` creates an instance with a `currentInstanceBootMode` parameter of `uefi`.
- An AMI with a boot mode parameter of `legacy-bios` creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with a boot mode parameter of `uefi-preferred` creates an instance with a `currentInstanceBootMode` parameter of `uefi` if the instance type supports UEFI; otherwise, it creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with no boot mode parameter value creates an instance with a `currentInstanceBootMode` parameter value that is dependent on whether the AMI architecture is ARM or x86 and the supported boot mode of the instance type. The default boot mode is `uefi` on Graviton instance types, and `legacy-bios` on Intel and AMD instance types.

### Console

#### To determine the boot mode of an instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, inspect the **Boot mode** field.

## AWS CLI

### To determine the boot mode of an instance (AWS CLI)

Use the [describe-instances](#) command to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to create the instance.

```
$ aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0

{
 "Reservations": [
 {
 "Groups": [],
 "Instances": [
 {
 "AmiLaunchIndex": 0,
 "ImageId": "ami-0e2063e7f6dc3bee8",
 "InstanceId": "i-1234567890abcdef0",
 "InstanceType": "m5.2xlarge",
 ...
 },
 "BootMode": "uefi",
 "CurrentInstanceBootMode": "uefi"
 }
],
 "OwnerId": "1234567890",
 "ReservationId": "r-1234567890abcdef0"
 }
]
}
```

## PowerShell

### To determine the boot mode of an instance (Tools for PowerShell)

Use the [Get-EC2Image](#) Cmdlet to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to create the instance.

#### [Get-EC2Image](#) (AWS Tools for Windows PowerShell)

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances | Format-List BootMode,
CurrentInstanceBootMode, InstanceType, ImageId

BootMode : uefi
```

```
CurrentInstanceBootMode : uefi
InstanceType : c5a.large
ImageId : ami-0265446f88eb4021b
```

In the output, the following parameters describe the boot mode:

- BootMode – The boot mode of the AMI that was used to create the instance.
- CurrentInstanceBootMode – The boot mode that is used to boot the instance at launch or start.

## Determine the boot mode of the operating system

The boot mode of the AMI guides Amazon EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance using SSH.

### To determine the boot mode of the instance's operating system

1. [Connect to your Linux instance using SSH](#).
2. To view the boot mode of the operating system, try one of the following:
  - Run the following command.

```
[ec2-user ~]$ sudo /usr/sbin/efibootmgr
```

Expected output from an instance booted in UEFI boot mode

```
BootCurrent: 0001
Timeout: 0 seconds
BootOrder: 0000,0001
Boot0000* UiApp
Boot0001* UEFI Amazon Elastic Block Store vol-xyz
```

- Run the following command to verify the existence of the `/sys/firmware/efi` directory. This directory exists only if the instance boots using UEFI. If this directory doesn't exist, the command returns Legacy BIOS Boot Detected.

```
[ec2-user ~]$ [-d /sys/firmware/efi] && echo "UEFI Boot Detected" || echo
"Legacy BIOS Boot Detected"
```

## Expected output from an instance booted in UEFI boot mode

UEFI Boot Detected

## Expected output from an instance booted in Legacy BIOS boot mode

Legacy BIOS Boot Detected

- Run the following command to verify that EFI appears in the dmesg output.

```
[ec2-user ~]$ dmesg | grep -i "EFI"
```

## Expected output from an instance booted in UEFI boot mode

```
[0.000000] efi: Getting EFI parameters from FDT:
[0.000000] efi: EFI v2.70 by EDK II
```

## Set the boot mode of an AMI

When you create an AMI using the [register-image](#) command, you can set the boot mode of the AMI to either `uefi`, `legacy-bios`, or `uefi-preferred`.

When the AMI boot mode is set to `uefi-preferred`, the instance boots as follows:

- For instance types that support both UEFI and Legacy BIOS (for example, `m5.large`), the instance boots using UEFI.
- For instance types that support only Legacy BIOS (for example, `m4.large`), the instance boots using Legacy BIOS.

### Note

If you set the AMI boot mode to `uefi-preferred`, the operating system must support the ability to boot both UEFI and Legacy BIOS.

Currently, you can't use the [register-image](#) command to create an AMI that supports both [NitroTPM](#) and UEFI Preferred.

## Warning

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI.

When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you need to perform a number of steps: First, modify the instance's volume and operating system to support the selected boot mode. Then, create a snapshot of the volume. Finally, use [register-image](#) to create the AMI using the snapshot.

You can't set the boot mode of an AMI using the [create-image](#) command. With [create-image](#), the AMI inherits the boot mode of the EC2 instance used for creating the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the AMI boot mode will be configured as `legacy-bios`. If you create an AMI from an EC2 instance that was launched using an AMI with a boot mode set to `uefi-preferred`, the AMI that is created will also have its boot mode set to `uefi-preferred`.

## Warning

Setting the AMI boot mode parameter does not automatically configure the operating system for the specified boot mode. Before proceeding with these steps, you must first make suitable modifications to the instance's volume and operating system to support booting using the selected boot mode; otherwise, the resulting AMI will not be usable. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

## To set the boot mode of an AMI (AWS CLI)

1. Make suitable modifications to the instance's volume and operating system to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

**Note**

If you don't perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the [describe-instances](#) command. You'll create a snapshot of this volume in the next step.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

**Expected output**

```
...
 "BlockDeviceMappings": [
 {
 "DeviceName": "/dev/sda1",
 "Ebs": {
 "AttachTime": "",
 "DeleteOnTermination": true,
 "Status": "attached",
 "VolumeId": "vol-1234567890abcdef0"
 }
 }
 ...
}
```

3. To create a snapshot of the volume, use the [create-snapshot](#) command. Use the volume ID from the previous step.

```
aws ec2 create-snapshot --region us-east-1 --volume-id vol-1234567890abcdef0 --
description "add text"
```

**Expected output**

```
{
 "Description": "add text",
 "Encrypted": false,
 "OwnerId": "123",
 "Progress": "",
 "SnapshotId": "snap-01234567890abcdef",
 "StartTime": "",
 "State": "pending",
```

```
"VolumeId": "vol-1234567890abcdef0",
"VolumeSize": 30,
"Tags": []
}
```

4. Note the snapshot ID in the output from the previous step.
5. Wait until the snapshot creation is completed before going to the next step. To query the state of the snapshot, use the [describe-snapshots](#) command.

```
aws ec2 describe-snapshots --region us-east-1 --snapshot-ids snap-01234567890abcdef
```

### Example output

```
{
 "Snapshots": [
 {
 "Description": "This is my snapshot",
 "Encrypted": false,
 "VolumeId": "vol-049df61146c4d7901",
 "State": "completed",

 "StartTime": "2019-02-28T21:28:32.000Z",
 "Progress": "100%",
 "OwnerId": "012345678910",
 "SnapshotId": "snap-01234567890abcdef",
 ...
 }
]
}
```

6. To create a new AMI, use the [register-image](#) command. Use the snapshot ID that you noted in the earlier step.
  - To set the boot mode to UEFI, add the `--boot-mode` parameter to the command and specify `uefi` as the value.

```
aws ec2 register-image \
--region us-east-1 \
--description "add description" \
--name "add name" \
--block-device-mappings "DeviceName=/dev/
sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \
--architecture x86_64 \
--root-device-name /dev/sda1 \
--virtualization-type hvm \
```

```
--ena-support \
--boot-mode uefi
```

- To set the boot mode to uefi-preferred, add the --boot-mode parameter to the command and specify uefi-preferred as the value.

```
aws ec2 register-image \
--region us-east-1 \
--description "add description" \
--name "add name" \
--block-device-mappings "DeviceName=/dev/
sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \
--architecture x86_64 \
--root-device-name /dev/sda1 \
--virtualization-type hvm \
--ena-support \
--boot-mode uefi-preferred
```

### Expected output

```
{
"ImageId": "ami-new_ami_123"
}
```

- To verify that the newly-created AMI has the boot mode that you specified in the previous step, use the [describe-images](#) command.

```
aws ec2 describe-images --region us-east-1 --image-id ami-new_ami_123
```

### Expected output

```
{
"Images": [
{
"Architecture": "x86_64",
"CreationDate": "2021-01-06T14:31:04.000Z",
"ImageId": "ami-new_ami_123",

...
"BootMode": "uefi"
}]
```

```
]
}
```

## 8. Launch a new instance using the newly-created AMI.

If the AMI boot mode is `uefi` or `legacy-bios`, instances created from this AMI will have the same boot mode as the AMI. If the AMI boot mode is `uefi-preferred`, the instance will boot using UEFI if the instance type supports UEFI; otherwise, the instance will boot using Legacy BIOS. For more information, see [Considerations](#).

## 9. To verify that the new instance has the expected boot mode, use the [describe-instances](#) command.

## UEFI variables

When you launch an instance where the boot mode is set to UEFI, a key-value store for variables is created. The store can be used by UEFI and the instance operating system for storing UEFI variables.

UEFI variables are used by the boot loader and the operating system to configure early system startup. They allow the operating system to manage certain settings of the boot process, like the boot order, or managing the keys for UEFI Secure Boot.

### Warning

Anyone who can connect to the instance (and potentially any software running on the instance), or anyone with permissions to use the [GetInstanceUefiData](#) API on the instance can read the variables. You should never store sensitive data, such as passwords or personally identifiable information, in the UEFI variable store.

## UEFI variable persistence

- For instances that were launched on or before May 10, 2022, UEFI variables are wiped on reboot or stop.
- For instances that are launched on or after May 11, 2022, UEFI variables that are marked as non-volatile are persisted on reboot and stop/start.
- Bare metal instances don't preserve UEFI non-volatile variables across instance stop/start operations.

# UEFI Secure Boot

UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2, and provides additional defense-in-depth that helps customers secure software from threats that persist across reboots. It ensures that the instance only boots software that is signed with cryptographic keys. The keys are stored in the key database of the [UEFI non-volatile variable store](#). UEFI Secure Boot prevents unauthorized modification of the instance boot flow.

## How UEFI Secure Boot works

UEFI Secure Boot is a feature specified in UEFI, which provides verification about the state of the boot chain. It is designed to ensure that only cryptographically verified UEFI binaries are executed after the self-initialization of the firmware. These binaries include UEFI drivers and the main bootloader, as well as chain-loaded components.

UEFI Secure Boot specifies four key databases, which are used in a chain of trust. The databases are stored in the UEFI variable store.

The chain of trust is as follows:

### Platform key (PK) database

The PK database is the root of trust. It contains a single public PK key that is used in the chain of trust for updating the key exchange key (KEK) database.

To change the PK database, you must have the private PK key to sign an update request. This includes deleting the PK database by writing an empty PK key.

### Key exchange key (KEK) database

The KEK database is a list of public KEK keys that are used in the chain of trust for updating the signature (db) and denylist (dbx) databases.

To change the public KEK database, you must have the private PK key to sign an update request.

## Signature (db) database

The db database is a list of public keys and hashes that are used in the chain of trust to validate all UEFI boot binaries.

To change the db database, you must have the private PK key or any of the private KEK keys to sign an update request.

## Signature denylist (dbx) database

The dbx database is a list of public keys and binary hashes that are not trusted, and are used in the chain of trust as a revocation file.

The dbx database always takes precedence over all other key databases.

To change the dbx database, you must have the private PK key or any of the private KEK keys to sign an update request.

The UEFI Forum maintains a publicly available dbx for many known-bad binaries and certs at <https://uefi.org/revocationlistfile>.

### Important

UEFI Secure Boot enforces signature validation on any UEFI binaries. To permit execution of a UEFI binary in UEFI Secure Boot, you sign it with any of the private db keys described above.

By default, UEFI Secure Boot is disabled and the system is in SetupMode. When the system is in SetupMode, all key variables can be updated without a cryptographic signature. When the PK is set, UEFI Secure Boot is enabled and the SetupMode is exited.

## Launch a Linux instance with UEFI Secure Boot support

When you [launch an instance](#) with the following prerequisites, the instance will automatically validate UEFI boot binaries against its UEFI Secure Boot database. You can also configure UEFI Secure Boot on an instance after launch.

## Note

UEFI Secure Boot protects your instance and its operating system against boot flow modifications. Typically, UEFI Secure Boot is configured as part of the AMI. If you create a new AMI with different parameters from the base AMI, such as changing the `UefiData` within the AMI, you can disable UEFI Secure Boot.

## Prerequisites for Linux instances

### AMI

Requires an AMI with UEFI Secure Boot enabled.

Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. However, UEFI Secure Boot isn't enabled in the default AMIs. For more information, see [UEFI Secure Boot](#) in the *AL2023 User Guide*. Older versions of Amazon Linux AMIs aren't enabled for UEFI Secure Boot. To use a supported AMI, you must perform a number of configuration steps on your own Linux AMI. For more information, see [Create a Linux AMI to support UEFI Secure Boot](#).

### Instance type

- Supported: All virtualized instance types that support UEFI also support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see [Considerations](#).
- Not supported: Bare metal instance types do not support UEFI Secure Boot.

For the prerequisites for Windows instances, see [Launch an instance with UEFI Secure Boot support](#) in the *Amazon EC2 User Guide for Windows Instances*.

## Verify whether a Linux instance is enabled for UEFI Secure Boot

You can use the `mokutil` utility to verify whether a Linux instance is enabled for UEFI Secure Boot. If `mokutil` is not installed on your instance, you must install it. For the installation instructions for Amazon Linux, see [Install software packages on an Amazon Linux instance](#). For other distributions, see their specific documentation.

### To verify whether a Linux instance is enabled for UEFI Secure Boot

Run the following command as `root` on the instance.

```
mokutil --sb-state
```

Expected output:

- If UEFI Secure Boot is enabled, the output contains SecureBoot enabled.
- If UEFI Secure Boot is not enabled, the output contains SecureBoot disabled or Failed to read SecureBoot.

To verify whether a Windows instance is enabled, see [Verify whether a Windows instance is supported for UEFI Secure Boot](#) in the *Amazon EC2 User Guide for Windows Instances*.

## Create a Linux AMI to support UEFI Secure Boot

The following procedures describe how to create your own UEFI variable store for secure boot with custom-made private keys. Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. For more information, see [UEFI Secure Boot](#) in the *AL2023 User Guide*.

### Important

The following procedures for creating an AMI to support UEFI Secure Boot are intended for advanced users only. You must have sufficient knowledge of SSL and Linux distribution boot flow to use these procedures.

## Prerequisites

- The following tools will be used:
  - OpenSSL – <https://www.openssl.org/>
  - efivar – <https://github.com/rhboot/efivar>
  - efitools – <https://git.kernel.org/pub/scm/linux/kernel/git/jejb/efitools.git/>
  - [get-instance-uefi-data](#) AWS CLI command
- Your Linux instance must have been launched with a Linux AMI that supports UEFI boot mode, and have non-volatile data present.

Newly created instances without UEFI Secure Boot keys are created in SetupMode, which allows you to enroll your own keys. Some AMIs come preconfigured with UEFI Secure Boot and you cannot

change the existing keys. If you want to change the keys, you must create a new AMI based on the original AMI.

You have two ways to propagate the keys in the variable store, which are described in Option A and Option B that follow. Option A describes how to do this from within the instance, mimicking the flow of real hardware. Option B describes how to create a binary blob, which is then passed as a base64-encoded file when you create the AMI. For both options, you must first create the three key pairs, which are used for the chain of trust.

**To create a Linux AMI to support UEFI Secure Boot, first create the three key pairs, and then complete either Option A or Option B:**

- [Create three key pairs](#)
- [Option A: Add keys to the variable store from within the instance](#)
- [Option B: Create a binary blob containing a pre-filled variable store](#)

 **Note**

These instructions can only be used to create a Linux AMI. If you need a Windows AMI, use one of the supported Windows AMIs. For more information, see [Launch an instance with UEFI Secure Boot support](#) in the *Amazon EC2 User Guide for Windows Instances*.

## Create three key pairs

UEFI Secure Boot is based on the following three key databases, which are used in a chain of trust: the platform key (PK), the key exchange key (KEK), and the signature database (db).<sup>1</sup>

You create each key on the instance. To prepare the public keys in a format that is valid for the UEFI Secure Boot standard, you create a certificate for each key. DER defines the SSL format (binary encoding of a format). You then convert each certificate into a UEFI signature list, which is the binary format that is understood by UEFI Secure Boot. And finally, you sign each certificate with the relevant key.

### Topics

- [Prepare to create the key pairs](#)
- [Key pair 1: Create the platform key \(PK\)](#)
- [Key pair 2: Create the key exchange key \(KEK\)](#)

- [Key pair 3: Create the signature database \(db\)](#)
- [Sign the boot image \(kernel\) with the private key](#)

## Prepare to create the key pairs

Before creating the key pairs, create a globally unique identifier (GUID) to be used in key generation.

1. [Connect to the instance.](#)
2. Run the following command in a shell prompt.

```
uuidgen --random > GUID.txt
```

## Key pair 1: Create the platform key (PK)

The PK is the root of trust for UEFI Secure Boot instances. The private PK is used to update the KEK, which in turn can be used to add authorized keys to the signature database (db).

The X.509 standard is used for creating the key pair. For information about the standard, see [X.509](#) on [Wikipedia](#).

### To create the PK

1. Create the key. You must name the variable PK.

```
openssl req -newkey rsa:4096 -nodes -keyout PK.key -new -x509 -sha256 -days 3650 -subj "/CN=Platform key/" -out PK.crt
```

The following parameters are specified:

- **-keyout PK.key** – The private key file.
- **-days 3650** – The number of days that the certificate is valid.
- **-out PK.crt** – The certificate that is used to create the UEFI variable.
- **CN=Platform key** – The common name (CN) for the key. You can enter the name of your own organization instead of *Platform key*.

2. Create the certificate.

```
openssl x509 -outform DER -in PK.crt -out PK.cer
```

- Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(cat GUID.txt)" PK.crt PK.esl
```

- Sign the UEFI signature list with the private PK (self-signed).

```
sign-efi-sig-list -g "$(cat GUID.txt)" -k PK.key -c PK.crt PK PK.esl PK.auth
```

## Key pair 2: Create the key exchange key (KEK)

The private KEK is used to add keys to the db, which is the list of authorized signatures to boot on the system.

### To create the KEK

- Create the key.

```
openssl req -newkey rsa:4096 -nodes -keyout KEK.key -new -x509 -sha256 -days 3650 -subj "/CN=Key Exchange Key/" -out KEK.crt
```

- Create the certificate.

```
openssl x509 -outform DER -in KEK.crt -out KEK.cer
```

- Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(cat GUID.txt)" KEK.crt KEK.esl
```

- Sign the signature list with the private PK.

```
sign-efi-sig-list -g "$(cat GUID.txt)" -k PK.key -c PK.crt KEK KEK.esl KEK.auth
```

## Key pair 3: Create the signature database (db)

The db list contains authorized keys that are authorized to be booted on the system. To modify the list, the private KEK is necessary. Boot images will be signed with the private key that is created in this step.

### To create the db

1. Create the key.

```
openssl req -newkey rsa:4096 -nodes -keyout db.key -new -x509 -sha256 -days 3650 -subj "/CN=Signature Database key/" -out db.crt
```

2. Create the certificate.

```
openssl x509 -outform DER -in db.crt -out db.cer
```

3. Convert the certificate into a UEFI signature list.

```
cert-to-efi-sig-list -g "$(cat GUID.txt)" db.cer db.esl
```

4. Sign the signature list with the private KEK.

```
sign-efi-sig-list -g "$(cat GUID.txt)" -k KEK.key -c KEK.crt db db.esl db.auth
```

## Sign the boot image (kernel) with the private key

For Ubuntu 22.04, the following images require signatures.

```
/boot/efi/EFI/ubuntu/shimx64.efi
/boot/efi/EFI/ubuntu/mmx64.efi
/boot/efi/EFI/ubuntu/grubx64.efi
/boot/vmlinuz
```

### To sign an image

Use the following syntax to sign an image.

```
sbsign --key db.key --cert db.crt --output /boot/vmlinuz /boot/vmlinuz
```

**Note**

You must sign all new kernels. `/boot/vmlinuz` will usually symlink to the last installed kernel.

Refer to the documentation for your distribution to find out about your boot chain and required images.

<sup>1</sup> Thanks to the ArchWiki community for all of the work they have done. The commands for creating the PK, creating the KEK, creating the DB, and signing the image are from [Creating keys](#), authored by the ArchWiki Maintenance Team and/or the ArchWiki contributors.

## Option A: Add keys to the variable store from within the instance

After you have created the [three key pairs](#), you can connect to your instance and add the keys to the variable store from within the instance by completing the following steps.

### Option A steps:

- [Step 1: Launch an instance that will support UEFI Secure Boot](#)
- [Step 2: Configure an instance to support UEFI Secure Boot](#)
- [Step 3: Create an AMI from the instance](#)

### Step 1: Launch an instance that will support UEFI Secure Boot

When you [launch an instance](#) with the following prerequisites, the instance will then be ready to be configured to support UEFI Secure Boot. You can only enable support for UEFI Secure Boot on an instance at launch; you can't enable it later.

#### Prerequisites

- **AMI** – The Linux AMI must support UEFI boot mode. To verify that the AMI supports UEFI boot mode, the AMI boot mode parameter must be `uefi`. For more information, see [Determine the boot mode parameter of an AMI](#).

Note that AWS only provides Linux AMIs configured to support UEFI for Graviton-based instance types. AWS currently does not provide x86\_64 Linux AMIs that support UEFI boot mode. You can configure your own AMI to support UEFI boot mode for all architectures. To configure your own

AMI to support UEFI boot mode, you must perform a number of configuration steps on your own AMI. For more information, see [Set the boot mode of an AMI](#).

- **Instance type** – All virtualized instance types that support UEFI also support UEFI Secure Boot. Bare metal instance types do not support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see [Considerations](#).
- Launch your instance after the release of UEFI Secure Boot. Only instances launched after May 10, 2022 (when UEFI Secure Boot was released) can support UEFI Secure Boot.

After you've launched your instance, you can verify that it is ready to be configured to support UEFI Secure Boot (in other words, you can proceed to [Step 2](#)) by checking whether UEFI data is present. The presence of UEFI data indicates that non-volatile data is persisted.

### To verify whether your instance is ready for Step 2

Use the [get-instance-uefi-data](#) command and specify the instance ID.

```
aws ec2 get-instance-uefi-data --instance-id i-0123456789example
```

The instance is ready for Step 2 if UEFI data is present in the output. If the output is empty, the instance cannot be configured to support UEFI Secure Boot. This can happen if your instance was launched before UEFI Secure Boot support became available. Launch a new instance and try again.

### Step 2: Configure an instance to support UEFI Secure Boot

#### Enroll the key pairs in your UEFI variable store on the instance

##### Warning

You must sign your boot images *after* you enroll the keys, otherwise you won't be able to boot your instance.

After you create the signed UEFI signature lists (PK, KEK, and db), they must be enrolled into the UEFI firmware.

Writing to the PK variable is possible only if:

- No PK is enrolled yet, which is indicated if the SetupMode variable is 1. Check this by using the following command. The output is either 1 or 0.

```
efivar -d -n 8be4df61-93ca-11d2-aa0d-00e098032b8c-SetupMode
```

- The new PK is signed by the private key of the existing PK.

## To enroll the keys in your UEFI variable store

The following commands must be run on the instance.

If SetupMode is enabled (the value is 1), the keys can be enrolled by running the following commands on the instance:

```
[ec2-user ~]$ efi-updatevar -f db.auth db
```

```
[ec2-user ~]$ efi-updatevar -f KEK.auth KEK
```

```
[ec2-user ~]$ efi-updatevar -f PK.auth PK
```

## To verify that UEFI Secure Boot is enabled

To verify that UEFI Secure Boot is enabled, follow the steps in [Verify whether a Linux instance is enabled for UEFI Secure Boot](#).

You can now export your UEFI variable store with the [get-instance-uefi-data](#) CLI command, or you continue to the next step and sign your boot images to reboot into a UEFI Secure Boot-enabled instance.

## Step 3: Create an AMI from the instance

To create an AMI from the instance, you can use the console or the CreateImage API, CLI, or SDKs. For the console instructions, see [Create an Amazon EBS-backed Linux AMI](#). For the API instructions, see [CreateImage](#).

### Note

The CreateImage API automatically copies the UEFI variable store of the instance to the AMI. The console uses the CreateImage API. After you launch instances using this AMI, the instances will have the same UEFI variable store.

## Option B: Create a binary blob containing a pre-filled variable store

After you have created the [three key pairs](#), you can create a binary blob containing a pre-filled variable store containing the UEFI Secure Boot keys.

### Warning

You must sign your boot images *before* you enroll the keys, otherwise you won't be able to boot your instance.

### Option B steps:

- [Step 1: Create a new variable store or update an existing one](#)
- [Step 2: Upload the binary blob on AMI creation](#)

#### Step 1: Create a new variable store or update an existing one

You can create the variable store *offline* without a running instance by using the `python-uefivars` tool. The tool can create a new variable store from your keys. The script currently supports the EDK2 format, the AWS format, and a JSON representation that is easier to edit with higher-level tooling.

##### To create the variable store offline without a running instance

1. Download the tool at the following link.

```
https://github.com/awslabs/python-uefivars
```

2. Create a new variable store from your keys by running the following command. This will create a base64-encoded binary blob in `your_binary_blob.bin`. The tool also supports updating a binary blob via the `-I` parameter.

```
./uefivars.py -i none -o aws -O your_binary_blob.bin -P PK.esl -K KEK.esl --db
db.esl --dbx dbx.esl
```

## Step 2: Upload the binary blob on AMI creation

Use [register-image](#) to pass your UEFI variable store data. For the --uefi-data parameter, specify your binary blob, and for the --boot-mode parameter, specify uefi.

```
aws ec2 register-image \
--name uefi_sb_tpm_register_image_test \
--uefi-data $(cat your_binary_blob.bin) \
--block-device-mappings "DeviceName=/dev/sda1,Ebs=
{SnapshotId=snap-0123456789example,DeleteOnTermination=true}" \
--architecture x86_64 \
--root-device-name /dev/sda1 \
--virtualization-type hvm \
--ena-support \
--boot-mode uefi
```

## How the AWS binary blob is created

You can use the following steps to customize the UEFI Secure Boot variables during AMI creation. The KEK that is used in these steps is current as of September 2021. If Microsoft updates the KEK, you must use the latest KEK.

### To create the AWS binary blob

1. Create an empty PK signature list.

```
touch empty_key.crt
cert-to-efi-sig-list empty_key.crt PK.esl
```

2. Download the KEK certificates.

<https://go.microsoft.com/fwlink/?LinkId=321185>

3. Wrap the KEK certificates in a UEFI signature list (siglist).

```
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
MS_Win_KEK.esl MicCorKEKCA2011_2011-06-24.crt
```

4. Download Microsoft's db certificates.

[https://www.microsoft.com/pkiops/certs/MicWinProPCA2011\\_2011-10-19.crt](https://www.microsoft.com/pkiops/certs/MicWinProPCA2011_2011-10-19.crt)

```
https://www.microsoft.com/pkiops/certs/MicCorUEFCA2011_2011-06-27.crt
```

## 5. Generate the db signature list.

```
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
MS_Win_db.esl MicWinProPCA2011_2011-10-19.crt
sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
MS_UEFI_db.esl MicCorUEFCA2011_2011-06-27.crt
cat MS_Win_db.esl MS_UEFI_db.esl > MS_db.esl
```

## 6. Download an updated dbx change request from the following link.

```
https://uefi.org/revocationlistfile
```

## 7. The dbx change request that you downloaded in the previous step is already signed with the Microsoft KEK, so you need to strip or unpack it. You can use the following links.

```
https://gist.github.com/out0xb2/f8e0bae94214889a89ac67fcbe37f8c0
```

```
https://support.microsoft.com/en-us/topic/microsoft-guidance-for-applying-secure-boot-dbx-update-e3b9e4cb-a330-b3ba-a602-15083965d9ca
```

## 8. Build a UEFI variable store using the uefivars.py script.

```
./uefivars.py -i none -o aws -O uefiblob-microsoft-keys-empty-pk.bin -P ~/PK.esl -K
~/MS_Win_KEK.esl --db ~/MS_db.esl --dbx ~/dbx-2021-April.bin
```

## 9. Check the binary blob and the UEFI variable store.

```
./uefivars.py -i aws -I uefiblob-microsoft-keys-empty-pk.bin -o json | less
```

## 10. You can update the blob by passing it to the same tool again.

```
./uefivars.py -i aws -I uefiblob-microsoft-keys-empty-pk.bin -o aws -O uefiblob-
microsoft-keys-empty-pk.bin -P ~/PK.esl -K ~/MS_Win_KEK.esl --db ~/MS_db.esl --dbx
~/dbx-2021-April.bin
```

## Expected output

```
Replacing PK
Replacing KEK
```

Replacing db  
Replacing dbx

## Find a Linux AMI

Before you can launch an instance, you must select an AMI from which to launch the instance. When you select an AMI, consider the following requirements you might have for the instances that you want to launch:

- The Region – AMI IDs are unique to each AWS Region.
- The operating system
- The architecture: 32-bit (`i386`), 64-bit (`x86_64`), or 64-bit ARM (`arm64`)
- The root device type: Amazon EBS or instance store
- The provider (for example, Amazon Web Services)
- Additional software (for example, SQL Server)

If you want to find a Windows AMI, see [Find a Windows AMI](#) in the *Amazon EC2 User Guide for Windows Instances*.

If you want to find an AL2023 AMI, see [Get started with AL2023](#) in the *AL2023 User Guide*.

If you want to find an Ubuntu AMI, see their [EC2 AMI Locator](#).

If you want to find a RedHat AMI, see the RHEL [knowledgebase article](#).

## Find a Linux AMI using the Amazon EC2 console

You can find Linux AMIs using the Amazon EC2 console. You can select from the list of AMIs when you use the launch instance wizard to launch an instance, or you can search through all available AMIs using the **Images** page. AMI IDs are unique to each AWS Region.

## To find a Linux AMI using the launch instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. (New console) Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, choose the operating system (OS) for your instance, and then, from **Amazon Machine Image (AMI)**, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose **Browse more AMIs** to browse the full AMI catalog. For more information, see [Application and OS Images \(Amazon Machine Image\)](#).

(Old console) On the **Quick Start** tab, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose the **My AMIs**, **AWS Marketplace**, or **Community AMIs** tab to find additional AMIs. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\)](#).

## To find a Linux AMI using the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **AMIs**.
4. (Optional) Use the filter and search options to scope the list of displayed AMIs to see only the AMIs that match your criteria. For example, to list all Linux AMIs provided by AWS, choose **Public images**. Then use the search options to further scope the list of displayed AMIs.

Choose the **Search** bar and, from the menu, choose **Owner alias**, then the = operator, and then the value **amazon**. Choose the **Search** bar again to choose **Platform**, then the = operator, and then the operating system from the list provided.

5. (Optional) Choose the **Preferences** icon to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties on the **Details** tab.
6. Before you select an AMI, it's important that you check whether it's backed by instance store or by Amazon EBS and that you are aware of the effects of this difference. For more information, see [Storage for the root device](#).

- To launch an instance from this AMI, select it and then choose **Launch instance from image**. For more information about launching an instance using the console, see [Launch an instance using the new launch instance wizard](#). If you're not ready to launch the instance now, make note of the AMI ID for later.

For more information about finding an AL2023 AMI, see [Get started with AL2023](#) in the *AL2023 User Guide*.

## Find an AMI using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to list only the Linux AMIs that match your requirements. After locating an AMI that matches your requirements, make note of its ID so that you can use it to launch instances. For more information, see [Launch your instance](#) in the *AWS Command Line Interface User Guide*.

The [describe-images](#) command supports filtering parameters. For example, use the `--owners` parameter to display public AMIs owned by Amazon.

```
aws ec2 describe-images --owners self amazon
```

You can add the following filter to the previous command to display only AMIs backed by Amazon EBS.

```
--filters "Name=root-device-type,Values=ebs"
```

### Important

Omitting the `--owners` flag from the `describe-images` command returns all images for which you have launch permissions, regardless of ownership.

## Find the latest Amazon Linux AMI using Systems Manager

Amazon EC2 provides AWS Systems Manager public parameters for public AMIs maintained by AWS that you can use when launching instances. For example, the EC2-provided parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions and always points to the latest version of the Amazon Linux 2 AMI in a given Region.

To find the latest AL2023 AMI using AWS Systems Manager, see [Get started with AL2023](#).

The Amazon EC2 AMI public parameters are available from the following path:

```
/aws/service/ami-amazon-linux-latest
```

You can view a list of all Linux AMIs in the current AWS Region by running the following AWS CLI command.

```
aws ssm get-parameters-by-path --path /aws/service/ami-amazon-linux-latest --query "Parameters[].Name"
```

## To launch an instance using a public parameter

The following example uses the EC2-provided public parameter to launch an m5.xlarge instance using the latest Amazon Linux 2 AMI.

To specify the parameter in the command, use the following syntax: `resolve:ssm:public-parameter`, where `resolve:ssm` is the standard prefix and `public-parameter` is the path and name of the public parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
 --image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2
 --instance-type m5.xlarge
 --key-name MyKeyPair
```

For more information, see [Using public parameters](#) in the *AWS Systems Manager User Guide* and [Query for the latest Amazon Linux AMI IDs Using AWS Systems Manager Parameter Store](#).

## Use a Systems Manager parameter to find an AMI

When you launch an instance using the EC2 launch instance wizard in the console, you can either select an AMI from the list, or you can select an AWS Systems Manager parameter that points to an AMI ID. If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your

application configuration values. For more information, see [AWS Systems Manager Parameter Store](#) in the *AWS Systems Manager User Guide*.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as `aws:ec2:image`. Specifying this data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see [Native parameter support for Amazon Machine Image IDs](#) in the *AWS Systems Manager User Guide*.

## Systems Manager parameter topics

- [Use cases](#)
- [Permissions](#)
- [Limitations](#)
- [Launch an instance using a Systems Manager parameter](#)

## Use cases

When you use Systems Manager parameters to point to AMI IDs, it is easier for your users to select the correct AMI when launching instances. Systems Manager parameters can also simplify the maintenance of automation code.

### Easier for users

If you require instances to be launched using a specific AMI, and the AMI is regularly updated, we recommend that you require your users to select a Systems Manager parameter to find the AMI. Requiring your users to select a Systems Manager parameter ensures that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, `golden-ami`) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't have to know about the periodic updates to the AMI because they continue to select the same Systems Manager parameter each time. Using a Systems Manager parameter for your AMI makes it easier for them to select the correct AMI for an instance launch.

### Simplify automation code maintenance

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you can change the AMI ID value in the parameter so that it points to the latest AMI. The automation code that references the parameter doesn't have to be modified each time a new version of the AMI is created. This simplifies the maintenance of the automation and helps to drive down deployment costs.

### Note

Running instances are not affected when you change the AMI ID pointed to by the Systems Manager parameter.

## Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your IAM policy. `ssm:DescribeParameters` grants your users permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your users permission to retrieve the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see [Use the EC2 launch instance wizard](#).

## Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, `golden-ami`). In each Region, point the Systems Manager parameter to an AMI in that Region.

## Launch an instance using a Systems Manager parameter

You can launch an instance using the console or the AWS CLI. Instead of specifying an AMI ID, you can specify an AWS Systems Manager parameter that points to an AMI ID.

New console

### To find a Linux AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.

3. From the console dashboard, choose **Launch instance**.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**.
6. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears below **Currently resolves to**.
7. Choose **Search**. The AMIs that match the AMI ID appear in the list.
8. Select the AMI from the list, and choose **Select**.

For more information about launching an instance using the launch instance wizard, see [Launch an instance using the new launch instance wizard](#).

## Old console

### To find a Linux AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Choose **Search by Systems Manager parameter** (at top right).
5. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
6. Choose **Search**. The AMIs that match the AMI ID appear in the list.
7. Select the AMI from the list, and choose **Select**.

For more information about launching an instance from an AMI using the launch instance wizard, see [Step 1: Choose an Amazon Machine Image \(AMI\)](#).

### To launch an instance using an AWS Systems Manager parameter instead of an AMI ID (AWS CLI)

The following example uses the Systems Manager parameter `golden-ami` to launch an `m5.xlarge` instance. The parameter points to an AMI ID.

To specify the parameter in the command, use the following syntax: `resolve:ssm:/parameter-name`, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter name. Note that the parameter name is case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, `/amis/production/golden-ami`. You can omit the backslash if the parameter is not part of a hierarchy.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
 --image-id resolve:ssm:/golden-ami
 --instance-type m5.xlarge
 ...
```

## To launch an instance using a specific version of an AWS Systems Manager parameter (AWS CLI)

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows `resolve:ssm:parameter-name:version`, where `version` is the unique version number. By default, the latest version of the parameter is used when no version is specified.

The following example uses version 2 of the parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
 --image-id resolve:ssm:/golden-ami:2
 --instance-type m5.xlarge
 ...
```

## To launch an instance using a public parameter provided by AWS

Amazon EC2 provides Systems Manager public parameters for public AMIs provided by AWS. For example, the public parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions, and always points to the latest version of the Amazon Linux 2 AMI in the Region.

```
aws ec2 run-instances
```

```
--image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-
gp2
--instance-type m5.xlarge
...
```

## Shared AMIs

A *shared AMI* is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center, and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source, such as a verified provider.

## Verified provider

In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked **Verified provider**.

You can also use the [describe-images](#) AWS CLI command to identify the public AMIs that come from a verified provider. Public images that are owned by Amazon or a verified partner have an aliased owner, which is either `amazon` or `aws-marketplace`. In the CLI output, these values appear for `ImageOwnerAlias`. Other users can't alias their AMIs. This enables you to easily find AMIs from Amazon or verified partners.

To become a verified provider, you must register as a seller on the AWS Marketplace. Once registered, you can list your AMI on the AWS Marketplace. For more information, see [Getting started as a seller](#) and [AMI-based products](#) in the *AWS Marketplace Seller Guide*.

## Find shared AMIs

You can use the Amazon EC2 console or the command line to find shared AMIs.

AMIs are a Regional resource. When you search for a shared AMI (public or private), you must search for it from the same Region from which it is shared. To make an AMI available in a different Region, copy the AMI to the Region, and then share it. For more information, see [Copy an AMI](#).

## Find a shared AMI (console)

### To find a shared private AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Private images**. All AMIs that have been shared with you are listed. To granulate your search, choose the **Search** bar and use the filter options provided in the menu.

### To find a shared public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.

3. In the first filter, choose **Public images**. To granulate your search, choose the **Search** field and use the filter options provided in the menu.

## To find Amazon's shared public AMIs using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**.
4. Choose the **Search** field and then, from the menu options that appear, choose **Owner alias**, then **=**, and then **amazon** to display only Amazon's public images.

## To find a shared public AMI from a verified provider using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMI Catalog**.
3. Choose **Community AMIs**.
4. The **Verified provider** label indicates the AMIs that are from Amazon or a verified partner.

## Find a shared AMI (AWS CLI)

Use the [describe-images](#) command (AWS CLI) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

### Example: List all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

### Example: List AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

### Example: List AMIs owned by verified providers

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as amazon or aws-marketplace in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
aws ec2 describe-images \
 --owners amazon aws-marketplace \
 --query 'Images[*].[ImageId]' \
 --output text
```

### Example: List AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

### Example: Scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

## Use shared AMIs

Before you use a shared AMI, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates authorized\_keys files:

```
[ec2-user ~]$ sudo find / -name "authorized_keys" -print -exec cat {} \;
```

2. Disable password-based authentication for the root user. Open the `sshd_config` file and edit the `PermitRootLogin` line as follows:

```
PermitRootLogin without-password
```

Alternatively, you can disable the ability to log into the instance as the root user:

```
PermitRootLogin No
```

Restart the `sshd` service.

3. Check whether there are any other users that are able to log in to your instance. Users with superuser privileges are particularly dangerous. Remove or lock the password of any unknown accounts.
4. Check for open ports that you aren't using and running network services listening for incoming connections.
5. To prevent preconfigured remote logging, you should delete the existing configuration file and restart the `rsyslog` service. For example:

```
[ec2-user ~]$ sudo rm /etc/rsyslog.conf
[ec2-user ~]$ sudo service rsyslog restart
```

6. Verify that all cron jobs are legitimate.

If you discover a public AMI that you feel presents a security risk, contact the AWS security team. For more information, see the [AWS Security Center](#).

## Make an AMI public

You can make your AMI publicly available by sharing it with all AWS accounts.

If you want to prevent the public sharing of your AMIs, you can enable *block public access for AMIs*. This blocks any attempts to make an AMI public, helping to prevent unauthorized access and potential misuse of AMI data. Note that enabling block public access does not affect your AMIs that are already publicly available; they remain publicly available.

To allow only specific accounts to use your AMI to launch instances, see [Share an AMI with specific AWS accounts](#).

## Topics

- [Considerations](#)
- [Share an AMI with all AWS accounts \(share publicly\)](#)
- [Block public access to your AMIs](#)

## Considerations

Consider the following before making an AMI public.

- **Ownership** – To make an AMI public, your AWS account must own the AMI.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI](#).
- **Block public access** – To publicly share an AMI, [block public access for AMIs](#) must be disabled in each Region in which the AMI will be publicly shared. After you've publicly shared the AMI, you can re-enable block public access for AMIs to prevent further public sharing of your AMIs.
- **Some AMIs can't be made public** – If your AMI includes one of the following components, you can't make it public (but you can [share the AMI with specific AWS accounts](#)):
  - Encrypted volumes
  - Snapshots of encrypted volumes
  - Product codes
- **Avoid exposing sensitive data** – To avoid exposing sensitive data when you share an AMI, read the security considerations in [Guidelines for shared Linux AMIs](#) and follow the recommended actions.
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.
- **Automatic deprecation** – By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only [sharing it with specific AWS accounts](#).
- **Remove obsolete AMIs** – After a public AMI reaches its deprecation date, if no new instances were launched from the AMI for six or more months, AWS eventually removes the public sharing property so that obsolete AMIs don't appear in the public AMI lists.

- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

## Share an AMI with all AWS accounts (share publicly)

After you make an AMI public, it is available in **Community AMIs** in the console, which you can access from the **AMI Catalog** in the left navigator in the EC2 console or when launching an instance using the console. Note that it can take a short while for an AMI to appear in **Community AMIs** after you make it public.

Console

### To make an AMI public

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Edit AMI permissions**.
4. Under **AMI availability**, choose **Public**.
5. Choose **Save changes**.

AWS CLI

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

### To make an AMI public

1. Use the [modify-image-attribute](#) command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
```

```
--launch-permission "Add=[{Group=all}]"
```

2. To verify the launch permissions of the AMI, use the [describe-image-attribute](#) command.

```
aws ec2 describe-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the all group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission "Remove=[{Group=all}]"
```

## Block public access to your AMIs

To prevent the public sharing of your AMIs, you can enable *block public access for AMIs*. This setting is enabled at the account level, but you need to enable it in each AWS Region in which you want to prevent the public sharing of your AMIs.

When block public access is enabled, any attempt to make an AMI public is automatically blocked. However, if you already have public AMIs, they will remain publicly available.

If you want to publicly share AMIs, you'll need to disable block public access. When you're done sharing, it's best practice to re-enable block public access to prevent any unintended public sharing of your AMIs.

You can restrict IAM permissions to an administrator user so that only they can enable or disable block public access for AMIs.

## Default settings

The **Block public access for AMIs** setting is either enabled or disabled by default depending on whether your account is new or existing, and whether you have public AMIs. The following table lists the default settings:

| AWS account                                        | Block public access for AMIs default setting |
|----------------------------------------------------|----------------------------------------------|
| New accounts                                       | Enabled                                      |
| Existing accounts with no public AMIs <sup>1</sup> | Enabled                                      |
| Existing accounts with one or more public AMIs     | Disabled                                     |

<sup>1</sup> If your account had one or more public AMIs on or after July 15, 2023, **Block public access for AMIs** is disabled by default for your account, even if you subsequently made all the AMIs private.

## Required IAM permissions

To use block public access for AMIs, you must have the following IAM permissions:

- `EnableImageBlockPublicAccess`
- `DisableImageBlockPublicAccess`
- `GetImageBlockPublicAccessState`

## Enable block public access for AMIs

To prevent the public sharing of your AMIs, enable block public access for AMIs at the account level. You must enable block public access for AMIs in each AWS Region in which you want to prevent the public sharing of your AMIs. If you already have public AMIs, they will remain publicly available.

### Console

#### To enable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. From the navigation bar (at the top of the screen), select the Region in which to enable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, choose **Manage**.
6. Select the **Block new public sharing** check box, and then choose **Update**.

 **Note**

The API can take up to 10 minutes to configure this setting. During this time, the value will be **New public sharing allowed**. When the API has completed the configuration, the value will automatically change to **New public sharing blocked**.

## AWS CLI

### To enable block public access for AMIs in the specified Region

Use the [enable-image-block-public-access](#) command and specify the Region in which to enable block public access for AMIs. For the `--image-block-public-access-state` parameter, specify `block-new-sharing`.

```
aws ec2 enable-image-block-public-access \
--region us-east-1 \
--image-block-public-access-state block-new-sharing
```

### Expected output

```
{
 "ImageBlockPublicAccessState": "block-new-sharing"
}
```

 **Note**

The API can take up to 10 minutes to configure this setting. During this time, if you run the [get-image-block-public-access-state](#) command, the response will be unblocked.

When the API has completed the configuration, the response will be `block-new-sharing`.

## Disable block public access for AMIs

To allow the users in your account to publicly share your AMIs, disable block public access at the account level. You must disable block public access for AMIs in each AWS Region in which you want to allow the public sharing of your AMIs.

### Console

#### To disable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar (at the top of the screen), select the Region in which to disable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, choose **Manage**.
6. Clear the **Block new public sharing** check box, and then choose **Update**.
7. Enter **confirm** when prompted for confirmation, and then choose **Allow public sharing**.

#### Note

The API can take up to 10 minutes to configure this setting. During this time, the value will be **New public sharing blocked**. When the API has completed the configuration, the value will automatically change to **New public sharing allowed**.

### AWS CLI

#### To disable block public access for AMIs in the specified Region

Use the [disable-image-block-public-access](#) command and specify the Region in which to disable block public access for AMIs.

```
aws ec2 disable-image-block-public-access --region us-east-1
```

## Expected output

```
{
 "ImageBlockPublicAccessState": "unblocked"
}
```

### Note

The API can take up to 10 minutes to configure this setting. During this time, if you run the [get-image-block-public-access-state](#) command, the response will be block-new-sharing. When the API has completed the configuration, the response will be unblocked.

## View the block public access state for AMIs

To see whether the public sharing of your AMIs is blocked in your account, you can view the state for block public access for AMIs. You must view the state in each AWS Region in which you want to see whether the public sharing of your AMIs is blocked.

### Console

#### To view the block public access state for AMIs in the specified Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar (at the top of the screen), select the Region in which to view the block public access state for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose **EC2 Dashboard**.
4. Under **Account attributes**, choose **Data protection and security**.
5. Under **Block public access for AMIs**, check the **Public access** field. The value is either **New public sharing blocked** or **New public sharing allowed**.

### AWS CLI

#### To get the block public access state for AMIs in the specified Region

Use the [get-image-block-public-access-state](#) command and specify the Region in which to get the block public access state for AMIs.

```
aws ec2 get-image-block-public-access-state --region us-east-1
```

Expected output – The value is either `block-new-sharing` or `unblocked`.

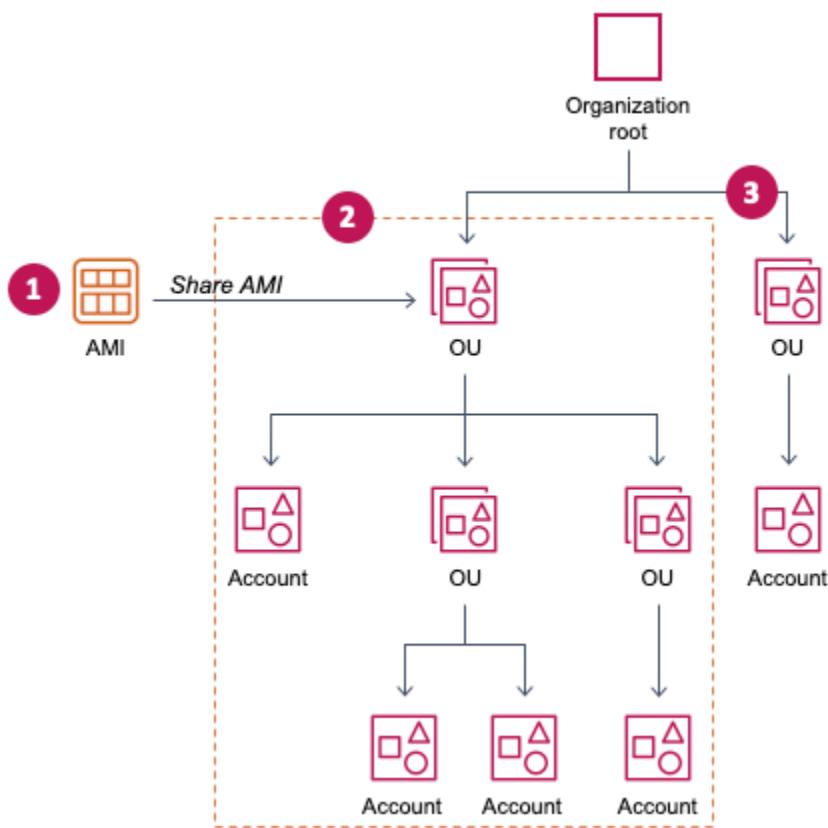

```
{
 "ImageBlockPublicAccessState": "block-new-sharing"
}
```

## Share an AMI with specific organizations or organizational units

[AWS Organizations](#) is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage. You can share an AMI with an organization or an organizational unit (OU) that you have created, in addition to [sharing it with specific accounts](#).

An organization is an entity that you create to consolidate and centrally manage your AWS accounts. You can organize the accounts in a hierarchical, tree-like structure, with a [root](#) at the top and [organizational units](#) nested under the organization root. Each account can be added directly to the root, or placed in one of the OUs in the hierarchy. For more information, see [AWS Organizations terminology and concepts](#) in the *AWS Organizations User Guide*.

When you share an AMI with an organization or an OU, all of the children accounts gain access to the AMI. For example, in the following diagram, the AMI is shared with a top-level OU (indicated by the arrow at the number 1). All of the OUs and accounts that are nested underneath that top-level OU (indicated by the dotted line at number 2) also have access to the AMI. The accounts in the organization and OU outside the dotted line (indicated by the number 3) do not have access to the AMI because they are not children of the OU that the AMI is shared with.

## Considerations

Consider the following when sharing AMIs with specific organizations or organizational units.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – The AMI owner can share an AMI with any organization or OU, including organizations and OUs that they're not a member of.

For the maximum number of entities to which an AMI can be shared within a Region, see the [Amazon EC2 service quotas](#).

- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account in an organization or OU with which the AMI is shared.
- **ARN format** – When you specify an organization or OU in a command, make sure to use the correct ARN format. You'll get an error if you specify only the ID, for example, if you specify only `o-123example` or `ou-1234-5example`.

Correct ARN formats:

- Organization ARN: `arn:aws:organizations::account-id:organization/organization-id`
- OU ARN: `arn:aws:organizations::account-id:ou/organization-id/ou-id`

Where:

- *account-id* is the 12-digit management account number, for example, 123456789012. If you don't know the management account number, you can describe the organization or the organizational unit to get the ARN, which includes the management account number. For more information, see [Get the ARN](#).
- *organization-id* is the organization ID, for example, o-123example.
- *ou-id* is the organizational unit ID, for example, ou-1234-5example.

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *IAM User Guide*.

- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
  - The encrypted snapshots must be encrypted with a customer managed key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.
  - If you share an AMI that is backed by encrypted snapshots, you must allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key](#).
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI](#).
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

## Allow organizations and OUs to use a KMS key

If you share an AMI that is backed by encrypted snapshots, you must also allow the organizations or OUs to use the AWS KMS keys that were used to encrypt the snapshots.

Use the `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` keys to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be a user, IAM role, federated user, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or OUs in AWS Organizations. For more example condition statements, see [aws:PrincipalOrgID](#) and [aws:PrincipalOrgPaths](#) in the *IAM User Guide*.

For information about editing a key policy, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

To give an organization or OU permission to use a KMS key, add the following statement to the key policy.

```
{
 "Sid": "Allow access for organization root",
 "Effect": "Allow",
 "Principal": "*",
 "Action": [
 "kms:Describe*",
 "kms>List*",
 "kms:Get*",
 "kms:Encrypt",
 "kms:Decrypt",
 "kms:ReEncrypt*",
 "kms:GenerateDataKey"
],
 "Resource": "*",
 "Condition": {
 "StringEquals": {
 "aws:PrincipalOrgID": "o-123example"
 }
 }
}
```

To share a KMS key with multiple OUs, you can use a policy similar to the following example.

```
{
 "Sid": "Allow access for specific OUs and their descendants",
 "Effect": "Allow",
 "Principal": "*",
 "Action": [
 "kms:Describe*",
 "kms:Encrypt",
 "kms:Decrypt",
 "kms:ReEncrypt*",
 "kms:GenerateDataKey"
],
 "Resource": "arn:aws:kms:us-east-1:123456789012:key/12345678-1234-1234-1234-123456789012",
 "Condition": {
 "StringEquals": {
 "aws:PrincipalOrgID": "o-123example",
 "aws:PrincipalOrgPaths": "ou-123example/*"
 }
 }
}
```

```
 "kms>List*",
 "kms:Get*",
 "kms:Encrypt",
 "kms:Decrypt",
 "kms:ReEncrypt*",
 "kms:GenerateDataKey"
],
 "Resource": "*",
 "Condition": {
 "StringEquals": {
 "aws:PrincipalOrgID": "o-123example"
 },
 "ForAnyValue:StringLike": {
 "aws:PrincipalOrgPaths": [
 "o-123example/r-ab12/ou-ab12-33333333/*",
 "o-123example/r-ab12/ou-ab12-22222222/*"
]
 }
 }
}
```

## Share an AMI

You can use the Amazon EC2 console or the AWS CLI to share an AMI with an organization or OU.

### Share an AMI (console)

#### To share an AMI with an organization or an OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Under **AMI availability**, choose **Private**.
5. Next to **Shared organizations/OUs**, choose **Add organization/OU ARN**.
6. For **Organization/OU ARN**, enter the organization ARN or OU ARN with which you want to share the AMI, and then choose **Share AMI**. Note that you must specify the full ARN, not just the ID.

To share this AMI with multiple organizations or OUs, repeat this step until you have added all of the required organizations or OUs.

**Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key](#).

7. Choose **Save changes** when you're done.
8. (Optional) To view the organizations or OUs with which you have shared the AMI, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**. To find AMIs that are shared with you, see [Find shared AMIs](#).

## Share an AMI (AWS CLI)

Use the [modify-image-attribute](#) command (AWS CLI) to share an AMI.

### To share an AMI with an organization using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified organization. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationArn=arn:aws:organizations::123456789012:organization/
o-123example}]"
```

### To share an AMI with an OU using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified OU. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationalUnitArn=arn:aws:organizations::123456789012:ou/o-123example/
ou-1234-5example}]"
```

**Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key](#).

## Stop sharing an AMI

You can use the Amazon EC2 console or the AWS CLI to stop sharing an AMI with an organization or OU.

### Stop sharing an AMI (console)

#### To stop sharing an AMI with an organization or OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Under **Shared organizations/OUs**, select the organizations or OUs with which you want to stop sharing the AMI, and then choose **Remove selected**.
5. Choose **Save changes** when you're done.
6. (Optional) To confirm that you have stopped sharing the AMI with the organizations or OUs, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

### Stop sharing an AMI (AWS CLI)

Use the [modify-image-attribute](#) or [reset-image-attribute](#) commands (AWS CLI) to stop sharing an AMI.

#### To stop sharing an AMI with an organization or OU using the AWS CLI

The [modify-image-attribute](#) command removes launch permissions for the specified AMI from the specified organization. Note that you must specify the ARN.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Remove=[{OrganizationArn=arn:aws:organizations::123456789012:organization/
o-123example}]"
```

## To stop sharing an AMI with all organizations, OUs, and AWS accounts using the AWS CLI

The [reset-image-attribute](#) command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

### Note

You can't stop sharing an AMI with a specific account if it's in an organization or OU with which an AMI is shared. If you try to stop sharing the AMI by removing launch permissions for the account, Amazon EC2 returns a success message. However, the AMI continues to be shared with the account.

## View the organizations and OUs with which an AMI is shared

You can use the Amazon EC2 console or the AWS CLI to check with which organizations and OUs you've shared your AMI.

### View the organizations and OUs with which an AMI is shared (console)

#### To check with which organizations and OUs you've shared your AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

To find AMIs that are shared with you, see [Find shared AMIs](#).

## View the organizations and OUs with which an AMI is shared (AWS CLI)

You can check which organizations and OUs you've shared your AMI with by using the [describe-image-attribute](#) command (AWS CLI) and the launchPermission attribute.

### To check with which organizations and OUs you've shared your AMI using the AWS CLI

The [describe-image-attribute](#) command describes the launchPermission attribute for the specified AMI, and returns the organizations and OUs with which you've shared the AMI.

```
aws ec2 describe-image-attribute \
--image-id ami-0abcdef1234567890 \
--attribute launchPermission
```

#### Example response

```
{
 "ImageId": "ami-0abcdef1234567890",
 "LaunchPermissions": [
 {
 "OrganizationalUnitArn": "arn:aws:organizations::111122223333:ou/o-123example/ou-1234-5example"
 }
]
}
```

## Get the ARN

The organization and the organizational unit ARNs contain the 12-digit management account number. If you don't know the management account number, you can describe the organization and the organizational unit to get the ARN for each. In the following examples, 123456789012 is the management account number.

Before you can get the ARNs, you must have the permission to describe organizations and organizational units. The following policy provides the necessary permission.

```
{
 "Version": "2012-10-17",
 "Statement": [
 {
 "Effect": "Allow",
```

```
 "Action": [
 "organizations:Describe*"
],
 "Resource": "*"
 }
]
```

## To get the ARN of an organization

Use the [describe-organization](#) command and the --query parameter set to 'Organization.Arn' to return only the organization ARN.

```
aws organizations describe-organization --query 'Organization.Arn'
```

### Example response

```
"arn:aws:organizations::123456789012:organization/o-123example"
```

## To get the ARN of an organizational unit

Use the [describe-organizational-unit](#) command, specify the OU ID, and set the --query parameter to 'OrganizationalUnit.Arn' to return only the organizational unit ARN.

```
aws organizations describe-organizational-unit --organizational-unit-
id ou-1234-5example --query 'OrganizationalUnit.Arn'
```

### Example response

```
"arn:aws:organizations::123456789012:ou/o-123example/ou-1234-5example"
```

## Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need are the AWS account IDs.

An AWS account ID is a 12-digit number, such as 012345678901, that uniquely identifies an AWS account. For more information, see [Viewing AWS account identifiers](#) in the *AWS Account Management Reference Guide*.

## Considerations

Consider the following when sharing AMIs with specific AWS accounts.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – For the maximum number of entities to which an AMI can be shared within a Region, see the [Amazon EC2 service quotas](#).
- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account that the AMI is shared with.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
  - The encrypted snapshots must be encrypted with a KMS key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.
  - If you share an AMI that is backed by encrypted snapshots, you must allow the AWS accounts to use the KMS keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key](#). To set up the key policy that you need to launch Auto Scaling instances when you use a customer managed key for encryption, see [Required AWS KMS key policy for use with encrypted volumes](#) in the *Amazon EC2 Auto Scaling User Guide*.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI](#).
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Copying shared AMIs** – If users in another account want to copy a shared AMI, you must grant them read permissions for the storage that backs the AMI. For more information, see [Cross-account copying](#).
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

## Share an AMI (console)

### To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Choose **Private**.
5. Under **Shared accounts**, choose **Add account ID**.
6. For **AWS account ID**, enter the AWS account ID with which you want to share the AMI, and then choose **Share AMI**.

To share this AMI with multiple accounts, repeat Steps 5 and 6 until you have added all the required account IDs.

 **Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot](#) in the *Amazon EBS User Guide*.

7. Choose **Save changes** when you are done.
8. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs](#).

## Share an AMI (AWS CLI)

Use the [modify-image-attribute](#) command (AWS CLI) to share an AMI as shown in the following examples.

### To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace **account-id** with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
```

```
--launch-permission "Add=[{UserId=account-id}]"
```

### Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot](#) in the *Amazon EBS User Guide*.

## To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace **account-id** with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \
 --image-id ami-0abcdef1234567890 \
 --launch-permission "Remove=[{UserId=account-id}]"
```

## To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command. In the following example, replace the example AMI ID with a valid AMI ID.

```
aws ec2 reset-image-attribute \
 --image-id ami-0abcdef1234567890 \
 --attribute launchPermission
```

## Cancel having an AMI shared with your AWS account

An Amazon Machine Image (AMI) can be [shared with specific AWS accounts](#) by adding the accounts to the AMI's launch permissions. If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions. You do this by running the `cancel-image-launch-permission` AWS CLI command. When running this command, your AWS account is removed from the launch permissions for the specified AMI.

You might cancel having an AMI shared with your account, for example, to reduce the likelihood of launching an instance with an unused or deprecated AMI that was shared with you. When you cancel having an AMI shared with your account, it no longer appears in any AMI lists in the EC2 console or in the output for [describe-images](#).

## Topics

- [Limitations](#)
- [Cancel having an AMI shared with your account](#)
- [Find AMIs that are shared with your account](#)

## Limitations

- You can remove your account from the launch permissions of an AMI that is shared with your AWS account only. You can't use `cancel-image-launch-permission` to remove your account from the launch permissions of an [AMI shared with an organization or organizational unit \(OU\)](#) or to remove access to public AMIs.
- You can't permanently remove your account from the launch permissions of an AMI. An AMI owner can share an AMI with your account again.
- AMIs are a Regional resource. When running `cancel-image-launch-permission`, you must specify the Region in which the AMI is located. Either specify the Region in the command, or use the `AWS_DEFAULT_REGION` [environment variable](#).
- Only the AWS CLI and SDKs support removing your account from the launch permissions of an AMI. The EC2 console does not currently support this action.

## Cancel having an AMI shared with your account

### Note

After you cancel having an AMI shared with your account, you can't undo it. To regain access to the AMI, the AMI owner must share it with your account.

## AWS CLI

### To cancel having an AMI shared with your AWS account

Use the [cancel-image-launch-permission](#) command and specify the AMI ID.

```
aws ec2 cancel-image-launch-permission \
--image-id ami-0123456789example \
--region us-east-1
```

Expected output

```
{
 "Return": true
}
```

PowerShell

## To cancel having an AMI shared with your AWS account using the AWS Tools for PowerShell

Use the [Stop-EC2ImageLaunchPermission](#) command and specify the AMI ID.

```
Stop-EC2ImageLaunchPermission `
-ImageId ami-0123456789example `
-Region us-east-1
```

Expected output

```
True
```

## Find AMIs that are shared with your account

To find the AMIs that are shared with your AWS account, see [Find shared AMIs](#).

## Use bookmarks

If you have created a public AMI, or shared an AMI with another AWS account, you can create a *bookmark* that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don't have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

## To create a bookmark for your AMI

1. Type a URL with the following information, where *region* is the Region in which your AMI resides:

```
https://console.aws.amazon.com/ec2/v2/home?
region=region#LaunchInstanceWizard:ami=ami_id
```

For example, this URL launches an instance from the ami-0abcdef1234567890 AMI in the US East (N. Virginia) us-east-1 Region:

```
https://console.aws.amazon.com/ec2/v2/home?region=us-
east-1#LaunchInstanceWizard:ami=ami-0abcdef1234567890
```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, choose the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.

## Guidelines for shared Linux AMIs

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.

### **Important**

No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

## Contents

- [Update the AMI tools before using them](#)
- [Disable password-based remote logins for the root user](#)
- [Disable local root access](#)
- [Remove SSH host key pairs](#)
- [Install public key credentials](#)
- [Disabling sshd DNS checks \(optional\)](#)

- [Protect yourself](#)

If you are building AMIs for AWS Marketplace, see [Best practices for building AMIs](#) in the *AWS Marketplace Seller Guide* for guidelines, policies, and best practices.

For additional information about sharing AMIs safely, see the following articles:

- [How To Share and Use Public AMIs in A Secure Manner](#)
- [Public AMI Publishing: Hardening and Clean-up Requirements](#)

## Update the AMI tools before using them

For AMIs backed by instance store, we recommend that your AMIs download and upgrade the Amazon EC2 AMI creation tools before you use them. This ensures that new AMIs based on your shared AMIs have the latest AMI tools.

For [Amazon Linux 2](#), install the aws-amitools-ec2 package and add the AMI tools to your PATH with the following command. For the [Amazon Linux AMI](#), aws-amitools-ec2 package is already installed by default.

```
[ec2-user ~]$ sudo yum install -y aws-amitools-ec2 && export PATH=$PATH:/opt/aws/bin
> /etc/profile.d/aws-amitools-ec2.sh && . /etc/profile.d/aws-amitools-ec2.sh
```

Upgrade the AMI tools with the following command:

```
[ec2-user ~]$ sudo yum upgrade -y aws-amitools-ec2
```

For other distributions, make sure you have the latest AMI tools.

## Disable password-based remote logins for the root user

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.

To solve this problem, disable password-based remote logins for the root user.

### To disable password-based remote logins for the root user

1. Open the /etc/ssh/sshd\_config file with a text editor and locate the following line:

```
#PermitRootLogin yes
```

## 2. Change the line to:

```
PermitRootLogin without-password
```

The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

## Disable local root access

When you work with shared AMIs, a best practice is to disable direct root logins. To do this, log into your running instance and issue the following command:

```
[ec2-user ~]$ sudo passwd -l root
```

 **Note**

This command does not impact the use of sudo.

## Remove SSH host key pairs

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in /etc/ssh. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

Remove all of the following key files that are present on your system.

- ssh\_host\_dsa\_key
- ssh\_host\_dsa\_key.pub
- ssh\_host\_key
- ssh\_host\_key.pub
- ssh\_host\_rsa\_key
- ssh\_host\_rsa\_key.pub

- ssh\_host\_ecdsa\_key
- ssh\_host\_ecdsa\_key.pub
- ssh\_host\_ed25519\_key
- ssh\_host\_ed25519\_key.pub

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

### **Warning**

Secure deletion utilities such as **shred** may not remove all copies of a file from your storage media. Hidden copies of files may be created by journalling file systems (including Amazon Linux default ext4), snapshots, backups, RAID, and temporary caching. For more information see the [shred documentation](#).

### **Important**

If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.

## Install public key credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the RunInstances API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to `CreateKeyPair` or `ImportKeyPair`) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to `/root/.ssh/authorized_keys` (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the `cloud-init` package to inject public key credentials for a configured user. If your distribution does not support `cloud-init`, you can add the following code to a system start-up script (such as `/etc/rc.local`) to pull in the public key you specified at launch for the root user.

 **Note**

In the following example, the IP address `http://169.254.169.254/` is a link-local address and is valid only from the instance.

## IMDSv2

```
if [! -d /root/.ssh] ; then
 mkdir -p /root/.ssh
 chmod 700 /root/.ssh
fi
Fetch public key using HTTP
TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" ` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key > /tmp/my-key
if [$? -eq 0] ; then
 cat /tmp/my-key >> /root/.ssh/authorized_keys
 chmod 700 /root/.ssh/authorized_keys
 rm /tmp/my-key
fi
```

## IMDSv1

```
if [! -d /root/.ssh] ; then
 mkdir -p /root/.ssh
 chmod 700 /root/.ssh
fi
Fetch public key using HTTP
curl http://169.254.169.254/latest/meta-data/public-keys/0/openssh-key > /tmp/my-key
if [$? -eq 0] ; then
```

```
cat /tmp/my-key >> /root/.ssh/authorized_keys
chmod 700 /root/.ssh/authorized_keys
rm /tmp/my-key
fi
```

This can be applied to any user; you do not need to restrict it to the `root` user.

 **Note**

Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key's inclusion, you must clear out (or delete) the `authorized_keys` file or exclude this file from rebundling.

## Disabling sshd DNS checks (optional)

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

### To disable sshd DNS checks

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

```
#UseDNS yes
```

2. Change the line to:

```
UseDNS no
```

 **Note**

The location of this configuration file can differ for your distribution or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

## Protect yourself

We recommend against storing sensitive data or software on any AMI that you share. Users who launch a shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you to avoid some easily overlooked security risks:

- We recommend using the `--exclude directory` option on `ec2-bundle-vol` to skip any directories and subdirectories that contain secret information that you would not like to include in your bundle. In particular, exclude all user-owned SSH public/private key pairs and SSH `authorized_keys` files when bundling the image. The Amazon public AMIs store these in `/root/.ssh` for the root user, and `/home/user_name/.ssh/` for regular users. For more information, see [ec2-bundle-vol](#).
- Always delete the shell history before bundling. If you attempt more than one bundle upload in the same AMI, the shell history contains your access key. The following example should be the last command you run before bundling from within the instance.

```
[ec2-user ~]$ shred -u ~/.history
```

### Warning

The limitations of `shred` described in the warning above apply here as well.

Be aware that bash writes the history of the current session to the disk on exit. If you log out of your instance after deleting `~/.bash_history`, and then log back in, you will find that `~/.bash_history` has been re-created and contains all of the commands you ran during your previous session.

Other programs besides bash also write histories to disk. Use caution and remove or exclude unnecessary dot-files and dot-directories.

- Bundling a running instance requires your private key and X.509 certificate. Put these and other credentials in a location that is not bundled (such as the instance store).

## Paid AMIs

A *paid AMI* is an AMI that you can purchase from a developer.

Amazon EC2 integrates with AWS Marketplace, enabling developers to charge other Amazon EC2 users for the use of their AMIs or to provide support for instances.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories, such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the [AWS Marketplace](#) website.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m1.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

### **Important**

Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see [Selling in AWS Marketplace](#). AWS Marketplace supports AMIs backed by Amazon EBS.

## Contents

- [Purchase a paid AMI](#)
- [Get the product code for your instance](#)
- [Use paid support](#)
- [Bills for paid and supported AMIs](#)
- [Manage your AWS Marketplace subscriptions](#)

## Sell your AMI

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see [Selling in AWS Marketplace](#).

## Find a paid AMI

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use [AWS Marketplace](#), the Amazon EC2 console, or the command line. Alternatively, a developer might let you know about a paid AMI themselves.

### Find a paid AMI using the console

#### To find a paid AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Choose **Public images** for the first filter.
4. In the Search bar, choose **Owner alias**, then **=**, and then **aws-marketplace**.
5. If you know the product code, choose **Product code**, then **=**, and then enter the product code.

### Find a paid AMI using AWS Marketplace

#### To find a paid AMI using AWS Marketplace

1. Open [AWS Marketplace](#).
2. Enter the name of the operating system in the search field, and then choose the search button (magnifying glass).
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either AMI or Software as a Service.

### Find a paid AMI using the AWS CLI

You can find a paid AMI using the following [describe-images](#) command (AWS CLI).

```
aws ec2 describe-images
 --owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from `describe-images` includes an entry for the product code like the following:

```
"ProductCodes": [
 {
 "ProductCodeId": "product_code",
 "ProductCodeType": "marketplace"
 }
,
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
aws ec2 describe-images
--owners aws-marketplace \
--filters "Name=product-code,Values=product_code" \
--query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

## Purchase a paid AMI

You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you're first asked to log into AWS, and then you can purchase the AMI.

### Purchase a paid AMI using the console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see [Launch an AWS Marketplace instance](#).

### Subscribe to a product using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. There are two ways to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website:** You can launch preconfigured software quickly with the 1-Click deployment feature.

- **Amazon EC2 launch wizard:** You can search for an AMI and launch an instance directly from the wizard. For more information, see [Launch an AWS Marketplace instance](#).

## Get the product code for your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. For more information about retrieving metadata, see [Instance metadata and user data](#).

To retrieve a product code, use the following command:

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/product-codes
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/product-codes
```

If the instance has a product code, Amazon EC2 returns it.

## Use paid support

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

### Important

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.

To associate a product code with your AMI, use one of the following commands, where *ami\_id* is the ID of the AMI and *product\_code* is the product code:

- [modify-image-attribute](#) (AWS CLI)

```
aws ec2 modify-image-attribute --image-id ami_id --product-codes "product_code"
```

- [Edit-EC2ImageAttribute](#) (AWS Tools for Windows PowerShell)

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami_id -ProductCode product_code
```

After you set the product code attribute, it cannot be changed or removed.

## Bills for paid and supported AMIs

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see [Paying for products](#) in the *AWS Marketplace Buyer Guide*.

## Manage your AWS Marketplace subscriptions

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

### To check your subscription details

1. Log in to the [AWS Marketplace](#).
2. Choose **Your Marketplace Account**.
3. Choose **Manage your software subscriptions**.
4. All your current subscriptions are listed. Choose **Usage Instructions** to view specific instructions for using the product, for example, a user name for connecting to your running instance.

### To cancel an AWS Marketplace subscription

1. Ensure that you have terminated any instances running from the subscription.

- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  - b. In the navigation pane, choose **Instances**.
  - c. Select the instance, and then choose **Instance state, Terminate instance**.
  - d. Choose **Terminate** when prompted for confirmation.
2. Log in to the [AWS Marketplace](#), and choose **Your Marketplace Account**, then **Manage your software subscriptions**.
  3. Choose **Cancel subscription**. You are prompted to confirm your cancellation.

 **Note**

After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

### Create an Amazon EBS-backed Linux AMI

To create an Amazon EBS-backed Linux AMI, start from an instance that you've launched from an existing Amazon EBS-backed Linux AMI. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the [AWS Server Migration Service](#) or [VM Import/Export](#), or any other AMI you can access. After you customize the instance to suit your needs, create and register a new AMI, which you can use to launch new instances with these customizations.

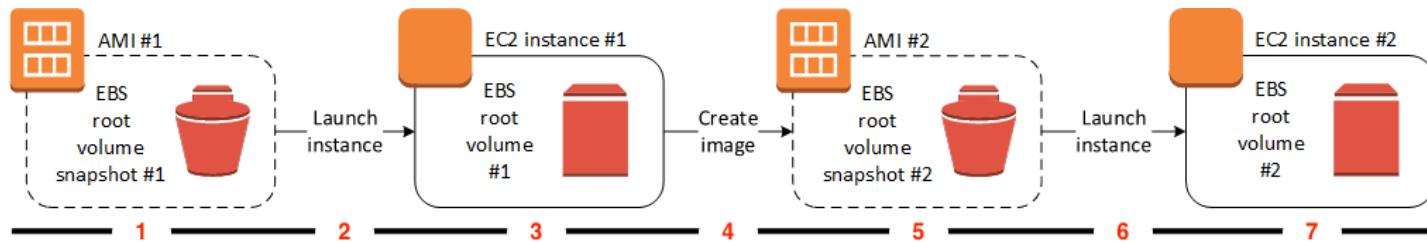

The procedures described below work for Amazon EC2 instances backed by encrypted Amazon Elastic Block Store (Amazon EBS) volumes (including the root volume) as well as for unencrypted volumes.

The AMI creation process is different for instance store-backed AMIs. For information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see [Storage for the root device](#). For information about creating an instance store-backed Linux AMI, see [Create an instance store-backed Linux AMI](#).

For information about creating an Amazon EBS-backed Windows AMI, see [Create an Amazon EBS-backed Windows AMI](#) in the *Amazon EC2 User Guide for Windows Instances*.

### Overview of creating Amazon EBS-backed AMIs

The following diagram summarizes the process for creating an Amazon EBS-backed AMI from a running EC2 instance: Start with an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The numbers in the diagram match the numbers in the description that follows.

## 1 – AMI #1: Start with an existing AMI

Find an existing AMI that is similar to the AMI that you'd like to create. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the [AWS Server Migration Service](#) or [VM Import/Export](#), or any other AMI you can access. You'll customize this AMI for your needs.

In the diagram, **EBS root volume snapshot #1** indicates that the AMI is an Amazon EBS-backed AMI and that information about the root volume is stored in this snapshot.

## 2 – Launch instance from existing AMI

The way to configure an AMI is to launch an instance from the AMI on which you'd like to base your new AMI, and then customize the instance (indicated at **3** in the diagram). Then, you'll create a new AMI that includes the customizations (indicated at **4** in the diagram).

## 3 – EC2 instance #1: Customize the instance

Connect to your instance and customize it for your needs. Your new AMI will include these customizations.

You can perform any of the following actions on your instance to customize it:

- Install software and applications
- Copy data
- Reduce start time by deleting temporary files and defragmenting your hard drive
- Attach additional EBS volumes

## 4 – Create image

When you create an AMI from an instance, Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you're confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as XFS, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.

During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You're charged for the snapshots until you [deregister the AMI](#) and delete the snapshots. If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instances that support Amazon EBS encryption.

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You might find it more efficient to create snapshots of your volumes before creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same).

## 5 – AMI #2: New AMI

After the process completes, you have a new AMI and snapshot (**snapshot #2**) created from the root volume of the instance. If you added instance-store volumes or EBS volumes to the instance, in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes.

Amazon EC2 automatically registers the AMI for you.

## 6 – Launch instance from new AMI

You can use the new AMI to launch an instance.

## 7 – EC2 instance #2: New instance

When you launch an instance using the new AMI, Amazon EC2 creates a new EBS volume for the instance's root volume using the snapshot. If you added instance-store volumes or EBS volumes when you customized the instance, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see [Block device mappings](#).

When you create a new instance from an EBS-backed AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see [Initialize Amazon EBS volumes](#) in the *Amazon EBS User Guide*.

## Create a Linux AMI from an instance

You can create an AMI using the AWS Management Console or the command line.

### Console

#### To create an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
  2. In the navigation pane, choose **Instances**.
  3. Select the instance from which to create the AMI, and then choose **Actions, Image and templates, Create image**.
-  **Tip**  
If this option is disabled, your instance isn't an Amazon EBS-backed instance.
4. On the **Create image** page, specify the following information:
    - a. For **Image name**, enter a unique name for the image, up to 127 characters.
    - b. For **Image description**, enter an optional description of the image, up to 255 characters.
    - c. For **No reboot**, either keep the **Enable** check box cleared (the default), or select it.
      - If the **Enable** check box for **No reboot** is cleared, when Amazon EC2 creates the new AMI, it reboots the instance so that it can take snapshots of the attached volumes while data is at rest, in order to ensure a consistent state.
      - If the **Enable** check box for **No reboot** is selected, when Amazon EC2 creates the new AMI, it does not shut down and reboot the instance.

 **Warning**

If you choose to enable **No reboot**, we can't guarantee the file system integrity of the created image.

- d. **Instance volumes** – You can modify the root volume, and add additional Amazon EBS and instance store volumes, as follows:

- i. The root volume is defined in the first row.
    - To change the size of the root volume, for **Size**, enter the required value.
    - If you select **Delete on termination**, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear **Delete on termination**, when you terminate the instance, the EBS volume is not deleted. For more information, see [Preserve data when an instance is terminated](#).
  - ii. To add an EBS volume, choose **Add volume** (which adds a new row). For **Storage type**, choose **EBS**, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
  - iii. To add an instance store volume, see [Add instance store volumes to an AMI](#). When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.
- e. **Tags** – You can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.
- To tag the AMI and the snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the AMI and every snapshot that is created.
  - To tag the AMI and the snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the AMI and the snapshots that are created. However, all the snapshots get the same tags; you can't tag each snapshot with a different tag.
- To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
- f. When you're ready to create your AMI, choose **Create image**.
5. To view the status of your AMI while it is being created:
    - a. In the navigation pane, choose **AMIs**.
    - b. Set the filter to **Owned by me**, and find your AMI in the list.

Initially, the status is pending but should change to available after a few minutes.

6. (Optional) To view the snapshot that was created for the new AMI:

- a. Note the ID of your AMI that you located in the previous step.
- b. In the navigation pane, choose **Snapshots**.
- c. Set the filter to **Owned by me**, and then find the snapshot with the new AMI ID in the **Description** column.

When you launch an instance from this AMI, Amazon EC2 uses this snapshot to create its root device volume.

## AWS CLI

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [create-image](#) (AWS CLI)
- [New-EC2Image](#) (AWS Tools for Windows PowerShell)

## Create a Linux AMI from a snapshot

If you have a snapshot of the root device volume of an instance, you can create an AMI from this snapshot using the AWS Management Console or the command line.

### Console

#### To create an AMI from a snapshot

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot from which to create the AMI, and then choose **Actions, Create image from snapshot**.
4. On the **Create image from snapshot** page, specify the following information:
  - a. For **Image name**, enter a descriptive name for the image.
  - b. For **Description**, enter a brief description for the image.

- c. For **Architecture**, choose the image architecture. Choose **i386** for 32-bit, **x86\_64** for 64-bit, **arm64** for 64-bit ARM, or **x86\_64** for 64-bit macOS.
- d. For **Root device name**, enter the device name to use for the root device volume. For more information, see [Device names on Linux instances](#).
- e. For **Virtualization type**, choose the virtualization type to be used by instances launched from this AMI. For more information, see [Linux AMI virtualization types](#).
- f. (For paravirtualization only) For **Kernel ID**, select the operating system kernel for the image. If you're using a snapshot of the root device volume of an instance, select the same kernel ID as the original instance. If you're unsure, use the default kernel.
- g. (For paravirtualization only) For **RAM disk ID**, select the RAM disk for the image. If you select a specific kernel, you may need to select a specific RAM disk with the drivers to support it.
- h. For **Boot mode**, choose the boot mode for the image, or choose **Use default** so that when an instance is launched with this AMI, it boots with the boot mode supported by the instance type. For more information, see [Set the boot mode of an AMI](#).
- i. (Optional) Under **Block device mappings**, customize the root volume and add additional data volumes.

For each volume, you can specify the size, type, performance characteristics, the behavior of delete on termination, and encryption status. For the root volume, the size can't be smaller than the size of the snapshot. For volume type, General Purpose SSD gp3 is the default selection.

- j. (Optional) Under **Tags**, you can add one or more tags to the new AMI. To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
- k. When you're ready to create your AMI, choose **Create image**.

## AWS CLI

### To create an AMI from a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [register-image](#) (AWS CLI)
- [Register-EC2Image](#) (AWS Tools for Windows PowerShell)

## Launch an instance from an AMI you created

You can launch an instance from an AMI that you created from an instance or snapshot.

### To launch an instance from your AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Set the filter to **Owned by me** and select your AMI.
4. Choose **Launch instance from AMI**.
5. Accept the default values or specify custom values in the launch instance wizard. For more information, see [Launch an instance using the new launch instance wizard](#).

## Create an instance store-backed Linux AMI

The AMI that you specify when you launch your instance determines the type of root device volume.

To create an instance store-backed Linux AMI, start from an instance that you've launched from an existing instance store-backed Linux AMI. After you've customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.

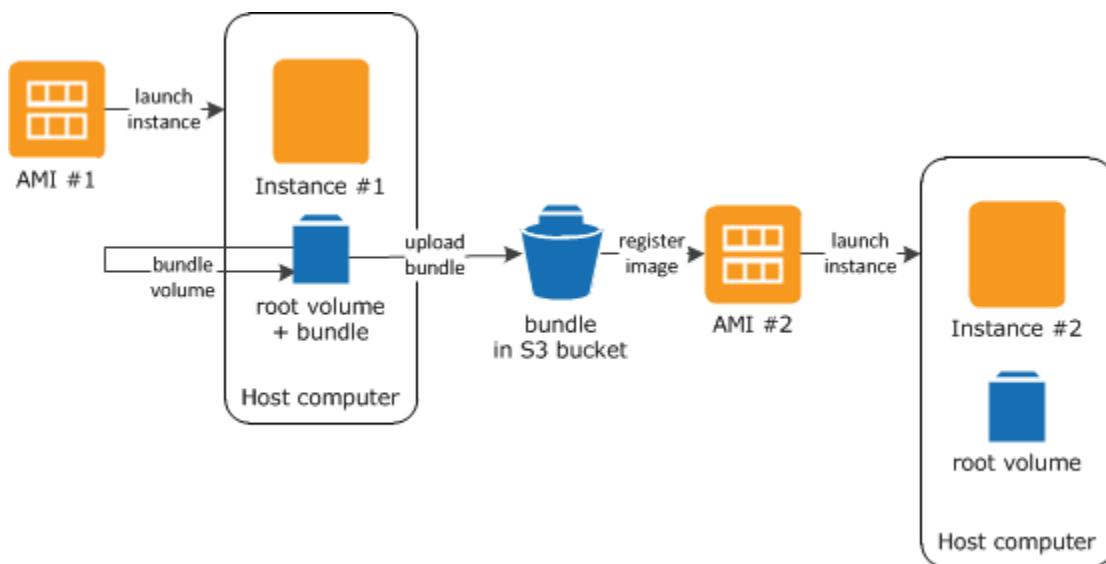

### **Important**

Only the following instance types support an instance store volume as the root device: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

The AMI creation process is different for Amazon EBS-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see [Storage for the root device](#). If you need to create an Amazon EBS-backed Linux AMI, see [Create an Amazon EBS-backed Linux AMI](#).

### Overview of the creation process for instance store-backed AMIs

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (`image.manifest.xml`) and files (`image.part.xx`) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

### Note

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see [Controlling ownership of uploaded objects using S3 Object Ownership](#).

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see [Deregister your AMI](#).

If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see [Block device mappings](#).

## Prerequisites

Before you can create an AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see [Set up the AMI tools](#).
- Install the AWS CLI. For more information, see [Getting Set Up with the AWS Command Line Interface](#).
- Ensure that you have an S3 bucket for the bundle, and that your bucket has ACLs enabled. For more information on configuring ACLs, see [Configuring ACLs](#).
  - To create an S3 bucket using the AWS Management Console, open the Amazon S3 console at <https://console.aws.amazon.com/s3/> and choose **Create Bucket**.
  - To create an S3 bucket with the AWS CLI, you can use the `mb` command. If your installed version of the AMI tools is 1.5.18 or later, you can also use the `ec2-upload-bundle` command to create the S3 bucket. For more information, see [ec2-upload-bundle](#).
- Ensure that you have your AWS account ID. For more information, see [View AWS account identifiers](#) in the *AWS Account Management Reference Guide*.
- Ensure that you have credentials to use the AWS CLI. For more information, see [Best Practices for AWS accounts](#) in the *AWS Account Management Reference Guide*.
- Ensure that you have an X.509 certificate and corresponding private key.
  - If you need to create an X.509 certificate, see [Manage signing certificates](#). The X.509 certificate and private key are used to encrypt and decrypt your AMI.
  - [China (Beijing)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-cn-north-1.pem` certificate.
  - [AWS GovCloud (US-West)] Use the `$EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-gov.pem` certificate.
- Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.

## Tasks

- [Set up the AMI tools](#)
- [Create an AMI from an instance store-backed Amazon Linux instance](#)
- [Create an AMI from an instance store-backed Ubuntu instance](#)
- [Convert your instance store-backed AMI to an Amazon EBS-backed AMI](#)

## Set up the AMI tools

You can use the AMI tools to create and manage instance store-backed Linux AMIs. To use the tools, you must install them on your Linux instance. The AMI tools are available as both an RPM and as a .zip file for Linux distributions that don't support RPM.

### To set up the AMI tools using the RPM

1. Install Ruby using the package manager for your Linux distribution, such as yum. For example:

```
[ec2-user ~]$ sudo yum install -y ruby
```

2. Download the RPM file using a tool such as wget or curl. For example:

```
[ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.noarch.rpm
```

3. Verify the RPM file's signature using the following command:

```
[ec2-user ~]$ rpm -K ec2-ami-tools.noarch.rpm
```

The command above should indicate that the file's SHA1 and MD5 hashes are OK. If the command indicates that the hashes are NOT OK, use the following command to view the file's Header SHA1 and MD5 hashes:

```
[ec2-user ~]$ rpm -Kv ec2-ami-tools.noarch.rpm
```

Then, compare your file's Header SHA1 and MD5 hashes with the following verified AMI tools hashes to confirm the file's authenticity:

- Header SHA1: a1f662d6f25f69871104e6a62187fa4df508f880
- MD5: 9faff05258064e2f7909b66142de6782

If your file's Header SHA1 and MD5 hashes match the verified AMI tools hashes, continue to the next step.

4. Install the RPM using the following command:

```
[ec2-user ~]$ sudo yum install ec2-ami-tools.noarch.rpm
```

5. Verify your AMI tools installation using the [ec2-ami-tools-version](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

 **Note**

If you receive a load error such as "cannot load such file -- ec2/amitools/version (LoadError)", complete the next step to add the location of your AMI tools installation to your RUBYLIB path.

6. (Optional) If you received an error in the previous step, add the location of your AMI tools installation to your RUBYLIB path.
  - a. Run the following command to determine the paths to add.

```
[ec2-user ~]$ rpm -qil ec2-ami-tools | grep ec2/amitools/version
/usr/lib/ruby/site_ruby/ec2/amitools/version.rb
/usr/lib64/ruby/site_ruby/ec2/amitools/version.rb
```

In the above example, the missing file from the previous load error is located at /usr/lib/ruby/site\_ruby and /usr/lib64/ruby/site\_ruby.

- b. Add the locations from the previous step to your RUBYLIB path.

```
[ec2-user ~]$ export RUBYLIB=$RUBYLIB:/usr/lib/ruby/site_ruby:/usr/lib64/ruby/
site_ruby
```

- c. Verify your AMI tools installation using the [ec2-ami-tools-version](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

## To set up the AMI tools using the .zip file

1. Install Ruby and unzip using the package manager for your Linux distribution, such as **apt-get**. For example:

```
[ec2-user ~]$ sudo apt-get update -y && sudo apt-get install -y ruby unzip
```

2. Download the .zip file using a tool such as wget or curl. For example:

```
[ec2-user ~]$ wget https://s3.amazonaws.com/ec2-downloads/ec2-ami-tools.zip
```

3. Unzip the files into a suitable installation directory, such as /usr/local/ec2.

```
[ec2-user ~]$ sudo mkdir -p /usr/local/ec2
$ sudo unzip ec2-ami-tools.zip -d /usr/local/ec2
```

Notice that the .zip file contains a folder ec2-ami-tools-*x.x.x*, where *x.x.x* is the version number of the tools (for example, ec2-ami-tools-1.5.7).

4. Set the EC2\_AMITOOL\_HOME environment variable to the installation directory for the tools. For example:

```
[ec2-user ~]$ export EC2_AMITOOL_HOME=/usr/local/ec2/ec2-ami-tools-x.x.x
```

5. Add the tools to your PATH environment variable. For example:

```
[ec2-user ~]$ export PATH=$EC2_AMITOOL_HOME/bin:$PATH
```

6. You can verify your AMI tools installation using the [ec2-ami-tools-version](#) command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

## Manage signing certificates

Certain commands in the AMI tools require a signing certificate (also known as X.509 certificate). You must create the certificate and then upload it to AWS. For example, you can use a third-party tool such as OpenSSL to create the certificate.

### To create a signing certificate

1. Install and configure OpenSSL.
2. Create a private key using the openssl genrsa command and save the output to a .pem file. We recommend that you create a 2048- or 4096-bit RSA key.

```
openssl genrsa 2048 > private-key.pem
```

3. Generate a certificate using the openssl req command.

```
openssl req -new -x509 -nodes -sha256 -days 365 -key private-key.pem -out certificate.pem
```

To upload the certificate to AWS, use the [upload-signing-certificate](#) command.

```
aws iam upload-signing-certificate --user-name user-name --certificate-body
file://path/to/certificate.pem
```

To list the certificates for a user, use the [list-signing-certificates](#) command:

```
aws iam list-signing-certificates --user-name user-name
```

To disable or re-enable a signing certificate for a user, use the [update-signing-certificate](#) command. The following command disables the certificate:

```
aws iam update-signing-certificate --certificate-id OFHPLP4ZULTHYPMSYEX704BEXAMPLE --
status Inactive --user-name user-name
```

To delete a certificate, use the [delete-signing-certificate](#) command:

```
aws iam delete-signing-certificate --user-name user-name --certificate-
id OFHPLP4ZULTHYPMSYEX704BEXAMPLE
```

## Create an AMI from an instance store-backed instance

The following procedures are for creating an instance store-backed AMI from an instance store-backed instance. Before you begin, ensure that you've read the [Prerequisites](#).

### Topics

- [Create an AMI from an instance store-backed Amazon Linux instance](#)
- [Create an AMI from an instance store-backed Ubuntu instance](#)

## Create an AMI from an instance store-backed Amazon Linux instance

This section describes the creation of an AMI from an Amazon Linux instance. The following procedures may not work for instances running other Linux distributions. For Ubuntu-specific procedures, see [Create an AMI from an instance store-backed Ubuntu instance](#).

## To prepare to use the AMI tools (HVM instances only)

1. The AMI tools require GRUB Legacy to boot properly. Use the following command to install GRUB:

```
[ec2-user ~]$ sudo yum install -y grub
```

2. Install the partition management packages with the following command:

```
[ec2-user ~]$ sudo yum install -y gdisk kpartx parted
```

## To create an AMI from an instance store-backed Amazon Linux instance

This procedure assumes that you have satisfied the prerequisites in [Prerequisites](#).

In the following commands, replace each *user input placeholder* with your own information.

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.
  - a. Create a temporary directory on your instance for your credentials as follows:

```
[ec2-user ~]$ mkdir /tmp/cert
```

This enables you to exclude your credentials from the created image.

- b. Copy your X.509 certificate and corresponding private key from your computer to the /tmp/cert directory on your instance using a secure copy tool such as [scp](#). The `-i my-private-key.pem` option in the following [scp](#) command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /
path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 717 0.7KB/s 00:00
cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 685 0.7KB/s 00:00
```

Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

2. Prepare the bundle to upload to Amazon S3 by running the [ec2-bundle-vol](#) command from inside your instance. Be sure to specify the -e option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include \* .sw, \* .swo, \* .swp, \* .pem, \* .priv, \*id\_rsa\*, \*id\_dsa\* \* .gpg, \* .jks, \* /.ssh/authorized\_keys, and \* /.bash\_history. To include all of these files, use the --no-filter option. To include some of these files, use the --include option.

**⚠ Important**

By default, the AMI bundling process creates a compressed, encrypted collection of files in the /tmp directory that represents your root volume. If you do not have enough free disk space in /tmp to store the bundle, you need to specify a different location for the bundle to be stored with the -d */path/to/bundle/storage* option. Some instances have ephemeral storage mounted at /mnt or /media/ephemeral0 that you can use, or you can also create, attach, and mount a new Amazon EBS volume to store the bundle. For more information, see [Create an Amazon EBS volume](#) in the *Amazon EBS User Guide*.

- a. You must run the **ec2-bundle-vol** command as root. For most commands, you can use **sudo** to gain elevated permissions, but in this case, you should run **sudo -E su** to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
[root ec2-user]#
```

- b. To create the AMI bundle, run the [ec2-bundle-vol](#) command as follows:

```
[root ec2-user]# ec2-bundle-vol -k /tmp/cert/pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 123456789012 -r x86_64 -e /tmp/cert --
partition gpt
```

 **Note**

For the China (Beijing) and AWS GovCloud (US-West) Regions, use the `--ec2cert` parameter and specify the certificates as per the [prerequisites](#).

It can take a few minutes to create the image. When this command completes, your `/tmp` (or non-default) directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

- c. Exit from the root shell.

```
[root ec2-user]# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see [Block device mappings](#).

- a. Create a backup of your `image.manifest.xml` file.

```
[ec2-user ~]$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

- b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
[ec2-user ~]$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/
image.manifest.xml
```

- c. Edit the block device mappings in `image.manifest.xml` with a text editor. The example below shows a new entry for the `ephemeral1` instance store volume.

 **Note**

For a list of excluded files, see [ec2-bundle-vol](#).

```
<block_device_mapping>
 <mapping>
 <virtual>ami</virtual>
 <device>sda</device>
 </mapping>
 <mapping>
 <virtual>ephemeral0</virtual>
 <device>sdb</device>
 </mapping>
 <mapping>
 <virtual>ephemeral1</virtual>
 <device>sdc</device>
 </mapping>
 <mapping>
 <virtual>root</virtual>
 <device>/dev/sda1</device>
 </mapping>
</block_device_mapping>
```

- d. Save the `image.manifest.xml` file and exit your text editor.
4. To upload your bundle to Amazon S3, run the [ec2-upload-bundle](#) command as follows.

```
[ec2-user ~]$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/
image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

**⚠ Important**

To register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

```
[ec2-user ~]$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

**⚠ Important**

If you specified a path with the -d `/path/to/bundle/storage` option in [Step 2](#), use that path instead of /tmp.

6. To register your AMI, run the [register-image](#) command as follows.

```
[ec2-user ~]$ aws ec2 register-image --image-location my-s3-bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
```

**⚠ Important**

If you previously specified a Region for the [ec2-upload-bundle](#) command, specify that Region again for this command.

## Create an AMI from an instance store-backed Ubuntu instance

This section describes the creation of an AMI from an Ubuntu Linux instance with an instance store volume as the root volume. The following procedures may not work for instances running other Linux distributions. For procedures specific to Amazon Linux, see [Create an AMI from an instance store-backed Amazon Linux instance](#).

### To prepare to use the AMI tools (HVM instances only)

The AMI tools require GRUB Legacy to boot properly. However, Ubuntu is configured to use GRUB 2. You must check to see that your instance uses GRUB Legacy, and if not, you need to install and configure it.

HVM instances also require partitioning tools to be installed for the AMI tools to work properly.

1. GRUB Legacy (version 0.9x or less) must be installed on your instance. Check to see if GRUB Legacy is present and install it if necessary.
  - a. Check the version of your GRUB installation.

```
ubuntu:~$ grub-install --version
grub-install (GRUB) 1.99-21ubuntu3.10
```

In this example, the GRUB version is greater than 0.9x, so you must install GRUB Legacy.

Proceed to [Step 1.b](#). If GRUB Legacy is already present, you can skip to [Step 2](#).

- b. Install the grub package using the following command.

```
ubuntu:~$ sudo apt-get install -y grub
```

2. Install the following partition management packages using the package manager for your distribution.

- gdisk (some distributions may call this package gptfdisk instead)
- kpartx
- parted

Use the following command.

```
ubuntu:~$ sudo apt-get install -y gdisk kpartx parted
```

3. Check the kernel parameters for your instance.

```
ubuntu:~$ cat /proc/cmdline
BOOT_IMAGE=/boot/vmlinuz-3.2.0-54-virtual root=UUID=4f392932-ed93-4f8f-
aee7-72bc5bb6ca9d ro console=ttyS0 xen_emul_unplug=unnecessary
```

Note the options following the kernel and root device parameters: ro, console=ttyS0, and xen\_emul\_unplug=unnecessary. Your options may differ.

4. Check the kernel entries in /boot/grub/menu.lst.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=hvc0
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
kernel /boot/memtest86+.bin
```

Note that the console parameter is pointing to hvc0 instead of ttyS0 and that the xen\_emul\_unplug=unnecessary parameter is missing. Again, your options may differ.

5. Edit the /boot/grub/menu.lst file with your favorite text editor (such as **vim** or **nano**) to change the console and add the parameters you identified earlier to the boot entries.

```

title Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual
root (hd0)
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs
ro console=ttyS0 xen_emul_unplug=unnecessary
initrd /boot/initrd.img-3.2.0-54-virtual

title Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual (recovery mode)
root (hd0)
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro
single console=ttyS0 xen_emul_unplug=unnecessary
initrd /boot/initrd.img-3.2.0-54-virtual

title Ubuntu 12.04.3 LTS, memtest86+
root (hd0)
kernel /boot/memtest86+.bin

```

- Verify that your kernel entries now contain the correct parameters.

```

ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=ttyS0
 xen_emul_unplug=unnecessary
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
 console=ttyS0 xen_emul_unplug=unnecessary
kernel /boot/memtest86+.bin

```

- [For Ubuntu 14.04 and later only] Starting with Ubuntu 14.04, instance store backed Ubuntu AMIs use a GPT partition table and a separate EFI partition mounted at /boot/efi. The **ec2-bundle-vol** command will not bundle this boot partition, so you need to comment out the /etc/fstab entry for the EFI partition as shown in the following example.

```

LABEL=cloudimg-rootfs / ext4 defaults 0 0
#LABEL=UEFI /boot/efi vfat defaults 0 0
/dev/xvdb /mnt auto defaults,nobootwait,comment=cloudconfig 0 2

```

## To create an AMI from an instance store-backed Ubuntu instance

This procedure assumes that you have satisfied the prerequisites in [Prerequisites](#).

In the following commands, replace each *user input placeholder* with your own information.

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.
  - a. Create a temporary directory on your instance for your credentials as follows:

```
ubuntu:~$ mkdir /tmp/cert
```

This enables you to exclude your credentials from the created image.

- b. Copy your X.509 certificate and private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as [scp](#). The `-i my-private-key.pem` option in the following [scp](#) command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /
path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 717 0.7KB/s 00:00
cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 685 0.7KB/s 00:00
```

Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

2. Prepare the bundle to upload to Amazon S3 by running the [ec2-bundle-vol](#) command from your instance. Be sure to specify the `-e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*`, `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

### Important

By default, the AMI bundling process creates a compressed, encrypted collection of files in the /tmp directory that represents your root volume. If you do not have enough free disk space in /tmp to store the bundle, you need to specify a different location for the bundle to be stored with the `-d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at /mnt or /media/ephemeral0 that you

can use, or you can also create, attach, and mount a new Amazon EBS volume to store the bundle. For more information, see [Create an Amazon EBS volume](#) in the *Amazon EBS User Guide*.

- a. You must run the **ec2-bundle-vol** command needs as root. For most commands, you can use **sudo** to gain elevated permissions, but in this case, you should run **sudo -E su** to keep your environment variables.

```
ubuntu:~$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
root@ubuntu:#
```

- b. To create the AMI bundle, run the [ec2-bundle-vol](#) command as follows.

```
root@ubuntu:# ec2-bundle-vol -k /tmp/cert/pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u your_aws_account_id -r x86_64 -e /tmp/
cert --partition gpt
```

**⚠ Important**

For Ubuntu 14.04 and later HVM instances, add the `--partition mbr` flag to bundle the boot instructions properly; otherwise, your newly-created AMI will not boot.

It can take a few minutes to create the image. When this command completes, your tmp directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

- c. Exit from the root shell.

```
root@ubuntu:# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see [Block device mappings](#).

- a. Create a backup of your `image.manifest.xml` file.

```
ubuntu:~$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

- b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
ubuntu:~$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/
image.manifest.xml
```

- c. Edit the block device mappings in `image.manifest.xml` with a text editor. The example below shows a new entry for the `ephemeral1` instance store volume.

```
<block_device_mapping>
 <mapping>
 <virtual>ami</virtual>
 <device>sda</device>
 </mapping>
 <mapping>
 <virtual>ephemeral0</virtual>
 <device>sdb</device>
 </mapping>
 <mapping>
 <virtual>ephemeral1</virtual>
 <device>sdc</device>
 </mapping>
 <mapping>
 <virtual>root</virtual>
 <device>/dev/sda1</device>
 </mapping>
</block_device_mapping>
```

- d. Save the `image.manifest.xml` file and exit your text editor.

4. To upload your bundle to Amazon S3, run the [ec2-upload-bundle](#) command as follows.

```
ubuntu:~$ ec2-upload-bundle -b my-s3-bucket/bundle_folder/bundle_name -m /tmp/
image.manifest.xml -a your_access_key_id -s your_secret_access_key
```

**⚠️ Important**

If you intend to register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

```
ubuntu:~$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

**⚠️ Important**

If you specified a path with the `-d /path/to/bundle/storage` option in [Step 2](#), use that same path below, instead of `/tmp`.

6. To register your AMI, run the [`register-image`](#) AWS CLI command as follows.

```
ubuntu:~$ aws ec2 register-image --image-location my-s3-bucket/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
```

**⚠️ Important**

If you previously specified a Region for the [`ec2-upload-bundle`](#) command, specify that Region again for this command.

7. [Ubuntu 14.04 and later] Uncomment the EFI entry in `/etc/fstab`; otherwise, your running instance will not be able to reboot.

## Convert your instance store-backed AMI to an Amazon EBS-backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

**⚠ Important**

You can't convert an instance store-backed Windows AMI to an Amazon EBS-backed Windows AMI and you cannot convert an AMI that you do not own.

**To convert an instance store-backed AMI to an Amazon EBS-backed AMI**

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see [Launch an instance using the new launch instance wizard](#). Amazon Linux instances have the AWS CLI and AMI tools pre-installed.
2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.
  - a. Create a temporary directory on your instance for your X.509 private key as follows:

```
[ec2-user ~]$ mkdir /tmp/cert
```

- b. Copy your X.509 private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as [scp](#). The *my-private-key* parameter in the following command is the private key you use to connect to your instance with SSH. For example:

```
you@your_computer:~ $ scp -i my-private-key.pem /
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-
user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/

- a. (Recommended) Set environment variables for your AWS access key, secret key, and session token.
- ```
[ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id  
[ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key  
[ec2-user ~]$ export AWS_SESSION_TOKEN=your_session_token
```
- b. Set environment variables for your AWS access key, and secret key.

```
[ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id  
[ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
```

4. Prepare an Amazon Elastic Block Store (Amazon EBS) volume for your new AMI.

- Create an empty EBS volume in the same Availability Zone as your instance using the [create-volume](#) command. Note the volume ID in the command output.

⚠ Important

This EBS volume must be the same size or larger than the original instance store root volume.

```
[ec2-user ~]$ aws ec2 create-volume --size 10 --region us-west-2 --  
availability-zone us-west-2b
```

- Attach the volume to your Amazon EBS-backed instance using the [attach-volume](#) command.

```
[ec2-user ~]$ aws ec2 attach-volume --volume-id volume_id --instance-  
id instance_id --device /dev/sdb --region us-west-2
```

5. Create a folder for your bundle.

```
[ec2-user ~]$ mkdir /tmp/bundle
```

6. Download the bundle for your instance store-based AMI to /tmp/bundle using the [ec2-download-bundle](#) command.

```
[ec2-user ~]$ ec2-download-bundle -b my-s3-bucket/bundle_folder/bundle_name -m  
image.manifest.xml -a $AWS_ACCESS_KEY_ID -s $AWS_SECRET_ACCESS_KEY --privatekey /  
path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d /tmp/bundle
```

7. Reconstitute the image file from the bundle using the [ec2-unbundle](#) command.

- Change directories to the bundle folder.

```
[ec2-user ~]$ cd /tmp/bundle/
```

- b. Run the [ec2-unbundle](#) command.

```
[ec2-user bundle]$ ec2-unbundle -m image.manifest.xml --privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem
```

8. Copy the files from the unbundled image to the new EBS volume.

```
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Probe the volume for any new partitions that were unbundled.

```
[ec2-user bundle]$ sudo partprobe /dev/sdb1
```

10. List the block devices to find the device name to mount.

```
[ec2-user bundle]$ lsblk
NAME      MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
/dev/sda    202:0   0   8G  0 disk
##/dev/sda1 202:1   0   8G  0 part /
/dev/sdb    202:80  0  10G  0 disk
##/dev/sdb1 202:81  0  10G  0 part
```

In this example, the partition to mount is `/dev/sdb1`, but your device name will likely be different. If your volume is not partitioned, then the device to mount will be similar to `/dev/sdb` (without a device partition trailing digit).

11. Create a mount point for the new EBS volume and mount the volume.

```
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb1 /mnt/ebs
```

12. Open the `/etc/fstab` file on the EBS volume with your favorite text editor (such as `vim` or `nano`) and remove any entries for instance store (ephemeral) volumes. Because the EBS volume is mounted on `/mnt/ebs`, the `fstab` file is located at `/mnt/ebs/etc/fstab`.

```
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab
#
LABEL=/      /          ext4      defaults,noatime 1 1
tmpfs       /dev/shm    tmpfs     defaults        0 0
devpts      /dev/pts    devpts    gid=5,mode=620 0 0
sysfs       /sys        sysfs    defaults        0 0
```

```
proc      /proc      proc      defaults      0      0
/dev/sdb    /media/ephemeral0    auto      defaults,comment=cloudconfig      0
2
```

In this example, the last line should be removed.

13. Unmount the volume and detach it from the instance.

```
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ aws ec2 detach-volume --volume-id volume_id --region us-west-2
```

14. Create an AMI from the new EBS volume as follows.

- Create a snapshot of the new EBS volume.

```
[ec2-user bundle]$ aws ec2 create-snapshot --region us-west-2 --description
"your_snapshot_description" --volume-id volume_id
```

- Check to see that your snapshot is complete.

```
[ec2-user bundle]$ aws ec2 describe-snapshots --region us-west-2 --snapshot-
id snapshot_id
```

- Identify the processor architecture, virtualization type, and the kernel image (aki) used on the original AMI with the **describe-images** command. You need the AMI ID of the original instance store-backed AMI for this step.

```
[ec2-user bundle]$ aws ec2 describe-images --region us-west-2 --image-id ami_id
--output text
IMAGES x86_64 amazon/amzn-ami-pv-2013.09.2.x86_64-s3 ami-8ef297be amazon
available public machine aki-fc8f11cc instance-store paravirtual xen
```

In this example, the architecture is x86_64 and the kernel image ID is aki-fc8f11cc. Use these values in the following step. If the output of the above command also lists an ari ID, take note of that as well.

- Register your new AMI with the snapshot ID of your new EBS volume and the values from the previous step. If the previous command output listed an ari ID, include that in the following command with **--ramdisk-id ari_id**.

```
[ec2-user bundle]$ aws ec2 register-image --region us-west-2 --
name your_new_ami_name --block-device-mappings DeviceName=device-
```

```
name,Ebs={SnapshotId=snapshot_id} --virtualization-type paravirtual --  
architecture x86_64 --kernel-id aki-fc8f11cc --root-device-name device-name
```

15. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the EBS volume that you created for this procedure.

```
aws ec2 delete-volume --volume-id volume_id
```

AMI tools reference

You can use the AMI tools commands to create and manage instance store-backed Linux AMIs. To set up the tools, see [Set up the AMI tools](#).

For information about your access keys, see [Best Practices for AWS accounts](#) in the *AWS Account Management Reference Guide*.

Commands

- [ec2-ami-tools-version](#)
- [ec2-bundle-image](#)
- [ec2-bundle-vol](#)
- [ec2-delete-bundle](#)
- [ec2-download-bundle](#)
- [ec2-migrate-manifest](#)
- [ec2-unbundle](#)
- [ec2-upload-bundle](#)
- [Common options for AMI tools](#)

ec2-ami-tools-version

Description

Describes the version of the AMI tools.

Syntax

ec2-ami-tools-version

Output

The version information.

Example

This example command displays the version information for the AMI tools that you're using.

```
[ec2-user ~]$ ec2-ami-tools-version  
1.5.2 20071010
```

ec2-bundle-image

Description

Creates an instance store-backed Linux AMI from an operating system image created in a loopback file.

Syntax

```
ec2-bundle-image -c path -k path -u account -i path [-d path] [--ec2cert path] [-r architecture] [--productcodes code1,code2,...] [-B mapping] [-p prefix]
```

Options

-c, --cert *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey *path*

The path to a PEM-encoded RSA key file. You'll need to specify this key to unbundle this bundle, so keep it in a safe place. Note that the key doesn't have to be registered to your AWS account.

Required: Yes

-u, --user *account*

The user's AWS account ID, without dashes.

Required: Yes

-i, --image *path*

The path to the image to bundle.

Required: Yes

-d, --destination *path*

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in [Set up the AMI tools](#), the certificates are located at \$EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch *architecture*

Image architecture. If you don't provide the architecture on the command line, you'll be prompted for it when bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- `ami`—The root file system device, as seen by the instance
- `root`—The root file system device, as seen by the kernel
- `swap`—The swap device, as seen by the instance
- `ephemeralN`—The Nth instance store volume

Required: No

`-p, --prefix prefix`

The filename prefix for bundled AMI files.

Default: The name of the image file. For example, if the image path is `/var/spool/my-image/version-2/debian.img`, then the default prefix is `debian.img`.

Required: No

`--kernel kernel_id`

Deprecated. Use [register-image](#) to set the kernel.

Required: No

`--ramdisk ramdisk_id`

Deprecated. Use [register-image](#) to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example creates a bundled AMI from an operating system image that was created in a loopback file.

```
[ec2-user ~]$ ec2-bundle-image -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -i image.img -d bundled/ -r x86_64

ec2-bundle-vol

Description

Creates an instance store-backed Linux AMI by compressing, encrypting, and signing a copy of the root device volume for the instance.

Amazon EC2 attempts to inherit product codes, kernel settings, RAM disk settings, and block device mappings from the instance.

By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*`, `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

For more information, see [Create an instance store-backed Linux AMI](#).

Syntax

```
ec2-bundle-vol -c path -k path -u account [-d path] [--ec2cert path] [-r architecture] [--productcodes code1,code2,...] [-B mapping] [--all] [-e
```

directory1, directory2, ...] [-i file1, file2, ...] [--no-filter] [-p prefix]
[-s size] [--[no-]inherit] [-v volume] [-P type] [-S script] [--fstab path]
--generate-fstab] [--grub-config path]

Options

-c, --cert path

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey path

The path to the user's PEM-encoded RSA key file.

Required: Yes

-u, --user account

The user's AWS account ID, without dashes.

Required: Yes

-d, --destination destination

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in [Set up the AMI tools](#), the certificates are located at \$EC2_AMIT0OL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch *architecture*

The image architecture. If you don't provide this on the command line, you'll be prompted to provide it when the bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes *code1,code2,...*

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping *mapping*

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- `ami`—The root file system device, as seen by the instance
- `root`—The root file system device, as seen by the kernel
- `swap`—The swap device, as seen by the instance
- `ephemeralN`—The Nth instance store volume

Required: No

-a, --all

Bundle all directories, including those on remotely mounted file systems.

Required: No

-e, --exclude *directory1,directory2,...*

A list of absolute directory paths and files to exclude from the bundle operation. This parameter overrides the `--all` option. When `exclude` is specified, the directories and subdirectories listed with the parameter will not be bundled with the volume.

Required: No

-i, --include *file1,file2,...*

A list of files to include in the bundle operation. The specified files would otherwise be excluded from the AMI because they might contain sensitive information.

Required: No

--no-filter

If specified, we won't exclude files from the AMI because they might contain sensitive information.

Required: No

-p, --prefix *prefix*

The file name prefix for bundled AMI files.

Default: image

Required: No

-s, --size *size*

The size, in MB (1024 * 1024 bytes), of the image file to create. The maximum size is 10240 MB.

Default: 10240

Required: No

--[no-]inherit

Indicates whether the image should inherit the instance's metadata (the default is to inherit). Bundling fails if you enable **--inherit** but the instance metadata is not accessible.

Required: No

-v, --volume *volume*

The absolute path to the mounted volume from which to create the bundle.

Default: The root directory (/)

Required: No

-P, --partition *type*

Indicates whether the disk image should use a partition table. If you don't specify a partition table type, the default is the type used on the parent block device of the volume, if applicable, otherwise the default is gpt.

Valid values: mbr | gpt | none

Required: No

-S, --script *script*

A customization script to be run right before bundling. The script must expect a single argument, the mount point of the volume.

Required: No

--fstab *path*

The path to the fstab to bundle into the image. If this is not specified, Amazon EC2 bundles /etc/fstab.

Required: No

--generate-fstab

Bundles the volume using an Amazon EC2-provided fstab.

Required: No

--grub-config

The path to an alternate grub configuration file to bundle into the image. By default, ec2-bundle-vol expects either /boot/grub/menu.lst or /boot/grub/grub.conf to exist on the cloned image. This option allows you to specify a path to an alternative grub configuration file, which will then be copied over the defaults (if present).

Required: No

--kernel *kernel_id*

Deprecated. Use [register-image](#) to set the kernel.

Required: No

--ramdiskramdisk_id

Deprecated. Use [register-image](#) to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling.

Example

This example creates a bundled AMI by compressing, encrypting and signing a snapshot of the local machine's root file system.

```
[ec2-user ~]$ ec2-bundle-vol -d /mnt -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -r x86_64

ec2-delete-bundle

Description

Deletes the specified bundle from Amazon S3 storage. After you delete a bundle, you can't launch instances from the corresponding AMI.

Syntax

```
ec2-delete-bundle -b bucket -a access_key_id -s secret_access_key [-t token] [--url url] [--region region] [--sigv version] [-m path] [-p prefix] [--clear] [--retry] [-y]
```

Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket containing the bundled AMI, followed by an optional '/'- delimited path prefix

Required: Yes

-a, --access-key *access_key_id*

The AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

The AWS secret access key.

Required: Yes

-t, --delegation-token *token*

The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#).

Required: Only when you are using temporary security credentials.

Default: The value of the AWS_DELEGATION_TOKEN environment variable (if set).

--region*region*

The Region to use in the request signature.

Default: us-east-1

Required: Required if using signature version 4

--sigvversion

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

-m, --manifestpath

The path to the manifest file.

Required: You must specify --prefix or --manifest.

-p, --prefix *prefix*

The bundled AMI filename prefix. Provide the entire prefix. For example, if the prefix is image.img, use -p image.img and not -p image.

Required: You must specify --prefix or --manifest.

--clear

Deletes the Amazon S3 bucket if it's empty after deleting the specified bundle.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

`-y, --yes`

Automatically assumes the answer to all prompts is yes.

Required: No

Output

Amazon EC2 displays status messages indicating the stages and status of the delete process.

Example

This example deletes a bundle from Amazon S3.

```
[ec2-user ~]$ ec2-delete-bundle -b DOC-EXAMPLE-BUCKET1 -a your_access_key_id -

ec2-download-bundle

Description

Downloads the specified instance store-backed Linux AMIs from Amazon S3 storage.

Syntax

```
ec2-download-bundle -b bucket -a access_key_id -s secret_access_key -k path
[--url url] [--region region] [--sigv version] [-m file] [-p prefix] [-d
directory] [--retry]
```

Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket where the bundle is located, followed by an optional '/'- delimited path prefix.

Required: Yes

-a, --access-key *access_key_id*

The AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

The AWS secret access key.

Required: Yes

-k, --privatekey *path*

The private key used to decrypt the manifest.

Required: Yes

--url *url*

The Amazon S3 service URL.

Default: `https://s3.amazonaws.com/`

Required: No

`--region region`

The Region to use in the request signature.

Default: `us-east-1`

Required: Required if using signature version 4

`--sigv version`

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

`-m, --manifest file`

The name of the manifest file (without the path). We recommend that you specify either the manifest (`-m`) or a prefix (`-p`).

Required: No

`-p, --prefix prefix`

The filename prefix for the bundled AMI files.

Default: `image`

Required: No

`-d, --directory directory`

The directory where the downloaded bundle is saved. The directory must exist.

Default: The current working directory.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

Output

Status messages indicating the various stages of the download process are displayed.

Example

This example creates the bundled directory (using the Linux `mkdir` command) and downloads the bundle from the `DOC-EXAMPLE-BUCKET1` Amazon S3 bucket.

```
[ec2-user ~]$ mkdir bundled  
[ec2-user ~]$ ec2-download-bundle -b DOC-EXAMPLE-BUCKET1/bundles/bundle_name

ec2-migrate-manifest

Description

Modifies an instance store-backed Linux AMI (for example, its certificate, kernel, and RAM disk) so that it supports a different Region.

Syntax

```
ec2-migrate-manifest -c path -k path -m path {(-a access_key_id -  
s secret_access_key --region region) | (--no-mapping)} [--ec2cert  
ec2_cert_path] [--kernel kernel-id] [--ramdisk ramdisk_id]
```

Options

-c, --cert *path*

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey *path*

The path to the user's PEM-encoded RSA key file.

Required: Yes

--manifest *path*

The path to the manifest file.

Required: Yes

-a, --access-key *access_key_id*

The AWS access key ID.

Required: Required if using automatic mapping.

-s, --secret-key *secret_access_key*

The AWS secret access key.

Required: Required if using automatic mapping.

--region *region*

The Region to look up in the mapping file.

Required: Required if using automatic mapping.

--no-mapping

Disables automatic mapping of kernels and RAM disks.

During migration, Amazon EC2 replaces the kernel and RAM disk in the manifest file with a kernel and RAM disk designed for the destination region. Unless the **--no-mapping** parameter is given, `ec2-migrate-bundle` might use the `DescribeRegions` and `DescribeImages` operations to perform automated mappings.

Required: Required if you're not providing the **-a**, **-s**, and **--region** options used for automatic mapping.

--ec2cert *path*

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The `us-gov-west-1` and `cn-north-1` Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at `/opt/aws/amitools/ec2/etc/ec2/amitools/`. If you installed the AMI tools from the ZIP file in [Set up the AMI tools](#), the certificates are located at `$EC2_AMITOOL_HOME/etc/ec2/amitools/`.

Required: Only for the `us-gov-west-1` and `cn-north-1` Regions.

--kernel *kernel_id*

The ID of the kernel to select.

⚠ Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see [User provided kernels](#).

Required: No

--ramdisk *ramdisk_id*

The ID of the RAM disk to select.

⚠ Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see [User provided kernels](#).

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example copies the AMI specified in the `my-ami.manifest.xml` manifest from the US to the EU.

```
[ec2-user ~]$ ec2-migrate-manifest --manifest my-ami.manifest.xml  
--cert cert-HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CL0.pem --privatekey pk-  
HKZYKTAIG2ECMXYIBH3HXV4ZBZQ55CL0.pem --region eu-west-1  
  
Backing up manifest...  
Successfully migrated my-ami.manifest.xml It is now suitable for use in eu-west-1.
```

ec2-unbundle

Description

Re-creates the bundle from an instance store-backed Linux AMI.

Syntax

```
ec2-unbundle -k path -m path [-s source_directory] [-d  
destination_directory]
```

Options

-k, --privatekey *path*

The path to your PEM-encoded RSA key file.

Required: Yes

-m, --manifest *path*

The path to the manifest file.

Required: Yes

-s, --source *source_directory*

The directory containing the bundle.

Default: The current directory.

Required: No

-d, --destination *destination_directory*

The directory in which to unbundle the AMI. The destination directory must exist.

Default: The current directory.

Required: No

Example

This Linux and UNIX example unbundles the AMI specified in the `image.manifest.xml` file.

```
[ec2-user ~]$ mkdir unbundled
$ ec2-unbundle -m mybundle/image.manifest.xml -k pk-
HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -s mybundle -d unbundled
$ ls -l unbundled
total 1025008
-rw-r--r-- 1 root root 1048578048 Aug 25 23:46 image.img
```

Output

Status messages indicating the various stages of the unbundling process are displayed.

ec2-upload-bundle

Description

Uploads the bundle for an instance store-backed Linux AMI to Amazon S3 and sets the appropriate access control lists (ACLs) on the uploaded objects. For more information, see [Create an instance store-backed Linux AMI](#).

Note

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see [Controlling ownership of uploaded objects using S3 Object Ownership](#).

Syntax

```
ec2-upload-bundle -b bucket -a access_key_id -s secret_access_key [-t token] -m path [--url url] [--region region] [--sigv version] [--acl acl] [-d directory] [--part part] [--retry] [--skipmanifest]
```

Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket in which to store the bundle, followed by an optional '/'-delimited path prefix. If the bucket doesn't exist, it's created if the bucket name is available. Additionally, if the bucket doesn't exist and the AMI tools version is 1.5.18 or later, this command sets the ACLs for the bucket.

Required: Yes

-a, --access-key *access_key_id*

Your AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

Your AWS secret access key.

Required: Yes

-t, --delegation-token *token*

The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#).

Required: Only when you are using temporary security credentials.

Default: The value of the AWS_DELEGATION_TOKEN environment variable (if set).

-m, --manifest *path*

The path to the manifest file. The manifest file is created during the bundling process and can be found in the directory containing the bundle.

Required: Yes

--url *url*

Deprecated. Use the --region option instead unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.

The Amazon S3 endpoint service URL.

Default: <https://s3.amazonaws.com/>

Required: No

--region *region*

The Region to use in the request signature for the destination S3 bucket.

- If the bucket doesn't exist and you don't specify a Region, the tool creates the bucket without a location constraint (in us-east-1).
- If the bucket doesn't exist and you specify a Region, the tool creates the bucket in the specified Region.
- If the bucket exists and you don't specify a Region, the tool uses the bucket's location.
- If the bucket exists and you specify us-east-1 as the Region, the tool uses the bucket's actual location without any error message, any existing matching files are over-written.
- If the bucket exists and you specify a Region (other than us-east-1) that doesn't match the bucket's actual location, the tool exits with an error.

If your bucket is constrained to the EU location (and not eu-west-1), use the --location flag instead. The --location flag is the only way to target that specific location restraint.

Default: us-east-1

Required: Required if using signature version 4

--sigv *version*

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

--acl *acl*

The access control list policy of the bundled image.

Valid values: public-read | aws-exec-read

Default: aws-exec-read

Required: No

-d, --directory *directory*

The directory containing the bundled AMI parts.

Default: The directory containing the manifest file (see the **-m** option).

Required: No

--part *part*

Starts uploading the specified part and all subsequent parts. For example, **--part 04**.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

--skipmanifest

Does not upload the manifest.

Required: No

--location *location*

Deprecated. Use the --region option instead, unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.

The location constraint of the destination Amazon S3 bucket. If the bucket exists and you specify a location that doesn't match the bucket's actual location, the tool exits with an error. If the bucket exists and you don't specify a location, the tool uses the bucket's location. If the bucket doesn't exist and you specify a location, the tool creates the bucket in the specified location. If the bucket doesn't exist and you don't specify a location, the tool creates the bucket without a location constraint (in us-east-1).

Default: If --region is specified, the location is set to that specified Region. If --region is not specified, the location defaults to us-east-1.

Required: No

Output

Amazon EC2 displays status messages that indicate the stages and status of the upload process.

Example

This example uploads the bundle specified by the image.manifest.xml manifest.

```
[ec2-user ~]$ ec2-upload-bundle -b DOC-EXAMPLE-BUCKET1/bundles/bundle_name -m

Common options for AMI tools

Most of the AMI tools accept the following optional parameters.

--help, -h

Displays the help message.

--version

Displays the version and copyright notice.

--manual

Displays the manual entry.

--batch

Runs in batch mode, suppressing interactive prompts.

--debug

Displays information that can be useful when troubleshooting problems.

Modify an AMI

You can modify a limited set of Amazon Machine Image (AMI) attributes, such as the AMI's description and sharing properties. However, AMI content (volume binary data) can't be modified. To modify the AMI content, you must [create a new AMI](#).

Important

You can't modify the content (volume binary data) of an EBS-backed AMI because the snapshots that back them are immutable. You also can't modify the content (volume binary data) of an instance store-backed (S3-backed) AMI because the content is signed, and instance launches will fail if the signatures do not match.

For the AMI attributes that can be modified, see [ModifyImageAttribute in the Amazon EC2 API Reference](#).

The following topics provide instructions for using the Amazon EC2 console and AWS CLI to modify the attributes of an AMI:

- [Make an AMI public](#)
- [Share an AMI with specific organizations or organizational units](#)
- [Share an AMI with specific AWS accounts](#)
- [Use paid support](#)
- [Configure the AMI](#)

Copy an AMI

You can copy an Amazon Machine Image (AMI) within or across AWS Regions. You can copy both Amazon EBS-backed AMIs and instance store-backed AMIs. You can copy EBS-backed AMIs with encrypted snapshots, and also change encryption status during the copy process. You can copy AMIs that are shared with you.

Copying a source AMI results in an identical but distinct new AMI that we also refer to as the *target* AMI. The target AMI has its own unique AMI ID. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

Considerations

- **Permission to copy AMIs** – You can use IAM policies to grant or deny users permission to copy AMIs. Resource-level permissions specified for the CopyImage action apply only to the new AMI. You cannot specify resource-level permissions for the source AMI.
- **Launch permissions and Amazon S3 bucket permissions** – AWS does not copy launch permissions or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions and Amazon S3 bucket permissions to the new AMI.
- **Tags** – You can only copy user-defined AMI tags that you attached to the source AMI. System tags (prefixed with aws :) and user-defined tags that are attached by other AWS accounts will not be copied. When copying an AMI, you can attach new tags to the target AMI and its backing snapshots.

Costs

There are no charges for copying an AMI. However, standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

IAM permissions

To copy an EBS-backed or instance store-backed AMI, you need the following IAM permissions:

- `ec2:CopyImage` – To copy the AMI. For EBS-backed AMIs, it also grants permission to copy the AMI's backing snapshots.
- `ec2:CreateTags` – To tag the target AMI. For EBS-backed AMIs, it also grants permission to tag the target AMI's backing snapshots.

If you're copying an instance stored-backed AMI, you need the following *additional* IAM permissions:

- `s3:CreateBucket` – To create the S3 bucket in the target Region for the new AMI

- `s3:GetBucketAcl` – To read the ACL permissions for the source bucket
- `s3>ListAllMyBuckets` – To find an existing S3 bucket for AMIs in the target Region
- `s3:GetObject` – To read the objects in the source bucket
- `s3:PutObject` – To write the objects in the target bucket
- `s3:PutObjectAcl` – To write the permissions for the new objects in the target bucket

Example IAM policy for copying an EBS-backed AMI and tagging the target AMI and snapshots

The following example policy grants you permission to copy any EBS-backed AMI and tag the target AMI and its backing snapshots.

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Sid": "PermissionToCopyAllImages",  
        "Effect": "Allow",  
        "Action": [  
            "ec2:CopyImage",  
            "ec2:CreateTags"  
        ],  
        "Resource": "arn:aws:ec2:*::image/*"  
    }]  
}
```

Example IAM policy for copying an EBS-backed AMI but denying tagging the new snapshots

The `ec2:CopySnapshot` permission is automatically granted when you get the `ec2:CopyImage` permission. This includes the permission to tag the new backing snapshots of the target AMI. Permission to tag the new backing snapshots can be explicitly denied.

The following example policy grants you permission to copy any EBS-backed AMI, but denies you from tagging the new backing snapshots of the target AMI.

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Effect": "Allow",  
        "Action": [  
            "ec2:CopyImage",  
            "ec2:CopySnapshot"  
        ],  
        "Resource": "arn:aws:ec2:*::image/*"  
    }]  
}
```

```
        "ec2:CreateTags"
    ],
    "Resource": "arn:aws:ec2:::image/*"
},
{
    "Effect": "Deny",
    "Action": "ec2:CreateTags",
    "Resource": "arn:aws:ec2:::snapshot/*"
}
]
}
```

Example IAM policy for copying an instance store-backed AMI and tagging the target AMI

The following example policy grants you permission to copy any instance store-backed AMI in the specified source bucket to the specified Region, and tag the target AMI.

```

                "ec2:CopyImage",
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:::image/*"
        },
        {
            "Effect": "Allow",
            "Action": "s3>ListAllMyBuckets",
            "Resource": [
                "arn:aws:s3:::ami-source-bucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": [
                "arn:aws:s3:::ami-source-bucket/*"
            ]

                "arn:aws:s3:::ami-target-bucket/*"
            ]
        }
    ]
}
```

```
        "Effect": "Allow",

            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::amis-for-account-in-region-hash"
        ]
    }
]
```

To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>, in the navigation pane choose **AMIs**, and locate the bucket name in the **Source** column.

Note

The `s3:CreateBucket` permission is only needed the first time that you copy an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

Copy an AMI

You can copy an AMI using the AWS Management Console, the AWS Command Line Interface or SDKs, or the Amazon EC2 API, all of which support the `CopyImage` action.

Prerequisite

Create or obtain an AMI to copy. Note that you can use the Amazon EC2 console to search a wide variety of AMIs provided by AWS. For more information, see [Create an Amazon EBS-backed Linux AMI](#) and [Finding an AMI](#).

Console

To copy an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. From the console navigation bar, select the Region that contains the AMI.
3. In the navigation pane, choose **AMIs** to display the list of AMIs available to you in the Region.
4. If you don't see the AMI you want to copy, choose a different filter. You can filter by AMIs **Owned by me**, **Private images**, **Public images**, and **Disabled images**.
5. Select the AMI to copy, and then choose **Actions**, **Copy AMI**.
6. On the **Copy AMI** page, specify the following information:
 - a. **AMI copy name:** A name for the new AMI. You can include the operating system information in the name because Amazon EC2 does not provide this information when displaying details about the AMI.
 - b. **AMI copy description:** By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
 - c. **Destination Region:** The Region in which to copy the AMI. For more information, see [Cross-Region copying](#).
 - d. **Copy tags:** Select this check box to include your user-defined AMI tags when copying the AMI. System tags (prefixed with aws :) and user-defined tags that are attached by other AWS accounts will not be copied.
 - e. (EBS-backed AMIs only) **Encrypt EBS snapshots of AMI copy:** Select this check box to encrypt the target snapshots, or to re-encrypt them using a different key. If encryption by default is enabled, the **Encrypt EBS snapshots of AMI copy** check box is selected and cannot be cleared. For more information, see [Encryption and copying](#).
 - f. (EBS-backed AMIs only) **KMS key:** The KMS key to used to encrypt the target snapshots.
 - g. **Tags:** You can tag the new AMI and the new snapshots with the same tags, or you can tag them with different tags.
 - To tag the new AMI and the new snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the new AMI and every snapshot that is created.
 - To tag the new AMI and the new snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the new AMI and the snapshots that are created. Note, however, that all the new snapshots that are created get the same tags; you can't tag each new snapshot with a different tag.

To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

- h. When you're ready to copy the AMI, choose **Copy AMI**.

The initial status of the new AMI is Pending. The AMI copy operation is complete when the status is Available.

AWS CLI

To copy an AMI using the AWS CLI

You can copy an AMI using the [copy-image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using either the `--region` parameter or an environment variable. For more information, see [Configuring the AWS Command Line Interface](#).

(EBS-backed AMIs only) When you encrypt a target snapshot during copying, you must specify these additional parameters: `--encrypted` and `--kms-key-id`.

For example commands, see the [Examples](#) under [copy-image](#) in the *AWS CLI Command Reference*.

PowerShell

To copy an AMI using the Tools for Windows PowerShell

You can copy an AMI using the [Copy-EC2Image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `-SourceRegion` parameter. You can specify the destination Region using either the `-Region` parameter or the `Set-AWSDefaultRegion` command. For more information, see [Specifying AWS Regions](#).

(EBS-backed AMIs only) When you encrypt a target snapshot during copying, you must specify these additional parameters: `-Encrypted` and `-KmsKeyId`.

Stop a pending AMI copy operation

You can stop a pending AMI copy using the AWS Management Console or the command line.

Console

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying, and then choose **Actions, Deregister AMI**.
5. When asked for confirmation, choose **Deregister AMI**.

Command line

To stop an AMI copy operation using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [deregister-image](#) (AWS CLI)
- [Unregister-EC2Image](#) (AWS Tools for Windows PowerShell)

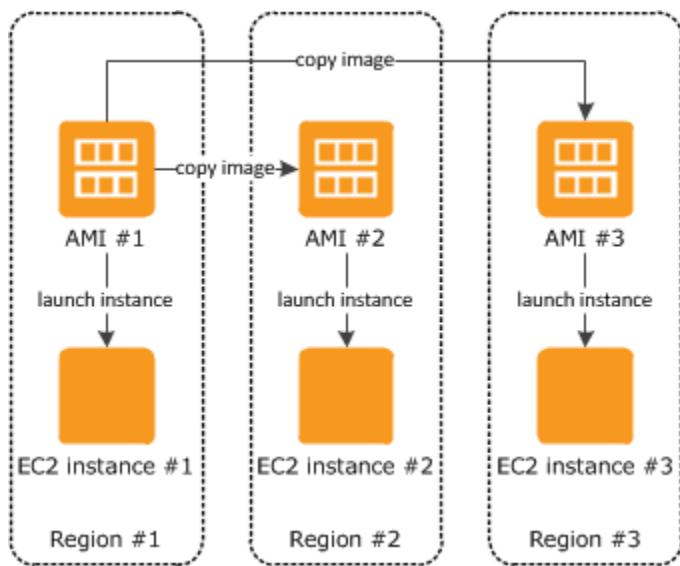

Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- Consistent global deployment: Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- Scalability: You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- Performance: You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- High availability: You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relationship between a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance

from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.

When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: `amis-for-account-in-region-hash`. For example: `amis-for-123456789012-in-us-east-2-yhjmxvp6`.

Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region might still use the resources from the source Region, which can impact performance and cost.

Limitations

- Destination Regions are limited to 100 concurrent AMI copies.
- You can't copy a paravirtual (PV) AMI to a Region that does not support PV AMIs. For more information, see [Linux AMI virtualization types](#).

Cross-account copying

You can share an AMI with another AWS account. Sharing an AMI does not affect the ownership of the AMI. The owning account is charged for the storage in the Region. For more information, see [Share an AMI with specific AWS accounts](#).

If you copy an AMI that has been shared with your account, you are the owner of the target AMI in your account. The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees, and you are charged for the storage of the target AMI in the destination Region.

Resource permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI. The storage is either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you as well. For more information about granting resource permissions, for EBS snapshots, see [Share an Amazon EBS snapshot in the Amazon EBS User Guide](#), and for S3 buckets, see [Identity and access management in Amazon S3 in the Amazon Simple Storage Service User Guide](#).

 **Note**

To copy an AMI with its tags, you must have launch permissions for the source AMI.

Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

Scenario	Description	Supported
1	Unencrypted-to-unencrypted	Yes
2	Encrypted-to-encrypted	Yes
3	Unencrypted-to-encrypted	Yes

Scenario	Description	Supported
4	Encrypted-to-unencrypted	No

Note

Encrypting during the `CopyImage` action applies only to Amazon EBS-backed AMIs.

Because an instance store-backed AMI does not rely on snapshots, you cannot use copying to change its encryption status.

By default (i.e., without specifying encryption parameters), the backing snapshot of an AMI is copied with its original encryption status. Copying an AMI backed by an unencrypted snapshot results in an identical target snapshot that is also unencrypted. If the source AMI is backed by an encrypted snapshot, copying it results in an identical target snapshot that is encrypted by the same AWS KMS key. Copying an AMI backed by multiple snapshots preserves, by default, the source encryption status in each target snapshot.

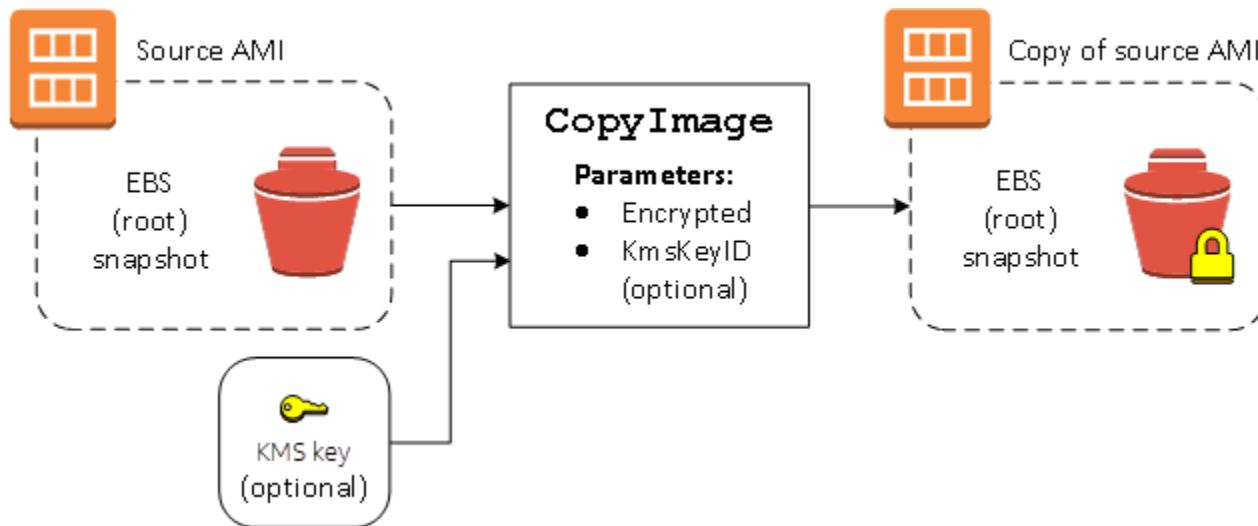

If you specify encryption parameters while copying an AMI, you can encrypt or re-encrypt its backing snapshots. The following example shows a non-default case that supplies encryption parameters to the `CopyImage` action in order to change the target AMI's encryption state.

Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling encryption by default has the same effect as setting the `Encrypted` parameter to `true` for all snapshots in the AMI.

Setting the **Encrypted** parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see [Use encryption with EBS-backed AMIs](#).

Store and restore an AMI using S3

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3 buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are `CreateStoreImageTask`, `DescribeStoreImageTasks`, and `CreateRestoreImageTask`.

`CopyImage` is the recommended API to use for copying AMIs *within* an AWS partition. However, `CopyImage` can't copy an AMI to *another* partition.

For information about the AWS partitions, see *partition* on the [Amazon Resource Names \(ARNs\)](#) page in the *IAM User Guide*.

Warning

Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

Copy an AMI from one AWS partition to another AWS partition

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the us-east-2 Region to the us-gov-east-1 Region.

To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using `CreateStoreImageTask`. In this example, the S3 bucket is located in us-east-2. For an example command, see [Store an AMI in an S3 bucket](#).

- Monitor the progress of the store task by using `DescribeStoreImageTasks`. The object becomes visible in the S3 bucket when the task is completed. For an example command, see [Describe the progress of an AMI store task](#).
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in `us-gov-east-1`.

 **Note**

Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.

- To copy one AMI across partitions, the copy process could be as straightforward as the following: [Download the object](#) from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then [upload the object](#) from the intermediate host to the target bucket. For each stage of the process, use the AWS credentials for the partition.
 - For more sustained usage, consider developing an application that manages the copies, potentially using S3 [multipart downloads and uploads](#).
- Restore the AMI from the S3 bucket in the target partition by using `CreateRestoreImageTask`. In this example, the S3 bucket is located in `us-gov-east-1`. For an example command, see [Restore an AMI from an S3 bucket](#).
 - Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

Make archival copies of AMIs

You can make archival copies of AMIs by storing them in an S3 bucket. For an example command, see [Store an AMI in an S3 bucket](#).

The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs that contain data that can easily be compressed will result in smaller objects

in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see [Amazon S3 Storage Classes](#) and [Amazon S3 pricing](#)

How the AMI store and restore APIs work

To store and restore an AMI using S3, you use the following APIs:

- `CreateStoreImageTask` – Stores the AMI in an S3 bucket
- `DescribeStoreImageTasks` – Provides the progress of the AMI store task
- `CreateRestoreImageTask` – Restores the AMI from an S3 bucket

How the APIs work

- [CreateStoreImageTask](#)
- [DescribeStoreImageTasks](#)
- [CreateRestoreImageTask](#)

CreateStoreImageTask

The [CreateStoreImageTask](#) API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an [S3 multipart upload](#) to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a .bin extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The time it takes to complete the task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can track the progress of the task by calling the [DescribeStoreImageTasks](#) API.

The sum of the sizes of all the AMIs in progress is limited to 600 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For

example, if an AMI with 100 GB of snapshot data and another AMI with 200 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 300 GB, which is less than the limit. But if a single AMI with 800 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The [DescribeStoreImageTasks](#) API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is `InProgress`, `Completed`, or `Failed`. For tasks `InProgress`, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The [CreateRestoreImageTask](#) API starts a task that restores an AMI from an S3 object that was previously created by using a [CreateStoreImageTask](#) request.

The restore task can be performed in the same or a different Region in which the store task was performed.

The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI ([describe-images](#)) or its EBS snapshots ([describe-snapshots](#)). If the task fails, the AMI and snapshots are moved to a failed state.

The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

Limitations

- To store an AMI, your AWS account must either own the AMI and its snapshots, or the AMI and its snapshots must be [shared directly with your account](#). You can't store an AMI if it is only [publicly shared](#).
- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to 5,000 GB.
- Quota on [store image](#) requests: 600 GB of storage work (snapshot data) in progress.
- Quota on [restore image](#) requests: 300 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can't create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can't be restored with its original AMI ID. You can mitigate this by using [AMI aliasing](#).
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can't store and restore an AMI using the Amazon EC2 console.

Costs

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see [Amazon S3 pricing](#) and [Amazon EBS pricing](#).

Securing your AMIs

To use the store and restore APIs, the S3 bucket and the AMI must be in the same Region. It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can't be done, use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling [Server Side Encryption](#) for the S3 buckets in which you store the AMIs, although it's not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- [Blocking public access to your Amazon S3 storage](#)
- [Setting default server-side encryption behavior for Amazon S3 buckets](#)
- [What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?](#)
- [Enabling Amazon S3 server access logging](#)

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

Permissions for storing and restoring AMIs using S3

If your IAM principals will store or restore AMIs using Amazon S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.

You can also create IAM policies that grant principals access to specific resources only. For more example policies, see [Access management for AWS resources](#) in the *IAM User Guide*.

 **Note**

If the snapshots that make up the AMI are encrypted, or if your account is enabled for encryption by default, your IAM principal must have permission to use the KMS key.

Store an AMI in an S3 bucket

To store an AMI (AWS CLI)

Use the [create-store-image-task](#) command. Specify the ID of the AMI and the name of the S3 bucket in which to store the AMI.

```
aws ec2 create-store-image-task \
--image-id ami-1234567890abcdef0 \
--bucket myamibucket
```

Expected output

```
{  
    "ObjectKey": "ami-1234567890abcdef0.bin"  
}
```

Describe the progress of an AMI store task

To describe the progress of an AMI store task (AWS CLI)

Use the [describe-store-image-tasks](#) command.

```
aws ec2 describe-store-image-tasks
```

Expected output

```
{  
    "AmiId": "ami-1234567890abcdef0",  
    "Bucket": "myamibucket",  
    "ProgressPercentage": 17,  
    "S3ObjectKey": "ami-1234567890abcdef0.bin",  
    "StoreTaskState": "InProgress",  
    "StoreTaskFailureReason": null,  
    "TaskStartTime": "2021-01-01T01:01:01.001Z"  
}
```

Restore an AMI from an S3 bucket

To restore an AMI (AWS CLI)

Use the [create-restore-image-task](#) command. Using the values for S3ObjectKey and Bucket from the `describe-store-image-tasks` output, specify the object key of the AMI and the name of the S3 bucket to which the AMI was copied. Also specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account.

Note

The restored AMI gets a new AMI ID.

```
aws ec2 create-restore-image-task \  
    --object-key ami-1234567890abcdef0.bin \  
    --bucket myamibucket \  
    --region us-west-2
```

```
--name "New AMI Name"
```

Expected output

```
{  
  "ImageId": "ami-0eab20fe36f83e1a8"  
}
```

Use file paths in S3

You can use file paths when storing and restoring AMIs, in the following way:

- When storing an AMI in S3, the file path can be added to the bucket name. Internally, the system separates the path from the bucket name, and then adds the path to the object key that is generated to store the AMI. The full object path is shown in the response from the API call.
- When restoring the AMI, because an object key parameter is available, the path can be added to the beginning of the object key value.

You can use file paths when using the AWS CLI and SDKs.

Example: Use a file path when storing and restoring an AMI (AWS CLI)

The following example first stores an AMI in S3, with the file path appended to the bucket name. The example then restores the AMI from S3, with the file path prepended to the object key parameter.

1. Store the AMI. For `--bucket`, specify the file path after the bucket name, as follows:

```
aws ec2 create-store-image-task \  
  --image-id ami-1234567890abcdef0 \  
  --bucket myamibucket/path1/path2
```

Expected output

```
{  
  "ObjectKey": "path1/path2/ami-1234567890abcdef0.bin"  
}
```

2. Restore the AMI. For `--object-key`, specify the value from the output in the previous step, which includes the file path.

```
aws ec2 create-restore-image-task \
--object-key path1/path2/ami-1234567890abcdef0.bin \
--bucket myamibucket \
--name "New AMI Name"
```

Deprecate an AMI

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must [deregister](#) it.

After an AMI is deprecated:

- For AMI users, the deprecated AMI does not appear in [DescribeImages](#) API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in [DescribeImages](#) API calls.
- For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.
- For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.
- EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

You can also create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see [Automate AMI lifecycles](#).

Note

By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only [sharing it with specific AWS accounts](#).

- [Costs](#)
- [Limitations](#)
- [Deprecate an AMI](#)
- [Describe deprecated AMIs](#)
- [Cancel the deprecation of an AMI](#)

Costs

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by [deregistering](#) it.

Limitations

- To deprecate an AMI, you must be the owner of the AMI.

Deprecate an AMI

You can deprecate an AMI on a specific date and time. You must be the AMI owner to perform this procedure.

Console

To deprecate an AMI on a specific date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.

3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to set the same deprecation date of several AMIs at once.
5. Select the **Enable** check box, and then enter the deprecation date and time.

The upper limit for the deprecation date is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

6. Choose **Save**.

AWS CLI

To deprecate an AMI on a specific date

Use the [enable-image-deprecation](#) command. Specify the ID of the AMI and the date and time on which to deprecate the AMI. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

The upper limit for deprecate-at is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

```
aws ec2 enable-image-deprecation \
--image-id ami-1234567890abcdef0 \
--deprecate-at "2021-10-15T13:17:12.000Z"
```

Expected output

```
{  
    "Return": "true"  
}
```

Last launched time

LastLaunchedTime is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deprecation or [deregistering](#).

Note

- When an AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- `lastLaunchedTime` data is available starting April 2017.

Console

To view the last launched time of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then check the **Last launched time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the date and time when the AMI was last used to launch an instance.

AWS CLI

To view the last launched time of an AMI

Run the [describe-image-attribute](#) command and specify `--attribute lastLaunchedTime`. You must be the AMI owner to run this command.

```
aws ec2 describe-image-attribute \
  --image-id ami-1234567890example \
  --attribute lastLaunchedTime
```

Example output

```
{  
    "LastLaunchedTime": {  
        "Value": "2022-02-10T02:03:18Z"  
    },  
    "ImageId": "ami-1234567890example",  
}
```

Describe deprecated AMIs

You can view the deprecation date and time of an AMI, and filter all the AMIs by deprecation date. You can also use the AWS CLI to describe all the AMIs that have been deprecated, where the deprecation date is in the past.

Console

To view the deprecation date of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**, and then select the AMI.
3. Check the **Deprecation time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the deprecation date and time of the AMI. If the field is empty, the AMI is not deprecated.

To filter AMIs by deprecation date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me or Private images** (private images include AMIs that are shared with you as well as owned by you).
4. In the Search bar, enter **Deprecation time** (as you enter the letters, the **Deprecation time** filter appears), and then choose an operator and a date and time.

AWS CLI

When you describe all AMIs using the [describe-images](#) command, the results are different depending on whether you are an AMI user or the AMI owner.

- If you are an AMI user:

By default, when you describe all AMIs using the [describe-images](#) command, deprecated AMIs that are not owned by you, but which are shared with you, do not appear in the results. This is because the default is `--no-include-deprecated`. To include deprecated AMIs in the results, you must specify the `--include-deprecated` parameter.

- If you are the AMI owner:

When you describe all AMIs using the [describe-images](#) command, all the AMIs that you own, including deprecated AMIs, appear in the results. You do not need to specify the --include-deprecated parameter. Furthermore, you cannot exclude deprecated AMIs that you own from the results by using --no-include-deprecated.

If an AMI is deprecated, the `DeprecationTime` field appears in the results.

 **Note**

A deprecated AMI is an AMI whose deprecation date is in the past. If you have set the deprecation date to a date in the future, the AMI is not yet deprecated.

To include all deprecated AMIs when describing all AMIs

Use the [describe-images](#) command and specify the --include-deprecated parameter to include all deprecated AMIs that are not owned by you in the results.

```
aws ec2 describe-images \
--region us-east-1 \
--owners 123456example
--include-deprecated
```

To describe the deprecation date of an AMI

Use the [describe-images](#) command and specify the ID of the AMI.

Note that if you specify --no-include-deprecated together with the AMI ID, the deprecated AMI will be returned in the results.

```
aws ec2 describe-images \
--region us-east-1 \
--image-ids ami-1234567890EXAMPLE
```

Expected output

The `DeprecationTime` field displays the date on which the AMI is set to be deprecated. If the AMI is not set to be deprecated, the `DeprecationTime` field does not appear in the output.

Cancel the deprecation of an AMI

You can cancel the deprecation of an AMI, which removes the date and time from the **Deprecation time** field (console) or the `DeprecationTime` field from the [describe-images](#) output (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To cancel the deprecation of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to cancel the deprecation of several AMIs at once.
5. Clear the **Enable** check box, and then choose **Save**.

AWS CLI

To cancel the deprecation of an AMI

Use the [disable-image-deprecation](#) command and specify the ID of the AMI.

```
aws ec2 disable-image-deprecation \
--image-id ami-1234567890abcdef0
```

Expected output

```
{  
    "Return": "true"  
}
```

Disable an AMI

You can disable an AMI to prevent it from being used for instance launches. You can't launch new instances from a disabled AMI. You can re-enable a disabled AMI so that it can be used again for instance launches.

Warning

Disabling an AMI removes all its launch permissions.

When an AMI is disabled:

- The AMI's state changes to **disabled**.
- A disabled AMI can't be shared. If an AMI was public or previously shared, it is made private. If an AMI was shared with an AWS account, organization, or Organizational Unit, they lose access to the disabled AMI.
- A disabled AMI does not appear in [DescribeImages](#) API calls by default.
- A disabled AMI does not appear under the **Owned by me** console filter. To find disabled AMIs, use the **Disabled images** console filter.
- A disabled AMI is not available to select for instance launches in the EC2 console. For example, a disabled AMI does not appear in the AMI catalog in the launch instance wizard or when creating a launch template.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference disabled AMIs. Subsequent instance launches from a disabled AMI will fail, so we recommend updating launch templates and Auto Scaling groups to reference available AMIs only.
- EC2 instances that were previously launched using an AMI that is subsequently disabled are not affected, and can be stopped, started, and rebooted.
- You can't delete snapshots associated with disabled AMIs. Attempting to delete an associated snapshot results in the `snapshot is currently in use` error.

When an AMI is re-enabled:

- The AMI's state changes to **available**, and it can be used to launch instances.
- The AMI can be shared.
- AWS accounts, organizations, and Organizational Units that lost access to the AMI when it was disabled do not regain access automatically, but the AMI can be shared with them again.

You can disable both private and public AMIs.

Costs

When you disable an AMI, the AMI is not deleted. If the AMI is an EBS-backed AMI, you continue to pay for the AMI's EBS snapshots. If you want to keep the AMI, you might be able to reduce your storage costs by archiving the snapshots. For more information, see [Archive Amazon EBS snapshots](#) in the *Amazon EBS User Guide*. If you don't want to keep the AMI and its snapshots, you must deregister the AMI and delete the snapshots. For more information, see [Clean up your Amazon EBS-backed AMI](#).

Prerequisites

To disable or re-enable an AMI, you must be the owner of the AMI.

Required IAM permissions

To disable and re-enable an AMI, you must have the following IAM permissions:

- `ec2:DisableImage`
- `ec2:EnableImage`

Disable an AMI

You can disable an AMI by using the EC2 console or the AWS Command Line Interface (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To disable an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Disable AMI**. You can select multiple AMIs to disable at once.
5. In the **Disable AMI** window, choose **Disable AMI**.

AWS CLI

To disable an AMI

Use the [disable-image](#) command and specify the ID of the AMI.

```
aws ec2 disable-image --image-id ami-1234567890abcdef0
```

Expected output

```
{  
    "Return": "true"  
}
```

Describe disabled AMIs

You can view disabled AMIs in the EC2 console and by using the AWS CLI.

You must be the AMI owner to view disabled AMIs. Because disabled AMIs are made private, you can't view disabled AMIs if you're not the owner.

Console

To view disabled AMIs

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Disabled images**.

The screenshot shows the 'Amazon Machine Images (AMIs)' page. On the left, there's a sidebar with a dropdown menu showing 'Disabled images' selected (indicated by a blue border and a checkmark). Other options include 'Owned by me', 'Private images', and 'Public images'. At the top right is a search bar with the placeholder 'Find AMI by attribute or tag'. Below the search bar are two columns: 'AMI name' and 'AMI ID', each with a downward arrow indicating they can be sorted.

AWS CLI

By default, when you use the [describe-images](#) command to describe all AMIs, disabled AMIs do not appear in the results. This is because the default is `--no-include-disabled`. To include disabled AMIs in the results, you must specify the `--include-disabled` parameter.

To include all disabled AMIs when describing all AMIs

Use the [describe-images](#) command and specify the `--include-disabled` parameter to retrieve disabled AMIs in addition to all other AMIs. Optionally, specify `--owners self` to retrieve only the AMIs that you own.

```
aws ec2 describe-images \
--region us-east-1 \
--owners self \
--include-disabled
```

If you specify the ID of a disabled AMI, but do not specify `--include-disabled`, the disabled AMI is returned in the results.

```
aws ec2 describe-images \
--region us-east-1 \
--image-ids ami-1234567890EXAMPLE
```

To retrieve only disabled AMIs

Specify `--filters Name=state,Values=disabled`. You must also specify `--include-disabled`, otherwise you'll get an error.

```
aws ec2 describe-images \
--include-disabled \
--filters Name=state,Values=disabled
```

Example output

The State field displays the state of an AMI. disabled indicates that the AMI is disabled.

Re-enable a disabled AMI

You can re-enable a disabled AMI. You must be the AMI owner to perform this procedure.

Console

To re-enable a disabled AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Disabled images**.
4. Select the AMI, and then choose **Actions, Enable AMI**. You can select multiple AMIs to re-enable several AMIs at once.
5. In the **Enable AMI** window, choose **Enable**.

AWS CLI

To re-enable a disabled AMI

Use the [enable-image](#) command and specify the ID of the AMI.

```
aws ec2 enable-image --image-id ami-1234567890abcdef0
```

Expected output

```
{  
    "Return": "true"  
}
```

Archive AMI snapshots

You can archive the snapshots that are associated with your disabled EBS-backed AMIs. This can help you to reduce the storage costs associated with your rarely-used AMIs that need to be

retained for long periods. For more information, see [Archive Amazon EBS snapshots](#) in the *Amazon EBS User Guide*.

To archive snapshots associated with an AMI

1. [Disable the AMI](#).
2. [Archive the snapshots](#).

You can't use an AMI while it is disabled and its associated snapshots are archived.

To restore a disabled AMI with archived snapshots for use

1. [Restore the archived snapshots](#) associated with the AMI.
2. [Enable the AMI](#).

Deregister your AMI

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances.

When you deregister an AMI, it doesn't affect any instances that you've already launched from the AMI or any snapshots created during the AMI creation process. You'll continue to incur usage costs for these instances and storage costs for the snapshot. Therefore, you should terminate any instances and delete any snapshots that you're finished with.

The procedure that you'll use to clean up your AMI depends on whether it's backed by Amazon EBS or instance store. For more information, see [Determine the root device type of your AMI](#).

Considerations

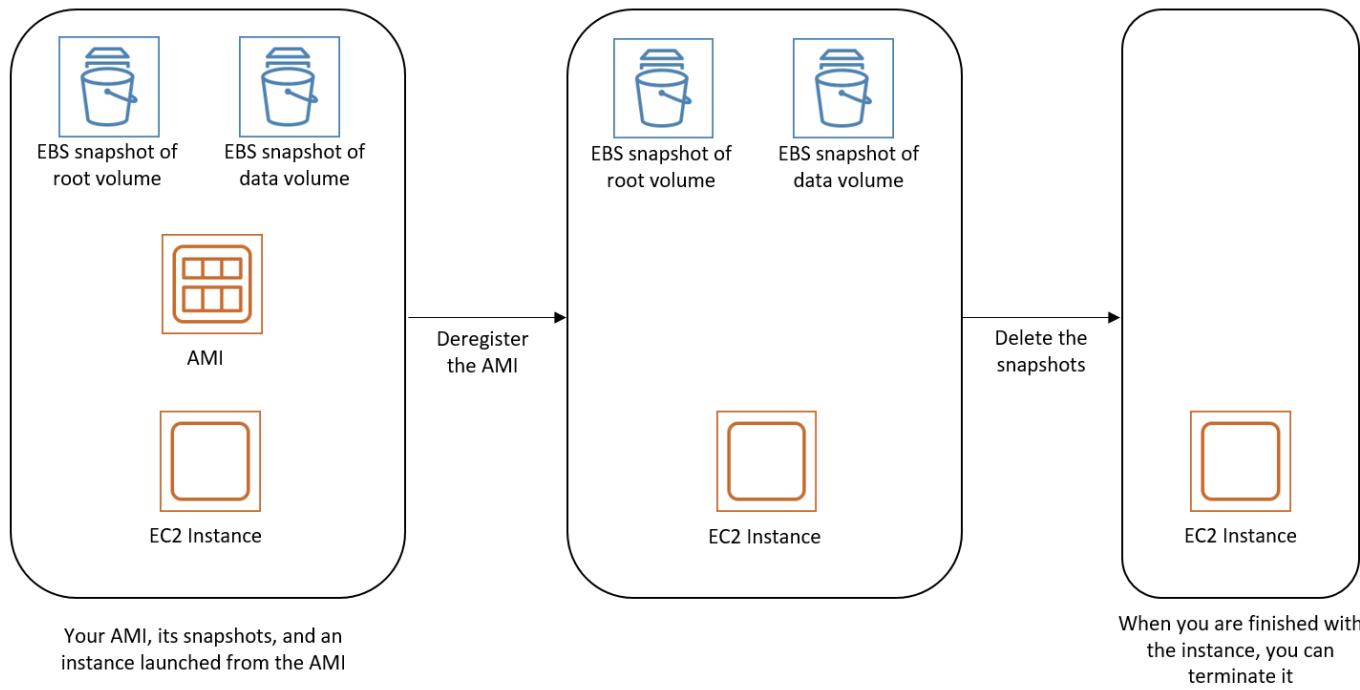

The following considerations apply to deregistering AMIs:

- You can't deregister an AMI that is not owned by your account.
- You can't deregister an AMI that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see [Deleting backups](#) in the *AWS Backup Developer Guide*.

Clean up your Amazon EBS-backed AMI

When you deregister an Amazon EBS-backed AMI, it doesn't affect the snapshot(s) that were created for the volume(s) of the instance during the AMI creation process. You'll continue to incur storage costs for the snapshots. Therefore, if you are finished with the snapshots, you should delete them.

The following diagram illustrates the process for cleaning up your Amazon EBS-backed AMI.

You can use one of the following methods to clean up your Amazon EBS-backed AMI.

Console

To clean up your Amazon EBS-backed AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. **Deregister the AMI**

- a. In the navigation pane, choose **AMIs**.
- b. From the filter bar, choose **Owned by me** to list your available AMIs or **Disabled images** to list your disabled AMIs.
- c. Select the AMI to deregister, and take note of its ID—this can help you find the snapshots to delete in the next step.
- d. Choose **Actions, Deregister AMI**. When prompted for confirmation, choose **Deregister AMI**.

 **Note**

It might take a few minutes before the console removes the AMI from the list. Choose **Refresh** to refresh the status.

3. Delete snapshots that are no longer needed

- a. In the navigation pane, choose **Snapshots**.
- b. Select a snapshot to delete (look for the AMI ID from the prior step in the **Description** column).
- c. Choose **Actions, Delete snapshot**. When prompted for confirmation, choose **Delete**.

4. (Optional) Terminate instances

If you are finished with an instance that you launched from the AMI, you can terminate it.

- a. In the navigation pane, choose **Instances**, and then select the instance to terminate.
- b. Choose **Instance state, Terminate instance**. When prompted for confirmation, choose **Terminate**.

AWS CLI

Follow these steps to clean up your Amazon EBS-backed AMI

1. Deregister the AMI

Deregister the AMI using the [deregister-image](#) command:

```
aws ec2 deregister-image --image-id ami-12345678
```

2. Delete snapshots that are no longer needed

Delete snapshots that are no longer needed by using the [delete-snapshot](#) command:

```
aws ec2 delete-snapshot --snapshot-id snap-1234567890abcdef0
```

3. Terminate instances (Optional)

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [terminate-instances](#) command:

```
aws ec2 terminate-instances --instance-ids i-12345678
```

PowerShell

Follow these steps to clean up your Amazon EBS-backed AMI

1. Deregister the AMI

Deregister the AMI using the [Unregister-EC2Image](#) cmdlet:

```
Unregister-EC2Image -ImageId ami-12345678
```

2. Delete snapshots that are no longer needed

Delete snapshots that are no longer needed by using the [Remove-EC2Snapshot](#) cmdlet:

```
Remove-EC2Snapshot -SnapshotId snap-12345678
```

3. Terminate instances (Optional)

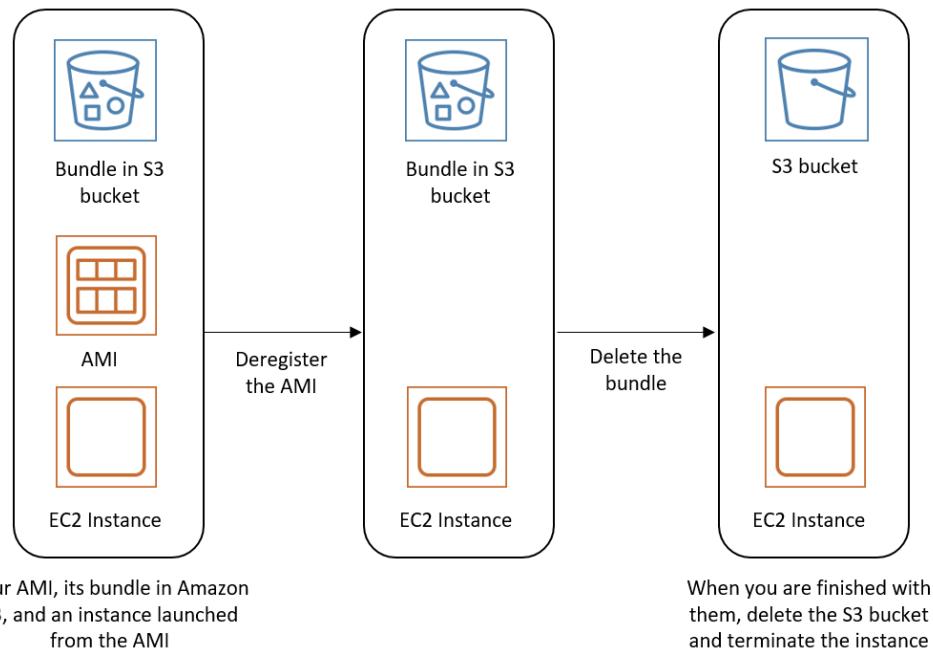

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [Remove-EC2Instance](#) cmdlet:

```
Remove-EC2Instance -InstanceId i-12345678
```

Clean up your instance store-backed AMI

When you deregister an instance store-backed AMI, it doesn't affect the files that you uploaded to Amazon S3 when you created the AMI. You'll continue to incur usage costs for these files in Amazon S3. Therefore, if you are finished with these files, you should delete them.

The following diagram illustrates the process for cleaning up your instance store-backed AMI.

To clean up your instance store-backed AMI

1. Deregister the AMI using the [deregister-image](#) command as follows.

```
aws ec2 deregister-image --image-id ami_id
```

2. Delete the bundle in Amazon S3 using the [ec2-delete-bundle](#) (AMI tools) command as follows.

```
ec2-delete-bundle -b myawsbucket/myami -a your_access_key_id -  
s your_secret_access_key -p image
```

3. (Optional) If you are finished with an instance that you launched from the AMI, you can terminate it using the [terminate-instances](#) command as follows.

```
aws ec2 terminate-instances --instance-ids instance_id
```

4. (Optional) If you are finished with the Amazon S3 bucket that you uploaded the bundle to, you can delete the bucket. To delete an Amazon S3 bucket, open the Amazon S3 console, select the bucket, choose **Actions**, and then choose **Delete**.

Last launched time

`LastLaunchedTime` is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deregistering or [deprecation](#).

Note

- When the AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- `lastLaunchedTime` data is available starting April 2017.

Console

To view the last launched time of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then check the **Last launched time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the date and time when the AMI was last used to launch an instance.

AWS CLI

To view the last launched time of an AMI

Run the [describe-image-attribute](#) command and specify `--attribute lastLaunchedTime`. You must be the AMI owner to run this command.

```
aws ec2 describe-image-attribute \
--image-id ami-1234567890example \
```

```
--attribute lastLaunchedTime
```

Example output

```
{  
    "LastLaunchedTime": {  
        "Value": "2022-02-10T02:03:18Z"  
    },  
    "ImageId": "ami-1234567890example",  
}
```

Automate the EBS-backed AMI lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. For more information, see [Amazon Data Lifecycle Manager](#).

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see [Shared AMIs](#).

Encryption with EBS-backed AMIs topics

- [Instance-launching scenarios](#)
- [Image-copying scenarios](#)

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the `RunInstances` action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information about block device mapping, see [Block device mapping](#). For examples of controlling block device mapping from the AWS CLI, see [Launch, List, and Terminate EC2 Instances](#).

By default, without explicit encryption parameters, a `RunInstances` action maintains the existing encryption state of an AMI's source snapshots while restoring EBS volumes from them. If encryption by default is enabled, all volumes created from the AMI (whether from encrypted or unencrypted snapshots) are encrypted. If encryption by default is not enabled, the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

Launch with no encryption parameters

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Instance launch behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)

- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the Encrypted parameter has no effect.)

Setting both the Encrypted and KmsKeyId parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

Instance with both Encrypted and KmsKeyId set

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.

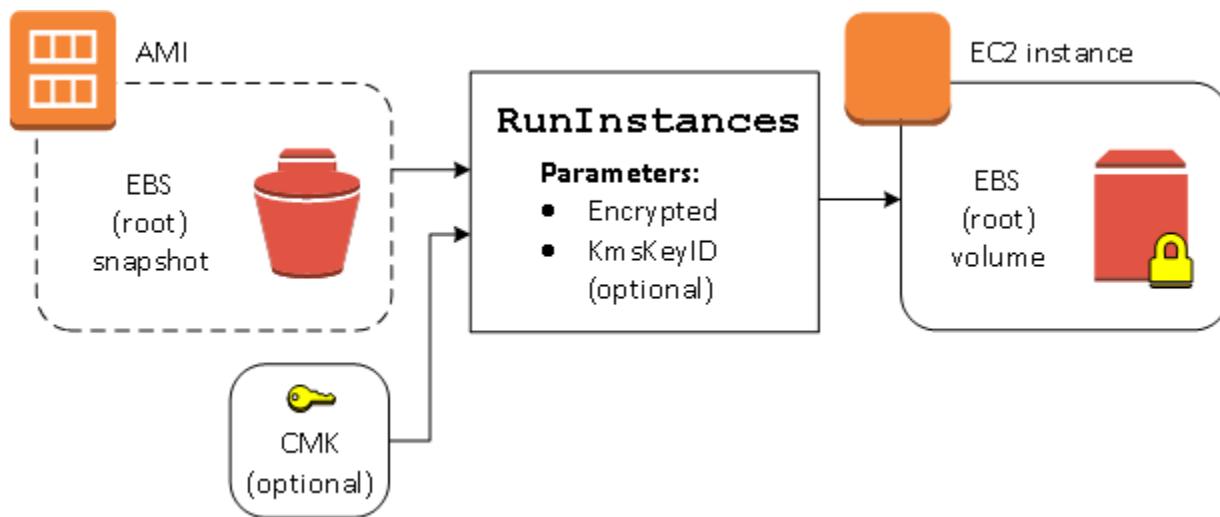

Submitting a KmsKeyId without also setting the Encrypted parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the RunInstances action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see [Launch your instance](#).

Encrypt a volume during launch

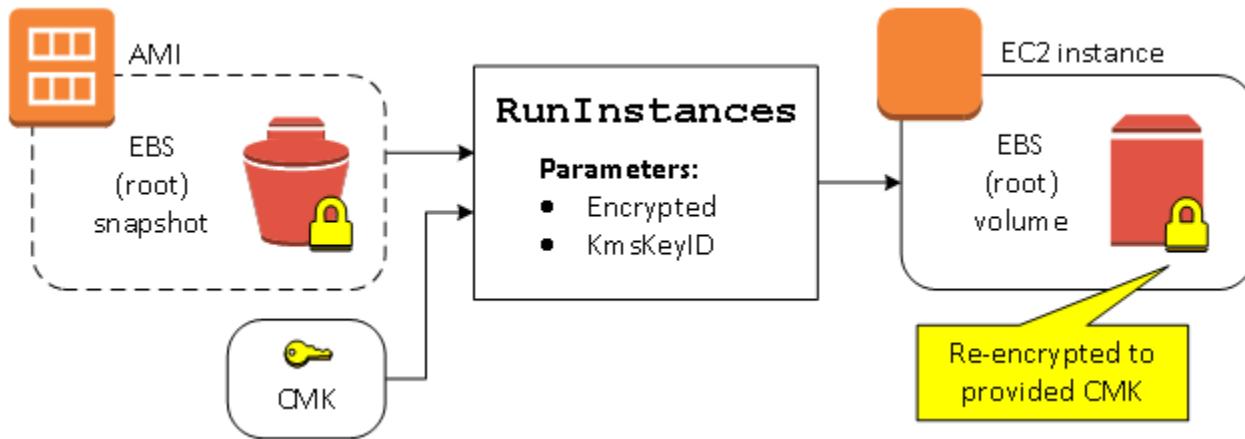

In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.

The `Encrypted` parameter alone results in the volume for this instance being encrypted. Providing a `KmsKeyId` parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the `KmsKeyId` parameter.

Re-encrypt a volume during launch

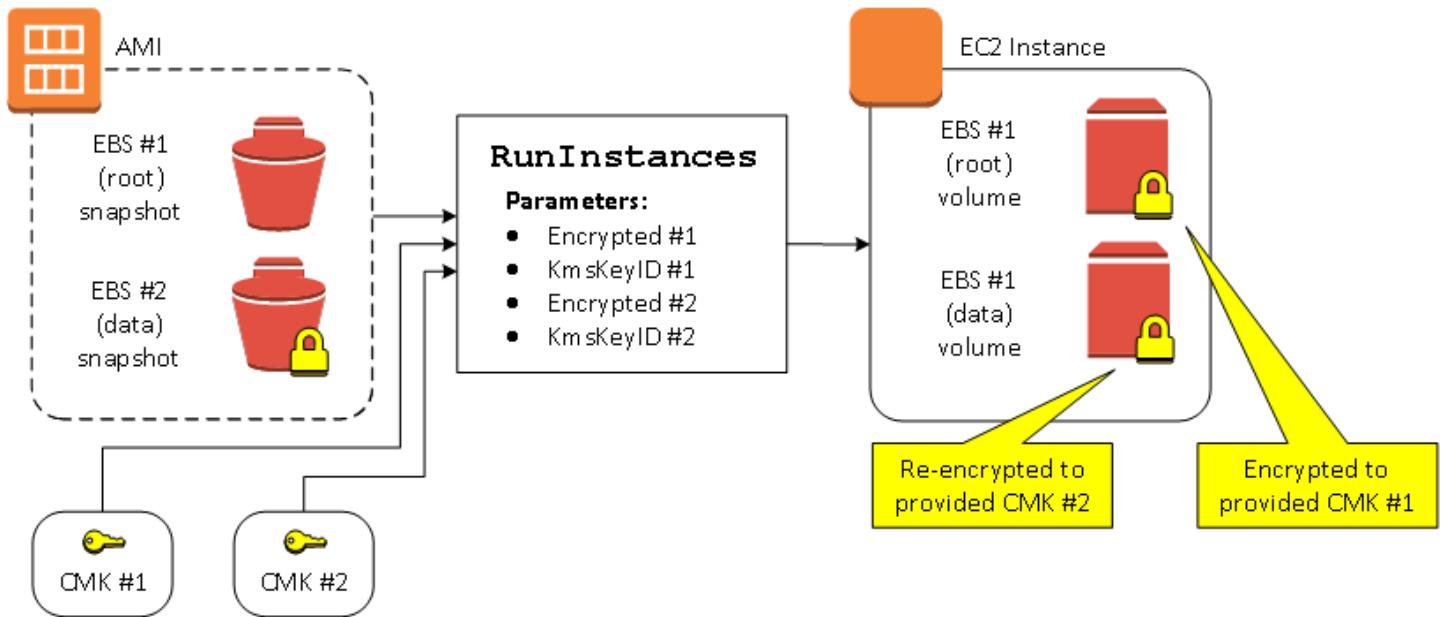

In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.

If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

Change encryption state of multiple volumes during launch

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.

In this scenario, the `RunInstances` action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.

Image-copying scenarios

Amazon EC2 AMIs are copied using the `CopyImage` action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a `CopyImage` action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

Copy with no encryption parameters

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
- An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
- An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

Copy-image behaviors with `Encrypted` set, but no `KmsKeyId` specified

- An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
- An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

Copy-image behaviors with both `Encrypted` and `KmsKeyId` set

- An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.
- An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a `KmsKeyId` without also setting the `Encrypted` parameter results in an error.

The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

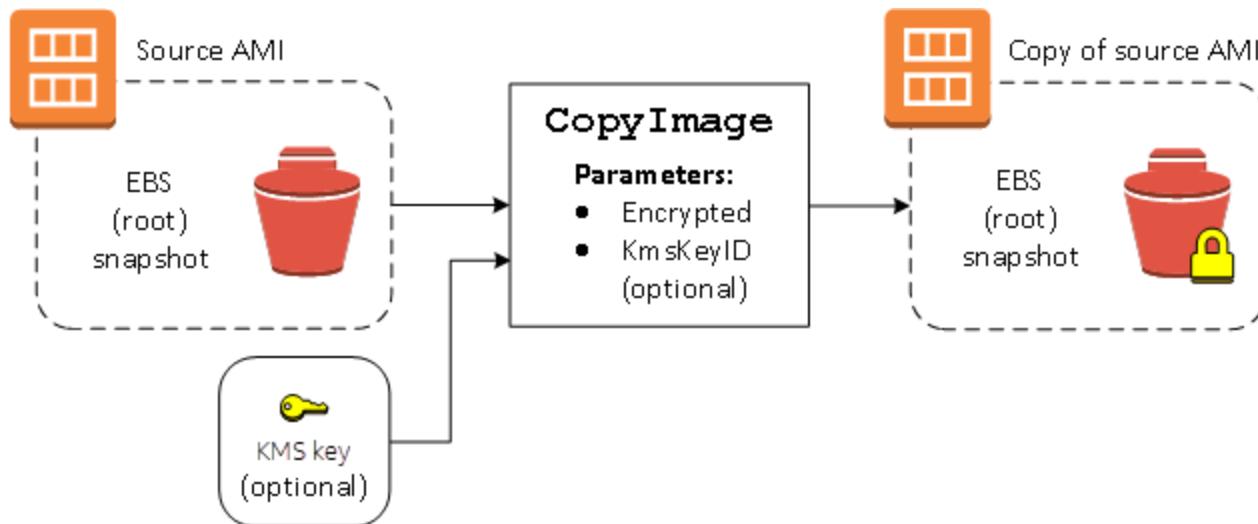

For detailed instructions using the console, see [Copy an AMI](#).

Encrypt an unencrypted image during copy

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The `CopyImage` action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling encryption by default has the same effect as setting the `Encrypted` parameter to true for all snapshots in the AMI.

Setting the `Encrypted` parameter encrypts the single snapshot for this instance. If you do not specify the `KmsKeyId` parameter, the default customer managed key is used to encrypt the snapshot copy.

Note

You can also copy an image with multiple snapshots and configure the encryption state of each individually.

Monitor AMI events using Amazon EventBridge

When the state of an Amazon Machine Image (AMI) changes, Amazon EC2 generates an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). You can use Amazon EventBridge to detect and react to these events. You do this by creating rules in EventBridge that trigger an action in response to an event. For example, you can create an EventBridge rule that detects when the AMI creation process has completed and then invokes an Amazon SNS topic to send an email notification to you.

Amazon EC2 generates an event when an AMI enters any of the following states:

- [available](#)
- [failed](#)
- [deregistered](#)
- [disabled](#)

The following table lists the AMI operations and the states that an AMI can enter. In the table, Yes indicates the states that the AMI can enter when the corresponding operation runs.

AMI operations	available	failed	deregistered	disabled
CopyImage	Yes	Yes		
CreateImage	Yes	Yes		
CreateResstoreImageTask	Yes	Yes		
DeregisterImage			Yes	
DisableImage				Yes
EnableImage	Yes			
RegisterImage	Yes	Yes		

Events are generated on a best effort basis.

AMI events

There are four EC2 AMI State Change events:

- [available](#)
- [failed](#)

- [deregistered](#)
- [disabled](#)

The events are sent to the default EventBridge event bus in JSON format.

The following fields in the event can be used to create rules that trigger an action:

"source": "aws.ec2"

Identifies that the event is from Amazon EC2.

"detail-type": "EC2 AMI State Change"

Identifies the event name.

"detail": { "ImageId": "ami-0123456789example", "State": "available", }

Provides the following information:

- The AMI ID – If you want to track a specific AMI.
- The state of the AMI (available, failed, deregistered, or disabled).

available

The following is an example of an event that Amazon EC2 generates when the AMI enters the available state following a successful CreateImage, CopyImage, RegisterImage, CreateRestoreImageTask, or EnableImage operation.

"State": "available" indicates that the operation was successful.

```
{  
    "version": "0",  
    "id": "example-9f07-51db-246b-d8b8441bcdf0",  
    "detail-type": "EC2 AMI State Change",  
    "source": "aws.ec2",  
    "account": "012345678901",  
    "time": "yyyy-mm-ddThh:mm:ssZ",

        "State": "available",
        "ErrorMessage": ""
    }
}
```

failed

The following is an example of an event that Amazon EC2 generates when the AMI enters the failed state following a failed CreateImage, CopyImage, RegisterImage, or CreateRestoreImageTask operation.

The following fields provide pertinent information:

- "State": "failed" – Indicates that the operation failed.
- "ErrorMessage": "" – Provides the reason for the failed operation.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdf0",

        "State": "failed",
        "ErrorMessage": "Description of failure"
    }
}
```

deregistered

The following is an example of an event that Amazon EC2 generates when the AMI enters the deregistered state following a successful DeregisterImage operation. If the operation fails, no event is generated. Any failure is known immediately because DeregisterImage is a synchronous operation.

"State": "deregistered" indicates that the DeregisterImage operation was successful.

```

disabled

The following is an example of an event that Amazon EC2 generates when the AMI enters the disabled state following a successful DisableImage operation. If the operation fails, no event is generated. Any failure is known immediately because DisableImage is a synchronous operation.

"State": "disabled" indicates that the DisableImage operation was successful.

Create Amazon EventBridge rules

You can create an Amazon EventBridge [rule](#) that specifies an action to take when EventBridge receives an [event](#) that matches the [event pattern](#) in the rule. When an event matches, EventBridge sends the event to the specified [target](#) and triggers the action defined in the rule.

Event patterns have the same structure as the events they match. An event pattern either matches an event or it doesn't.

When creating a rule for an AMI state change event, you can include the following fields in the event pattern:

```
"source": "aws.ec2"
```

Identifies that the event is from Amazon EC2.

```
"detail-type": "EC2 AMI State Change"
```

Identifies the event name.

```
"detail": { "ImageId": "ami-0123456789example", "State": "available", }
```

Provides the following information:

- The AMI ID – If you want to track a specific AMI.
- The state of the AMI (available, failed, deregistered, or disabled).

Example: Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification when any AMI is in the available state after the CreateImage operation has completed successfully.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when an AMI is created and in the available state

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.

2. Choose **Create rule**.
3. For **Define rule detail**, do the following:

- a. Enter a **Name** for the rule, and, optionally, a description.

A rule can't have the same name as another rule in the same Region and on the same event bus.

- b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
- c. For **Rule type**, choose **Rule with an event pattern**.
- d. Choose **Next**.

4. For **Build event pattern**, do the following:

- a. For **Event source**, choose **AWS events or EventBridge partner events**.
- b. For **Event pattern**, for this example you'll specify the following event pattern to match any EC2 AMI State Change event that is generated when an AMI enters the available state:

```
{  
  "source": ["aws.ec2"],  
  "detail-type": ["EC2 AMI State Change"],  
  "detail": {"State": ["available"]}  
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

- i. To use a template to create the event pattern, do the following:
 - A. Choose **Event pattern form**.
 - B. For **Event source**, choose **AWS services**.
 - C. For **AWS Service**, choose **EC2**.
 - D. For **Event type**, choose **EC2 AMI State Change**.
 - E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.
- ii. To specify a custom event pattern, do the following:

- A. Choose **Custom pattern (JSON editor)**.
 - B. In the **Event pattern** box, add the event pattern for this example.
 - c. Choose **Next**.
5. For **Select target(s)**, do the following:
- a. For **Target types**, choose **AWS service**.
 - b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
 - c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person \(A2P\) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.
 - d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events](#) (step 16) in the *Amazon EventBridge User Guide*.
 - e. Choose **Next**.
6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.
7. For **Review and create**, do the following:
- a. Review the details of the rule and modify them as necessary.
 - b. Choose **Create rule**.

For more information, see the following topics in the *Amazon EventBridge User Guide*:

- [Amazon EventBridge events](#)
- [Amazon EventBridge event patterns](#)
- [Amazon EventBridge rules](#)

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see [Tutorial: Log the state of an Amazon EC2 instance using EventBridge](#) in the *AWS Lambda Developer Guide*.

Understand AMI billing information

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the **AMI Platform details** to confirm that the AMI is supported for Spot Instances.
- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the **AMI Platform details**.

For more information about instance pricing, see [Amazon EC2 pricing](#).

AMI billing information fields

The following fields provide billing information associated with an AMI:

Platform details

The platform details associated with the billing code of the AMI. For example, Red Hat Enterprise Linux.

Usage operation

The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, `RunInstances:0010`. **Usage operation** corresponds to the [lineitem/Operation](#) column on your AWS Cost and Usage Report (CUR) and in the [AWS Price List API](#).

You can view these fields on the **Instances** or **AMIs** page in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) or [Get-EC2Image](#) command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the **Instances** or **AMIs** pages in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) or [Get-EC2Image](#) command.

Platform details	Usage operation ²
Linux/UNIX	RunInstances
Red Hat BYOL Linux	RunInstances:00g0 ³
Red Hat Enterprise Linux	RunInstances:0010
Red Hat Enterprise Linux with HA	RunInstances:1010
Red Hat Enterprise Linux with SQL Server Standard and HA	RunInstances:1014
Red Hat Enterprise Linux with SQL Server Enterprise and HA	RunInstances:1110
Red Hat Enterprise Linux with SQL Server Standard	RunInstances:0014
Red Hat Enterprise Linux with SQL Server Web	RunInstances:0210
Red Hat Enterprise Linux with SQL Server Enterprise	RunInstances:0110
SQL Server Enterprise	RunInstances:0100
SQL Server Standard	RunInstances:0004

Platform details	Usage operation ²
SQL Server Web	RunInstances:0200
SUSE Linux	RunInstances:000g
Ubuntu Pro	RunInstances:0g00
Windows	RunInstances:0002
Windows BYOL	RunInstances:0800
Windows with SQL Server Enterprise ¹	RunInstances:0102
Windows with SQL Server Standard ¹	RunInstances:0006
Windows with SQL Server Web ¹	RunInstances:0202

¹ If two software licenses are associated with an AMI, the **Platform details** field shows both.

² If you are running Spot Instances, the [lineitem/Operation](#) on your AWS Cost and Usage Report might be different from the **Usage operation** value that is listed here. For example, if [lineitem/Operation](#) displays RunInstances :0010:SV006, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (N. Virginia) in Zone 6.

³ This appears as RunInstances (Linux/UNIX) in your usage reports.

Finding AMI billing and usage details

In the Amazon EC2 console, you can view the AMI billing information from the **AMIs** page or from the **Instances** page. You can also find billing information using the AWS CLI or the instance metadata service.

The following fields can help you verify AMI charges on your bill:

- **Platform details**

- **Usage operation**
- **AMI ID**

Find AMI billing information (console)

Follow these steps to view AMI billing information in the Amazon EC2 console:

Look up AMI billing information from the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select an AMI.
3. On the **Details** tab, check the values for **Platform details** and **Usage operation**.

Look up AMI billing information from the Instances page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select an instance.
3. On the **Details** tab (or the **Description** tab if you are using the prior version of the console), check the values for **Platform details** and **Usage operation**.

Find AMI billing information (AWS CLI)

To find the AMI billing information using the AWS CLI, you need to know the AMI ID. If you don't know the AMI ID, you can get it from the instance using the [describe-instances](#) command.

To find the AMI ID

If you know the instance ID, you can get the AMI ID for the instance by using the [describe-instances](#) command.

```
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

In the output, the AMI ID is specified in the `ImageId` field.

```
... "Instances": [  
{  
    "AmiLaunchIndex": 0,
```

```
"ImageId": "ami-0123456789EXAMPLE",
"InstanceId": "i-123456789abcde123",
...
}]
```

To find the AMI billing information

If you know the AMI ID, you can use the [describe-images](#) command to get the AMI platform and usage operation details.

```
$ aws ec2 describe-images --image-ids ami-0123456789EXAMPLE
```

The following example output shows the PlatformDetails and UsageOperation fields. In this example, the ami-0123456789EXAMPLE platform is Red Hat Enterprise Linux and the usage operation and billing code is RunInstances:0010.

Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the [lineitem/Operation](#) column. That value should match the value for **Usage operation** that's associated with the AMI.

For example, the AMI ami-0123456789EXAMPLE has the following billing information:

- **Platform details** = Red Hat Enterprise Linux
- **Usage operation** = RunInstances:0010

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the [lineitem/Operation](#) column. In this example, the value should be RunInstances:0010.

Amazon Linux

Amazon Linux is provided by Amazon Web Services (AWS). It is designed to provide a stable, secure, and high-performance execution environment for applications running on Amazon EC2. It also includes packages that enable easy integration with AWS, including launch configuration tools and many popular AWS libraries and tools. AWS provides ongoing security and maintenance updates for all instances running Amazon Linux. Many applications developed on CentOS (and similar distributions) run on Amazon Linux.

Amazon Linux availability

AWS provides AL2023, Amazon Linux 2, and the Amazon Linux AMI. If you are migrating from another Linux distribution to Amazon Linux, we recommend that you migrate to AL2023.

 **Note**

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

For more information about Amazon Linux, see [AL2023](#), [Amazon Linux 2](#), and [Amazon Linux AMI](#).

For Amazon Linux container images, see [Amazon Linux container image](#) in the *Amazon Elastic Container Registry User Guide*.

Connect to an Amazon Linux instance

Amazon Linux does not allow remote root secure shell (SSH) by default. Also, password authentication is disabled to prevent brute-force password attacks. To enable SSH logins to an Amazon Linux instance, you must provide your key pair to the instance at launch. You must also set the security group used to launch your instance to allow SSH access. By default, the only account that can log in remotely using SSH is `ec2-user`; this account also has **sudo** privileges. If you enable remote root login, be aware that it is less secure than relying on key pairs and a secondary user.

Identify Amazon Linux images

Each image contains a unique `/etc/image-id` file that identifies it. This file contains the following information about the image:

- `image_name`, `image_version`, `image_arch` – Values from the build recipe that Amazon used to construct the image.
- `image_stamp` – A unique, random hex value generated during image creation.
- `image_date` – The UTC time of image creation, in `YYYYMMDDhhmmss` format.
- `recipe_name`, `recipe_id` – The name and ID of the build recipe Amazon used to construct the image.

Amazon Linux contains an `/etc/system-release` file that specifies the current release that is installed. This file is updated using **yum** and is part of the `system-release` RPM Package Manager (RPM).

Amazon Linux also contains a machine-readable version of `/etc/system-release` that follows the Common Platform Enumeration (CPE) specification; see `/etc/system-release-cpe`.

Amazon Linux 2

The following is an example of `/etc/image-id` for the current version of Amazon Linux 2.

```
[ec2-user ~]$ cat /etc/image-id
image_name="amzn2-ami-hvm"
image_version="2"
image_arch="x86_64"
image_file="amzn2-ami-hvm-2.0.20180810-x86_64.xfs.gpt"
image_stamp="8008-2abd"

```

The following is an example of `/etc/system-release` for the current version of Amazon Linux 2.

```
[ec2-user ~]$ cat /etc/system-release

ANSI_COLOR="0;33"  
CPE_NAME="cpe:2.3:o:amazon:amazon_linux:2"  
HOME_URL="https://amazonlinux.com/"
```

Amazon Linux AMI

The following is an example of `/etc/image-id` for the current Amazon Linux AMI.

```
[ec2-user ~]$ cat /etc/image-id  
image_name="amzn-ami-hvm"  
image_version="2018.03"  
image_arch="x86_64"  
image_file="amzn-ami-hvm-2018.03.0.20180811-x86_64.ext4.gpt"

recipe_id="5b283820-dc60-a7ea-d436-39fa-439f-02ea-5c802dbd"
```

The following is an example of `/etc/system-release` for the current Amazon Linux AMI.

```
[ec2-user ~]$ cat /etc/system-release  
Amazon Linux AMI release 2018.03
```

Amazon Linux 2 AMI boot mode

Amazon Linux 2 AMIs don't have a boot mode parameter set. Instances launched from Amazon Linux 2 AMIs follow the default boot mode value of the instance type. For more information, see [Boot modes](#).

AWS command line tools

The AWS Command Line Interface (AWS CLI) is an open source tool that provides a consistent interface to interact with AWS services using commands in your command-line shell. For more information, see [What is the AWS Command Line Interface?](#) in the *AWS Command Line Interface User Guide*.

Amazon Linux 2 and the Amazon Linux AMI have version 1 of the AWS CLI preinstalled. The current release of Amazon Linux, AL2023, has version 2 of the AWS CLI preinstalled. For more information about using the AWS CLI on AL2023, see [Get started with AL2023](#) in the *AL2023 User Guide*.

Package repository

This information applies to Amazon Linux 2 and the Amazon Linux AMI. For information about AL2023, see [Managing packages and operating system updates in the AL2023 User Guide](#).

Amazon Linux 2 and the Amazon Linux AMI are designed to be used with online package repositories hosted in each Amazon EC2 AWS Region. The repositories are available in all Regions and are accessed using **yum** update tools. Hosting repositories in each Region enables us to deploy updates quickly and without any data transfer charges.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

If you don't need to preserve data or customizations for your instances, you can launch new instances using the current Amazon Linux 2 AMI. If you need to preserve data or customizations for your instances, you can maintain those instances through the Amazon Linux package repositories.

These repositories contain all the updated packages. You can choose to apply these updates to your running instances. Older versions of the AMI and update packages continue to be available for use, even as new versions are released.

Note

To update and install packages without internet access on an EC2 instance, see [How can I update yum or install packages without internet access on my Amazon EC2 instances running Amazon Linux, Amazon Linux 2, or AL2023?](#)

To install packages, use the following command:

```
[ec2-user ~]$ sudo yum install package
```

If you find that Amazon Linux doesn't contain an application that you need, you can install the application directly on your Amazon Linux instance. Amazon Linux uses RPMs and yum for package management, and that is likely the simplest way to install new applications. You should check to see if an application is available in our central Amazon Linux repository first, because many applications are available there. These applications can be easily added to your Amazon Linux instance.

To upload your applications onto a running Amazon Linux instance, use **scp** or **sftp** and then configure the application by logging in to your instance. Your applications can also be uploaded during the instance launch by using the **PACKAGE_SETUP** action from the built-in cloud-init package. For more information, see [cloud-init](#).

Security updates

Security updates are provided using the package repositories as well as updated AMI security alerts are published in the [Amazon Linux Security Center](#). For more information about AWS security policies or to report a security problem, see [AWS Cloud Security](#).

Amazon Linux and Amazon Linux 2 are configured to download and install critical or important security updates at launch time. Kernel updates are not included in this configuration.

In AL2023, this configuration has changed compared to Amazon Linux AMI and Amazon Linux 2. For more information about security updates for AL2023, see [Security updates and features](#) in the [AL2023 User Guide](#).

We recommend that you make the necessary updates for your use case after launch. For example, you may want to apply all updates (not just security updates) at launch, or evaluate each update and apply only the ones applicable to your system. This is controlled using the following cloud-init setting: `repo_upgrade`. The following snippet of cloud-init configuration shows how you can change the settings in the user data text you pass to your instance initialization:

```
#cloud-config
repo_upgrade: security
```

The possible values for `repo_upgrade` are as follows:

`critical`

Apply outstanding critical security updates.

`important`

Apply outstanding critical and important security updates.

`medium`

Apply outstanding critical, important, and medium security updates.

`low`

Apply all outstanding security updates, including low-severity security updates.

`security`

Apply outstanding critical or important updates that Amazon marks as security updates.

`bugfix`

Apply updates that Amazon marks as bug fixes. Bug fixes are a larger set of updates, which include security updates and fixes for various other minor bugs.

`all`

Apply all applicable available updates, regardless of their classification.

`none`

Don't apply any updates to the instance on start up.

The default setting for `repo_upgrade` is `security`. That is, if you don't specify a different value in your user data, by default, Amazon Linux performs the security upgrades at launch for any

packages installed at that time. Amazon Linux also notifies you of any updates to the installed packages by listing the number of available updates upon login using the /etc/motd file. To install these updates, you need to run **sudo yum upgrade** on the instance.

Repository configuration

For Amazon Linux and Amazon Linux 2, AMIs are a snapshot of the packages available at the time the AMI was created, with the exception of security updates. Any packages not on the original AMI, but installed at run time, will be the latest version available. To get the latest packages available for Amazon Linux 2, run **yum update -y**.

Troubleshooting tip

If you get a `cannot allocate memory` error running **yum update** on nano instance types, such as `t3.nano`, you might need to allocate swap space to enable the update.

For AL2023, the repository configuration has changed compared to the Amazon Linux AMI and Amazon Linux 2. For more information about the AL2023 repository, see [Managing packages and operating system updates](#).

Versions up to AL2023 were configured to deliver a continuous flow of updates to roll from one minor version of Amazon Linux to the next version, also called *rolling releases*. As a best practice, we recommend you update your AMI to the latest available AMI. Don't launch Amazon Linux AMIs that use an older version, such as 2017.09.

In-place upgrades are not supported between major Amazon Linux versions, such as from Amazon Linux to Amazon Linux 2 or from Amazon Linux 2 to AL2023. For more information, see [Amazon Linux availability](#).

Using lock-on-launch in Amazon Linux

You can disable rolling releases by enabling the *lock-on-launch* feature. The lock-on-launch feature locks your instance to receive updates only from the specified release of the AMI. For example, you can launch a 2017.09 AMI and have it receive only the updates that were released prior to the 2018.03 AMI, until you are ready to migrate to the 2018.03 AMI.

Important

If you enable the lock-on-launch feature and choose a version of the repositories that is not the latest, you don't receive further updates. To receive rolling releases, you must use the latest AMI, or consistently update your AMI with the repositories pointed to latest.

To enable the lock-on-launch feature in new instances, launch it with the following user data passed to cloud-init:

```
#cloud-config
repo_releasever: 2017.09
```

To lock existing instances to their current AMI version

1. Edit `/etc/yum.conf`.
2. Comment out `releasever=latest`.
3. To clear the cache, run `yum clean all`.

Extras library (Amazon Linux 2)

With Amazon Linux 2, you can use the Extras Library to install application and software updates on your instances. These software updates are known as *topics*. You can install a specific version of a topic or omit the version information to use the most recent version.

To list the available topics, use the following command:

```
[ec2-user ~]$ amazon-linux-extras list
```

To enable a topic and install the latest version of its package to ensure freshness, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic
```

To enable topics and install specific versions of their packages to ensure stability, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras install topic=version topic=version
```

To remove a package installed from a topic, use the following command:

```
[ec2-user ~]$ sudo yum remove $(yum list installed | grep amzn2extra-topic | awk '{ print $1 }')
```

 **Note**

This command does not remove packages that were installed as dependencies of the extra.

To disable a topic and make the packages inaccessible to the yum package manager, use the following command:

```
[ec2-user ~]$ sudo amazon-linux-extras disable topic
```

 **Important**

This command is intended for advanced users. Improper usage of this command could cause package compatibility conflicts.

Amazon Linux 2 supported kernels

Supported kernel versions

Currently, Amazon Linux 2 (AL2) AMIs are available with kernel versions 4.14 and 5.10, with version 5.10 being a default. You also have an option of upgrading the kernel on AL2 to version 5.15 by using the extras repository. Note that an upgrade to 5.15 requires a reboot for the new kernel to take effect. Review new features and limitations of the kernel version 5.15 on AL2 before deciding whether an upgrade is required for your use case. If you require live patching support, we recommend you use AL2 AMI with kernel 5.10.

AL2023 AMIs are available with kernel version 6.1. For more information, see [AL2023 Kernel changes from Amazon Linux 2](#) in the *AL2023 User Guide*.

New features in kernel 5.15

- [Kernel-based Virtual Machine \(KVM\)](#) now defaults to the new x86 TDP MMU and adds AMD SVM 5-level paging to allow for greater parallelism and scalability compared to the original KVM x86 MMU code.
- [OverlayFS](#) has improved performance and now also handles copying immutable/append/sync/noatime attributes.
- New optimizations and improvements for EXT4 are added, such as addition of a new orphan_file feature to eliminate bottlenecks in cases of large parallel truncates, file deletions and moving the DISCARD work out of the JBD2 commit thread to help with devices having slow DISCARD behavior and not blocking the JBD2 commit KThread.
- New optimizations and improvements for XFS are added, such as batch inode activations in per-CPU background threads that improve directory tree deletion times and enablement of pipelining to help with performance around handling lots of metadata updates.
- [DAMON](#) is better supported as the data access monitoring framework for proactive memory reclamation and performance analysis.

Limitations for kernel 5.15

- LustreFSx is not supported (support will be added later).
- Kernel live patching is not supported.

Instructions for installing kernel 5.15

You can upgrade to kernel 5.15 from both Amazon Linux 2 AMI with kernel 4.14 and AL2 AMI with kernel 5.10 using the following commands:

1. Enable the kernel-5.15 topic in amazon-linux-extras and install kernel 5.15 on the host.

```
sudo amazon-linux-extras install kernel-5.15
```

2. Reboot the host with the installed kernel 5.15.

```
sudo reboot
```

3. Check the system kernel version.

```
uname -r
```

Support Timeframe

All Linux kernels available on Amazon Linux 2 (4.14, 5.10, and 5.15) will be supported until Amazon Linux 2 AMI reaches the end of standard support.

Live patching support

Amazon Linux 2 kernel version	Kernel live patching supported
4.14	Yes
5.10	Yes
5.15	No

Access source packages for reference

You can view the source of packages you have installed on your instance for reference purposes by using tools provided in Amazon Linux. Source packages are available for all of the packages included in Amazon Linux and the online package repository. Simply determine the package name for the source package you want to install and use the **yumdownloader --source** command to view source within your running instance. For example:

```
[ec2-user ~]$ yumdownloader --source bash
```

The source RPM can be unpacked, and, for reference, you can view the source tree using standard RPM tools. After you finish debugging, the package is available for use.

cloud-init

The cloud-init package is an open-source application built by Canonical used to bootstrap Linux images in a cloud computing environment, such as Amazon EC2. Amazon Linux contains a customized version of cloud-init. With the customized version of cloud-init, you can specify the actions that should happen to your instance at boot time. You can pass desired actions to cloud-init through the user data fields when launching an instance. This means you can use common APIs for many use cases and configure them dynamically at startup. Amazon Linux also uses cloud-init to perform initial configuration of the ec2-user account.

For more information, see the [cloud-init documentation](#).

Amazon Linux uses the cloud-init actions found in `/etc/cloud/cloud.cfg.d` and `/etc/cloud/cloud.cfg`. You can create your own cloud-init action files in `/etc/cloud/cloud.cfg.d`. All files in this directory are read by cloud-init. They are read in lexical order, and later files overwrite values in earlier files.

The cloud-init package performs these (and other) common configuration tasks for instances at boot:

- Set the default locale.
- Set the hostname.
- Parse and handle user data.
- Generate host private SSH keys.
- Add a user's public SSH keys to `.ssh/authorized_keys` for easy login and administration.
- Prepare the repositories for package management.
- Handle package actions defined in user data.
- Execute user scripts found in user data.
- Mount instance store volumes, if applicable.
 - By default, the `ephemeral0` instance store volume is mounted at `/media/ephemeral0` if it is present and contains a valid file system; otherwise, it is not mounted.
 - By default, any swap volumes associated with the instance are mounted (only for `m1.small` and `c1.medium` instance types).
 - You can override the default instance store volume mount with the following cloud-init directive:

```
#cloud-config
mounts:
- [ ephemeral0 ]
```

For more control over mounts, see [Mounts](#) in the cloud-init documentation.

- Instance store volumes that support TRIM are not formatted when an instance launches, so you must partition and format them before you can mount them. For more information, see [Instance store volume TRIM support](#). You can use the `disk_setup` module to partition and format your instance store volumes at boot. For more information, see [Disk Setup](#) in the cloud-init documentation.

Supported user-data formats

The cloud-init package supports user-data handling of a variety of formats:

- Gzip
 - If user-data is gzip compressed, cloud-init decompresses the data and handles it appropriately.
- MIME multipart
 - Using a MIME multipart file, you can specify more than one type of data. For example, you could specify both a user-data script and a cloud-config type. Each part of the multipart file can be handled by cloud-init if it is one of the supported formats.
- Base64 decoding
 - If user-data is base64-encoded, cloud-init determines if it can understand the decoded data as one of the supported types. If it understands the decoded data, it decodes the data and handles it appropriately. If not, it returns the base64 data intact.
- User-Data script
 - Begins with #! or Content-Type: text/x-shellscript.
 - The script is run by /etc/init.d/cloud-init-user-scripts during the first boot cycle. This occurs late in the boot process (after the initial configuration actions are performed).
- Include file
 - Begins with #include or Content-Type: text/x-include-url.
 - This content is an include file. The file contains a list of URLs, one per line. Each of the URLs is read, and their content passed through this same set of rules. The content read from the URL can be gzip compressed, MIME-multi-part, or plaintext.
- Cloud Config Data
 - Begins with #cloud-config or Content-Type: text/cloud-config.
 - This content is cloud-config data. For a commented example of supported configuration formats, see the examples.
- Upstart job (not supported on Amazon Linux 2)
 - Begins with #upstart-job or Content-Type: text/upstart-job.
 - This content is stored in a file in /etc/init, and upstart consumes the content as per other upstart jobs.
- Cloud Boothook
 - Begins with #cloud-boothook or Content-Type: text/cloud-boothook.

- This content is boothook data. It is stored in a file under `/var/lib/cloud` and then runs immediately.
- This is the earliest *hook* available. There is no mechanism provided for running it only one time. The booothook must take care of this itself. It is provided with the instance ID in the environment variable `INSTANCE_ID`. Use this variable to provide a once-per-instance set of booothook data.

Subscribe to Amazon Linux notifications

To be notified when new Amazon Linux AMIs are released, you can subscribe using Amazon SNS.

For information about subscribing to notifications for AL2023, see [Receiving notifications on new updates](#) in the *AL2023 User Guide*.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

To subscribe to Amazon Linux notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select the Region in which the SNS notification that you are subscribing to was created.
3. In the navigation pane, choose **Subscriptions**, **Create subscription**.
4. For the **Create subscription** dialog box, do the following:
 - a. [Amazon Linux 2] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN): **arn:aws:sns:us-east-1:137112412989:amazon-linux-2-ami-updates**.
 - b. [Amazon Linux] For **Topic ARN**, copy and paste the following Amazon Resource Name (ARN): **arn:aws:sns:us-east-1:137112412989:amazon-linux-ami-updates**.
 - c. For **Protocol**, choose **Email**.

- d. For **Endpoint**, enter an email address that you can use to receive the notifications.
 - e. Choose **Create subscription**.
5. You receive a confirmation email with the subject line "AWS Notification - Subscription Confirmation". Open the email and choose **Confirm subscription** to complete your subscription.

Whenever AMIs are released, we send notifications to the subscribers of the corresponding topic. To stop receiving these notifications, use the following procedure to unsubscribe.

To unsubscribe from Amazon Linux notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use the Region in which the SNS notification was created.
3. In the navigation pane, choose **Subscriptions**, select the subscription, and choose **Actions**, **Delete subscriptions**.
4. When prompted for confirmation, choose **Delete**.

Amazon Linux AMI SNS message format

The schema for the SNS message is as follows.

```

Run Amazon Linux 2 as a virtual machine on premises

Use the Amazon Linux 2 virtual machine (VM) images for on-premises development and testing. We offer a different Amazon Linux 2 VM image for each of the supported virtualization platforms. You can view the list of supported platforms on the [Amazon Linux 2 virtual machine images](#) page.

To use the Amazon Linux 2 virtual machine images with one of the supported virtualization platforms, do the following:

- [Step 1: Prepare the seed.iso boot image](#)
- [Step 2: Download the Amazon Linux 2 VM image](#)
- [Step 3: Boot and connect to your new VM](#)

Step 1: Prepare the seed.iso boot image

The seed.iso boot image includes the initial configuration information that is needed to boot your new VM, such as the network configuration, host name, and user data.

 **Note**

The seed.iso boot image includes only the configuration information required to boot the VM. It does not include the Amazon Linux 2 operating system files.

To generate the seed.iso boot image, you need two configuration files:

- meta-data – This file includes the hostname and static network settings for the VM.
- user-data – This file configures user accounts, and specifies their passwords, key pairs, and access mechanisms. By default, the Amazon Linux 2 VM image creates an `ec2-user` user account. You use the user-data configuration file to set the password for the default user account.

To create the seed.iso boot disc

1. Create a new folder named `seedconfig` and navigate into it.
2. Create the meta-data configuration file.
 - a. Create a new file named `meta-data`.

- b. Open the meta-data file using your preferred editor and add the following.

```
local-hostname: vm_hostname
# eth0 is the default network interface enabled in the image. You can configure
# static network settings with an entry like the following.
network-interfaces: |
    auto eth0
    iface eth0 inet static
        address 192.168.1.10
        network 192.168.1.0
        netmask 255.255.255.0
        broadcast 192.168.1.255
        gateway 192.168.1.254
```

Replace *vm_hostname* with a VM host name of your choice, and configure the network settings as required.

- c. Save and close the meta-data configuration file.

For an example meta-data configuration file that specifies a VM hostname (amazonlinux.onprem), configures the default network interface (eth0), and specifies static IP addresses for the necessary network devices, see the [sample Seed.iso file](#).

3. Create the user-data configuration file.

- a. Create a new file named user-data.
- b. Open the user-data file using your preferred editor and add the following.

```
#cloud-config
#vim:syntax=yaml
users:
# A user by the name `ec2-user` is created in the image by default.
- default
chpasswd:
  list: |
    ec2-user:plain_text_password
# In the above line, do not add any spaces after 'ec2-user:'.
```

Replace *plain_text_password* with a password of your choice for the default ec2-user user account.

- c. (Optional) By default, cloud-init applies network settings each time the VM boots. Add the following to prevent cloud-init from applying network settings at each boot, and to retain the network settings applied during the first boot.

```
# NOTE: Cloud-init applies network settings on every boot by default. To retain
network settings
# from first boot, add the following 'write_files' section:
write_files:
  - path: /etc/cloud/cloud.cfg.d/80_disable_network_after_firstboot.cfg
    content: |
      # Disable network configuration after first boot
      network:
        config: disabled
```

- d. Save and close the user-data configuration file.

You can also create additional user accounts and specify their access mechanisms, passwords, and key pairs. For more information about the supported directives, see [Module reference](#). For an example user-data file that creates three additional users and specifies a custom password for the default ec2-user user account, see the [sample Seed.iso file](#).

4. Create the seed.iso boot image using the meta-data and user-data configuration files.

For Linux, use a tool such as **genisoimage**. Navigate into the seedconfig folder, and run the following command.

```
$ genisoimage -output seed.iso -volid cidata -joliet -rock user-data meta-data
```

For macOS, use a tool such as **hdiutil**. Navigate one level up from the seedconfig folder, and run the following command.

```
$ hdiutil makehybrid -o seed.iso -hfs -joliet -iso -default-volume-name cidata
seedconfig/
```

Step 2: Download the Amazon Linux 2 VM image

We offer a different Amazon Linux 2 VM image for each of the supported virtualization platforms. You can view the list of supported platforms and download the correct VM image for your chosen platform from the [Amazon Linux 2 virtual machine images](#) page.

Step 3: Boot and connect to your new VM

To boot and connect to your new VM, you must have the seed .iso boot image (created in [Step 1](#)) and an Amazon Linux 2 VM image (downloaded in [Step 2](#)). The steps vary depending on your chosen VM platform.

VMware vSphere

The VM image for VMware is made available in the OVF format.

To boot the VM using VMware vSphere

1. Create a new datastore for the seed .iso file, or add it to an existing datastore.
2. Deploy the OVF template, but do not start the VM yet.
3. In the **Navigator** panel, right-click the new virtual machine and choose **Edit Settings**.
4. On the **Virtual Hardware** tab, for **New device**, choose **CD/DVD Drive**, and then choose **Add**.
5. For **New CD/DVD Drive**, choose **Datastore ISO File**. Select the datastore to which you added the seed .iso file, browse to and select the seed .iso file, and then choose **OK**.
6. For **New CD/DVD Drive**, select **Connect**, and then choose **OK**.

After you have associated the datastore with the VM, you should be able to boot it.

KVM virt-manager

To boot the VM using KVM

1. Open the **Create new VM** wizard.
2. For Step 1, choose **Import existing disk image**.
3. For Step 2, browse to and select the VM image. For **OS type** and **Version**, choose **Linux** and **Red Hat Enterprise Linux 7.0** respectively.
4. For Step 3, specify the amount of RAM and the number of CPUs to use.
5. For Step 4, enter a name for the new VM and select **Customize configuration before install**, and choose **Finish**.
6. In the Configuration window for the VM, choose **Add Hardware**.
7. In the **Add New Virtual Hardware** window, choose **Storage**.

8. In the Storage configuration, choose **Select or create custom storage**. For **Device type**, choose **CDROM device**. Choose **Manage**, **Browse Local**, and then navigate to and select the `seed.iso` file. Choose **Finish**.
9. Choose **Begin Installation**.

Oracle VirtualBox

To boot the VM using Oracle VirtualBox

1. Open Oracle VirtualBox and choose **New**.
2. For **Name**, enter a descriptive name for the virtual machine, and for **Type** and **Version**, select **Linux** and **Red Hat (64-bit)** respectively. Choose **Continue**.
3. For **Memory size**, specify the amount of memory to allocate to the virtual machine, and then choose **Continue**.
4. For **Hard disk**, choose **Use an existing virtual hard disk file**, browse to and open the VM image, and then choose **Create**.
5. Before you start the VM, you must load the `seed.iso` file in the virtual machine's virtual optical drive:
 - a. Select the new VM, choose **Settings**, and then choose **Storage**.
 - b. In the **Storage Devices** list, under **Controller: IDE**, choose the *Empty* optical drive.
 - c. In the **Attributes** section for the optical drive, choose the browse button, select **Choose Virtual Optical Disk File**, and then select the `seed.iso` file. Choose **OK** to apply the changes and close the Settings.

After you have added the `seed.iso` file to the virtual optical drive, you should be able to start the VM.

Microsoft Hyper-V

The VM image for Microsoft Hyper-V is compressed into a zip file. You must extract the contents of the zip file.

To boot the VM using Microsoft Hyper-V

1. Open the **New Virtual Machine Wizard**.
2. When prompted to select a generation, select **Generation 1**.

3. When prompted to configure the network adapter, for **Connection** choose **External**.
4. When prompted to connect a virtual hard disk, choose **Use an existing virtual hard disk**, choose **Browse**, and then navigate to and select the VM image. Choose **Finish** to create the VM.
5. Right-click the new VM and choose **Settings**. In the **Settings** window, under **IDE Controller 1**, choose **DVD Drive**.
6. For the DVD drive, choose **Image file** and then browse to and select the `seed.iso` file.
7. Apply the changes and start the VM.

After the VM has booted, log in using one of the user accounts that is defined in the user-data configuration file. After you have logged in for the first time, you can then disconnect the `seed.iso` boot image from the VM.

Kernel Live Patching on Amazon Linux 2

With Kernel Live Patching for Amazon Linux 2, you can apply security vulnerability and critical bug patches to a running Linux kernel, without reboots or disruptions to running applications. You benefit from improved service and application availability, while keeping your infrastructure secure and up to date.

For information about Kernel Live Patching for AL2023, see [Kernel Live Patching on AL2023](#) in the *AL2023 User Guide*.

AWS releases two types of kernel live patches for Amazon Linux 2:

- **Security updates** – Include updates for Linux common vulnerabilities and exposures (CVE). These updates are typically rated as *important* or *critical* using the Amazon Linux Security Advisory ratings. They generally map to a Common Vulnerability Scoring System (CVSS) score of 7 and higher. In some cases, AWS might provide updates before a CVE is assigned. In these cases, the patches might appear as bug fixes.
- **Bug fixes** – Include fixes for critical bugs and stability issues that are not associated with CVEs.

AWS provides kernel live patches for an Amazon Linux 2 kernel version for up to 3 months after its release. After the 3-month period, you must update to a later kernel version to continue to receive kernel live patches.

Amazon Linux 2 kernel live patches are made available as signed RPM packages in the existing Amazon Linux 2 repositories. The patches can be installed on individual instances using existing **yum** workflows, or they can be installed on a group of managed instances using AWS Systems Manager.

Kernel Live Patching on Amazon Linux 2 is provided at no additional cost.

Supported configurations and prerequisites

Kernel Live Patching is supported on Amazon EC2 instances and [on-premises virtual machines](#) running Amazon Linux 2.

To use Kernel Live Patching on Amazon Linux 2, you must use:

- Kernel version 4.14 or 5.10 on the x86_64 architecture
- Kernel version 5.10 on the ARM64 architecture

Policy Requirements

To download packages from Amazon Linux repositories, Amazon Elastic Compute Cloud needs access to service-owned Amazon S3 buckets. If you are using a Amazon Virtual Private Cloud (VPC) endpoint for Amazon S3 in your environment, you need to ensure that your VPC endpoint policy allows access to those public buckets.

The table describes each of the Amazon S3 buckets that EC2 might need to access for Kernel Live Patching.

S3 bucket ARN	Description
arn:aws:s3:::packages. <i>region</i> .amazonaws.com/*	

S3 bucket ARN	Description
	Amazon S3 bucket containing Amazon Linux AMI packages
arn:aws:s3:::repo. <i>region</i> .amazonaws.com/*	Amazon S3 bucket containing Amazon Linux AMI repositories
arn:aws:s3:::amazonlinux. <i>region</i> .amazonaws.com/*	Amazon S3 bucket containing Amazon Linux 2 repositories
arn:aws:s3:::amazonlinux-2-repos- <i>region</i> /*	Amazon S3 bucket containing Amazon Linux 2 repositories

The following policy illustrates how to restrict access to identities and resources that belong to your organization and provide access to the Amazon S3 buckets required for Kernel Live Patching. Replace *region*, *principal-org-id* and *resource-org-id* with your organization's values.

Work with Kernel Live Patching

You can enable and use Kernel Live Patching on individual instances using the command line on the instance itself, or you can enable and use Kernel Live Patching on a group of managed instances using AWS Systems Manager.

The following sections explain how to enable and use Kernel Live Patching on individual instances using the command line.

For more information about enabling and using Kernel Live Patching on a group of managed instances, see [Use Kernel Live Patching on Amazon Linux 2 instances](#) in the *AWS Systems Manager User Guide*.

Enable Kernel Live Patching

Kernel Live Patching is disabled by default on Amazon Linux 2. To use live patching, you must install the **yum** plugin for Kernel Live Patching and enable the live patching functionality.

Prerequisites

Kernel Live Patching requires **binutils**. If you do not have **binutils** installed, install it using the following command:

```
$ sudo yum install binutils
```

To enable Kernel Live Patching

1. Kernel live patches are available for the following Amazon Linux 2 kernel versions:

- Kernel version **4.14 or 5.10** on the **x86_64** architecture
- Kernel version **5.10** on the **ARM64** architecture

To check your kernel version, run the following command.

```
$ sudo yum list kernel
```

2. If you already have a supported kernel version, skip this step. If you do not have a supported kernel version, run the following commands to update the kernel to the latest version and to reboot the instance.

```
$ sudo yum install -y kernel
```

```
$ sudo reboot
```

3. Install the **yum** plugin for Kernel Live Patching.

```
$ sudo yum install -y yum-plugin-kernel-livepatch
```

4. Enable the **yum** plugin for Kernel Live Patching.

```
$ sudo yum kernel-livepatch enable -y
```

This command also installs the latest version of the kernel live patch RPM from the configured repositories.

- To confirm that the **yum** plugin for kernel live patching has installed successfully, run the following command.

```
$ rpm -qa | grep kernel-livepatch
```

When you enable Kernel Live Patching, an empty kernel live patch RPM is automatically applied. If Kernel Live Patching was successfully enabled, this command returns a list that includes the initial empty kernel live patch RPM. The following is example output.

```
yum-plugin-kernel-livepatch-1.0-0.11.amzn2.noarch  
kernel-livepatch-5.10.102-99.473-1.0-0.amzn2.x86_64
```

- Install the **kpatch** package.

```
$ sudo yum install -y kpatch-runtime
```

- Update the **kpatch** service if it was previously installed.

```
$ sudo yum update kpatch-runtime
```

- Start the **kpatch** service. This service loads all of the kernel live patches upon initialization or at boot.

```
$ sudo systemctl enable kpatch.service
```

- Enable the Kernel Live Patching topic in the Amazon Linux 2 Extras Library. This topic contains the kernel live patches.

```
$ sudo amazon-linux-extras enable livepatch
```

View the available kernel live patches

Amazon Linux security alerts are published to the Amazon Linux Security Center. For more information about the Amazon Linux 2 security alerts, which include alerts for kernel live patches, see the [Amazon Linux Security Center](#). Kernel live patches are prefixed with ALASLIVEPATCH. The Amazon Linux Security Center might not list kernel live patches that address bugs.

You can also discover the available kernel live patches for advisories and CVEs using the command line.

To list all available kernel live patches for advisories

Use the following command.

```
$ yum updateinfo list
```

The following shows example output.

```

Apply kernel live patches

You apply kernel live patches using the **yum** package manager in the same way that you would apply regular updates. The **yum** plugin for Kernel Live Patching manages the kernel live patches that are to be applied and eliminates the need to reboot.

Tip

We recommend that you update your kernel regularly using Kernel Live Patching to ensure that it remains secure and up to date.

You can choose to apply a specific kernel live patch, or to apply any available kernel live patches along with your regular security updates.

To apply a specific kernel live patch

1. Get the kernel live patch version using one of the commands described in [View the available kernel live patches](#).
2. Apply the kernel live patch for your Amazon Linux 2 kernel.

```
$ sudo yum install kernel-livepatch-kernel_version.x86_64
```

For example, the following command applies a kernel live patch for Amazon Linux 2 kernel version 5.10.102-99.473.

```
$ sudo yum install kernel-livepatch-5.10.102-99.473-1.0-4.amzn2.x86_64
```

To apply any available kernel live patches along with your regular security updates

Use the following command.

```
$ sudo yum update --security
```

Omit the --security option to include bug fixes.

⚠ Important

- The kernel version is not updated after applying kernel live patches. The version is only updated to the new version after the instance is rebooted.
- An Amazon Linux 2 kernel receives kernel live patches for a period of three months. After the three month period has lapsed, no new kernel live patches are released for that kernel version. To continue to receive kernel live patches after the three-month

period, you must reboot the instance to move to the new kernel version, which will then continue receiving kernel live patches for the next three months. To check the support window for your kernel version, run `yum kernel-livepatch supported`.

View the applied kernel live patches

To view the applied kernel live patches

Use the following command.

```
$ kpatch list
```

The command returns a list of the loaded and installed security update kernel live patches. The following is example output.

```
Loaded patch modules:  
livepatch_cifs_lease_buffer_len [enabled]  
livepatch_CVE_2019_20096 [enabled]  
livepatch_CVE_2020_8648 [enabled]  
  
Installed patch modules:  
livepatch_cifs_lease_buffer_len (5.10.102-99.473.amzn2.x86_64)  
livepatch_CVE_2019_20096 (5.10.102-99.473.amzn2.x86_64)  
livepatch_CVE_2020_8648 (5.10.102-99.473.amzn2.x86_64)
```

Note

A single kernel live patch can include and install multiple live patches.

Disable Kernel Live Patching

If you no longer need to use Kernel Live Patching, you can disable it at any time.

To disable Kernel Live Patching

1. Remove the RPM packages for the applied kernel live patches.

```
$ sudo yum kernel-livepatch disable
```

2. Uninstall the **yum** plugin for Kernel Live Patching.

```
$ sudo yum remove yum-plugin-kernel-livepatch
```

3. Reboot the instance.

```
$ sudo reboot
```

Limitations

Kernel Live Patching has the following limitations:

- While applying a kernel live patch, you can't perform hibernation, use advanced debugging tools (such as SystemTap, kprobes, and eBPF-based tools), or access ftrace output files used by the Kernel Live Patching infrastructure.

Frequently asked questions

For frequently asked questions about Kernel Live Patching for Amazon Linux 2, see the [Amazon Linux 2 Kernel Live Patching FAQ](#).

User provided kernels

If you need a custom kernel on your Amazon EC2 instances, you can start with an AMI that is close to what you want, compile the custom kernel on your instance, and update the bootloader to point to the new kernel. This process varies depending on the virtualization type that your AMI uses. For more information, see [Linux AMI virtualization types](#).

Contents

- [HVM AMIs \(GRUB\)](#)
- [Paravirtual AMIs \(PV-GRUB\)](#)

HVM AMIs (GRUB)

HVM instance volumes are treated like actual physical disks. The boot process is similar to that of a bare metal operating system with a partitioned disk and bootloader, which enables it to work with all currently supported Linux distributions. The most common bootloader is GRUB or GRUB2.

By default, GRUB does not send its output to the instance console because it creates an extra boot delay. For more information, see [Instance console output](#). If you are installing a custom kernel, you should consider enabling GRUB output.

You don't need to specify a fallback kernel, but we recommend that you have a fallback when you test a new kernel. GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel enables the instance to boot even if the new kernel isn't found.

The legacy GRUB for Amazon Linux uses `/boot/grub/menu.1st`. GRUB2 for Amazon Linux 2 uses `/etc/default/grub`. For more information about updating the default kernel in the bootloader, see the documentation for your Linux distribution.

Paravirtual AMIs (PV-GRUB)

Amazon Machine Images that use paravirtual (PV) virtualization use a system called *PV-GRUB* during the boot process. PV-GRUB is a paravirtual bootloader that runs a patched version of GNU GRUB 0.97. When you start an instance, PV-GRUB starts the boot process and then chain loads the kernel specified by your image's `menu.1st` file.

PV-GRUB understands standard `grub.conf` or `menu.1st` commands, which allows it to work with all currently supported Linux distributions. Older distributions such as Ubuntu 10.04 LTS, Oracle Enterprise Linux, or CentOS 5.x require a special "ec2" or "xen" kernel package, while newer distributions include the required drivers in the default kernel package.

Most modern paravirtual AMIs use a PV-GRUB AKI by default (including all of the paravirtual Linux AMIs available in the Amazon EC2 Launch Wizard Quick Start menu), so there are no additional steps that you need to take to use a different kernel on your instance, provided that the kernel you want to use is compatible with your distribution. The best way to run a custom kernel on your instance is to start with an AMI that is close to what you want and then to compile the custom kernel on your instance and modify the `menu.1st` file to boot with that kernel.

You can verify that the kernel image for an AMI is a PV-GRUB AKI. Run the following [describe-images](#) command (substituting your kernel image ID) and check whether the Name field starts with `pv-grub`:

```
aws ec2 describe-images --filters Name=image-id,Values=aki-880531cd
```

Contents

- [Limitations of PV-GRUB](#)

- [Configure GRUB for paravirtual AMIs](#)
- [Amazon PV-GRUB Kernel Image IDs](#)
- [Update PV-GRUB](#)

Limitations of PV-GRUB

PV-GRUB has the following limitations:

- You can't use the 64-bit version of PV-GRUB to start a 32-bit kernel or vice versa.
- You can't specify an Amazon ramdisk image (ARI) when using a PV-GRUB AKI.
- AWS has tested and verified that PV-GRUB works with these file system formats: EXT2, EXT3, EXT4, JFS, XFS, and ReiserFS. Other file system formats might not work.
- PV-GRUB can boot kernels compressed using the gzip, bzip2, lzo, and xz compression formats.
- Cluster AMIs don't support or need PV-GRUB, because they use full hardware virtualization (HVM). While paravirtual instances use PV-GRUB to boot, HVM instance volumes are treated like actual disks, and the boot process is similar to the boot process of a bare metal operating system with a partitioned disk and bootloader.
- PV-GRUB versions 1.03 and earlier don't support GPT partitioning; they support MBR partitioning only.
- If you plan to use a logical volume manager (LVM) with Amazon Elastic Block Store (Amazon EBS) volumes, you need a separate boot partition outside of the LVM. Then you can create logical volumes with the LVM.

Configure GRUB for paravirtual AMIs

To boot PV-GRUB, a GRUB menu.1st file must exist in the image; the most common location for this file is /boot/grub/menu.1st.

The following is an example of a menu.1st configuration file for booting an AMI with a PV-GRUB AKI. In this example, there are two kernel entries to choose from: Amazon Linux 2018.03 (the original kernel for this AMI), and Vanilla Linux 4.16.4 (a newer version of the Vanilla Linux kernel from <https://www.kernel.org/>). The Vanilla entry was copied from the original entry for this AMI, and the kernel and initrd paths were updated to the new locations. The default 0 parameter points the bootloader to the first entry it sees (in this case, the Vanilla entry), and the fallback 1 parameter points the bootloader to the next entry if there is a problem booting the first.

```
default 0
fallback 1
timeout 0
hiddenmenu

title Vanilla Linux 4.16.4
root (hd0)
kernel /boot/vmlinuz-4.16.4 root=LABEL=/ console=hvc0
initrd /boot/initrd.img-4.16.4

title Amazon Linux 2018.03 (4.14.26-46.32.amzn1.x86_64)
root (hd0)
kernel /boot/vmlinuz-4.14.26-46.32.amzn1.x86_64 root=LABEL=/ console=hvc0
initrd /boot/initramfs-4.14.26-46.32.amzn1.x86_64.img
```

You don't need to specify a fallback kernel in your `menu.lst` file, but we recommend that you have a fallback when you test a new kernel. PV-GRUB can fall back to another kernel in the event that the new kernel fails. Having a fallback kernel allows the instance to boot even if the new kernel isn't found.

PV-GRUB checks the following locations for `menu.lst`, using the first one it finds:

- `(hd0)/boot/grub`
- `(hd0,0)/boot/grub`
- `(hd0,0)/grub`
- `(hd0,1)/boot/grub`
- `(hd0,1)/grub`
- `(hd0,2)/boot/grub`
- `(hd0,2)/grub`
- `(hd0,3)/boot/grub`
- `(hd0,3)/grub`

Note that PV-GRUB 1.03 and earlier only check one of the first two locations in this list.

Amazon PV-GRUB Kernel Image IDs

PV-GRUB AKIs are available in all Amazon EC2 regions, excluding Asia Pacific (Osaka). There are AKIs for both 32-bit and 64-bit architecture types. Most modern AMIs use a PV-GRUB AKI by default.

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Use the following [describe-images](#) command to get a list of the PV-GRUB AKIs for the current region:

```
aws ec2 describe-images --owners amazon --filters Name=name,Values=pv-grub-* .gz
```

PV-GRUB is the only AKI available in the ap-southeast-2 Region. You should verify that any AMI you want to copy to this Region is using a version of PV-GRUB that is available in this Region.

The following are the current AKI IDs for each Region. Register new AMIs using an hd0 AKI.

 **Note**

We continue to provide hd00 AKIs for backward compatibility in Regions where they were previously available.

Update PV-GRUB

We recommend that you always use the latest version of the PV-GRUB AKI, as not all versions of the PV-GRUB AKI are compatible with all instance types. Also, older versions of PV-GRUB are not available in all regions, so if you copy an AMI that uses an older version to a Region that does not support that version, you will be unable to boot instances launched from that AMI until you update the kernel image. Use the following procedures to check your instance's version of PV-GRUB and update it if necessary.

To check your PV-GRUB version

1. Find the kernel ID for your instance.

```
aws ec2 describe-instance-attribute --instance-id instance_id --attribute kernel --region region

{
    "InstanceId": "instance_id",
    "KernelId": "aki-70cb0e10"
}
```

The kernel ID for this instance is aki-70cb0e10.

2. View the version information of that kernel ID.

```
aws ec2 describe-images --image-ids aki-70cb0e10 --region region

{
    "Images": [
        {
            "VirtualizationType": "paravirtual",
            "Name": "pv-grub-hd0_1.05-x86_64.gz",
            ...
            "Description": "PV-GRUB release 1.05, 64-bit"
        }
    ]
}
```

This kernel image is PV-GRUB 1.05. If your PV-GRUB version is not the newest version (as shown in [Amazon PV-GRUB Kernel Image IDs](#)), you should update it using the following procedure.

To update your PV-GRUB version

If your instance is using an older version of PV-GRUB, you should update it to the latest version.

1. Identify the latest PV-GRUB AKI for your Region and processor architecture from [Amazon PV-GRUB Kernel Image IDs](#).
2. Stop your instance. Your instance must be stopped to modify the kernel image used.

```
aws ec2 stop-instances --instance-ids instance_id --region region
```

3. Modify the kernel image used for your instance.

```
aws ec2 modify-instance-attribute --instance-id instance_id --kernel kernel_id --region region
```

4. Restart your instance.

```
aws ec2 start-instances --instance-ids instance_id --region region
```

Configure the Amazon Linux 2 MATE desktop connection

The [MATE desktop environment](#) is pre-installed and pre-configured in AMIs with the following description:

".NET Core *x.x*, Mono *x.xx*, PowerShell *x.x*, and MATE DE pre-installed to run your .NET applications on Amazon Linux 2 with Long Term Support (LTS)."

The environment provides an intuitive graphical user interface for administering Amazon Linux 2 instances with minimal use of the command line. The interface uses graphical representations, such as icons, windows, toolbars, folders, wallpapers, and desktop widgets. Built-in, GUI-based tools are available to perform common tasks. For example, there are tools for adding and removing software, applying updates, organizing files, launching programs, and monitoring system health.

 **Important**

xrdp is the remote desktop software bundled in the AMI. By default, xrdp uses a self-signed TLS certificate to encrypt remote desktop sessions. Neither AWS nor the xrdp maintainers recommend using self-signed certificates in production. Instead, obtain a certificate from an appropriate certificate authority (CA) and install it on your instances. For more information about TLS configuration, see [TLS security layer](#) on the xrdp wiki.

Note

If you prefer to use a virtual network computing (VNC) service instead of xrdp, see the [How do I install a GUI on my Amazon EC2 instance running Amazon Linux 2](#) AWS Knowledge Center article.

Prerequisite

To run the commands shown in this topic, you must install the AWS Command Line Interface (AWS CLI) or AWS Tools for Windows PowerShell, and configure your AWS profile.

Options

1. Install the AWS CLI – For more information, see [Installing the AWS CLI](#) and [Configuration basics](#) in the *AWS Command Line Interface User Guide*.
2. Install the Tools for Windows PowerShell – For more information, see [Installing the AWS Tools for Windows PowerShell](#) and [Shared credentials](#) in the *AWS Tools for Windows PowerShell User Guide*.

Configure the RDP connection

Follow these steps to set up a Remote Desktop Protocol (RDP) connection from your local machine to an Amazon Linux 2 instance running the MATE desktop environment.

1. To get the ID of the AMI for Amazon Linux 2 that includes MATE in the AMI name, you can use the [describe-images](#) command from your local command line tool. If you have not installed the command line tools, you can perform the following query directly from an AWS CloudShell session. For information about how to launch a shell session from CloudShell, see [Getting started with AWS CloudShell](#). From the Amazon EC2 console, you can find the MATE-included AMI by launching an instance, and then entering MATE in the AMI search bar. The Amazon Linux 2 Quick Start with MATE pre-installed will appear in the search results.

```
aws ec2 describe-images --filters "Name=name,Values=amzn2*MATE*" --query  
"Images[*].[ImageId,Name,Description]"  
[  
  [  
    "ami-0123example0abc12",
```

```
        "amzn2-x86_64-MATEDE_DOTNET-2020.12.04",
        ".NET Core 5.0, Mono 6.12, PowerShell 7.1, and MATE DE pre-installed to run
your .NET applications on Amazon Linux 2 with Long Term Support (LTS)."
    ],
    [
        "ami-0456example0def34",
        "amzn2-x86_64-MATEDE_DOTNET-2020.04.14",
        "Amazon Linux 2 with .Net Core, PowerShell, Mono, and MATE Desktop
Environment"
    ]
]
```

Choose the AMI that is appropriate for your use.

2. Launch an EC2 instance with the AMI that you located in the previous step. Configure the security group to allow for inbound TCP traffic to port 3389. For more information about configuring security groups, see [Security groups for your VPC](#). This configuration enables you to use an RDP client to connect to the instance.
3. Connect to the instance using [SSH](#).
4. Update the software and kernel on the instance.

```
[ec2-user ~]$ sudo yum update
```

After the update completes, reboot the instance to ensure that it is using the latest packages and libraries from the update; kernel updates are not loaded until a reboot occurs.

```
[ec2-user ~]$ sudo reboot
```

5. Reconnect to the instance and run the following command on your Linux instance to set the password for ec2-user.

```
[ec2-user ~]$ sudo passwd ec2-user
```

6. Install the certificate and key.

If you already have a certificate and key, copy them to the /etc/xrdp/ directory as follows:

- Certificate — /etc/xrdp/cert.pem
- Key — /etc/xrdp/key.pem

If you do not have a certificate and key, use the following command to generate them in the /etc/xrdp directory.

```
$ sudo openssl req -x509 -sha384 -newkey rsa:3072 -nodes -keyout /etc/xrdp/key.pem  
-out /etc/xrdp/cert.pem -days 365
```

 **Note**

This command generates a certificate that is valid for 365 days.

7. Open an RDP client on the computer from which you will connect to the instance (for example, Remote Desktop Connection on a computer running Microsoft Windows). Enter ec2-user as the user name and enter the password that you set in the previous step.

To disable xrdp on your Amazon EC2 instance

You can disable xrdp at any time by running one of the following commands on your Linux instance. The following commands do not impact your ability to use MATE using an X11 server.

```
[ec2-user ~]$ sudo systemctl disable xrdp
```

```
[ec2-user ~]$ sudo systemctl stop xrdp
```

To enable xrdp on your Amazon EC2 instance

To re-enable xrdp so that you can connect to your Amazon Linux 2 instance running the MATE desktop environment, run one of the following commands on your Linux instance.

```
[ec2-user ~]$ sudo systemctl enable xrdp
```

```
[ec2-user ~]$ sudo systemctl start xrdp
```

AMI quotas

The following quotas apply to creating and sharing AMIs. The quotas apply per AWS Region.

Quota name	Description	Default quota per Region
AMIs	The maximum number of public and private AMIs allowed per Region. These include available, pending, and disabled AMIs, and AMIs in the Recycle Bin.	50,000
Public AMIs	The maximum number of public AMIs, including public AMIs in the Recycle Bin, allowed per Region.	5
AMI sharing	The maximum number of entities (organizations, organizational units (OUs), and accounts) that an AMI can be shared with in a Region. Note that if you share an AMI with an organization or OU, the number of accounts in the organization or OU does not count towards the quota.	1,000

If you exceed your quotas and you want to create or share more AMIs, you can do the following:

- If you exceed your total AMIs or public AMIs quota, consider deregistering unused images.
- If you exceed your public AMIs quota, consider making one or more public AMIs private.
- If you exceed your AMI sharing quota, consider sharing your AMIs with an organization or OU instead of separate accounts.
- Request a quota increase for AMIs.

Request a quota increase for AMIs

If you need more than the default quota for AMIs, you can request a quota increase.

To request a quota increase for AMIs

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home>.
2. In the navigation pane, choose **AWS services**.
3. Choose **Amazon Elastic Compute Cloud (Amazon EC2)** from the list, or type the name of the service in the search box.
4. Choose the AMI quota to request an increase. The AMI quotas you can select are:
 - AMIs
 - Public AMIs
 - AMI sharing
5. Choose **Request quota increase**.
6. For **Change quota value**, enter the new quota value, and then choose **Request**.

To view any pending or recently resolved requests, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number under **Support Center case number**. Choose the case number to open the ticket for your request.

After the request is resolved, the **Applied quota value** for the quota is set to the new value.

For more information, see the [Service Quotas User Guide](#).

Amazon EC2 instances

Note

For detailed instance type specifications, see [Specifications](#) in the *Amazon EC2 Instance Types Guide*. For pricing information, see [Amazon EC2 On-Demand Pricing](#).

If you're new to Amazon EC2, see the following topics to get started:

- [What is Amazon EC2?](#)
- [Set up to use Amazon EC2](#)
- [Tutorial: Get started with Amazon EC2 Linux instances](#)
- [Instance lifecycle](#)

Before you launch a production environment, you need to answer the following questions.

Q. What instance type best meets my needs?

Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see [Amazon EC2 instance types](#).

Q. What purchasing option best meets my needs?

Amazon EC2 supports On-Demand Instances (the default), Spot Instances, and Reserved Instances. For more information, see [Instance purchasing options](#).

Q. Which type of root volume meets my needs?

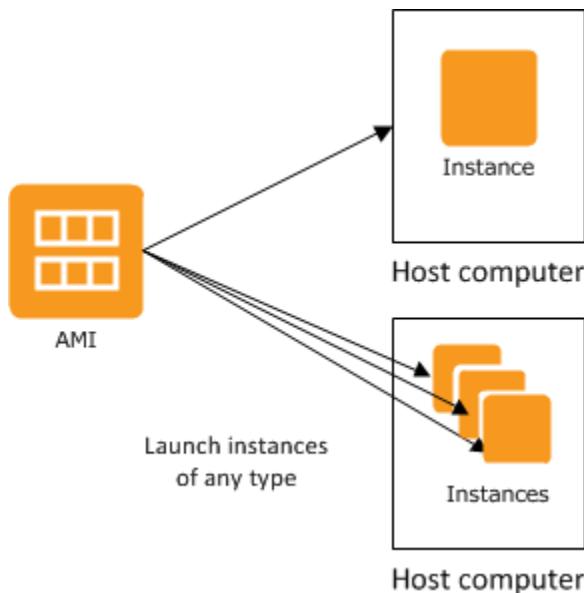

Each instance is backed by Amazon EBS or backed by instance store. Select an AMI based on which type of root volume you need. For more information, see [Storage for the root device](#).

Q. Can I remotely manage a fleet of EC2 instances and machines in my hybrid environment?

AWS Systems Manager enables you to remotely and securely manage the configuration of your Amazon EC2 instances, and your on-premises instances and virtual machines (VMs) in hybrid environments, including VMs from other cloud providers. For more information, see the [AWS Systems Manager User Guide](#).

Instances and AMIs

An *Amazon Machine Image (AMI)* is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch an *instance*, which is a copy of the AMI running as a virtual server in the cloud. You can launch multiple instances of an AMI, as shown in the following figure.

Your instances keep running until you stop, hibernate, or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

Instances

An instance is a virtual server in the cloud. Its configuration at launch is a copy of the AMI that you specified when you launched the instance.

You can launch different types of instances from a single AMI. An *instance type* essentially determines the hardware of the host computer used for your instance. Each instance type offers different compute and memory capabilities. Select an instance type based on the amount of memory and computing power that you need for the application or software that you plan to run on the instance. For detailed instance type specifications, see [Specifications](#) in the *Amazon EC2 Instance Types Guide*. For pricing information, see [Amazon EC2 On-Demand Pricing](#).

After you launch an instance, it looks like a traditional host, and you can interact with it as you would any computer. You have complete control of your instances; you can use **sudo** to run commands that require root privileges.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see [How many instances can I run in Amazon EC2](#) in the Amazon EC2 General FAQ.

Storage for your instance

The root device for your instance contains the image used to boot the instance. The root device is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information, see [Amazon EC2 instance root volume](#).

Your instance may include local storage volumes, known as instance store volumes, which you can configure at launch time with block device mapping. For more information, see [Block device mappings](#). After these volumes have been added to and mapped on your instance, they are available for you to mount and use. If your instance fails, or if your instance is stopped or terminated, the data on these volumes is lost; therefore, these volumes are best used for temporary data. To keep important data safe, you should use a replication strategy across multiple instances, or store your persistent data in Amazon S3 or Amazon EBS volumes. For more information, see [Storage options for your Amazon EC2 instances](#).

Security best practices

- Use AWS Identity and Access Management (IAM) to control access to your AWS resources, including your instances. For more information, see [Identity and access management for Amazon EC2](#).
- Restrict access by only allowing trusted hosts or networks to access ports on your instance. For example, you can restrict SSH access by restricting incoming traffic on port 22. For more information, see [Amazon EC2 security groups for Linux instances](#).
- Review the rules in your security groups regularly, and ensure that you apply the principle of *least privilege*—only open up permissions that you require. You can also create different security groups to deal with instances that have different security requirements. Consider creating a bastion security group that allows external logins, and keep the remainder of your instances in a group that does not allow external logins.
- Disable password-based logins for instances launched from your AMI. Passwords can be found or cracked, and are a security risk. For more information, see [Disable password-based remote logins for the root user](#). For more information about sharing AMIs safely, see [Shared AMIs](#).

Stop and terminate instances

You can stop or terminate a running instance at any time.

Stop an instance

When an instance is stopped, the instance performs a normal shutdown, and then transitions to a stopped state. All of its Amazon EBS volumes remain attached, and you can start the instance again at a later time.

You are not charged for additional instance usage while the instance is in a stopped state. A minimum of one minute is charged for every transition from a stopped state to a running state. If the instance type was changed while the instance was stopped, you will be charged the rate for the new instance type after the instance is started. All of the associated Amazon EBS usage of your instance, including root device usage, is billed using typical Amazon EBS prices.

When an instance is in a stopped state, you can attach or detach Amazon EBS volumes. You can also create an AMI from the instance, and you can change the kernel, RAM disk, and instance type.

Terminate an instance

When an instance is terminated, the instance performs a normal shutdown. The root device volume is deleted by default, but any attached Amazon EBS volumes are preserved by default, determined by each volume's `deleteOnTermination` attribute setting. The instance itself is also deleted, and you can't start the instance again at a later time.

To prevent accidental termination, you can disable instance termination. If you do so, ensure that the `disableApiTermination` attribute is set to `true` for the instance. To control the behavior of an instance shutdown, such as `shutdown -h` in Linux or `shutdown` in Windows, set the `instanceInitiatedShutdownBehavior` instance attribute to `stop` or `terminate` as desired. Instances with Amazon EBS volumes for the root device default to `stop`, and instances with instance-store root devices are always terminated as the result of an instance shutdown.

For more information, see [Instance lifecycle](#).

Note

Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#)

in the *AWS Billing User Guide*. For more information about Amazon EBS costs, see [Amazon EBS pricing](#).

AMIs

Amazon Web Services (AWS) publishes many [Amazon Machine Images \(AMIs\)](#) that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMI or AMIs; doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or a web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

All AMIs are categorized as either *backed by Amazon EBS*, which means that the root device for an instance launched from the AMI is an Amazon EBS volume, or *backed by instance store*, which means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

The description of an AMI indicates the type of root device (either `ebs` or `instance store`). This is important because there are significant differences in what you can do with each type of AMI. For more information about these differences, see [Storage for the root device](#).

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances. Existing instances launched from the AMI are not affected. Therefore, if you are also finished with the instances launched from these AMIs, you should terminate them.

Amazon EC2 instance types

When you launch an instance, the *instance type* that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as

the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

Available instance types

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instance types comprise varying combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your applications. Each instance type includes one or more instance sizes, allowing you to scale your resources to the requirements of your target workload. For more information, see [Instance types](#) in the *Amazon EC2 Instance Types Guide*.

Instance type naming conventions

Names are based on instance family, generation, processor family, capabilities, and size. For more information, see [Naming conventions](#) in the *Amazon EC2 Instance Types Guide*.

Find an instance type

To determine which instance types meet your requirements, such as supported Regions, compute resources, or storage resources, see [Find an Amazon EC2 instance type](#) and the [Amazon EC2 Instance Types Guide](#).

For more information about features and use cases, see [Amazon EC2 Instance Types Details](#).

Hardware specifications

For detailed instance type specifications, see [Specifications](#) in the *Amazon EC2 Instance Types Guide*. For pricing information, see [Amazon EC2 On-Demand Pricing](#).

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, even after you make a decision, you can change the instance type later. For more information, see [Change the instance type](#).

Intel processor features

Amazon EC2 instances that run on Intel processors may include the following features. Not all of the following processor features are supported by all instance types. For detailed information about which features are available for each instance type, see [Amazon EC2 Instance types](#).

- **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.
- **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.
- **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.
- **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance

over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

The following instances support VNNI: M5n, R5n, M5dn, M5zn, R5b, R5dn, D3, D3en, and C6i. C5 and C5d instances support VNNI for only 12xlarge, 24xlarge, and metal instances.

Confusion may result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an instance running Ubuntu or Windows displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.

AWS Graviton processors

[AWS Graviton](#) is a family of processors designed to deliver the best price performance for your workloads running on Amazon EC2 instances.

For more information, see [Getting started with Graviton](#).

AWS Trainium

Instances powered by [AWS Trainium](#) are purpose built for high-performance, cost-effective deep learning training. You can use these instances to train natural language processing, computer vision, and recommender models used across a broad set of applications, such as speech recognition, recommendation, fraud detection, and image and video classification. Use your existing workflows in popular ML frameworks, such as PyTorch and TensorFlow.

AWS Inferentia

Instances powered by [AWS Inferentia](#) are designed to accelerate machine learning. They provide high performance and low latency machine learning inference. These instances are optimized for deploying deep learning (DL) models for applications, such as natural language processing, object detection and classification, content personalization and filtering, and speech recognition.

There are a variety of ways that you can get started:

- Use SageMaker, a fully-managed service that is the easiest way to get started with machine learning models. For more information, see [Get Started with SageMaker](#) in the *Amazon SageMaker Developer Guide*.
- Launch an Inf1 or Inf2 instance using the Deep Learning AMI. For more information, see [AWS Inferentia with DLAMI](#) in the *AWS Deep Learning AMI Developer Guide*.
- Launch an Inf1 or Inf2 instance using your own AMI and install the [AWS Neuron SDK](#), which enables you to compile, run, and profile deep learning models for AWS Inferentia.
- Launch a container instance using an Inf1 or Inf2 instance and an Amazon ECS-optimized AMI. For more information, see [Amazon Linux 2 \(Inferentia\) AMIs](#) in the *Amazon Elastic Container Service Developer Guide*.
- Create an Amazon EKS cluster with nodes running Inf1 instances. For more information, see [Inferentia support](#) in the *Amazon EKS User Guide*.

AMI virtualization types

The virtualization type of your instance is determined by the AMI that you use to launch it. Current generation instance types support hardware virtual machine (HVM) only. Some previous generation instance types support paravirtual (PV) and some AWS Regions support PV instances. For more information, see [Linux AMI virtualization types](#).

For best performance, we recommend that you use an HVM AMI. In addition, HVM AMIs are required to take advantage of enhanced networking. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.

Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on the resources that your workload requires, such as compute, memory, or storage resources. It can be beneficial to identify several instance types that might suit your workload and evaluate their performance in a test environment. There is no substitute for measuring the performance of your application under load.

If you already have running EC2 instances, you can use AWS Compute Optimizer to get recommendations about the instance types that you should use to improve performance, save money, or both. For more information, see [the section called “For existing workloads”](#).

Tasks

- [Find an instance type using the console](#)
- [Find an instance type using the AWS CLI](#)

Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

To find an instance type using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **Instance Types**.
4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select the name of an instance type to open its details page and view all attributes available through the console. The console does not display all the attributes available through the API or the command line.
5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can filter on the following attributes:
 - **Availability zones** – The name of the Availability Zone, Local Zone, or Wavelength Zone. For more information, see [the section called “Regions and Zones”](#).
 - **vCPUs or Cores** – The number of vCPUs or cores.
 - **Memory (GiB)** – The memory size, in GiB.
 - **Network performance** – The network performance, in Gigabits.
 - **Local instance storage** – Indicates whether the instance type has local instance storage (true | false).
6. (Optional) To see a side-by-side comparison, select the checkbox for multiple instance types. The comparison is displayed at the bottom of the screen.
7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose **Actions, Download list CSV**. The file includes all instance types that match the filters you set.

8. (Optional) To launch instances using an instance type that meet your needs, select the checkbox for the instance type and choose **Actions, Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

Find an instance type using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to find an instance type that meet your needs.

To find an instance type using the AWS CLI

1. If you have not done so already, install the AWS CLI. For more information, see the [AWS Command Line Interface User Guide](#).
2. Use the [describe-instance-types](#) command to filter instance types based on instance attributes. For example, you can use the following command to display only current generation instance types with 64 GiB (65536 MiB) of memory.

```
aws ec2 describe-instance-types --filters "Name=current-generation,Values=true"  
"Name=memory-info.size-in-mib,Values=65536" --query "InstanceTypes[*].  
[InstanceType]" --output text | sort
```

3. Use the [describe-instance-type-offerings](#) command to filter instance types offered by location (Region or Zone). For example, you can use the following command to display the instance types offered in the specified Zone.

```
aws ec2 describe-instance-type-offerings --location-type "availability-  
zone" --filters Name=location,Values=us-east-2a --region us-east-2 --query  
"InstanceTypeOfferings[*].[InstanceType]" --output text | sort
```

4. After locating the instance types that meet your needs, save the list so that you can use these instance types when you launch instances. For more information, see [Launching your instance](#) in the *AWS Command Line Interface User Guide*.

Get recommendations for an instance type

The following tools can help you select the optimal instance types for your new or existing workloads:

- **New workloads** – Amazon Q EC2 instance type selector considers your use case, workload type, and CPU manufacturer preference, as well as how you prioritize price and performance. It then

uses this data to provide guidance and suggestions for Amazon EC2 instance types that are best suited to your new workloads.

- **Existing workloads** – AWS Compute Optimizer analyzes your existing instance specifications and utilization metrics. It then uses the compiled data to recommend which Amazon EC2 instance types are optimized for cost or performance, or both, for your existing workloads.

Note

Powered by Amazon Bedrock: AWS implements [automated abuse detection](#). Because Amazon Q EC2 instance type selector is built on Amazon Bedrock, users can take full advantage of the controls implemented in Amazon Bedrock to enforce safety, security, and the responsible use of artificial intelligence (AI).

Amazon Q EC2 instance type selector is in preview release for Amazon EC2 and is subject to change.

Amazon Q EC2 instance type selector considers your use case, workload type, and CPU manufacturer preference, as well as how you prioritize price and performance. It then uses this data to provide guidance and suggestions for Amazon EC2 instance types that are best suited to your new workloads.

With so many instance types available, it can be time-consuming and difficult finding the right instance types for your workload. By using the Amazon Q EC2 instance type selector, you can remain up to date with the latest instance types and achieve the best price-performance for your workloads.

This topic outlines how to get guidance and suggestions for EC2 instance types through the Amazon EC2 console. You can also go directly to Amazon Q to ask for instance type advice. For more information, see the [Amazon Q \(For AWS Builder Use\) User Guide](#).

If you're looking for instance type recommendations for an *existing* workload, use AWS Compute Optimizer. For more information, see [Get instance type recommendations for an existing workload](#).

Supported AWS Regions

Because Amazon Q EC2 instance type selector uses Amazon Q, it is supported in the same Regions in which Amazon Q is supported. For more information, see [Supported Regions for Amazon Q](#) in the *Amazon Q (For AWS Builder Use) User Guide*.

Use Amazon Q EC2 instance type selector

In the Amazon EC2 console, you can choose the **Get advice** link to ask Amazon Q for instance type advice. Once you've specified your use case, workload type, CPU manufacturer preference, and price and performance priorities, the Amazon Q AI assistant opens to provide you with instance type suggestions. You can also go directly to Amazon Q to ask for instance type advice. For more information, see the [Amazon Q \(For AWS Builder Use\) User Guide](#).

The **Get advice** link appears on the following EC2 console pages:

- Amazon EC2 launch instance wizard
- Amazon EC2 launch template

Use the following instructions to get guidance and suggestions for EC2 instance types using the Amazon Q EC2 instance type selector in the Amazon EC2 console.

To get instance type advice using the Amazon Q EC2 instance type selector

1. Follow the procedure to [launch an instance](#) or [create a launch template](#).
2. To use the Amazon Q EC2 instance type selector to get instance type advice, do the following:
 - a. Next to **Instance type**, choose the **Get advice** link.
 - b. In the **Get advice on instance type selection from Amazon Q** window, specify your instance type requirements by selecting options from the drop-down lists. For **Use Case** and **Workload type**, you can select **Other**, and then enter your requirements.

c. Choose **Get instance type advice**.

The Amazon Q AI assistant opens with suggestions for instance types customized for your requirements.

- d. You can continue to chat in natural language with Amazon Q about more instance type requirements.
3. When you've decided on an instance type to use, in the launch instance wizard or launch template, for **Instance type**, select the instance type.
 4. Complete the procedure to launch an instance or create a launch template.

Get instance type recommendations for an existing workload

AWS Compute Optimizer provides Amazon EC2 instance recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to move to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance

types are best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing.

This topic outlines how to view recommendations through the Amazon EC2 console. For more information, see the [AWS Compute Optimizer User Guide](#).

Note

To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see [Getting Started with AWS Compute Optimizer](#) in the *AWS Compute Optimizer User Guide*.

If you're looking for instance type recommendations for a *new* workload, use Amazon Q EC2 instance type selector. For more information, see [Get instance type recommendations for a new workload](#).

Contents

- [Limitations](#)
- [Findings](#)
- [View recommendations](#)
- [Considerations for evaluating recommendations](#)
- [Additional resources](#)

Limitations

Compute Optimizer currently generates recommendations for C, D, H, I, M, R, T, X, and z instance types. Other instance types are not considered by Compute Optimizer. If you're using other instance types, they will not be listed in the Compute Optimizer recommendations view. For more information about the supported and unsupported instance types, see [Amazon EC2 instance requirements](#) in the *AWS Compute Optimizer User Guide*.

Findings

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance

requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.

- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.
- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.
- **None** – There are no recommendations for this instance. This might occur if you've been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer. For more information, see [Limitations](#) in the previous section.

View recommendations

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.

To view a recommendation for an EC2 instance through the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then choose the instance ID .
3. On the instance summary page, in the **AWS Compute Optimizer** banner near the bottom of the page, choose **View detail**.

The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose settings

)

to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

 **Note**

If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Determine whether you want to use one of the recommendations. Decide whether to optimize for performance improvement, for cost reduction, or for a combination of the two. For more information, see [Viewing Resource Recommendations](#) in the *AWS Compute Optimizer User Guide*.

To view recommendations for all EC2 instances across all Regions through the Compute Optimizer console

1. Open the Compute Optimizer console at <https://console.aws.amazon.com/compute-optimizer/>.
2. Choose **View recommendations for all EC2 instances**.
3. You can perform the following actions on the recommendations page:
 - a. To filter recommendations to one or more AWS Regions, enter the name of the Region in the **Filter by one or more Regions** text box, or choose one or more Regions in the drop-down list that appears.
 - b. To view recommendations for resources in another account, choose **Account**, and then select a different account ID.

This option is available only if you are signed in to a management account of an organization, and you opted in all member accounts within the organization.

- c. To clear the selected filters, choose **Clear filters**.
- d. To change the purchasing option that is displayed for the current and recommended instance types, choose settings

),

and then choose **On-Demand Instances**, **Reserved Instances, standard 1-year no upfront**, or **Reserved Instances, standard 3-year no upfront**.

- e. To view details, such as additional recommendations and a comparison of utilization metrics, choose the finding (**Under-provisioned**, **Over-provisioned**, or **Optimized**) listed next to the desired instance. For more information, see [Viewing Resource Details](#) in the *AWS Compute Optimizer User Guide*.

Considerations for evaluating recommendations

Before changing an instance type, consider the following:

- The recommendations don't forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.
- Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see [Viewing Available Metrics](#) in the *Amazon CloudWatch User Guide*.
- Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see [Key concepts and definitions for burstable performance instances](#).
- If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.
- Consider conversions to newer generation instances, where possible.
- When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see [Compatibility for changing the instance type](#).
- Finally, consider the performance risk rating that's provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

There are other considerations when resizing an EC2 instance. For more information, see [Change the instance type](#).

Additional resources

For more information:

- [Amazon EC2 instance types](#)
- [AWS Compute Optimizer User Guide](#)

Change the instance type

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your t2.micro instance is too small for its workload, you can increase its size by changing it to a bigger T2 instance type, such as t2.large. Or you can change it to another instance type, such as m5.large. You might also want to change from a previous generation to a current generation instance type to take advantage of some features, such as support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see [Get instance type recommendations for an existing workload](#).

When you change the instance type, you'll start paying the rate of the new instance type. For the on-demand rates of all instance types, see [Amazon EC2 On-Demand Pricing](#).

To add additional storage to your instance without changing the instance type, add an EBS volume to the instance. For more information, see [Attach an Amazon EBS volume to an instance](#) in the [Amazon EBS User Guide](#).

Which instructions to follow?

There are different instructions for changing the instance type. The instructions to use depend on the instance's root volume, and whether the instance type is compatible with the instance's current configuration. For information about how compatibility is determined, see [Compatibility for changing the instance type](#).

Use the following table to determine which instructions to follow.

Root volume	Compatibility	Use these instructions
EBS	Compatible	Change the instance type of an existing EBS-backed instance
EBS	Not compatible	Change the instance type by launching a new instance
Instance store	Not applicable	Change the instance type of an instance store-backed instance

Considerations for compatible instance types

Consider the following when changing the instance type of an existing instance:

- You must stop your Amazon EBS-backed instance before you can change its instance type. Ensure that you plan for downtime while your instance is stopped. Stopping the instance and changing its instance type might take a few minutes, and restarting your instance might take a variable amount of time depending on your application's startup scripts. For more information, see [Stop and start Amazon EC2 instances](#).
- When you stop and start an instance, we move the instance to new hardware. If your instance has a public IPv4 address, we release the address and give your instance a new public IPv4 address. If you require a public IPv4 address that does not change, use an [Elastic IP address](#).
- You can't change the instance type of a [Spot Instance](#).
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you're changing the instance type. For more information, see [Suspending and resuming a process for an Auto Scaling group](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you change the instance type of an instance with NVMe instance store volumes, the updated instance might have additional instance store volumes, because all NVMe instance store volumes are available even if they are not specified in the AMI or instance block device mapping. Otherwise, the updated instance has the same number of instance store volumes that you specified when you launched the original instance.
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. You can't change to an instance type or instance size that

does not support the number of volumes that are already attached to your instance. For more information, see [Instance volume limits](#).

Change the instance type of an existing EBS-backed instance

Use the following instructions to change the instance type of an EBS-backed instance if the instance type that you need is compatible with the instance's current configuration.

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see [Compatibility for changing the instance type](#).
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. Select the instance and choose **Instance state, Stop instance**. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance settings, Change instance type**. This option is grayed out if the instance state is not stopped.
6. On the **Change instance type** page, do the following:
 - a. For **Instance type**, select the instance type that you want.
If the instance type is not in the list, then it's not compatible with the configuration of your instance. Instead, use the following instructions: [Change the instance type by launching a new instance](#).

- b. (Optional) If the instance type that you selected supports EBS optimization, select **EBS-optimized** to enable EBS optimization, or deselect **EBS-optimized** to disable EBS optimization. If the instance type that you selected is EBS optimized by default, **EBS-optimized** is selected and you can't deselect it.
 - c. Choose **Apply** to accept the new settings.
7. To start the instance, select the instance and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the `running` state. If your instance won't start, see [Troubleshoot changing the instance type](#).

Change the instance type by launching a new instance

If the current configuration of your EBS-backed instance is incompatible with the new instance type that you want, then you can't change the instance type of the original instance. Instead, you must launch a new instance with a configuration that is compatible with the new instance type that you want, and then migrate your application to the new instance. For example, if you launched your original instance from a PV AMI, but want to change to a current generation instance type that is only supported by an HVM AMI, you'll need to launch a new instance from an HVM AMI. For information about how compatibility is determined, see [Compatibility for changing the instance type](#).

To migrate your application to a new instance, do the following:

- Back up the data on your original instance.
- Launch a new instance with a configuration that is compatible with the new instance type that you want, and attach any EBS volumes that were attached to your original instance.
- Install your application and any software on your new instance.
- Restore any data.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see [Elastic IP address](#).

To change the instance type for a new instance configuration

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Back up data that you need to keep, as follows:
 - For data on your instance store volumes, back up the data to persistent storage.
 - For data on your EBS volumes, create a snapshot of the volumes or detach the volumes from the instance so that you can attach them to the new instance later.
3. In the navigation pane, choose **Instances**.
4. Choose **Launch instances**. When you configure the instance, do the following:
 - a. Select an AMI that will support the instance type that you want. Note that current generation instance types require an HVM AMI.

- b. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you selected.
 - c. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.
 - d. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
 - e. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.
5. If required, attach any new EBS volumes based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.
 6. Install your application and any required software on the new instance.
 7. Restore any data that you backed up from the instance store volumes of the original instance.
 8. If you are using an Elastic IP address, assign it to the new instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
 - c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.
 - d. For **Resource type**, choose **Instance**.
 - e. For **Instance**, choose the new instance with which to associate the Elastic IP address.
 - f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
 - g. Choose **Associate**.
 9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.

Compatibility for changing the instance type

You can change the instance type only if the instance's current configuration is compatible with the instance type that you want. If the instance type that you want is not compatible with the

instance's current configuration, you must launch a new instance with a configuration that is compatible with the instance type, and then migrate your application to the new instance.

For compatibility information for changing Windows instance types, see [Compatibility for changing the instance type](#) in the *User Guide for Windows Instances*.

Tip

You can use the `AWSSupport-MigrateXenToNitroLinux` runbook to migrate compatible instances from a Xen instance type to a Nitro instance type. For more information, see [AWSSupport-MigrateXenToNitroLinux runbook](#) in the AWS Systems Manager Automation runbook reference.

Compatibility is determined in the following ways:

Virtualization type

Linux AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). If an instance was launched from a PV AMI, you can't change to an instance type that is HVM only. For more information, see [Linux AMI virtualization types](#). To check the virtualization type of your instance, check the **Virtualization** value on the details pane of the **Instances** screen in the Amazon EC2 console.

Architecture

AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:

- If the current instance type has a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
- The following instance types are the only instance types that support 32-bit AMIs: t2.nano, t2.micro, t2.small, t2.medium, c3.large, t1.micro, m1.small, m1.medium, and c1.medium. If you are changing the instance type of a 32-bit instance, you are limited to these instance types.

Network cards

Some instance types support multiple [network cards](#). You must select an instance type that supports the same number of network cards as the current instance type.

Enhanced networking

Instance types that support [enhanced networking](#) require the necessary drivers installed. For example, [instances built on the AWS Nitro System](#) require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To change from an instance type that does not support enhanced networking to an instance type that supports enhanced networking, you must install the [ENA drivers](#) or [ixgbevf drivers](#) on the instance, as appropriate.

Note

When you resize an instance with ENA Express enabled, the new instance type must also support ENA Express. For a list of instance types that support ENA Express, see [Supported instance types for ENA Express](#).

To change from an instance type that supports ENA Express to an instance type that does not support it, ensure that ENA Express is not currently enabled before you resize the instance.

NVMe

EBS volumes are exposed as NVMe block devices on [instances built on the AWS Nitro System](#). If you change from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the NVMe drivers on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (`/dev/nvme[0-26]n1`). Therefore, to mount file systems at boot time using `/etc/fstab`, you must use UUID/Label instead of device names.

Volumes limits

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits](#).

You can only change to an instance type or instance size that supports the same number or a larger number of volumes than is currently attached to the instance. If you change to an instance type or instance size that does not support the number of currently attached volumes, the request fails. For example, if you change from an `m7i.4xlarge` instance with 32 attached volumes to an `m6i.4xlarge`, which supports a maximum of 27 volumes, the request fails.

Troubleshoot changing the instance type

Use the following information to help diagnose and fix issues that you might encounter when changing the instance type.

Instance won't start after changing instance type

Possible cause: Requirements for new instance type not met

If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see [Why is my Linux instance not booting after I changed its type?](#)

Possible cause: AMI does not support instance type

If you use the EC2 console to change the instance type, only the instance types that are supported by the selected AMI are available. However, if you use the AWS CLI to launch an instance, you can specify an incompatible AMI and instance type. If the AMI and instance type are incompatible, the instance can't start. For more information, see [Compatibility for changing the instance type](#).

Possible cause: Instance is in cluster placement group

If your instance is in a [cluster placement group](#) and, after changing the instance type, the instance fails to start, try the following:

1. Stop all the instances in the cluster placement group.
2. Change the instance type of the affected instance.
3. Start all the instances in the cluster placement group.

Application or website not reachable from the internet after changing instance type

Possible cause: Public IPv4 address is released

When you change the instance type, you must first stop the instance. When you stop an instance, we release the public IPv4 address and give your instance a new public IPv4 address.

To retain the public IPv4 address between instance stops and starts, we recommend that you use an Elastic IP address, at no extra cost provided your instance is running. For more information, see [Elastic IP addresses](#).

Change the instance type of an instance store-backed instance

An instance store-backed instance is an instance that has an instance store root volume. You can't change the instance type of an instance that has an instance store root volume. Instead, you must create an AMI from your instance, launch a new instance from this AMI and select the instance type that you want, and then migrate your application to the new instance. Note that the instance type that you want must be compatible with the AMI you create. For information about how compatibility is determined, see [Compatibility for changing the instance type](#).

To migrate your application to a new instance, do the following:

- Back up the data on your original instance.
- Create an AMI from your original instance.
- Launch a new instance from this AMI and select the instance type that you want.
- Install your application on the new instance.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see [Elastic IP address](#).

To change the instance type of an instance store-backed instance

1. Back up data that you need to keep, as follows:
 - For data on your instance store volumes, back up the data to persistent storage.
 - For data on your EBS volumes, create a snapshot of the volumes or detach the volume from the instance so that you can attach it to the new instance later.
2. Create an AMI from your instance by satisfying the prerequisites and following the procedures in [Create an instance store-backed Linux AMI](#). When you are finished creating an AMI from your instance, return to this procedure.
3. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
4. In the navigation pane, choose **AMIs**. From the filter lists, choose **Owned by me**, and select the image that you created in Step 2. Notice that **AMI name** is the name that you specified when you registered the image and **Source** is your Amazon S3 bucket.

Note

If you do not see the AMI that you created in Step 2, make sure that you have selected the Region in which you created your AMI.

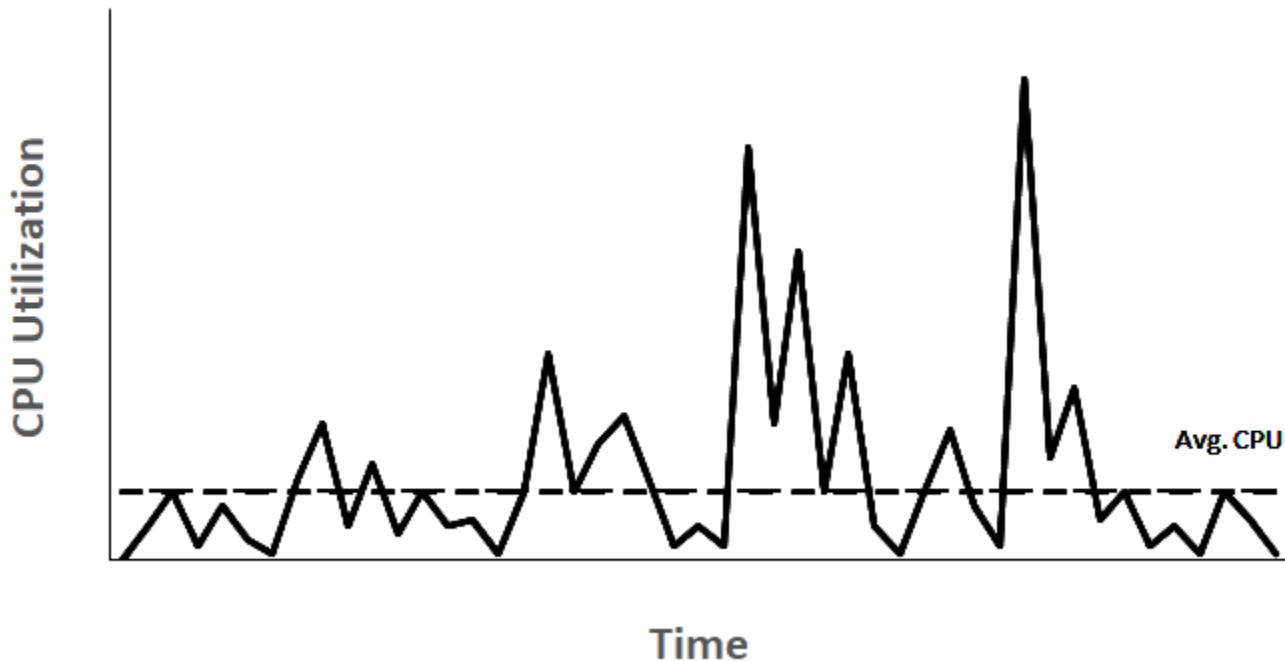

5. With the AMI selected, choose **Launch instance from image**. When you configure the instance, do the following:
 - a. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you created. For more information, see [Compatibility for changing the instance type](#).
 - b. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.
 - c. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
 - d. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.
6. If required, attach any new EBS volumes based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.
7. Install your application and any required software on the new instance.
8. If you are using an Elastic IP address, assign it to the new instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
 - c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.
 - d. For **Resource type**, choose **Instance**.
 - e. For **Instance**, choose the new instance with which to associate the Elastic IP address.
 - f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
 - g. Choose **Associate**.

9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.

Burstable performance instances

Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.

Many common workloads look like this

These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute,

memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory. The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

 **Note**

This topic describes burstable CPU. For information about burstable network performance, see [Amazon EC2 instance network bandwidth](#).

EC2 burstable instance types

The EC2 burstable instances consist of T4g, T3a and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based [AWS Graviton2](#) processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

Type	Description	Processor family
Latest generation		
T4g	Lowest cost EC2 instance type with up to 40% higher price/ performance and 20% lower costs vs T3	AWS Graviton2 processors with Arm Neoverse N1 cores
T3a	Lowest cost x86-based instances with 10% lower costs vs T3 instances	AMD 1st gen EPYC processors

Type	Description	Processor family
T3	Best peak price/performance for x86 workloads with up to 30% lower price/performance vs previous generation T2 instances	Intel Xeon Scalable (Skylake, Cascade Lake processors)
Previous generation		
T2	Previous generation burstable instances	Intel Xeon processors

For information about instance pricing and additional specifications, see [Amazon EC2 Pricing](#) and [Amazon EC2 Instance Types](#). For information about burstable network performance, see [Amazon EC2 instance network bandwidth](#).

If your account is less than 12 months old, you can use a t2.micro instance for free (or a t3.micro instance in Regions where t2.micro is unavailable) within certain usage limits. For more information, see [AWS Free Tier](#).

Supported purchasing options for T instances

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Dedicated Hosts (T3 only, in standard mode only)
- Spot Instances

For more information, see [Instance purchasing options](#).

Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a `t3.micro` or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.
- Enable [AWS Compute Optimizer](#) for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be upsized to improve performance or downsized for cost savings. Compute Optimizer may also recommend a different instance type based on your scenario. For more information, see [Viewing EC2 instance recommendations](#) in the *AWS Compute Optimizer User Guide*.

Key concepts and definitions for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credits when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

- If the CPU utilization is below baseline, then credits earned are greater than credits spent.
- If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
- If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, then the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.

In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a [flat additional rate](#) per vCPU-hour.

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per

instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see [Get statistics for a specific instance](#).

CPU credit

A unit of vCPU-time.

Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.

1 CPU credit = 1 vCPU * 50% utilization * 2 minutes

1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes.

For the baseline utilization of each burstable performance instance type, see the [credit table](#).

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:

If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = 6 – 2 vCPUs * 2% CPU utilization * 60 minutes = 6 – 2.4 = 3.6 accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.

Example:

For t3.nano, the credit accrual limit = 24 * 6 = 144 credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or

below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a [flat additional rate](#) per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
Latest generation			
T4g	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3a	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
Previous generation			
T2	Earned credits, Accrued credits, Spent credits, Launch credits (Standard mode only), Surplus	Standard (default), Unlimited	0 days (credits are lost when an instance stops)

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
	credits (Unlimited mode only)		

 **Note**

Unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don't have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a t3.large instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see [Baseline utilization](#).

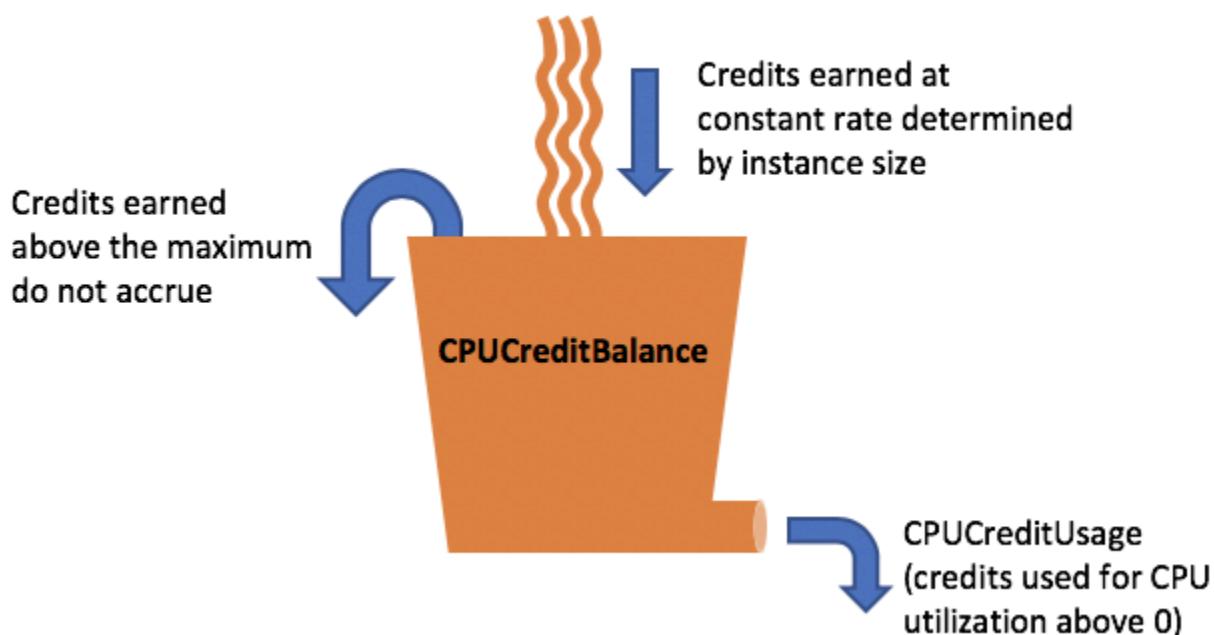

*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 and T4g instances.

CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a t3.nano earns six credits per hour, while a t3.small earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.

CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned credits that exceed the limit.

The CPU credit balance limit differs for each instance size. For example, a t3.micro instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see [Launch credits](#).

T4g, T3a and T3 instances do not earn launch credits. These instances launch as unlimited by default, and therefore can burst immediately upon start without any launch credits. T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.

Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T4g, T3a and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see `CPUCreditBalance` in the [CloudWatch metrics table](#).

Baseline utilization

The *baseline utilization* is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as *the baseline*.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

$$(\text{number of credits earned}/\text{number of vCPUs})/60 \text{ minutes} = \% \text{ baseline utilization}$$

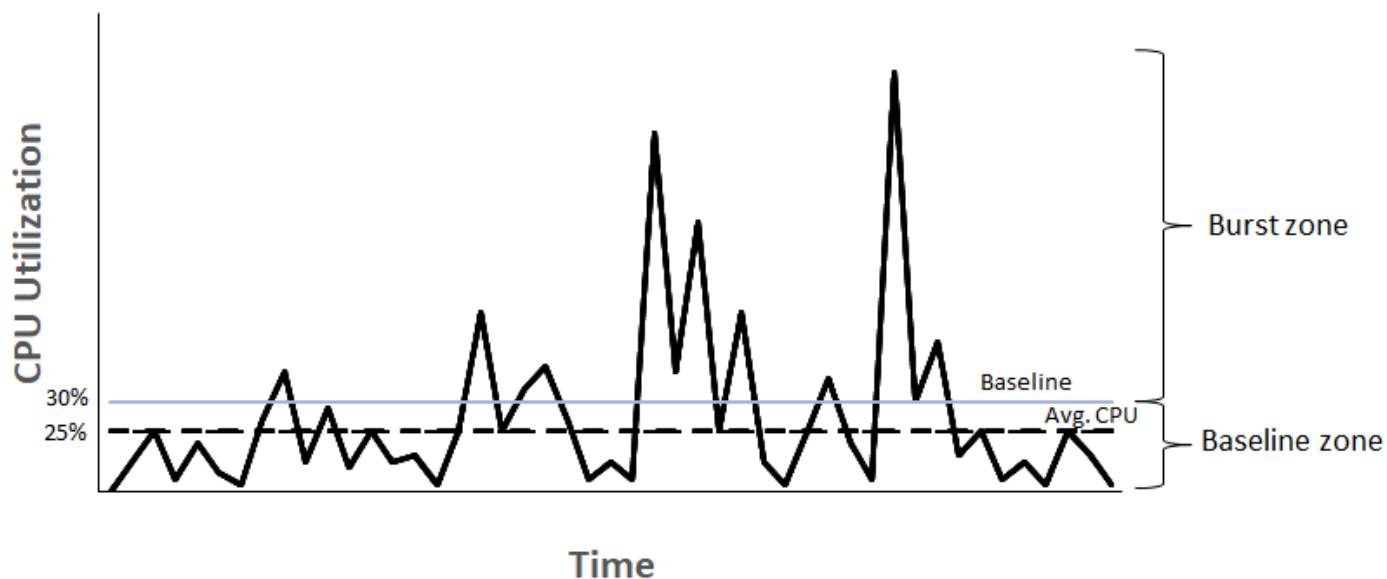

For example, a t3.nano instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5% , which is calculated as follows:

$$(6 \text{ credits earned}/2 \text{ vCPUs})/60 \text{ minutes} = 5\% \text{ baseline utilization}$$

A t3.large instance, with 2 vCPUs, earns 36 credits per hour, resulting in a baseline utilization of 30% $((36/2)/60)$.

The following graph provides an example of a t3.large with an average CPU utilization below the baseline.

Example of t3.large

Unlimited mode for burstable performance instances

A burstable performance instance configured as unlimited can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as unlimited provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see [Amazon EC2 pricing](#) and [T2/T3/T4 Unlimited Mode Pricing](#).

If you use a `t2.micro` or `t3.micro` instance under the [AWS Free Tier](#) offer and use it in unlimited mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the [baseline utilization](#) of the instance.

T4g, T3a and T3 instances launch as unlimited by default (unless you [change the default](#)). If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as unlimited and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in [standard](#) mode to avoid paying higher costs. For more information, see [Surplus credits can incur charges](#) and [Burstable performance instances](#).

Note

T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.

Unlimited mode concepts

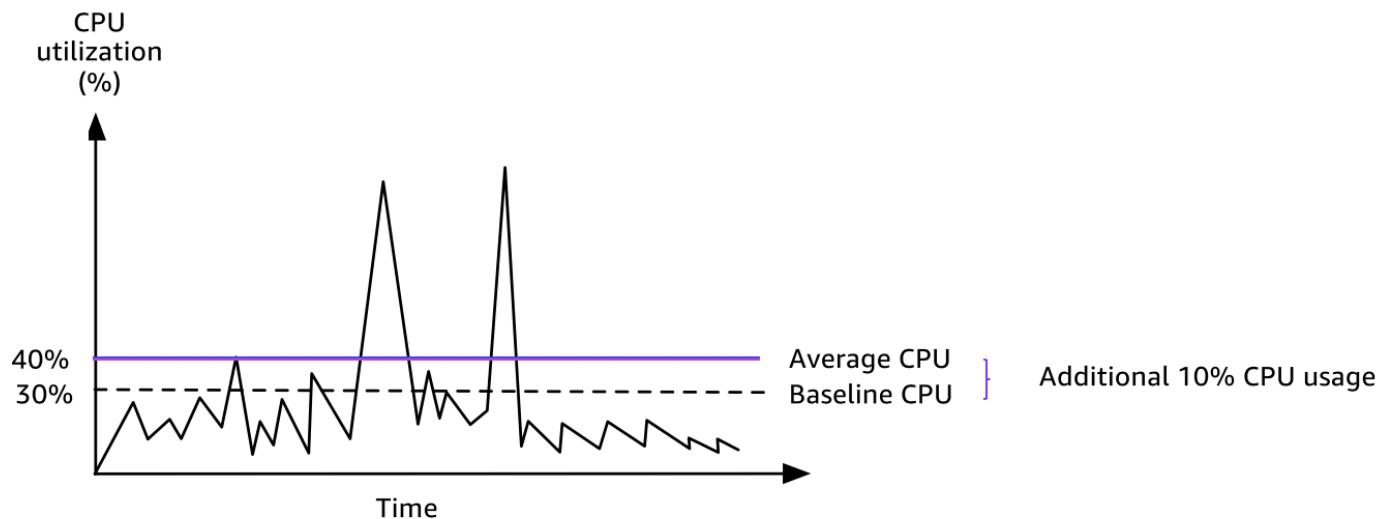

The unlimited mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can [set unlimited as the default credit option](#) at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How Unlimited burstable performance instances work

If a burstable performance instance configured as unlimited depletes its CPU credit balance, it can spend *surplus* credits to burst beyond the [baseline](#). When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour

period exceeds the baseline, the instance is billed for the additional usage at a [flat additional rate](#) per vCPU-hour.

The following graph shows the CPU usage of a t3.large. The baseline CPU utilization for a t3.large is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a [flat additional rate](#) per vCPU-hour.

For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the [credit table](#).

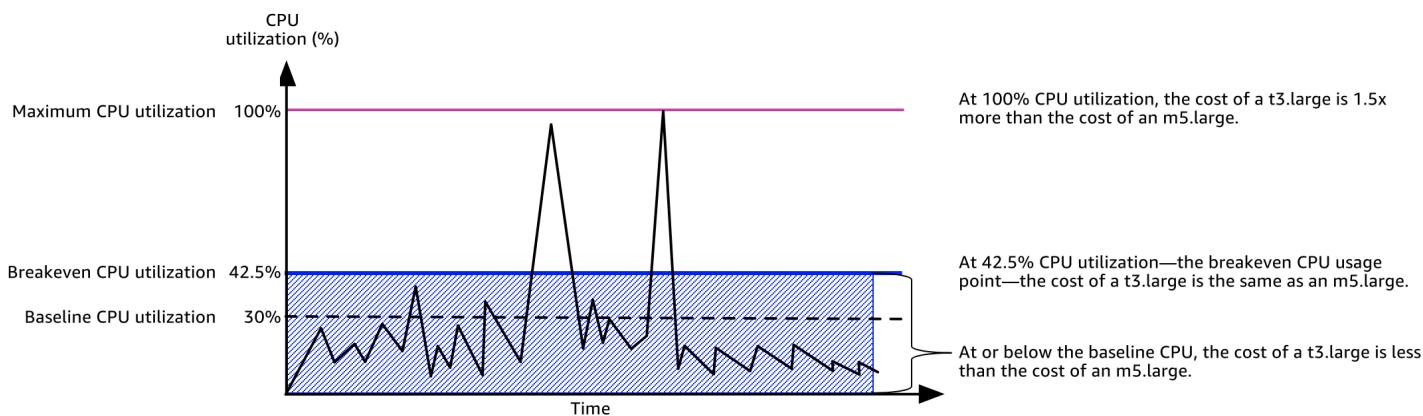

When to use unlimited mode versus fixed CPU

When determining whether you should use a burstable performance instance in unlimited mode, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:

- If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a burstable performance instance in unlimited mode so that you can benefit from the lower price of a burstable performance instance while getting the same performance as a fixed performance instance.

- If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable performance instance will cost more than the equivalently-sized fixed performance instance. If a T3 instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a t3.large costs the same as an m5.large. The breakeven CPU usage point for a t3.large is 42.5%. If the average CPU usage is at 42.5%, the cost of running the t3.large is the same as an m5.large, and is more expensive if the average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can benefit from the lower price of the t3.large while getting the same performance as an m5.large.

The following table shows how to calculate the breakeven CPU usage threshold so that you can determine when it's less expensive to use a burstable performance instance in unlimited mode or a fixed performance instance. The columns in the table are labeled A through K.

Instance type	vCPUs	T3 price*/hour	M5 price*/hour	Price difference	T3 utilization on vCPU per vCPU	Charge per minute available	Charge per minute available	Addition I = E / 60	Addition J = (I / F) / 60	Breakeven CPU %
A	B	C	D	E = D - C	F	G	H = G / 60	I = E / H	J = (I / F) / 60	K = F + J

Instance type	vCPUs	T3 price*/hour	M5 price*/hour	Price difference	T3 baseline utilization	Charge per vCPU on	Charge per vCPU hour	Charge per minute	Additional burst minutes available	Additional CPU % available	Break-even CPU %
t3.large	2	\$0.0835	\$0.096	\$0.0125	30%	\$0.05	\$0.00083:	15	12.5%	42.5%	60) / B

* Price is based on us-east-1 and Linux OS.

The table provides the following information:

- Column A shows the instance type, t3.large.
- Column B shows the number of vCPUs for the t3.large.
- Column C shows the price of a t3.large per hour.
- Column D shows the price of an m5.large per hour.
- Column E shows the price difference between the t3.large and the m5.large.
- Column F shows the baseline utilization per vCPU of the t3.large, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.
- Column G shows the [flat additional rate](#) per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column H shows the [flat additional rate](#) per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column I shows the number of additional minutes that the t3.large can burst per hour at 100% CPU while paying the same price per hour as an m5.large.
- Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an m5.large.

- Column K shows the breakeven CPU usage (in %) that the t3.large can burst without paying more than the m5.large. Anything above this, and the t3.large costs more than the m5.large.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

T3 instance type	Breakeven CPU usage (in %) for T3 compared to M5
t3.large	42.5%
t3.xlarge	52.5%
t3.2xlarge	52.5%

Surplus credits can incur charges

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a [maximum number of credits](#) in a 24-hour period (for example, a t3.micro instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see [T2/T3/T4g Unlimited Mode Pricing](#).

Surplus credits that were spent earlier are charged when any of the following occurs:

- The spent surplus credits exceed the [maximum number of credits](#) the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.
- The instance is stopped or terminated.
- The instance is switched from unlimited to standard.

Spent surplus credits are tracked by the CloudWatch metric `CPUSurplusCreditBalance`. Surplus credits that are charged are tracked by the CloudWatch metric `CPUSurplusCreditsCharged`. For more information, see [Additional CloudWatch metrics for burstable performance instances](#).

No launch credits for T2 Unlimited instances

T2 Standard instances receive [launch credits](#), but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.

If a T2 instance is switched from standard to unlimited, any accrued launch credits are removed from the `CPUCreditBalance` before the remaining `CPUCreditBalance` is carried over.

T4g, T3a and T3 instances never receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Enable unlimited mode

You can switch from unlimited to standard, and from standard to unlimited, at any time on a running or stopped instance. For more information, see [Launch a burstable performance instance as Unlimited or Standard](#) and [Modify the credit specification of a burstable performance instance](#).

You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see [Set the default credit specification for the account](#).

You can check whether your burstable performance instance is configured as unlimited or standard using the Amazon EC2 console or the AWS CLI. For more information, see [View the credit specification of a burstable performance instance](#) and [View the default credit specification](#).

What happens to credits when switching between Unlimited and Standard

`CPUCreditBalance` is a CloudWatch metric that tracks the number of credits accrued by an instance. `CPUSurplusCreditBalance` is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as unlimited to standard, the following occurs:

- The CPUCreditBalance value remains unchanged and is carried over.
- The CPUSurplusCreditBalance value is immediately charged.

When a standard instance is switched to unlimited, the following occurs:

- The CPUCreditBalance value containing accrued earned credits is carried over.
- For T2 Standard instances, any launch credits are removed from the CPUCreditBalance value, and the remaining CPUCreditBalance value containing accrued earned credits is carried over.

Monitor credit usage

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see [Monitor your CPU credits for burstable performance instances](#).

Unlimited mode examples

The following examples explain credit use for instances that are configured as unlimited.

Examples

- [Example 1: Explain credit use with T3 Unlimited](#)
- [Example 2: Explain credit use with T2 Unlimited](#)

Example 1: Explain credit use with T3 Unlimited

In this example, you see the CPU utilization of a t3.nano instance launched as unlimited, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A t3.nano instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a t3.nano instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as unlimited and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits.

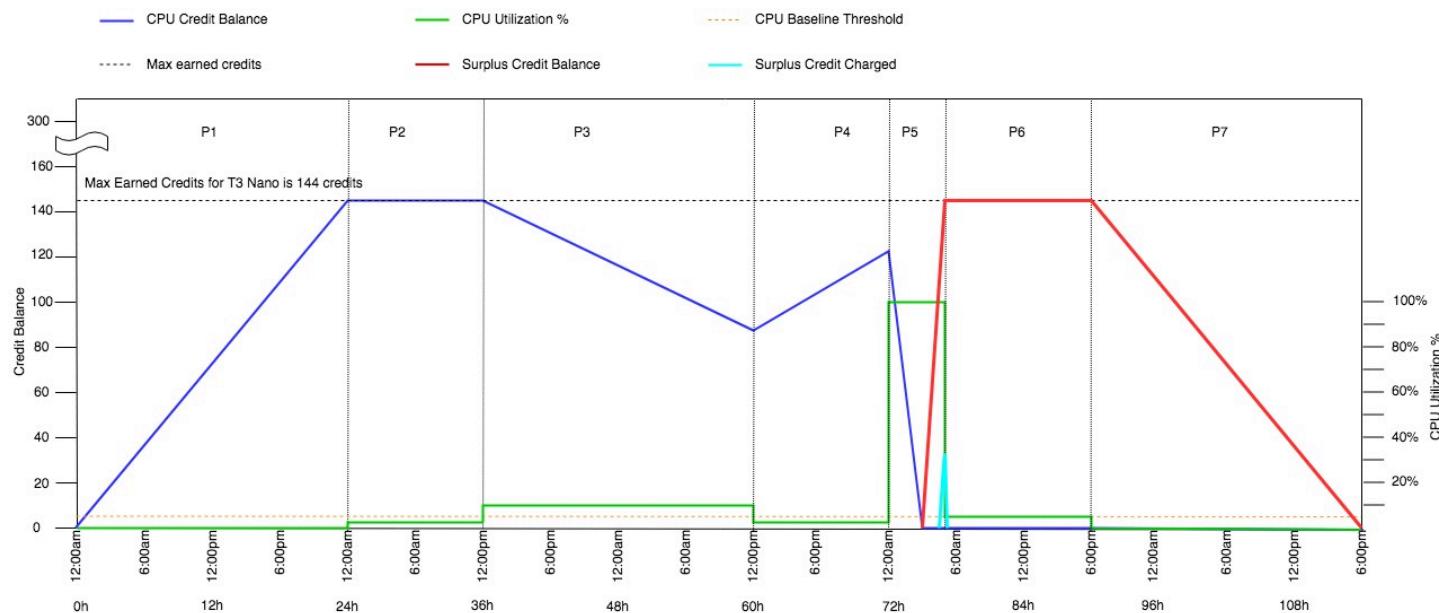

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire CPUCreditBalance of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period ($570 - 122 = 448$). When the CPUSurplusCreditBalance value reaches 144 CPU credits (the maximum a t3.nano instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits ($448 - 144 = 304$), which results in a small additional charge at the end of the hour for 304 credits.

P6 – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the CPUSurplusCreditBalance. The CPUSurplusCreditBalance value remains at 144 credits.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the CPUSurplusCreditBalance.

Example 2: Explain credit use with T2 Unlimited

In this example, you see the CPU utilization of a t2.nano instance launched as `unlimited`, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A t2.nano instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric `CPUCreditBalance`), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a t2.nano instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

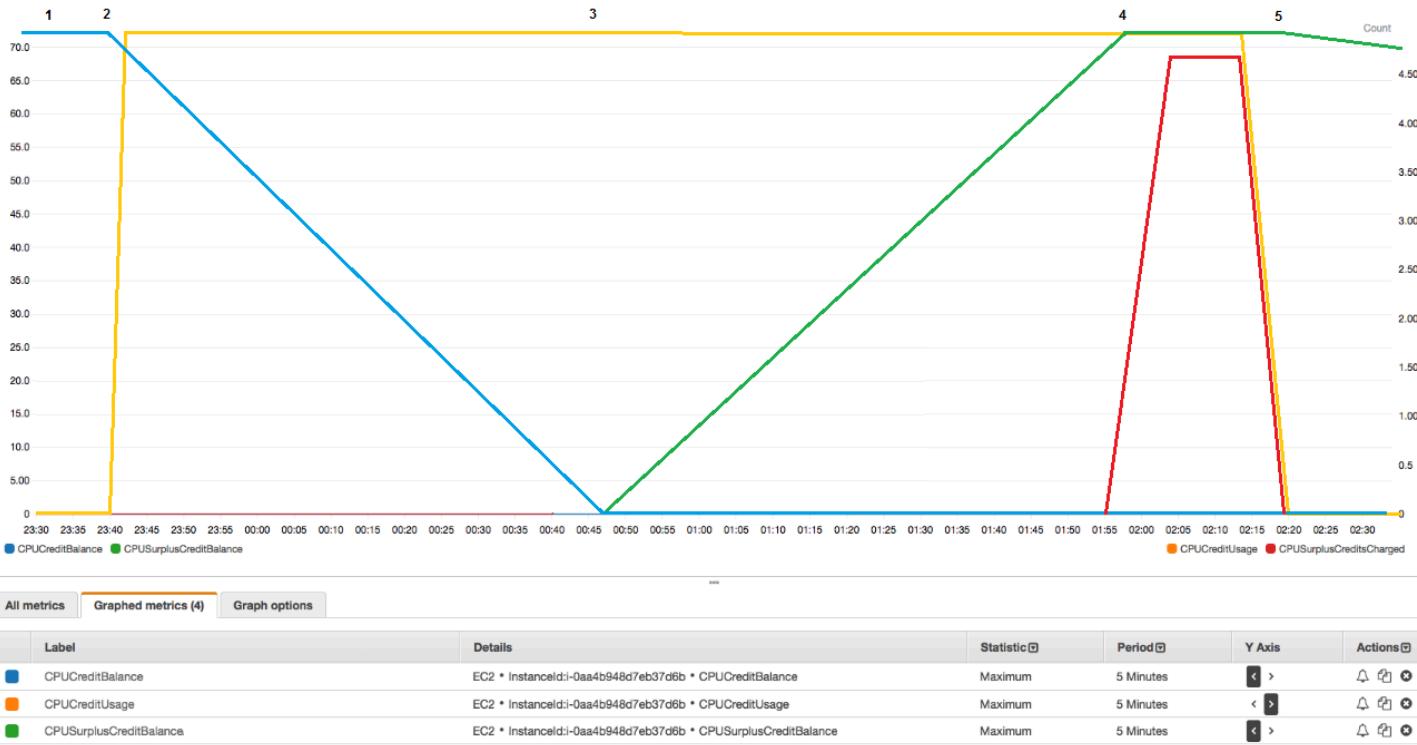

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its `CPUCreditBalance`. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

- 1** – In the first 10 minutes, `CPUCreditUsage` is at 0, and the `CPUCreditBalance` value remains at its maximum of 72.
- 2** – At 23:40, as CPU utilization increases, the instance spends CPU credits and the `CPUCreditBalance` value decreases.

3 – At around 00:47, the instance depletes its entire CPUCreditBalance, and starts to spend surplus credits to sustain high CPU utilization.

4 – Surplus credits are spent until 01:55, when the CPUSurplusCreditBalance value reaches 72 CPU credits. This is equal to the maximum a t2.nano instance can earn in a 24-hour period. Any surplus credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.

5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the CPUSurplusCreditBalance. After the CPUSurplusCreditBalance value reduces to 0, the instance starts to accrue earned credits in its CPUCreditBalance at 0.25 credits every 5 minutes.

Calculating the bill

Surplus credits cost \$0.05 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours.

Additional charges for this instance are $0.42 \text{ vCPU-hours} \times \$0.05/\text{vCPU-hour} = \0.021 , rounded to \$0.02.

Here is the month-end bill for this T2 Unlimited instance:

Amazon Elastic Compute Cloud running Linux/UNIX		720.000 Hrs	\$4.18
\$0.0058 per On Demand Linux t2.nano Instance Hour			
Amazon Elastic Compute Cloud T2 CPU Credits		0.420 vCPU-Hours	\$0.02
\$0.05 per vCPU-Hour of T2 CPU credits			

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

Standard mode for burstable performance instances

A burstable performance instance configured as standard is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see [Key concepts and definitions for burstable performance instances](#).

Standard mode concepts

The standard mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can [set standard as the default credit option](#) at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How standard burstable performance instances work

When a burstable performance instance configured as standard is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T4g, T3a and T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of [CPU credits](#): *earned credits* and *launch credits*. When a T2 Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore, to provide a good startup experience, it receives launch credits at start, which it spends first while it accrues earned credits.

T4g, T3a and T3 instances do not receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start, and T1 Standard instances get 15 launch credits. For example, a t2.micro instance has one vCPU and gets 30 launch credits, while a t2.xlarge instance has four vCPUs and gets 120 launch credits. Launch credits are designed to provide a good startup experience to allow instances to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU credit balance, but do not count towards the CPU credit balance limit. For example, a t2.micro

instance has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours, its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit. However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more information about the CPU credit balance limit for each instance size, see the [credit table](#).

The following table lists the initial CPU credit allocation received at launch or start, and the number of vCPUs.

Instance type	Launch credits	vCPUs
t1.micro	15	1
t2.nano	30	1
t2.micro	30	1
t2.small	30	1
t2.medium	60	2
t2.large	60	2
t2.xlarge	120	4
t2.2xlarge	240	8

Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. For example, the limit is reached when one instance is stopped and started 100 times within a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your usage.

Tip

To ensure that your workloads always get the performance they need, switch to [Unlimited mode for burstable performance instances](#) or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

	Launch credits	Earned credits
Credit earn rate	T2 Standard instances get 30 launch credits per vCPU at launch or start. If a T2 instance is switched from unlimited to standard, it does not get launch credits at the time of switching.	Each T2 instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. For more information about the number of CPU credits earned per instance size, see the credit table .
Credit earn limit	The limit for receiving launch credits is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. New accounts may have a lower limit, which increases over time based on your usage.	A T2 instance cannot accrue more credits than the CPU credit balance limit. If the CPU credit balance has reached its limit, any credits that are earned after the limit is reached are discarded. Launch credits do not count towards the limit. For more information about the CPU credit balance limit for each T2 instance size, see the credit table .
Credit use	Launch credits are spent first, before earned credits.	Earned credits are spent only after all launch credits are spent.
Credit expiration	When a T2 Standard instance is running, launch credits do not expire. When a T2 Standard instance stops or	When a T2 instance is running, earned credits that have accrued do not expire. When the T2 instance stops, all accrued earned credits are lost.

	Launch credits	Earned credits
	is switched to T2 Unlimited, all launch credits are lost.	

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric CPUCreditBalance. For more information, see CPUCreditBalance in the [CloudWatch metrics table](#).

Standard mode examples

The following examples explain credit use when instances are configured as standard.

Examples

- [Example 1: Explain credit use with T3 Standard](#)
- [Example 2: Explain credit use with T2 Standard](#)

Example 1: Explain credit use with T3 Standard

In this example, you see how a t3.nano instance launched as standard earns, accrues, and spends *earned* credits. You see how the credit balance reflects the accrued *earned* credits.

A running t3.nano instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table](#).

You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance reaches its limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as standard and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

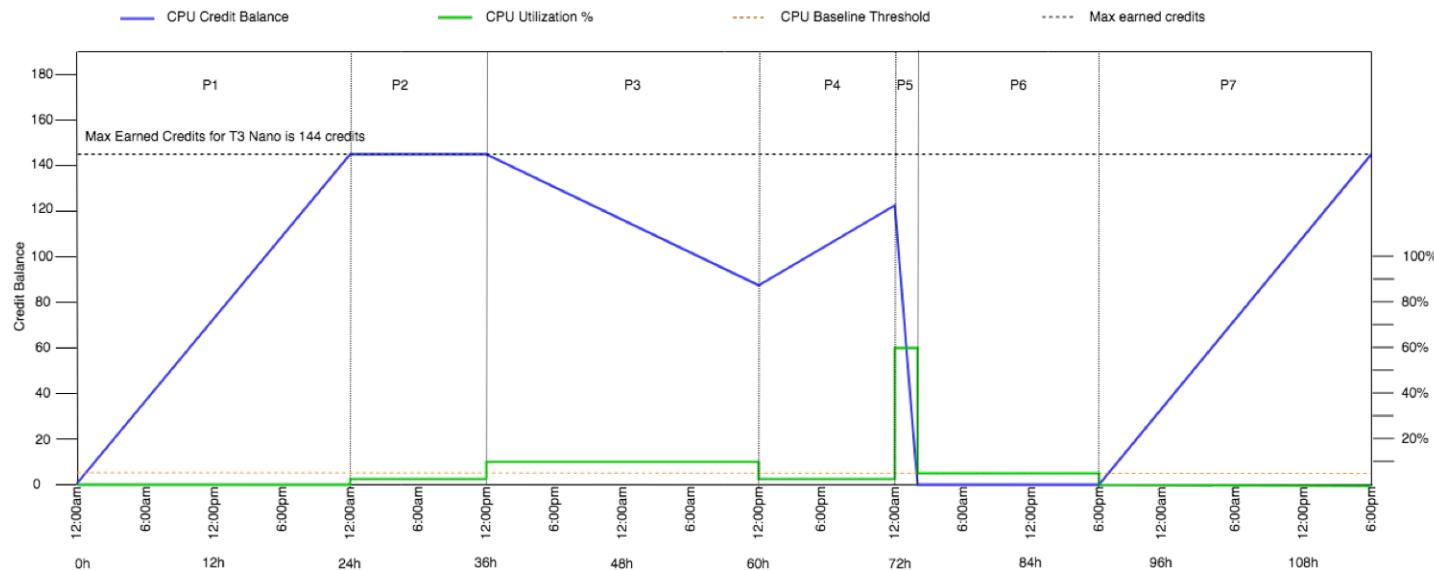

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next two hours, the instance bursts at 60% CPU utilization, and depletes its entire CPUCreditBalance value of 122 credits. At the end of this period, with the CPUCreditBalance at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

P6 – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The CPUCreditBalance value remains at 0.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its CPUCreditBalance.

Example 2: Explain credit use with T2 Standard

In this example, you see how a `t2.nano` instance launched as standard earns, accrues, and spends *launch* and *earned* credits. You see how the credit balance reflects not only accrued *earned* credits, but also accrued *launch* credits.

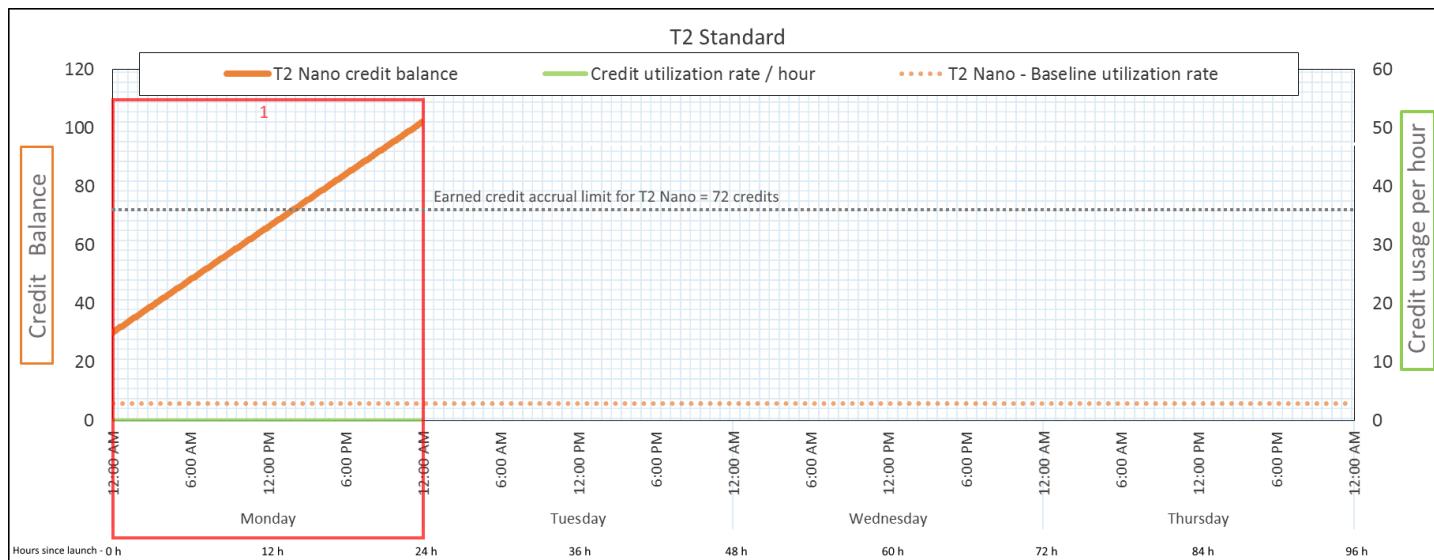

A `t2.nano` instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table](#). For more information about limits, see [Launch credit limits](#).

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

Period 1: 1 – 24 hours

At 0 hours on the graph, the T2 instance is launched as standard and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	0 credits per 24 hours
Credit Balance	102 credits (30 launch credits + 72 earned credits)

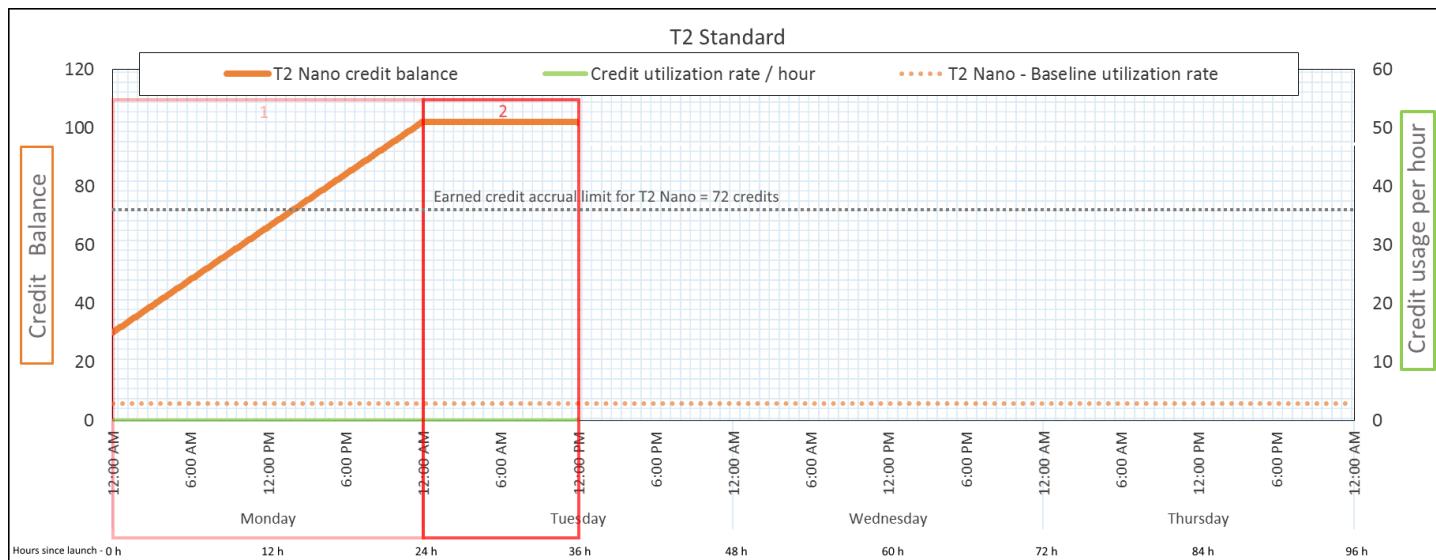

Conclusion

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.

Period 2: 25 – 36 hours

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.

Credit Spend Rate

0 credits per 24 hours (0% CPU utilization)

Credit Earn Rate

72 credits per 24 hours (3 credits per hour)

Credit Discard Rate

72 credits per 24 hours (100% of credit earn rate)

Credit Balance

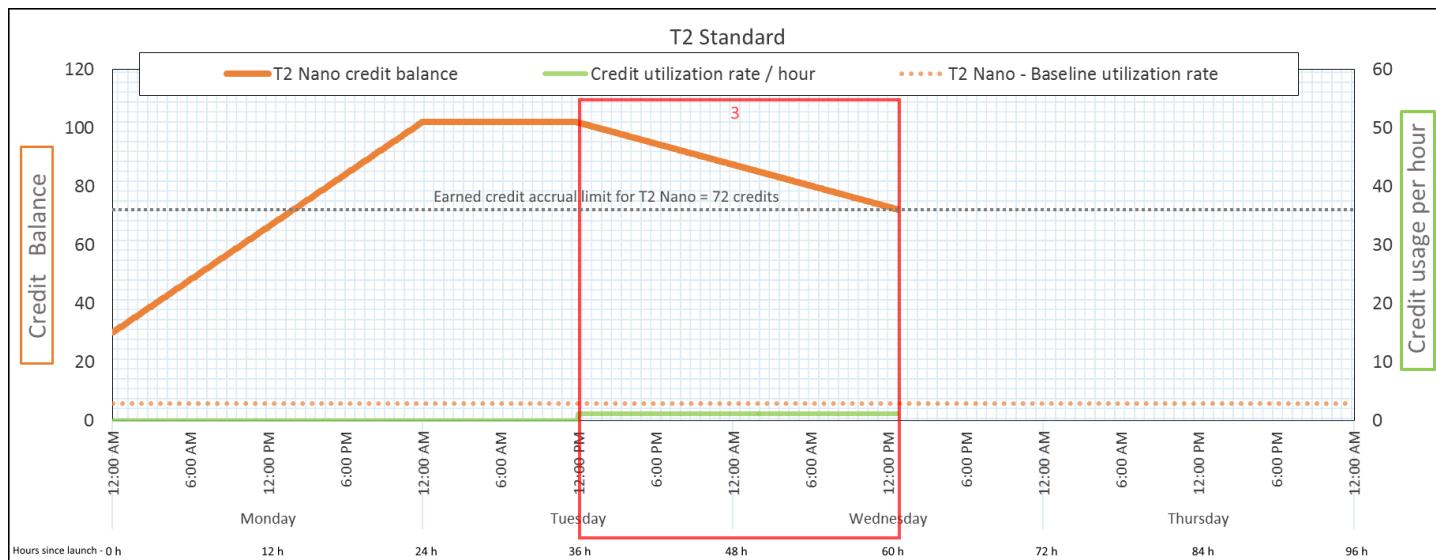

102 credits (30 launch credits + 72 earned credits)—balance is unchanged

Conclusion

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.

Period 3: 37 – 61 hours

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued *launch* credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.

Credit Spend Rate

28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours

Credit Earn Rate

72 credits per 24 hours

Credit Discard Rate

72 credits per 24 hours (100% of credit earn rate)

Credit Balance

72 credits (30 launch credits were spent; 72 earned credits remain unspent)

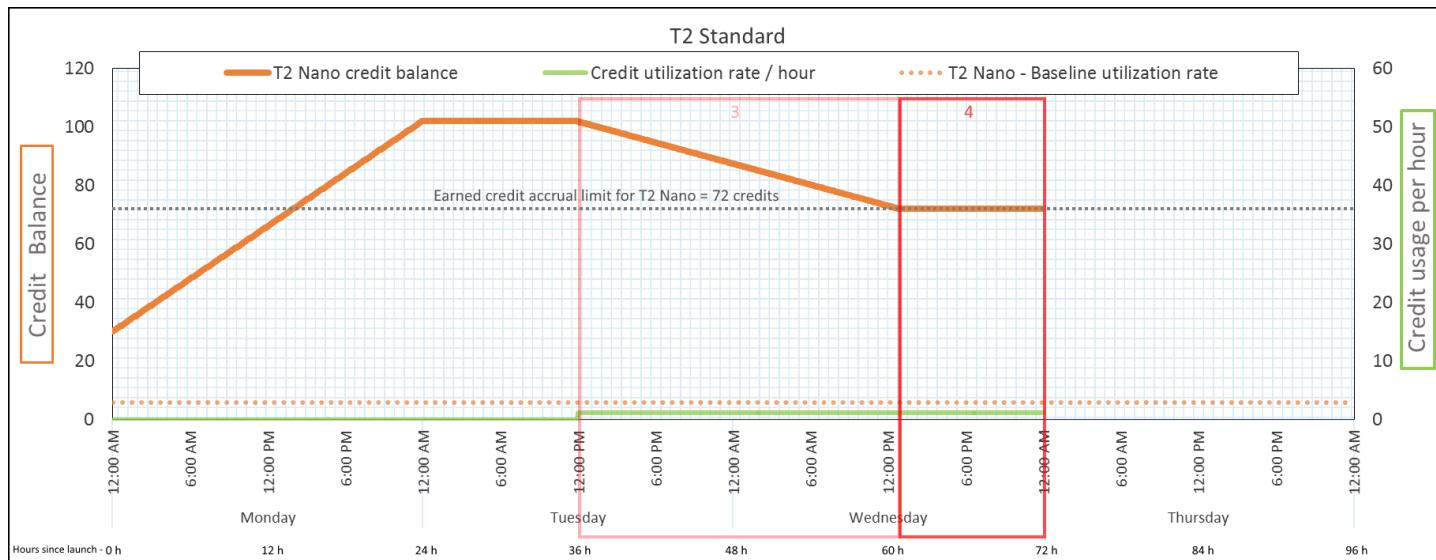

Conclusion

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.

Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.

Credit Spend Rate

28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—
13.2 credits over 11 hours

Credit Earn Rate

72 credits per 24 hours

Credit Discard Rate

43.2 credits per 24 hours (60% of credit earn rate)

Credit Balance

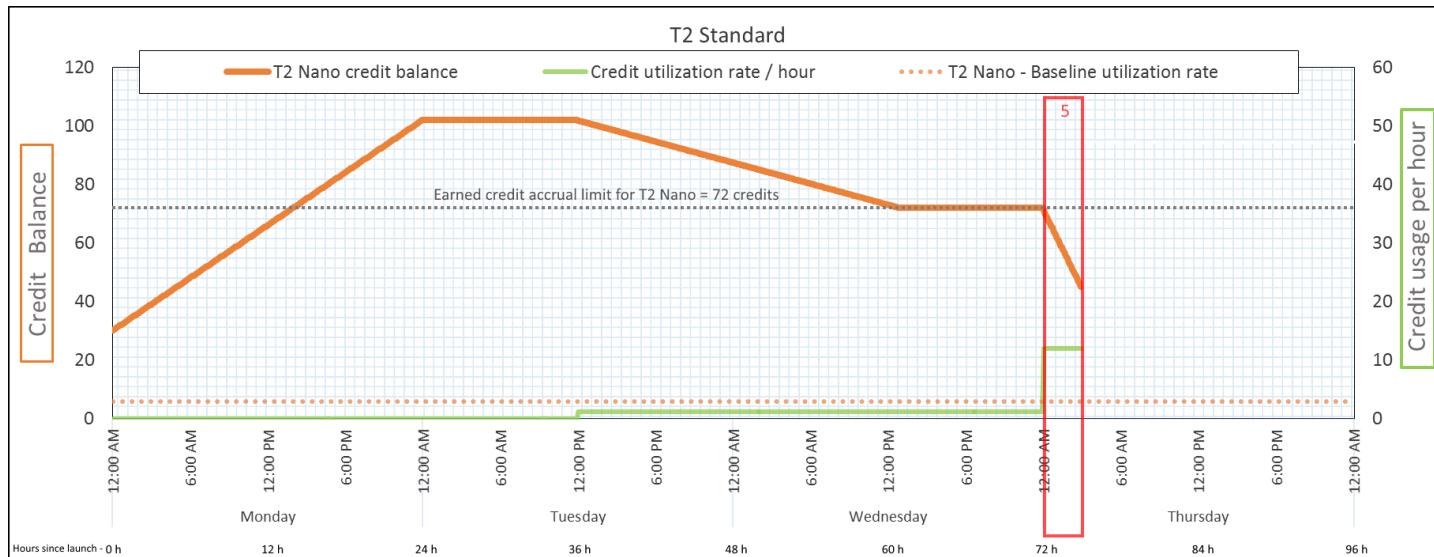

72 credits (0 launch credits, 72 earned credits)
—balance is at its limit

Conclusion

After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

Period 5: 73 – 75 hours

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.

Credit Spend Rate

288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate)—36 credits over 3 hours

Credit Earn Rate	72 credits per 24 hours (9 credits over 3 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)

Conclusion

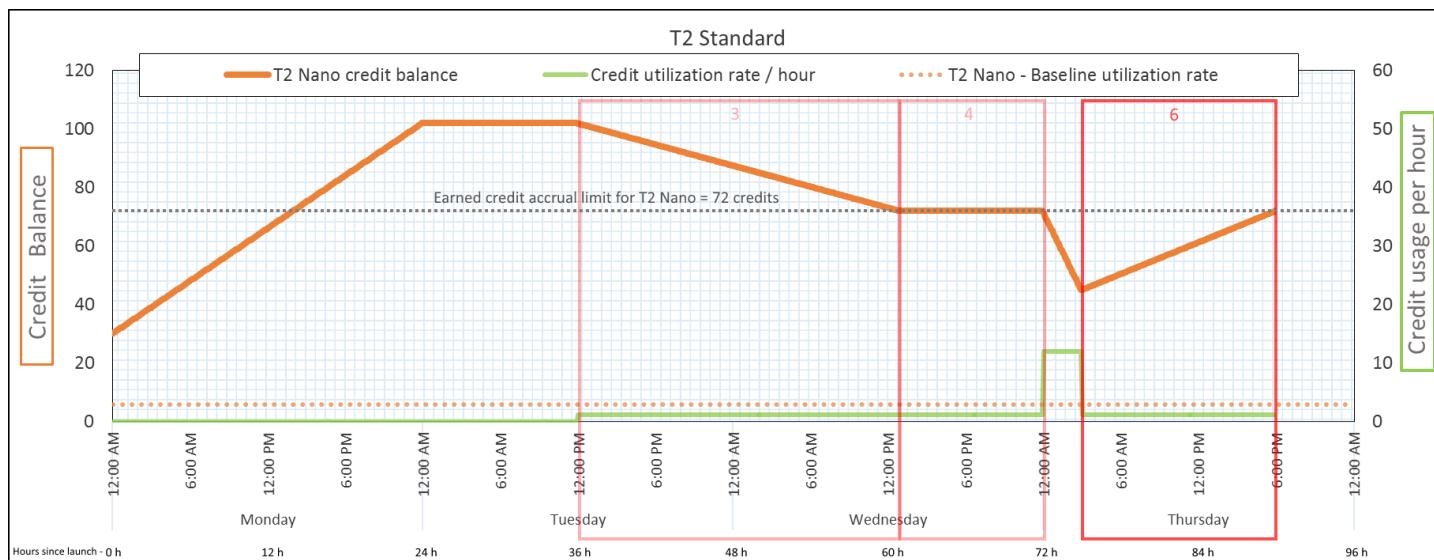

If an instance spends more credits than it earns, its credit balance decreases.

Period 6: 76 – 90 hours

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.

Credit Spend Rate

28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours

Credit Earn Rate

72 credits per 24 hours (45 credits over 15 hours)

Credit Discard Rate

0 credits per 24 hours

Credit Balance	72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate $28.8/24 + \text{earn rate } 72/24$)
----------------	-------------------------------------------------------------------------------------------------------------------------------------

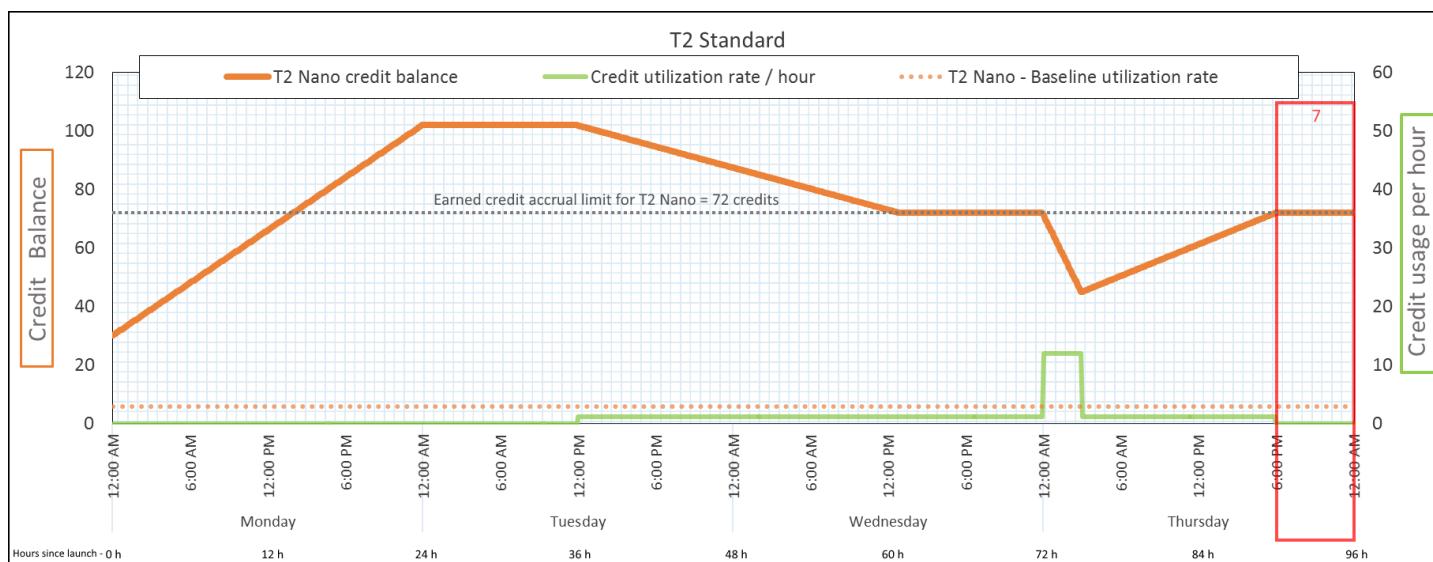

Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)

Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the [credit table](#).

Work with burstable performance instances

The steps for launching, monitoring, and modifying burstable performance instances (T instances) are similar. The key difference is the default credit specification when they launch.

Each T instance family comes with the following *default credit specification*:

- T4g, T3a and T3 instances launch as unlimited
- T3 instances on a Dedicated Host can only launch as standard
- T2 instances launch as standard

You can [change the default credit specification](#) for the account.

Contents

- [Launch a burstable performance instance as Unlimited or Standard](#)
- [Use an Auto Scaling group to launch a burstable performance instance as Unlimited](#)
- [View the credit specification of a burstable performance instance](#)
- [Modify the credit specification of a burstable performance instance](#)
- [Set the default credit specification for the account](#)
- [View the default credit specification](#)

Launch a burstable performance instance as Unlimited or Standard

You can launch your T instances as unlimited or standard using the Amazon EC2 console, an AWS SDK, a command line tool, or with an Auto Scaling group.

The following procedures describe how to use the EC2 console or the AWS CLI. For information about using an Auto Scaling group, see [Use an Auto Scaling group to launch a burstable performance instance as Unlimited](#).

Console

To launch a T instance as Unlimited or Standard

1. Follow the procedure to [launch an instance](#).
2. Under **Instance type**, select a T instance type.
3. Expand **Advanced details**, and for **Credit specification**, select a credit specification. If you do not make a selection, the default is used, which is standard for T2, and unlimited for T4g, T3a and T3.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

AWS CLI

To launch a T instance as Unlimited or Standard

Use the [run-instances](#) command to launch your instances. Specify the credit specification using the `--credit-specification CpuCredits=` parameter. Valid credit specifications are `unlimited` and `standard`.

- For T4g, T3a and T3, if you do not include the `--credit-specification` parameter, the instance launches as unlimited by default.
- For T2, if you do not include the `--credit-specification` parameter, the instance launches as standard by default.

```
aws ec2 run-instances \
  --image-id ami-abc12345 \
  --count 1 \
  --instance-type t3.micro \
  --key-name MyKeyPair \
  --credit-specification "CpuCredits=unlimited"
```

Use an Auto Scaling group to launch a burstable performance instance as Unlimited

When T instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend that you

configure your instances as unlimited. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

Create a launch template

You must use a *launch template* for launching instances as unlimited in an Auto Scaling group. A launch configuration does not support launching instances as unlimited.

 **Note**

unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Console

To create a launch template that launches instances as Unlimited

1. Follow the [Create a launch template using advanced settings](#) procedure in the *Amazon EC2 Auto Scaling User Guide*.
2. In **Launch template contents**, for **Instance type**, choose an instance size.
3. To launch instances as unlimited in an Auto Scaling group, under **Advanced details**, for **Credit specification**, choose **Unlimited**.
4. When you've finished defining the launch template parameters, choose **Create launch template**.

AWS CLI

To create a launch template that launches instances as Unlimited

Use the [create-launch-template](#) command and specify unlimited as the credit specification.

- For T4g, T3a and T3, if you do not include the CreditSpecification={CpuCredits=unlimited} value, the instance launches as unlimited by default.
- For T2, if you do not include the CreditSpecification={CpuCredits=unlimited} value, the instance launches as standard by default.

```
aws ec2 create-launch-template \
--launch-template-name MyLaunchTemplate \
--version-description FirstVersion \
--launch-template-data
ImageId=ami-8c1be5f6,InstanceType=t3.medium,CreditSpecification=[CpuCredits=unlimited]
```

Associate an Auto Scaling group with a launch template

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

Console

To create an Auto Scaling group using a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**, **Create Auto Scaling group**.
4. Choose **Launch Template**, select your launch template, and then choose **Next Step**.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the **Review page**, choose **Create Auto Scaling group**. For more information, see [Creating an Auto Scaling Group Using a Launch Template](#) in the *Amazon EC2 Auto Scaling User Guide*.

AWS CLI

To create an Auto Scaling group using a launch template

Use the [create-auto-scaling-group](#) AWS CLI command and specify the `--launch-template` parameter.

Console

To add a launch template to an existing Auto Scaling group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**.
4. From the Auto Scaling group list, select an Auto Scaling group, and choose **Actions, Edit**.
5. On the **Details** tab, for **Launch Template**, choose a launch template, and then choose **Save**.

AWS CLI

To add a launch template to an existing Auto Scaling group

Use the [update-auto-scaling-group](#) AWS CLI command and specify the `--launch-template` parameter.

View the credit specification of a burstable performance instance

You can view the credit specification (unlimited or standard) of a running or stopped T instance.

Console

To view the credit specification of a T instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Details** and view the **Credit specification** field. The value is either unlimited or standard.

AWS CLI

To describe the credit specification of a T instance

Use the [describe-instance-credit-specifications](#) command. If you do not specify one or more instance IDs, all instances with the credit specification of unlimited are returned, as well as instances that were previously configured with the unlimited credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as unlimited, Amazon EC2 returns the M4 instance.

```
aws ec2 describe-instance-credit-specifications --instance-id i-1234567890abcdef0
```

Example output

```
{  
    "InstanceCreditSpecifications": [  
        {  
            "InstanceId": "i-1234567890abcdef0",  
            "CpuCredits": "unlimited"  
        }  
    ]  
}
```

Modify the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped T instance at any time between unlimited and standard.

Note that in unlimited mode, an instance can spend surplus credits, which might incur an additional charge. For more information, see [Surplus credits can incur charges](#).

Console

To modify the credit specification of a T instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose **Actions, Instance settings, Change credit specification**. This option is enabled only if you selected a T instance.
5. To change the credit specification to unlimited, select the check box next to the instance ID. To change the credit specification to standard, clear the check box next to the instance ID.

AWS CLI

To modify the credit specification of a T instance

Use the [modify-instance-credit-specification](#) command. Specify the instance and its credit specification using the `--instance-credit-specification` parameter. Valid credit specifications are `unlimited` and `standard`.

```
aws ec2 modify-instance-credit-specification \
--region us-east-1 \
--instance-credit-specification
"InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

Example output

```
{
  "SuccessfulInstanceCreditSpecifications": [
    {
      "InstanceId": "i- 1234567890abcdef0"
    }
  ],
  "UnsuccessfulInstanceCreditSpecifications": []
}
```

Set the default credit specification for the account

Each T instance family comes with a [default credit specification](#). You can change the default credit specification for each T instance family at the account level per AWS Region.

If you use the launch instance wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new T instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

Consideration

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

Console

To set the default credit specification at the account level per Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.
5. Choose **Manage**.
6. For each instance family, choose **Unlimited** or **Standard**, and then choose **Update**.

AWS CLI

To set the default credit specification at the account level (AWS CLI)

Use the [modify-default-credit-specification](#) command. Specify the AWS Region, instance family, and the default credit specification using the --cpu-credits parameter. Valid default credit specifications are unlimited and standard.

```
aws ec2 modify-default-credit-specification \
    --region us-east-1 \
    --instance-family t2 \
    --cpu-credits unlimited
```

View the default credit specification

You can view the default credit specification of a T instance family at the account level per AWS Region.

Console

To view the default credit specification at the account level

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.

AWS CLI

To view the default credit specification at the account level

Use the [get-default-credit-specification](#) command. Specify the AWS Region and instance family.

```
aws ec2 get-default-credit-specification --region us-east-1 --instance-family t2
```

Monitor your CPU credits for burstable performance instances

EC2 sends metrics to Amazon CloudWatch. You can see the CPU credit metrics in the Amazon EC2 per-instance metrics of the CloudWatch console or by using the AWS CLI to list the metrics for each instance. For more information, see [List metrics using the console](#) and [List metrics using the AWS CLI](#).

Additional CloudWatch metrics for burstable performance instances

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

- CPUCreditUsage – The number of CPU credits spent during the measurement period.
- CPUCreditBalance – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
- CPUSurplusCreditBalance – The number of surplus CPU credits spent to sustain CPU utilization when the CPUCreditBalance value is zero.
- CPUSurplusCreditsCharged – The number of surplus CPU credits exceeding the [maximum number of CPU credits](#) that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as unlimited.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see [List the available CloudWatch metrics for your instances](#).

Metric	Description
CPUCreditUsage	The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100%

Metric	Description
	<p>utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</p> <p>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.</p> <p>Units: Credits (vCPU-minutes)</p>
CPUCreditBalance	<p>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.</p> <p>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.</p> <p>The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.</p> <p>When an instance is running, credits in the CPUCreditBalance do not expire. When a T4g, T3a or T3 instance stops, the CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost.</p> <p>CPU credit metrics are available at a five-minute frequency only.</p> <p>Units: Credits (vCPU-minutes)</p>

Metric	Description
CPUSurplusCreditBalance	<p>The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero.</p> <p>The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge.</p> <p>Units: Credits (vCPU-minutes)</p>
CPUSurplusCreditsCharged	<p>The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.</p> <p>Spent surplus credits are charged when any of the following occurs:</p> <ul style="list-style-type: none"> • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from unlimited to standard. <p>Units: Credits (vCPU-minutes)</p>

Calculate CPU credit usage

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the *prior* value of a metric at any point in time implies the previous value of the metric, sent *five minutes ago*.

Calculate CPU credit usage for Standard instances

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

Example

```
CPUCreditBalance = prior CPUCreditBalance + [Credits earned per hour * (5/60) - CPUCreditUsage]
```

The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the [credit table](#).

Example

This example uses a t3.nano instance. To calculate the CPUCreditBalance value of the instance, use the preceding equation as follows:

- CPUCreditBalance – The current credit balance to calculate.
- prior CPUCreditBalance – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- Credits earned per hour – A t3.nano instance earns six credits per hour.
- 5/60 – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by 5/60 (five minutes) to get the number of credits that the instance earned in the past five minutes. A t3.nano instance earns 0.5 credits every five minutes.
- CPUCreditUsage – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the CPUCreditBalance value:

Example

```
CPUCreditBalance = 2 + [0.5 - 1] = 1.5
```

Calculate CPU credit usage for Unlimited instances

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term `Adjusted balance` in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the `CPUCreditBalance` and `CPUSurplusCreditBalance` CloudWatch metrics.

Example

```
Adjusted balance = [prior CPUCreditBalance - prior CPUSurplusCreditBalance] + [Credits  
earned per hour * (5/60) - CPUCreditUsage]
```

A value of `0` for `Adjusted balance` indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both `CPUCreditBalance` and `CPUSurplusCreditBalance` are set to `0`.

A positive `Adjusted balance` value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the `Adjusted balance` value is assigned to `CPUCreditBalance`, and the `CPUSurplusCreditBalance` is set to `0`. The instance size determines the [maximum number of credits](#) that it can accrue.

Example

```
CPUCreditBalance = min [max earned credit balance, Adjusted balance]  
CPUSurplusCreditBalance = 0
```

A negative `Adjusted balance` value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the `Adjusted balance` value is assigned to `CPUSurplusCreditBalance` and `CPUCreditBalance` is set to `0`. Again, the instance size determines the [maximum number of credits](#) that it can accrue.

Example

```
CPUSurplusCreditBalance = min [max earned credit balance, -Adjusted balance]  
CPUCreditBalance = 0
```

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the CPUSurplusCreditsCharged metric.

Example

```
CPUSurplusCreditsCharged = max [-Adjusted balance - max earned credit balance, 0]
```

Finally, when the instance terminates, any surplus credits tracked by the CPUSurplusCreditBalance are charged. If the instance is switched from unlimited to standard, any remaining CPUSurplusCreditBalance is also charged.

Amazon EC2 Mac instances

Amazon EC2 Mac instances natively support the macOS operating system.

- EC2 x86 Mac instances (`mac1.metal`) are built on 2018 Mac mini hardware powered by 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processors.
- EC2 M1 Mac instances (`mac2.metal`) are built on 2020 Mac mini hardware powered by Apple silicon M1 processors.
- EC2 M2 Mac instances (`mac2-m2.metal`) are built on 2023 Mac mini hardware powered by Apple silicon M2 processors.
- EC2 M2 Pro Mac instances (`mac2-m2pro.metal`) are built on 2023 Mac mini hardware powered by Apple silicon M2 Pro processors.

EC2 Mac instances are ideal for developing, building, testing, and signing applications for Apple platforms, such as iPhone, iPad, Mac, Vision Pro, Apple Watch, Apple TV, and Safari. You can connect to your Mac instance using SSH or Apple Remote Desktop (ARD).

Note

The **unit of billing** is the **dedicated host**. The instances running on that host have no additional charge.

- [Amazon EC2 macOS AMIs release notes](#)

Considerations

The following considerations apply to Mac instances:

- Mac instances are available only as bare metal instances on [Dedicated Hosts](#), with a minimum allocation period of 24 hours before you can release the Dedicated Host. You can launch one Mac instance per Dedicated Host. You can share the Dedicated Host with the AWS accounts or organizational units within your AWS organization, or the entire AWS organization.

- Mac instances are available only as On-Demand Instances. They are not available as Spot Instances or Reserved Instances. You can save money on Mac instances by purchasing a [Savings Plan](#).
- Mac instances can run one of the following operating systems:
 - macOS Mojave (version 10.14) (x86 Mac instances only)
 - macOS Catalina (version 10.15) (x86 Mac instances only)
 - macOS Big Sur (version 11) (x86 and M1 Mac instances)
 - macOS Monterey (version 12) (x86 and M1 Mac instances)
 - macOS Ventura (version 13) (all Mac instances, M2 and M2 Pro Mac instances support macOS Ventura version 13.2 or later)
 - macOS Sonoma (version 14) (all Mac instances)
- EBS hotplug is supported.
- AWS does not manage or support the internal SSD on the Apple hardware. We strongly recommend that you use Amazon EBS volumes instead. EBS volumes provide the same elasticity, availability, and durability benefits on Mac instances as they do on any other EC2 instance.
- We recommend using General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2) with Mac instances for optimal EBS performance.
- [Mac instances support Amazon EC2 Auto Scaling.](#)
- On x86 Mac instances, automatic software updates are disabled. We recommend that you apply updates and test them on your instance before you put the instance into production. For more information, see [Update the operating system and software.](#)
- When you stop or terminate a Mac instance, a scrubbing workflow is performed on the Dedicated Host. For more information, see [Stop and terminate your Mac instance.](#)

Warning

Do not use FileVault. Enabling FileVault will result in the host failing to boot due to the partitions being locked. If data encryption is required, use Amazon EBS encryption to avoid boot issues and performance impact. With Amazon EBS encryption, encryption operations occur on the servers that host instances, ensuring the security of both data-at-rest and data-in-transit between an instance and its attached EBS storage. For more information, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*

Instance readiness

After you launch a Mac instance, you'll need to wait until the instance is ready before you can connect to it. For an AWS vended AMI with a x86 Mac instance or a Apple silicon Mac instance, the launch time can range from approximately 6 minutes to 20 minutes. Depending on the chosen Amazon EBS volume sizes, the inclusion of additional scripts to *user data*, or additional loaded software on a custom macOS AMI, the launch time might increase.

You can use a small shell script, like the one below, to poll the describe-instance-status API to know when the instance is ready to be connected to. In the following command, replace the example instance ID with your own.

```
for i in $(seq 1 200); do aws ec2 describe-instance-status --instance-ids=i-0123456789example \  
--query='InstanceStatuses[0].InstanceState.Status'; sleep 5; done;
```

Launch a Mac instance

EC2 Mac instances require a [Dedicated Host](#). You first need to allocate a host to your account, and then launch the instance onto the host.

You can launch a Mac instance using the AWS Management Console or the AWS CLI.

Launch a Mac instance using the console

To launch a Mac instance onto a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Allocate the Dedicated Host, as follows:
 - a. In the navigation pane, choose **Dedicated Hosts**.
 - b. Choose **Allocate Dedicated Host** and then do the following:
 - i. For **Instance family**, choose **mac1**, **mac2**, **mac2-m2**, or **mac2-m2pro**. If the instance family doesn't appear in the list, it's not supported in the currently selected Region.
 - ii. For **Instance type**, choose **mac1.metal**, **mac2.metal**, **mac2-m2.metal**, or **mac2-m2pro.metal** based on the instance family chosen.
 - iii. For **Availability Zone**, choose the Availability Zone for the Dedicated Host.
 - iv. For **Quantity**, keep **1**.

- v. Choose **Allocate**.
3. Launch the instance on the host, as follows:
 - a. Select the Dedicated Host that you created and then do the following:
 - i. Choose **Actions, Launch instance(s) onto host**.
 - ii. Under **Application and OS Images (Amazon Machine Image)**, select a macOS AMI.
 - iii. Under **Instance type**, select the appropriate instance type (**mac1.metal**, **mac2.metal**, **mac2-m2.metal**, or **mac2-m2pro.metal**).
 - iv. Under **Advanced details**, verify that **Tenancy**, **Tenancy host by**, and **Tenancy host ID** are preconfigured based on the Dedicated Host you created. Update **Tenancy affinity** as needed.
 - v. Complete the wizard, specifying EBS volumes, security groups, and key pairs as needed.
 - vi. In the **Summary** panel, choose **Launch instance**.
 - b. A confirmation page lets you know that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console. The initial state of an instance is pending. The instance is ready when its state changes to running and it passes status checks.

Launch a Mac instance using the AWS CLI

Allocate the Dedicated Host

Use the following [allocate-hosts](#) command to allocate a Dedicated Host for your Mac instance, replacing the `instance-type` with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, or `mac2-m2pro.metal`, and the `region` and `availability-zone` with the appropriate ones for your environment.

```
aws ec2 allocate-hosts --region us-east-1 --instance-type mac1.metal --availability-zone us-east-1b --auto-placement "on" --quantity 1
```

Launch the instance on the host

Use the following [run-instances](#) command to launch a Mac instance, again replacing the `instance-type` with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, or `mac2-m2pro.metal`, and the `region` and `availability-zone` with the ones used previously.

```
aws ec2 run-instances --region us-east-1 --instance-type mac1.metal --placement  
Tenancy=host --image-id ami_id --key-name my-key-pair
```

The initial state of an instance is pending. The instance is ready when its state changes to running and it passes status checks. Use the following [describe-instance-status](#) command to display status information for your instance.

```
aws ec2 describe-instance-status --instance-ids i-017f8354e2dc69c4f
```

The following is example output for an instance that is running and has passed status checks.

```
{  
    "InstanceStatuses": [  
        {  
            "AvailabilityZone": "us-east-1b",  
            "InstanceId": "i-017f8354e2dc69c4f",  
            "InstanceState": {  
                "Code": 16,  
                "Name": "running"  
            },  
            "InstanceStatus": {  
                "Details": [  
                    {  
                        "Name": "reachability",  
                        "Status": "passed"  
                    }  
                ],  
                "Status": "ok"  
            },  
            "SystemStatus": {  
                "Details": [  
                    {  
                        "Name": "reachability",  
                        "Status": "passed"  
                    }  
                ],  
                "Status": "ok"  
            }  
        }  
    ]  
}
```

Connect to your Mac instance

You can connect to your Mac instance using SSH or a graphical user interface.

Connect to your instance using SSH

⚠ Important

Multiple users can access the OS simultaneously. Typically there is a 1:1 user:GUI session due to the built-in Screen Sharing service on port 5900. Using SSH within macOS supports multiple sessions up until the "Max Sessions" limit in the `sshd_config` file.

Amazon EC2 Mac instances do not allow remote root SSH by default. Password authentication is disabled to prevent brute-force password attacks. The `ec2-user` account is configured to log in remotely using SSH. The `ec2-user` account also has **sudo** privileges. After you connect to your instance, you can add other users.

To support connecting to your instance using SSH, launch the instance using a key pair and a security group that allows SSH access, and ensure that the instance has internet connectivity. You provide the `.pem` file for the key pair when you connect to the instance.

Use the following procedure to connect to your Mac instance using an SSH client. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

To connect to your instance using SSH

1. Verify that your local computer has an SSH client installed by entering `ssh` at the command line. If your computer doesn't recognize the command, search for an SSH client for your operating system and install it.
2. Get the public DNS name of your instance. Using the Amazon EC2 console, you can find the public DNS name on both the **Details** and the **Networking** tabs. Using the AWS CLI, you can find the public DNS name using the [`describe-instances`](#) command.
3. Locate the `.pem` file for the key pair that you specified when you launched the instance.
4. Connect to your instance using the following `ssh` command, specifying the public DNS name of the instance and the `.pem` file.

```
ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

Connect to your instance's graphical user interface (GUI)

Use the following procedure to connect to your instance's GUI using VNC, Apple Remote Desktop (ARD), or the Apple Screen Sharing application (included with macOS).

Note

macOS 10.14 and later only allows control if Screen Sharing is enabled through [System Preferences](#).

To connect to your instance using ARD client or VNC client

1. Verify that your local computer has an ARD client or a VNC client that supports ARD installed. On macOS, you can leverage the built-in Screen Sharing application. Otherwise, search for ARD for your operating system and install it.
2. From your local computer, [connect to your instance using SSH](#).
3. Set up a password for the ec2-user account using the **passwd** command as follows.

```
[ec2-user ~]$ sudo passwd ec2-user
```

4. Install and start macOS Screen Sharing using the following command.

```
[ec2-user ~]$ sudo launchctl enable system/com.apple.screensharing  
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist
```

5. Disconnect from your instance by typing **exit** and pressing Enter.
6. From your computer, connect to your instance using the following **ssh** command. In addition to the options shown in the previous section, use the **-L** option to enable port forwarding and forward all traffic on local port 5900 to the ARD server on the instance.

```
ssh -L 5900:localhost:5900 -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

7. From your local computer, use the ARD client or VNC client that supports ARD to connect to localhost:5900. For example, use the Screen Sharing application on macOS as follows:
 - a. Open **Finder** and select **Go**.
 - b. Select **Connect to Server**.

- c. In the **Server Address** field, enter vnc://localhost:5900.
- d. Log in as prompted, using **ec2-user** as the user name and the password that you created for the ec2-user account.

Modify macOS screen resolution on Mac instances

After you connect to your EC2 Mac instance using ARD or a VNC client that supports ARD, you can modify the screen resolution of your macOS environment using any of the publicly available macOS tools or utilities, such as [displayplacer](#).

To modify the screen resolution using displayplacer

1. Install displayplacer.

```
[ec2-user ~]$ brew tap jakehilborn/jakehilborn && brew install displayplacer
```

2. Show the current screen information and possible screen resolutions.

```
[ec2-user ~]$ displayplacer list
```

3. Apply the desired screen resolution.

```
[ec2-user ~]$ displayplacer "id:<screenID> res:<width>x<height> origin:(0,0) degree:0"
```

For example:

```
RES="2560x1600"
displayplacer "id:69784AF1-CD7D-B79B-E5D4-60D937407F68 res:${RES} scaling:off
origin:(0,0) degree:0"
```

EC2 macOS AMIs

Amazon EC2 macOS is designed to provide a stable, secure, and high-performance environment for developer workloads running on Amazon EC2 Mac instances. EC2 macOS AMIs includes packages that enable easy integration with AWS, such as launch configuration tools and popular AWS libraries and tools.

For more information about EC2 macOS AMIs, see [Amazon EC2 macOS AMIs release notes](#).

AWS provides updated EC2 macOS AMIs on a regular basis that include updates to packages owned by AWS and the latest fully-tested macOS version. Additionally, AWS provides updated AMIs with the latest minor version updates or major version updates as soon as they can be fully tested and vetted. If you do not need to preserve data or customizations to your Mac instances, you can get the latest updates by launching a new instance using the current AMI and then terminating the previous instance. Otherwise, you can choose which updates to apply to your Mac instances.

For information about how to subscribe to macOS AMI notifications, see [Subscribe to macOS AMI notifications](#).

Update the operating system and software

Warning

Installation of beta or preview macOS versions is only available on Amazon EC2 M1 Mac instances. Amazon EC2 doesn't qualify beta or preview macOS versions and doesn't ensure instances will remain functional after an update to a pre-production macOS version.

Attempting to install beta or preview macOS versions on Amazon EC2 x86 Mac instances will lead to degradation of your Amazon EC2 Mac Dedicated Host when you stop or terminate your instances, and will prevent you from starting or launching a new instance on that host.

Steps to update software on x86 Mac instances and Apple silicon Mac instances.

- [Update software on x86 Mac instances](#)
- [Update software on Apple silicon Mac instances](#)

Update software on x86 Mac instances

On x86 Mac instances, you can install operating system updates from Apple using the softwareupdate command.

To install operating system updates from Apple on x86 Mac instances

1. List the packages with available updates using the following command.

```
[ec2-user ~]$ softwareupdate --list
```

2. Install all updates or only specific updates. To install specific updates, use the following command.

```
[ec2-user ~]$ sudo softwareupdate --install label
```

To install all updates instead, use the following command.

```
[ec2-user ~]$ sudo softwareupdate --install --all --restart
```

System administrators can use AWS Systems Manager to roll out pre-approved operating system updates on x86 Mac instances. For more information, see the [AWS Systems Manager User Guide](#).

You can use Homebrew to install updates to packages in the EC2 macOS AMIs, so that you have the latest version of these packages on your instances. You can also use Homebrew to install and run common macOS applications on Amazon EC2 macOS. For more information, see the [Homebrew Documentation](#).

To install updates using Homebrew

1. Update Homebrew using the following command.

```
[ec2-user ~]$ brew update
```

2. List the packages with available updates using the following command.

```
[ec2-user ~]$ brew outdated
```

3. Install all updates or only specific updates. To install specific updates, use the following command.

```
[ec2-user ~]$ brew upgrade package name
```

To install all updates instead, use the following command.

```
[ec2-user ~]$ brew upgrade
```

Update software on Apple silicon Mac instances

Considerations

Elastic Network Adapter (ENA) driver

Due to an update in the network driver configuration, ENA driver version 1.0.2 isn't compatible with macOS 13.3 or greater. If you want to install any beta, preview, or production macOS version 13.3 or later and have not installed the latest ENA driver, use the following procedure to install a new version of the driver.

To install a new version of the ENA driver

1. In a Terminal window, connect to your Apple silicon Mac instance using [SSH](#).
2. Download the ENA application into the Applications file using the following command.

```
[ec2-user ~]$ brew install amazon-ena-ethernet-dext
```

Troubleshooting tip

If you receive the warning No available formula with the name amazon-ena-ethernet-dext, run the following command.

```
[ec2-user ~]$ brew update
```

3. Disconnect from your instance by typing **exit** and pressing return.
4. Use the VNC client to activate the ENA application.
 - a. Setup the VNC client using [Connect to your instance's graphical user interface \(GUI\)](#).
 - b. Once you have connected to your instance using the Screen Sharing application, go to the **Applications** folder and open the ENA application.
 - c. Choose **Activate**
 - d. To confirm the driver was activated correctly, run the following command in the Terminal window. The output of the command shows that the old driver is in the terminating state and the new driver is in the activated state.

```
systemextensionsctl list;
```

- e. After you restart the instance, only the new driver will be present.

Software update on Apple silicon Mac instances

On Apple silicon Mac instances, you must complete several steps to perform an in-place operating system update. First, access the internal disk of the instance using the GUI with a VNC (Virtual Network Computing) client. This procedure uses macOS Screen Sharing, the built in VNC client. Then, delegate ownership to the administrative user (`ec2-user`) by signing in as `aws-managed-user` on the Amazon EBS volume.

As you work through this procedure, you create two passwords. One password is for the administrative user (`ec2-user`) and the other password is for a special administrative user (`aws-managed-user`). Remember these passwords since you will use them as you work through the procedure.

Note

With this procedure on macOS Big Sur, you can only perform minor updates such as updating from macOS Big Sur 11.7.3 to macOS Big Sur 11.7.4. For macOS Monterey or above, you can perform major software updates.

To access the internal disk

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using SSH with the following command. For more information, see [Connect to your instance using SSH](#).

```
ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

2. Install and start macOS Screen Sharing using the following command.

```
[ec2-user ~]$ sudo launchctl enable system/com.apple.screensharing  
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist
```

3. Set a password for `ec2-user` with the following command. Remember the password as you will use it later.

```
[ec2-user ~]$ sudo /usr/bin/dscl . -passwd /Users/ec2-user
```

4. Disconnect from the instance by typing **exit** and pressing return.
5. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

```
ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 ec2-user@instance-public-dns-name
```

Note

Do not exit this SSH session until the following VNC connection and GUI steps are completed. When the instance is restarted, the connection will close automatically.

6. From your local computer, connect to localhost:5900 using the following steps:
 - a. Open **Finder** and select **Go**.
 - b. Select **Connect to Server**.
 - c. In the **Server Address** field, enter vnc://localhost:5900.
7. In the macOS window, connect to the remote session of the Apple silicon Mac instance as ec2-user with the password you created in [Step 3](#).
8. Access the internal disk, named **InternalDisk**, using one of the following options.
 - a. For macOS Ventura or above: Open **System Settings**, select **General** in the left pane, then **Startup Disk** at the lower right of the pane.
 - b. For macOS Monterey or below: Open **System Preferences**, select **Startup Disk**, then unlock the pane by choosing the lock icon in the lower left of the window.

Troubleshooting tip

If you need to mount the internal disk, run the following command in the Terminal.

```
APFSVolumeName="InternalDisk" ; SSDContainer=$(diskutil list | grep "Physical Store disk0" -B 3 | grep "/dev/disk" | awk '{print $1}' ) ; diskutil apfs addVolume $SSDContainer APFS $APFSVolumeName
```

9. Choose the internal disk, named **InternalDisk**, and select **Restart**. Select **Restart** again when prompted.

⚠️ Important

If the internal disk is named **Macintosh HD** instead of **InternalDisk**, your instance needs to be stopped and restarted so the dedicated host can be updated. For more information, see [Stop and terminate your Mac instance](#).

Use the following procedure to delegate ownership to the administrative user. When you reconnect to your instance with SSH, you boot from the internal disk using the special administrative user (`aws-managed-user`). The initial password for `aws-managed-user` is blank, so you need to overwrite it on your first connection. Then, you need to repeat the steps to install and start macOS Screen Sharing since the boot volume has changed.

To delegate ownership to the administrator on an Amazon EBS volume

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using the following command.

```
ssh -i /path/key-pair-name.pem aws-managed-user@instance-public-dns-name
```

2. When you receive the warning `WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!`, use one of the following commands to resolve this issue.
 - a. Clear out the known hosts using the following command. Then, repeat the previous step.

```
rm ~/.ssh/known_hosts
```

- b. Add the following to the SSH command in the previous step.

```
-o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no
```

3. Set the password for `aws-managed-user` with the following command. The `aws-managed-user` initial password is blank, so you need to overwrite it on your first connection.

- a.

```
[aws-managed-user ~]$ sudo /usr/bin/dscl . -passwd /Users/aws-managed-user password
```
- b. When you receive the prompt, Permission denied. Please enter user's old password:, press enter.

(i) Troubleshooting tip

If you get the error passwd: DS error: eDSAuthFailed, use the following command.

```
[aws-managed-user ~]$ sudo passwd aws-managed-user
```

4. Install and start macOS Screen Sharing using the following command.

```
[aws-managed-user ~]$ sudo launchctl enable system/com.apple.screensharing  
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist
```

5. Disconnect from the instance by typing **exit** and pressing return.
6. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

```
ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 aws-managed-user@instance-public-dns-name
```

7. From your local computer, connect to localhost:5900 using the following steps:
 - a. Open **Finder** and select **Go**.
 - b. Select **Connect to Server**.
 - c. In the **Server Address** field, enter vnc://localhost:5900.
8. In the macOS window, connect to the remote session of the Apple silicon Mac instance as aws-managed-user with the password you created in [Step 3](#).

(i) Note

When prompted to sign in with your Apple ID, select **Set Up Later**.

9. Access the Amazon EBS volume using one of the following options.
 - a. For macOS Ventura or later: Open **System Settings**, select **General** in the left pane, then **Startup Disk** at the lower right of the pane.
 - b. For macOS Monterey or earlier: Open **System Preferences**, select **Startup Disk**, then unlock the pane using the lock icon in the lower left of the window.

 **Note**

Until the reboot takes place, when prompted for an administrator password, use the password you set above for `aws-managed-user`. This password might be different from the one you set for `ec2-user` or the default administrator account on your instance. The following instructions specify when to use your instance's administrator password.

10. Select the Amazon EBS volume (the volume not named **InternalDisk** in the **Startup Disk** window) and choose **Restart**.

 **Note**

If you have multiple bootable Amazon EBS volumes attached to your Apple silicon Mac instance, be sure to use a unique name for each volume.

11. Confirm the restart, then choose **Authorize Users** when prompted.
12. On the **Authorize user on this volume** pane, verify that the administrative user (`ec2-user` by default) is selected, then select **Authorize**.
13. Enter the `ec2-user` password you created in [Step 3](#) of the previous procedure, then select **Continue**.
14. Enter the password for the special administrative user (`aws-managed-user`) when prompted.
15. From your local computer, in the Terminal, reconnect to your instance using SSH with user name `ec2-user`.

 **Troubleshooting tip**

If you get the warning `WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!`, run the following command and reconnect to your instance using SSH.

```
rm ~/.ssh/known_hosts
```

16. To perform the software update, use the commands under [Update software on x86 Mac instances](#).

EC2 macOS Init

EC2 macOS Init is used to initialize EC2 Mac instances at launch. It uses priority groups to run logical groups of tasks at the same time.

The launchd plist file is `/Library/LaunchDaemons/com.amazon.ec2.macos-init.plist`. The files for EC2 macOS Init are located in `/usr/local/aws/ec2-macos-init`.

For more information, see <https://github.com/aws/ec2-macos-init>.

Amazon EC2 System Monitor for macOS

Amazon EC2 System Monitor for macOS provides CPU utilization metrics to Amazon CloudWatch. It sends these metrics to CloudWatch over a custom serial device in 1-minute periods. You can enable or disable this agent as follows. It is enabled by default.

```
sudo setup-ec2monitoring [enable | disable]
```

 **Note**

Amazon EC2 System Monitor for macOS is not currently supported on Apple silicon Mac instances.

Increase the size of an EBS volume on your Mac instance

You can increase the size of your Amazon EBS volumes on your Mac instance. For more information, see [Amazon EBS Elastic Volumes](#) in the *Amazon EBS User Guide*.

After you increase the size of the volume, you must increase the size of your APFS container as follows.

Make increased disk space available for use

1. Determine if a restart is required. If you resized an existing EBS volume on a running Mac instance, you must [reboot](#) the instance to make the new size available. If disk space modification was done during launch time, a reboot will not be required.

View current status of disk sizes:

```
[ec2-user ~]$ diskutil list external physical  
/dev/disk0 (external, physical):  
#:  
0: TYPE NAME SIZE IDENTIFIER  
GUID_partition_scheme *322.1 GB disk0  
1: EFI EFI 209.7 MB disk0s1  
2: Apple_APFS Container disk2 321.9 GB disk0s2
```

2. Copy and paste the following command.

```
[ec2-user ~]$ PDISK=$(diskutil list physical external | head -n1 | cut -d" " -f1)  
APFSCONT=$(diskutil list physical external | grep "Apple_APFS" | tr -s " " | cut -  
d" " -f8)  
yes | sudo diskutil repairDisk $PDISK
```

3. Copy and paste the following command.

```
[ec2-user ~]$ sudo diskutil apfs resizeContainer $APFSCONT 0
```

Stop and terminate your Mac instance

When you stop a Mac instance, the instance remains in the stopping state for about 15 minutes before it enters the stopped state.

When you stop or terminate a Mac instance, Amazon EC2 performs a scrubbing workflow on the underlying Dedicated Host to erase the internal SSD, to clear the persistent NVRAM variables, and to update to the latest device firmware. This ensures that Mac instances provide the same security and data privacy as other EC2 Nitro instances. It also allows you to run the latest macOS AMIs. During the scrubbing workflow, the Dedicated Host temporarily enters the pending state. On x86 Mac instances, the scrubbing workflow might take up to 50 minutes to complete. On Apple silicon Mac instances, the scrubbing workflow might take up to 110 minutes to complete. Additionally, on

x86 Mac instances, if the device firmware needs to be updated, the scrubbing workflow might take up to 3 hours to complete.

You can't start the stopped Mac instance or launch a new Mac instance until after the scrubbing workflow completes, at which point the Dedicated Host enters the available state.

Metering and billing is paused when the Dedicated Host enters the pending state. You are not charged for the duration of the scrubbing workflow.

Supported macOS versions for your Dedicated Host

You can view the latest macOS versions supported by your Amazon EC2 Mac Dedicated Host. With this functionality, you can validate whether your Dedicated Host can support instance launches with your preferred macOS versions.

Each macOS version requires a minimum firmware version on the underlying Apple Mac to successfully boot. The Apple Mac firmware version can become outdated if an allocated Mac Dedicated Host has remained idle for an extended period of time or if it has a long running instance on it.

To ensure supportability for the latest macOS versions, you can stop or terminate instances on your allocated Mac Dedicated Host. This triggers the host scrubbing workflow and updates the firmware on the underlying Apple Mac to support the latest macOS versions. A Dedicated Host with a long running instance will automatically be updated when you stop or terminate a running instance.

For more information about the scrubbing workflow, see [Stop and terminate your Mac instance](#).

For more information about launching Mac instances, see [Launch a Mac instance](#).

You can view information about the latest macOS versions supported on your allocated Dedicated Host using the Amazon EC2 console or the AWS CLI.

Console

To view Dedicated Host firmware information using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts details** page, under **Latest supported macOS versions**, you can see the latest macOS versions that the host can support.

AWS CLI

To view Dedicated Host firmware information using the AWS CLI

Use the [describe-mac-hosts](#) command, replacing `region` with the appropriate AWS Region.

```
$ aws ec2 describe-mac-hosts --region us-east-1
{
    "MacHosts": [
        {
            "HostId": "h-07879acf49EXAMPLE",
            "MacOSLatestSupportedVersions": [
                "14.3",
                "13.6.4",
                "12.7.3"
            ]
        }
    ]
}
```

Subscribe to macOS AMI notifications

To be notified when new AMIs are released or when bridgeOS has been updated, subscribe for notifications using Amazon SNS.

To subscribe to macOS AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. For the **Create subscription** dialog box, do the following:
 - a. For **Topic ARN**, copy and paste one of the following Amazon Resource Names (ARNs):
 - **arn:aws:sns:us-east-1:898855652048:amazon-ec2-macos-ami-updates**
 - **arn:aws:sns:us-east-1:898855652048:amazon-ec2-bridgeos-updates**

For Protocol:**b. Email:**

For **Endpoint**, type an email address that you can use to receive the notifications. After you create your subscription you'll receive a confirmation message with the subject line AWS Notification - Subscription Confirmation. Open the email and choose **Confirm subscription** to complete your subscription.

c. SMS:

For **Endpoint**, type a phone number that you can use to receive the notifications.

d. AWS Lambda, Amazon SQS, Amazon Data Firehose (*Notifications come in JSON format*):

For **Endpoint**, enter the ARN for the Lambda function, SQS queue, or Firehose stream you can use to receive the notifications.

e. Choose Create subscription.

Whenever macOS AMIs are released, we send notifications to the subscribers of the amazon-ec2-macos-ami-updates topic. Whenever bridgeOS is updated, we send notifications to the subscribers of the amazon-ec2-bridgeos-updates topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from macOS AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Select the subscriptions and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Release the Dedicated Host for your Mac instance

When you are finished with your Mac instance, you can release the Dedicated Host. Before you can release the Dedicated Host, you must stop or terminate the Mac instance. You cannot release the host until the allocation period exceeds the 24-hour minimum.

To release the Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, then choose either **Stop instance** or **Terminate instance**.
4. In the navigation pane, choose **Dedicated Hosts**.
5. Select the Dedicated Host and choose **Actions, Release host**.
6. When prompted for confirmation, choose **Release**.

Amazon EBS–optimized instances

An Amazon EBS–optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

EBS–optimized instances deliver dedicated bandwidth to Amazon EBS. When attached to an EBS–optimized instance, General Purpose SSD (gp2 and gp3) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99% of the time in a given year, and Provisioned IOPS SSD (io1 and io2) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99.9% of the time in a given year. Both Throughput Optimized HDD (st1) and Cold HDD (sc1) deliver at least 90% of their expected throughput performance 99% of the time in a given year. Non-compliant periods are approximately uniformly distributed, targeting 99% of expected total throughput each hour. For more information, see [Amazon EBS volume types](#) in the [Amazon EBS User Guide](#).

Important

An instance's EBS performance is bounded by the instance's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve 80,000 IOPS for `r6i.16xlarge`, the instance must have at least 5 gp3 volumes provisioned with 16,000 IOPS each (5 volumes x 16,000 IOPS = 80,000 IOPS).

Supported instance types

The following tables show which instance types support EBS optimization. They include the dedicated bandwidth to Amazon EBS, the typical maximum aggregate throughput that can be achieved on that connection with a streaming read workload and 128 KiB I/O size, and the maximum IOPS the instance can support if you are using a 16 KiB I/O size.

Choose an EBS–optimized instance that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.

EBS optimized by default

The following tables list the instance types that support EBS optimization and EBS optimization is enabled by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

Note

You can also view this information programmatically using the AWS CLI. For more information, see [View instances types that support EBS optimization](#).

⚠️ Important

¹ These instances can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

² These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Compute optimized

Important

¹ These instances can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

² These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

¹ These instances can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

² These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

⚠ Important

¹ These instances can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

² These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

¹ These instances can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

² These instances can sustain their stated performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

EBS optimization supported

The following table lists the instance types that support EBS optimization but EBS optimization is not enabled by default. You can enable EBS optimization when you launch these instances or after they are running. Instances must have EBS optimization enabled to achieve the level of performance described. When you enable EBS optimization for an instance that is not EBS-optimized by default, you pay an additional low, hourly fee for the dedicated capacity. For pricing information, see [EBS-Optimized Instances](#) on the [Amazon EC2 Pricing, On-Demand Pricing page](#).

 **Note**

You can also view this information programmatically using the AWS CLI. For more information, see [View instances types that support EBS optimization](#).

Instance size	Maximum bandwidth (Mbps)	Maximum throughput (MB/s, 128 KiB I/O)	Maximum IOPS (16 KiB I/O)

c3.xlarge	500	62.5	4000
c3.2xlarge	1000	125.0	8000
c3.4xlarge	2000	250.0	16000

Instance size	Maximum bandwidth (Mbps)	Maximum throughput (MB/s, 128 KiB I/O)	Maximum IOPS (16 KiB I/O)
i2.xlarge	500	62.5	4000

The `i2.8xlarge`, `c3.8xlarge`, and `r3.8xlarge` instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Get maximum performance

You can use the `EBSIOBalance%` and `EBSByteBalance%` metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see [Monitor your instances using CloudWatch](#).

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see [Storage Configuration for SAP HANA](#).

Considerations

- G4dn, I3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

View instances types that support EBS optimization

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

To view the instance types that support EBS optimization and that have it enabled by default

Use the following [describe-instance-types](#) command.

```
aws ec2 describe-instance-types \
--query 'InstanceTypes[].[{InstanceType:InstanceType,"MaxBandwidth(Mb/s)":EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps,MaxIOPS:EbsInfo.EbsOptimizedInfo.MaximumIOPS":EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps}]' \
--filters Name=ebs-info.ebs-optimized-support,Values=default --output=table
```

Example output for eu-west-1:

DescribeInstanceTypes

Enable EBS optimization at launch

You can enable optimization for an instance by setting its attribute for EBS optimization.

To enable Amazon EBS optimization when launching an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, select an AMI.
4. In **Step 2: Choose an Instance Type**, select an instance type that is listed as supporting Amazon EBS optimization.
5. In **Step 3: Configure Instance Details**, complete the fields that you need and choose **Launch as EBS-optimized instance**. If the instance type that you selected in the previous step doesn't support Amazon EBS optimization, this option is not present. If the instance type that you selected is Amazon EBS-optimized by default, this option is selected and you can't deselect it.
6. Follow the directions to complete the wizard and launch your instance.

To enable EBS optimization when launching an instance using the command line

You can use one of the following commands with the corresponding option. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [`run-instances`](#) with `--ebs-optimized` (AWS CLI)
- [`New-EC2Instance`](#) with `-EbsOptimized` (AWS Tools for Windows PowerShell)

Enable EBS optimization for an existing instance

You can enable or disable optimization for an existing instance by modifying its Amazon EBS-optimized instance attribute. If the instance is running, you must stop it first.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

To enable EBS optimization for an existing instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and select the instance.
3. To stop the instance, choose **Actions**, **Instance state**, **Stop instance**. It can take a few minutes for the instance to stop.
4. With the instance still selected, choose **Actions**, **Instance settings**, **Change instance type**.
5. For **Change Instance Type**, do one of the following:
 - If the instance type of your instance is Amazon EBS-optimized by default, **EBS-optimized** is selected and you can't change it. You can choose **Cancel**, because Amazon EBS optimization is already enabled for the instance.
 - If the instance type of your instance supports Amazon EBS optimization, choose **EBS-optimized** and then choose **Apply**.
 - If the instance type of your instance does not support Amazon EBS optimization, you can't choose **EBS-optimized**. You can select an instance type from **Instance type** that supports Amazon EBS optimization, choose **EBS-optimized**, and then choose **Apply**.
6. Choose **Instance state**, **Start instance**.

To enable EBS optimization for an existing instance using the command line

1. If the instance is running, use one of the following commands to stop it:
 - [stop-instances](#) (AWS CLI)
 - [Stop-EC2Instance](#) (AWS Tools for Windows PowerShell)
2. To enable EBS optimization, use one of the following commands with the corresponding option:
 - [modify-instance-attribute](#) with `--ebs-optimized` (AWS CLI)
 - [Edit-EC2InstanceAttribute](#) with `-EbsOptimized` (AWS Tools for Windows PowerShell)

Instance purchasing options

Amazon EC2 provides the following purchasing options to enable you to optimize your costs based on your needs:

- [**On-Demand Instances**](#) – Pay, by the second, for the instances that you launch.
- [**Savings Plans**](#) – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- [**Reserved Instances**](#) – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- [**Spot Instances**](#) – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- [**Dedicated Hosts**](#) – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- [**Dedicated Instances**](#) – Pay, by the hour, for instances that run on single-tenant hardware.
- [**Capacity Reservations**](#) – Reserve capacity for your EC2 instances in a specific Availability Zone.

If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Capacity Blocks can be used to reserve a cluster of GPU instances. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses. For more information, see [Amazon EC2 Pricing](#).

For more information about Savings Plans, see the [Savings Plans User Guide](#).

Determine the instance lifecycle

The lifecycle of an instance starts when it is launched and ends when it is terminated. The purchasing option that you choose affects the lifecycle of the instance. For example, an On-Demand Instance runs when you launch it and ends when you terminate it. A Spot Instance runs as long as capacity is available and your maximum price is higher than the Spot price.

Use one of the following methods to determine the lifecycle of an instance.

To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Lifecycle**. If the value is spot, the instance is a Spot Instance. If the value is normal, the instance is either an On-Demand Instance or a Reserved Instance.
5. On the **Details** tab, under **Host and placement group**, find **Tenancy**. If the value is host, the instance is running on a Dedicated Host. If the value is dedicated, the instance is a Dedicated Instance.
6. (Optional) If you have purchased a Reserved Instance and want to verify that it is being applied, you can check the usage reports for Amazon EC2. For more information, see [Amazon EC2 usage reports](#).

To determine the instance lifecycle using the AWS CLI

Use the following [describe-instances](#) command:

```
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

If the instance is running on a Dedicated Host, the output contains the following information:

```
"Tenancy": "host"
```

If the instance is a Dedicated Instance, the output contains the following information:

```
"Tenancy": "dedicated"
```

If the instance is a Spot Instance, the output contains the following information:

```
"InstanceLifecycle": "spot"
```

Otherwise, the output does not contain `InstanceLifecycle`.

On-Demand Instances

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over the instance's lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the `running` state, with a 60-second minimum. The price per second for a running On-Demand Instance is fixed, and is listed on the [Amazon EC2 Pricing, On-Demand Pricing page](#).

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use [AWS Savings Plans](#), [Spot Instances](#), or [Reserved Instances](#).

On-Demand Instance quotas

There are quotas for the number of running On-Demand Instances per AWS account per Region. On-Demand Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running On-Demand Instances are using, regardless of the instance type.

We provide the following quota types for On-Demand Instances:

- Running On-Demand DL instances
- Running On-Demand F instances
- Running On-Demand G and VT instances
- Running On-Demand High Memory instances
- Running On-Demand HPC instances
- Running On-Demand Inf instances
- Running On-Demand P instances
- Running On-Demand Standard (A, C, D, H, I, M, R, T, Z) instances
- Running On-Demand Trn instances
- Running On-Demand X instances

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

Each quota type specifies the maximum number of vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account quota. For example, with a Standard instance quota of 256 vCPUs, you could launch 32 m5.2xlarge instances (32 x 8 vCPUs) or 16 c5.4xlarge instances (16 x 16 vCPUs). For more information, see [EC2 On-Demand Instance limits](#).

Monitor On-Demand Instance quotas and usage

You can view and manage your On-Demand Instance quotas for each Region using the following methods.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/>.
2. From the navigation bar, select a Region.
3. In the filter field, enter **On-Demand**.
4. The **Applied quota value** column displays the maximum number of vCPUs for each On-Demand Instance quota type for your account.

To view your current quotas using the AWS Trusted Advisor console

Open [Service limits page](#) in the AWS Trusted Advisor console.

To configure CloudWatch alarms

With Amazon CloudWatch metrics integration, you can monitor your EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Request a quota increase

Even though Amazon EC2 automatically increases your On-Demand Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more

instances than your current quota allows, you can request a quota increase by using the Service Quotas console described in [Amazon EC2 service quotas](#).

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see [Using the AWS Price List API](#) in the *AWS Billing User Guide*.

Reserved Instances

Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

Note

Savings Plans also offer significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. With Savings Plans, you make a commitment to a consistent usage amount, measured in USD per hour. This provides you with the flexibility to use the instance configurations that best meet your needs and continue to save money, instead of making a commitment to a specific instance configuration. For more information, see the [AWS Savings Plans User Guide](#).

Reserved Instance overview

The following diagram shows a basic overview of purchasing and using Reserved Instances.

In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

Key variables that determine Reserved Instance pricing

The Reserved Instance pricing is determined by the following key variables.

Instance attributes

A Reserved Instance has four instance attributes that determine its price.

- **Instance type:** For example, m4.large. This is composed of the instance family (for example, m4) and the instance size (for example, large).

- **Region:** The Region in which the Reserved Instance is purchased.
- **Tenancy:** Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see [Dedicated Instances](#).
- **Platform:** The operating system; for example, Windows or Linux/Unix. For more information, see [Choosing a platform](#).

Term commitment

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year:** A year is defined as 31536000 seconds (365 days).
- **Three-year:** Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.

Important

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify](#), [exchange](#), or [sell](#) your Reserved Instance if your needs change.

Payment options

The following payment options are available for Reserved Instances:

- **All Upfront:** Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront:** A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront:** You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

Note

No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.

Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see [Sell in the Reserved Instance Marketplace](#).

Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard:** These provide the most significant discount, but can only be modified. Standard Reserved Instances can't be exchanged.
- **Convertible:** These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see [Types of Reserved Instances \(offering classes\)](#).

Important

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify](#), [exchange](#), or [sell](#) your Reserved Instance if your needs change.

For more information, see the [Amazon EC2 Reserved Instances Pricing page](#).

Regional and zonal Reserved Instances (scope)

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional:** When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.
- **Zonal:** When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.

The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see [Key variables that determine Reserved Instance pricing](#) and [Amazon EC2 Reserved Instances Pricing](#).

For more information about how to specify the scope of a Reserved Instance, see [RI Attributes](#), specifically the **Availability Zone** bullet.

Differences between regional and zonal Reserved Instances

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

	Regional Reserved Instances	Zonal Reserved Instances
Ability to reserve capacity	A regional Reserved Instance <i>does not</i> reserve capacity.	A zonal Reserved Instance reserves capacity in the specified Availability Zone.
Availability Zone flexibility	The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.	No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.
Instance size flexibility	The Reserved Instance discount applies to instance usage within the instance family, regardless of size. Only supported on Amazon Linux/Unix Reserved	No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.

	Regional Reserved Instances	Zonal Reserved Instances
	Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor .	
Queuing a purchase	You can queue purchases for regional Reserved Instances.	You can't queue purchases for zonal Reserved Instances.

For more information and examples, see [How Reserved Instances are applied](#).

Types of Reserved Instances (offering classes)

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

Differences between Standard and Convertible Reserved Instances

The following are the differences between Standard and Convertible Reserved Instances.

	Standard Reserved Instance	Convertible Reserved Instance
Modify Reserved Instances	Some attributes can be modified. For more information, see Modify Reserved Instances .	Some attributes can be modified. For more information, see Modify Reserved Instances .
Exchange Reserved Instances	Can't be exchanged.	Can be exchanged during the term for another Convertible Reserved Instance with

	Standard Reserved Instance	Convertible Reserved Instance
		new attributes, including instance family, instance type, platform, scope, or tenancy. For more information, see Exchange Convertible Reserved Instances .
Sell in the Reserved Instance Marketplace	Can be sold in the Reserved Instance Marketplace.	Can't be sold in the Reserved Instance Marketplace.
Buy in the Reserved Instance Marketplace	Can be bought in the Reserved Instance Marketplace.	Can't be bought in the Reserved Instance Marketplace.

How Reserved Instances are applied

Reserved Instances are not physical instances, but rather a billing discount that is applied to the running On-Demand Instances in your account. The On-Demand Instances must match certain specifications of the Reserved Instances in order to benefit from the billing discount.

If you purchase a Reserved Instance and you already have a running On-Demand Instance that matches the specifications of the Reserved Instance, the billing discount is applied immediately and automatically. You do not have to restart your instances. If you do not have an eligible running On-Demand Instance, launch an On-Demand Instance with the same specifications as your Reserved Instance. For more information, see [Use your Reserved Instances](#).

The offering class (Standard or Convertible) of the Reserved Instance does not affect how the billing discount is applied.

Topics

- [How zonal Reserved Instances are applied](#)
- [How regional Reserved Instances are applied](#)
- [Instance size flexibility](#)
- [Examples of applying Reserved Instances](#)

How zonal Reserved Instances are applied

A Reserved Instance that is purchased to reserve capacity in a specific Availability Zone is called a zonal Reserved Instance.

- The Reserved Instance discount applies to matching instance usage in that Availability Zone.
- The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

For example, if you purchase two c4.xlarge default tenancy Linux/Unix Standard Reserved Instances for Availability Zone us-east-1a, then up to two c4.xlarge default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount.

How regional Reserved Instances are applied

A Reserved Instance that is purchased for a Region is called a regional Reserved Instance, and provides Availability Zone and instance size flexibility.

- The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.
- The Reserved Instance discount applies to instance usage within the instance family, regardless of size—this is known as [instance size flexibility](#).

Instance size flexibility

With instance size flexibility, the Reserved Instance discount applies to instance usage for instances that have the same [family, generation, and attribute](#). The Reserved Instance is applied from the smallest to the largest instance size within the instance family based on the normalization factor. For an example of how the Reserved Instance discount is applied, see [Scenario 2: Reserved Instances in a single account using the normalization factor](#).

Limitations

- **Supported:** Instance size flexibility is only supported for Regional Reserved Instances.
- **Not supported:** Instance size flexibility is *not supported* for the following Reserved Instances:
 - Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
 - Reserved Instances for G4ad, G4dn, G5, G5g, Inf1, and Inf2 instances

- Reserved Instances for Windows Server, Windows Server with SQL Standard, Windows Server with SQL Server Enterprise, Windows Server with SQL Server Web, RHEL, and SUSE Linux Enterprise Server
- Reserved Instances with dedicated tenancy

Instance size flexibility determined by normalization factor

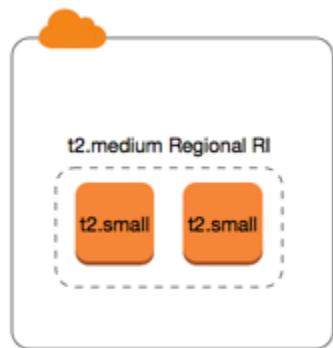

Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

The following table lists the different sizes within an instance family, and the corresponding normalization factor. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

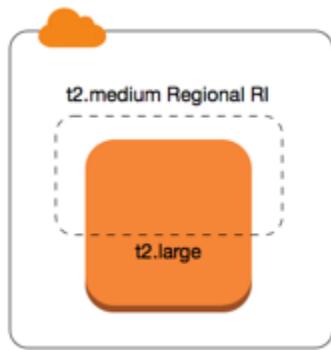

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64

Instance size	Normalization factor
9xlarge	72
10xlarge	80
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
48xlarge	384
56xlarge	448
112xlarge	896

For example, a `t2.medium` instance has a normalization factor of 2. If you purchase a `t2.medium` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running `t2.small` instances in your account in that Region, the billing benefit is applied in full to both instances.

Or, if you have one `t2.large` instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.

The normalization factor is also applied when modifying Reserved Instances. For more information, see [Modify Reserved Instances](#).

Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The `metal` instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an `i3.metal` instance has the same normalization factor as an `i3.16xlarge` instance.

Instance size	Normalization factor
<code>a1.metal</code>	32
<code>m5zn.metal</code> <code>z1d.metal</code>	96
<code>c6g.metal</code> <code>c6gd.metal</code> <code>i3.metal</code> <code>m6g.metal</code> <code>m6gd.metal</code> <code>r6g.metal</code> <code>r6gd.metal</code> <code>x2gd.metal</code>	128
<code>c5n.metal</code>	144

Instance size	Normalization factor
c5.metal c5d.metal i3en.metal m5.metal m5d.metal m5dn.metal m5n.metal r5.metal r5b.metal r5d.metal r5dn.metal r5n.metal	192
u-* .metal	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running `i3.16xlarge` in your account in that Region, the billing benefit is applied in full to the `i3.16xlarge` instance (`i3.16xlarge` normalization factor = 128).
- Or, if you have two running `i3.8xlarge` instances in your account in that Region, the billing benefit is applied in full to both `i3.8xlarge` instances (`i3.8xlarge` normalization factor = 64).
- Or, if you have four running `i3.4xlarge` instances in your account in that Region, the billing benefit is applied in full to all four `i3.4xlarge` instances (`i3.4xlarge` normalization factor = 32).

The opposite is also true. For example, if you purchase two `i3.8xlarge` default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running `i3.metal` instance in that Region, the billing benefit is applied in full to the `i3.metal` instance.

Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

- [Scenario 1: Reserved Instances in a single account](#)
- [Scenario 2: Reserved Instances in a single account using the normalization factor](#)
- [Scenario 3: Regional Reserved Instances in linked accounts](#)
- [Scenario 4: Zonal Reserved Instances in a linked account](#)

Scenario 1: Reserved Instances in a single account

You are running the following On-Demand Instances in account A:

- 4 x m3.large Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x c4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1c

You purchase the following Reserved Instances in account A:

- 4 x m3.large Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x m4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x c4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four m3.large zonal Reserved Instances is used by the four m3.large instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The m4.large regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

An m4.large is equivalent to 4 normalized units/hour.

You've purchased four m4.large regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two m4.xlarge instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four m4.large regional Reserved Instances provide the full billing benefit to the usage of the two m4.xlarge instances.

- The c4.large regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the c4.xlarge instance. A c4.large instance is equivalent to 4 normalized units/hour and a c4.xlarge is equivalent to 8 normalized units/hour.

In this case, the c4.large regional Reserved Instance provides partial benefit to c4.xlarge usage. This is because the c4.large Reserved Instance is equivalent to 4 normalized units/hour of usage, but the c4.xlarge instance requires 8 normalized units/hour. Therefore, the c4.large Reserved Instance billing discount applies to 50% of c4.xlarge usage. The remaining c4.xlarge usage is charged at the On-Demand rate.

Scenario 2: Reserved Instances in a single account using the normalization factor

You are running the following On-Demand Instances in account A:

- 2 x m3.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m3.large Amazon Linux, default tenancy instances in Availability Zone us-east-1b

You purchase the following Reserved Instance in account A:

- 1 x m3.2xlarge Amazon Linux, default tenancy Reserved Instance in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The m3.2xlarge regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy. It applies first to the m3.large instances and then to the m3.xlarge instances, because it applies from the smallest to the largest instance size within the instance family based on the normalization factor.

An m3.large instance is equivalent to 4 normalized units/hour.

An m3.xlarge instance is equivalent to 8 normalized units/hour.

An m3.2xlarge instance is equivalent to 16 normalized units/hour.

The benefit is applied as follows:

The m3.2xlarge regional Reserved Instance provides full benefit to 2 x m3.large usage, because together these instances account for 8 normalized units/hour. This leaves 8 normalized units/hour to apply to the m3.xlarge instances.

With the remaining 8 normalized units/hour, the m3.2xlarge regional Reserved Instance provides full benefit to 1 x m3.xlarge usage, because each m3.xlarge instance is equivalent to 8 normalized units/hour. The remaining m3.xlarge usage is charged at the On-Demand rate.

Scenario 3: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see [Reserved Instances and](#)

[consolidated billing](#). For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x m4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b
- 2 x c4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x c4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

- 4 x m4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1
- 2 x c4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1

The regional Reserved Instance benefits are applied in the following way:

- The discount of the four m4.xlarge Reserved Instances is used by the two m4.xlarge instances and the single m4.2xlarge instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two m4.xlarge that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
- The discount of the two c4.xlarge Reserved Instances applies to the two c4.xlarge instances, because they are a smaller instance size than the c4.2xlarge instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

Scenario 4: Zonal Reserved Instances in a linked account

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to

the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x m4.xlarge Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x m4.xlarge Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the m4.xlarge zonal Reserved Instance owned by account C is applied to the m4.xlarge usage in account A.
- The discount of the m4.xlarge regional Reserved Instance owned by account A is applied to the m4.xlarge usage in account B.
- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see [Reserved Instances in the Billing and Cost Management Report](#).

Note

Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use [On-Demand Capacity Reservations](#).

Use your Reserved Instances

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an On-Demand Instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information when you configure your On-Demand Instance:

Platform

You must specify an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified Linux/UNIX for your Reserved Instance, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

Instance type

If you purchased a zonal Reserved Instance, you must specify the same instance type as your Reserved Instance; for example, t3.large. For more information, see [How zonal Reserved Instances are applied](#).

If you purchased a regional Reserved Instance, you must specify an instance type from the same instance family as the instance type of your Reserved Instance. For example, if you specified t3.xlarge for your Reserved Instance, you must launch your instance from the T3 family, but you can specify any size, for example, t3.medium. For more information, see [How regional Reserved Instances are applied](#).

Availability Zone

If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone.

If you purchased a regional Reserved Instance, you can launch the instance into any Availability Zone in the Region that you specified for the Reserved Instance.

Tenancy

The tenancy (dedicated or shared) of the instance must match the tenancy of your Reserved Instance. For more information, see [Dedicated Instances](#).

For examples of how Reserved Instances are applied to your running On-Demand Instances, see [How Reserved Instances are applied](#). For more information, see [Why aren't my Amazon EC2 Reserved Instances applying to my AWS billing in the way that I expected?](#)

You can use various methods to launch the On-Demand Instances that use your Reserved Instance discount. For information about the different launch methods, see [Launch your instance](#). You can also use Amazon EC2 Auto Scaling to launch an instance. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

How you are billed

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the [payment option](#) specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see [Queue your purchase](#).

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged under standard pricing guidelines. For information, see [AWS Free Tier](#).

Usage billing

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see [Instance lifecycle](#).

A Reserved Instance billing benefit can be applied to a running instance on a per-second basis. Per-second billing is available for instances using an open-source Linux distribution, such as Amazon Linux and Ubuntu. Per-hour billing is used for commercial Linux distributions, such as Red Hat Enterprise Linux and SUSE Linux Enterprise Server.

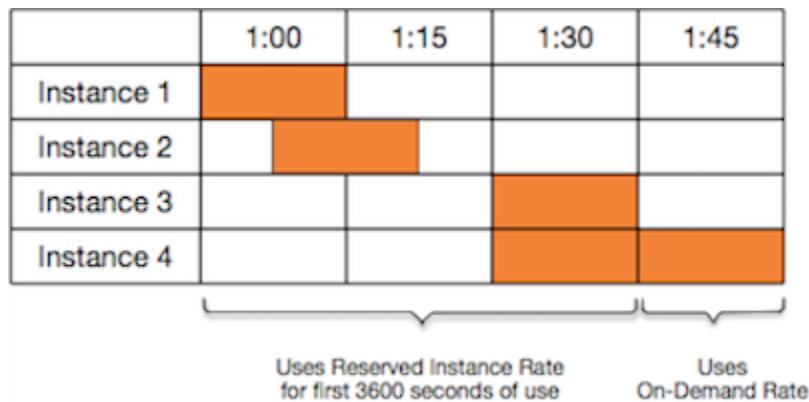

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

	1:00	1:15	1:30	1:45
Instance 1	Orange			
Instance 2		Orange		
Instance 3			Orange	
Instance 4				Orange

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.

Cost Explorer on the [Billing and Cost Management](#) console enables you to analyze the savings against running On-Demand Instances. The [Reserved Instances FAQ](#) includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.

Viewing your bill

You can find out about the charges and fees to your account by viewing the [AWS Billing and Cost Management](#) console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details** expand the **Elastic Compute Cloud** section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see [Reserved Instances](#) under Cost and Usage Report in the *AWS Billing User Guide*.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see [Consolidated billing for AWS Organizations](#).

If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved Instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

 **Note**

Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use [On-Demand Capacity Reservations](#).

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be \$500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

List value = fixed price + (undiscounted recurring hourly price * hours in term)

For example, for a 1-year Partial Upfront t2.small Reserved Instance, assume the upfront price is \$60.00 and the hourly rate is \$0.007. This provides a list value of \$121.32.

121.32 = 60.00 + (0.007 * 8760)

New console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. To display the **Upfront price** column, choose settings () in the top-right corner, turn on **Upfront price**, and choose **Confirm**.

Buy with a discount tier

When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can buy Reserved Instances using any of the Amazon EC2 tools. For more information, see [Buy Reserved Instances](#).

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more information about the temporary Reserved Instance IDs that are created during the purchase process, see [Crossing pricing tiers](#).

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount**—Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.

Crossing pricing tiers

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

Consolidated billing for pricing tiers

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see [Reserved Instances and consolidated billing](#).

Buy Reserved Instances

To purchase a Reserved Instance, search for *Reserved Instance offerings* from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. When you are purchasing a third-party seller's Reserved Instance from the EC2 Reserved Instance Marketplace, if there are offerings similar to your choice but at a lower upfront price, AWS sells you the offerings at the lower upfront price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase.

Note

To purchase and modify Reserved Instances, ensure that your user has the appropriate permissions, such as the ability to describe Availability Zones. For information, see [Example Policies for Working With the AWS CLI or an AWS SDK](#) and [Example Policies for Working in the Amazon EC2 Console](#).

Choosing a platform

Amazon EC2 supports the following Linux platforms for Reserved Instances:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- Red Hat Enterprise Linux with HA

When you purchase a Reserved Instance, you must choose an offering for a *platform* that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, you must choose offerings for those specific platforms, i.e., for the **SUSE Linux** or **Red Hat Enterprise Linux** platforms.
- For all other Linux distributions (including Ubuntu), choose an offering for the **Linux/UNIX** platform.
- If you bring your existing RHEL subscription, you must choose an offering for the **Linux/UNIX** platform, not an offering for the **Red Hat Enterprise Linux** platform.

Note

Ubuntu Pro is not available as a Reserved Instance. For significant savings compared to On-Demand Instance pricing, we recommend that you use Ubuntu Pro with Savings Plans. For more information, see the [Savings Plans User Guide](#).

Important

If you plan to purchase a Reserved Instance to apply to an On-Demand Instance that was launched from an AWS Marketplace AMI, first check the `PlatformDetails` field of the AMI. The `PlatformDetails` field indicates which Reserved Instance to purchase. The platform details of the AMI must match the platform of the Reserved Instance, otherwise the Reserved Instance will not be applied to the On-Demand Instance. For information about how to view the platform details of the AMI, see [Understand AMI billing information](#).

For information about the supported platforms for Windows, see [Choosing a platform](#) in the *Amazon EC2 User Guide for Windows Instances*.

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can queue a purchase for around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On

the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is **queued**. You can cancel a queued purchase any time before its scheduled time. For details, see [Cancel a queued purchase](#).

Buy Standard Reserved Instances

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

New console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.

5. Select other configurations as needed, and then choose **Search**.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose **Add to cart**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd party** in the **Seller** column in the search results. The **Term** column displays non-standard terms. For more information, see [Buy from the Reserved Instance Marketplace](#).

7. To see a summary of the Reserved Instances that you selected, choose **View cart**.
8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

 **Note**

If the status goes to **Retired**, AWS might not have received your payment.

Old console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd Party** in the **Seller** column in the search results. The **Term** column displays non-standard terms.

6. For each Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of the Reserved Instances that you selected, choose **View Cart**.

8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

 **Note**

If the status goes to `retired`, AWS might not have received your payment.

To buy a Standard Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the [describe-reserved-instances-offerings](#) command. Specify `standard` for the `--offering-class` parameter to return only Standard Reserved Instances. You can apply additional parameters to narrow your results. For example, if you want to purchase a regional `t2.large` Reserved Instance with a default tenancy for Linux/UNIX for a 1-year term only:

```
aws ec2 describe-reserved-instances-offerings \
  --instance-type t2.large \
  --offering-class standard \
  --product-description "Linux/UNIX" \
  --instance-tenancy default \
  --filters Name=duration,Values=31536000 Name=scope,Values=Region
```

To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1– or 3-year term.

```
aws ec2 describe-reserved-instances-offerings \
```

```
--instance-type t2.large \
--offering-class standard \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=marketplace,Values=true
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and

ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances](#).

For examples of how Reserved Instances are applied to your running instances, see [How Reserved Instances are applied](#).

Buy Convertible Reserved Instances

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

New console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.

5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.
7. To see a summary of your selection, choose **View cart**.
8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from Payment-pending to Active. When the Reserved Instance is Active, it is ready to use.

 **Note**

If the status goes to Retired, AWS might not have received your payment.

Old console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of your selection, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

 **Note**

If the status goes to `retired`, AWS might not have received your payment.

To buy a Convertible Reserved Instance using the AWS CLI

- Find available Reserved Instances using the [describe-reserved-instances-offerings](#) command. Specify `convertible` for the `--offering-class` parameter to return only Convertible Reserved Instances. You can apply additional parameters to narrow your results; for example, if you want to purchase a regional `t2.large` Reserved Instance with a default tenancy for Linux/UNIX:

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class convertible \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=scope,Values=Region
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

- Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances](#).

Buy from the Reserved Instance Marketplace

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see [Buy Standard Reserved Instances](#).

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:

- **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.

- **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer's purchase invoice. If you need additional information about the seller for tax or related reasons, contact [AWS Support](#).

View your Reserved Instances

You can view the Reserved Instances you've purchased using the Amazon EC2 console, or a command line tool.

To view your Reserved Instances in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Your queued, active, and retired Reserved Instances are listed. The **State** column displays the state.
4. If you are a seller in the Reserved Instance Marketplace, the **My Listings** tab displays the status of a reservation that's listed in the [Reserved Instance Marketplace](#). For more information, see [Reserved Instance listing states](#).

To view your Reserved Instances using the command line

- [describe-reserved-instances](#) (AWS CLI)

- [Get-EC2ReservedInstance](#) (Tools for Windows PowerShell)

Cancel a queued purchase

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.

New console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete queued Reserved Instances**.
5. When prompted for confirmation, choose **Delete**, and then **Close**.

Old console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete Queued Reserved Instances**.
5. When prompted for confirmation, choose **Yes, Delete**.

To cancel a queued purchase using the command line

- [delete-queued-reserved-instances](#) (AWS CLI)
- [Remove-EC2QueuedReservedInstance](#) (Tools for Windows PowerShell)

Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

New console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order all**, and then **Close**.

Old console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order**.

Sell in the Reserved Instance Marketplace

The Reserved Instance Marketplace is a platform that supports the sale of third-party and AWS customers' unused Standard Reserved Instances, which vary in term lengths and pricing options. For example, you might want to sell Reserved Instances after moving instances to a new AWS Region, changing to a new instance type, ending projects before the term expiration, when your business needs change, or if you have unneeded capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.

To fulfill a buyer's request to purchase a third-party seller's Reserved Instance via the EC2 Reserved Instance Marketplace, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see [Buy from the Reserved Instance Marketplace](#).

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see [Register as a seller](#).

The following limitations and restrictions apply when selling Reserved Instances:

- Only Amazon EC2 Standard regional and zonal Reserved Instances can be sold in the Reserved Instance Marketplace.
- Amazon EC2 Convertible Reserved Instances cannot be sold in the Reserved Instance Marketplace.
- Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold in the Reserved Instance Marketplace.
- There must be at least one month remaining in the term of the Standard Reserved Instance.
- You cannot sell a Standard Reserved Instance in a Region that is [disabled by default](#).
- The minimum price allowed in the Reserved Instance Marketplace is \$0.00.
- You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace as long as they have been active in your account for at least 30 days. Additionally, if there is an upfront payment on a Reserved Instance, it can only be sold after AWS has received the upfront payment.
- You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see [Price your Reserved Instances](#). You can also modify your Reserved Instances before listing them. For information, see [Modify Reserved Instances](#).
- AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.
- When you register as a seller, the bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.
- Amazon Internet Services Private Limited (AISPL) customers can't sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see [What are the differences between AWS accounts and AISPL accounts?](#)

Register as a seller

 **Note**

Only the AWS account root user can register an account as a seller.

To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

- **Bank information**—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see [Bank account for disbursement](#).
- **Tax information**—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see [Tax information](#).

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.

To register a default bank account for disbursements

1. Open the [Reserved Instance Marketplace Seller Registration](#) page and sign in using your AWS credentials.
2. On the **Manage Bank Account** page, provide the following information about the bank through to receive payment:
 - Bank account holder name
 - Routing number
 - Account number
 - Bank account type

 **Note**

If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).

After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the [Reserved Instance Marketplace Seller Registration](#) page, sign in with the account that you used when you registered.
2. On the **Manage Bank Account** page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the [Seller Registration Portal](#). The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following

the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see the [IRS](#) website.

Price your Reserved Instances

When setting the price for your Reserved Instances, consider the following:

- **Upfront price** – The upfront price is the only price that you can specify for the Reserved Instance that you're selling. The upfront price is the one-time price that the buyer pays when they purchase a Reserved Instance.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells. For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

The minimum allowed price in the Reserved Instance Marketplace is \$0.00.

- **Limits** – The following limits for selling Reserved Instances apply to the *lifetime* of your AWS account. They are not annual limits.
 - **You can sell up to \$50,000 in Reserved Instances.**
 - **You can sell up to 5,000 Reserved Instances.**

These limits typically can't be increased, but will be evaluated on a case-by-case basis if requested. To request a limit increase, complete the [Service limit increase](#) form. For **Limit type**, choose **EC2 Reserved Instance Sales**.

- **Can't modify** – You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.
- **Can cancel** – You can cancel your listing at any time, as long as it's in the active state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.

List your Reserved Instances

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than \$1.01, the suggested price is \$1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

To list a Reserved Instance in the Reserved Instance Marketplace using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instances to list, and choose **Actions, Sell Reserved Instances**.
4. On the **Configure Your Reserved Instance Listing** page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the **Months Remaining** column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose **Reset**.
6. Choose **Continue** when you are finished configuring your listing.
7. Confirm the details of your listing, on the **Confirm Your Reserved Instance Listing** page and if you're satisfied, choose **List Reserved Instance**.

To view your listings in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance that you've listed and choose the **My Listings** tab near the bottom of the page.

To manage Reserved Instances in the Reserved Instance Marketplace using the AWS CLI

1. Get a list of your Reserved Instances by using the [describe-reserved-instances](#) command.
2. Note the ID of the Reserved Instance you want to list and call [create-reserved-instances-listing](#). You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the [describe-reserved-instances-listings](#) command.
4. To cancel your listing, use the [cancel-reserved-instances-listings](#) command.

Reserved Instance listing states

Listing State on the **My Listings** tab of the Reserved Instances page displays the current status of your listings:

The information displayed by **Listing State** is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the **State** column in the **Reserved Instances** page. This **State** information is about your reservation.

- **active**—The listing is available for purchase.
- **canceled**—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- **closed**—The Reserved Instance is not listed. A Reserved Instance might be closed because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the **My Listings** tab shows that the **Total instance count** matches the count listed under **Sold**. Also, there are no **Available** instances left for your listing, and its **Status** is **closed**.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as **closed**.

For example, you create a listing *Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample* with a listing count of 5.

The **My Listings** tab in the **Reserved Instance** console page displays the listing this way:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.

This is how your listing looks in the **My Listings** tab:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 2
- Available = 3
- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

After your Reserved Instance is sold

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

To track the status of a Reserved Instance listing in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation page, choose **Reserved Instances**.

3. Choose the **My Listings** tab.

The **My Listings** tab contains the **Listing State** value. It also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

You can also use the [describe-reserved-instances-listings](#) command with the appropriate filter to obtain information about your listings.

Getting paid

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

Information shared with the buyer

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls AWS Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, [contact AWS Support](#).

Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone, instance size (within the same instance family and generation), and scope of your Reserved Instance.

Note

You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see [Exchange Convertible Reserved Instances](#).

You can modify all or a subset of your Reserved Instances. You can separate your original Reserved Instances into two or more new Reserved Instances. For example, if you have a reservation for 10 instances in us-east-1a and decide to move 5 instances to us-east-1b, the modification request results in two new reservations: one for 5 instances in us-east-1a and the other for 5 instances in us-east-1b.

You can also *merge* two or more Reserved Instances into a single Reserved Instance. For example, if you have four t2.small Reserved Instances of one instance each, you can merge them to create one t2.large Reserved Instance. For more information, see [Support for modifying instance sizes](#).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the [describe-reserved-instances](#) command.
- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If

you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.

- The modified reservation lists a \$0 fixed price and not the fixed price of the original reservation.
- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

Requirements and restrictions for modification

You can modify these attributes as follows.

Modifiable attribute	Supported platforms	Limitations and considerations
Change Availability Zones within the same Region	Linux and Windows	-
Change the scope from Availability Zone to Region and vice versa	Linux and Windows	A zonal Reserved Instance is scoped to an Availability Zone and reserves capacity

Modifiable attribute	Supported platforms	Limitations and considerations
		<p>in that Availability Zone. If you change the scope from Availability Zone to Region (in other words, from zonal to regional), you lose the capacity reservation benefit.</p> <p>A regional Reserved Instance is scoped to a Region. Your Reserved Instance discount can apply to instances running in any Availability Zone in that Region. Furthermore, the Reserved Instance discount applies to instance usage across all sizes in the selected instance family. If you change the scope from Region to Availability Zone (in other words, from regional to zonal), you lose Availability Zone flexibility and instance size flexibility (if applicable).</p> <p>For more information, see How Reserved Instances are applied.</p>

Modifiable attribute	Supported platforms	Limitations and considerations
Change the instance size within the same instance family and generation	Linux/UNIX only Instance size flexibility is not available for Reserved Instances on the other platforms, which include Linux with SQL Server Standard, Linux with SQL Server Web, Linux with SQL Server Enterprise, Red Hat Enterprise Linux, SUSE Linux, Windows, Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web.	The reservation must use default tenancy. Some instance families are not supported, because there are no other sizes available. For more information, see Support for modifying instance sizes .

Requirements

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
- There cannot be a pending modification request
- The Reserved Instance is not listed in the Reserved Instance Marketplace
- There must be a match between the instance size footprint of the original reservation and the new configuration. For more information, see [Support for modifying instance sizes](#).
- The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type
- The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances

- The Reserved Instance is not a G4, G4ad, G4dn, G5, G5g, Inf1, or Inf2 instance.

Support for modifying instance sizes

You can modify the instance size of a Reserved Instance if the following requirements are met.

Requirements

- The platform is Linux/UNIX.
- You must select another instance size in the same [instance family](#) (indicated by a letter, for example, T) and [generation](#) (indicated by a number, for example, 2).

For example, you can modify a Reserved Instance from t2.small to t2.large because they're both in the same T2 family and generation. But you can't modify a Reserved Instance from T2 to M2 or from T2 to T3, because in both these examples, the target instance family and generation are not the same as the original Reserved Instance.

- You can't modify the instance size of Reserved Instances for the following instances, because each of the following has only one size:
 - t1.micro
- You can't modify the instance size of Reserved Instances for the following combinations of instance family, generation, and attribute:
 - G4ad
 - G4dn
 - G5
 - G5g
 - Inf1
 - Inf2
- The original and new Reserved Instance must have the same instance size footprint.

Contents

- [Instance size footprint](#)
- [Normalization factors for bare metal instances](#)

Instance size footprint

Each Reserved Instance has an *instance size footprint*, which is determined by the normalization factor of the instance size and the number of instances in the reservation. When you modify the instance sizes in an Reserved Instance, the footprint of the new configuration must match that of the original configuration, otherwise the modification request is not processed.

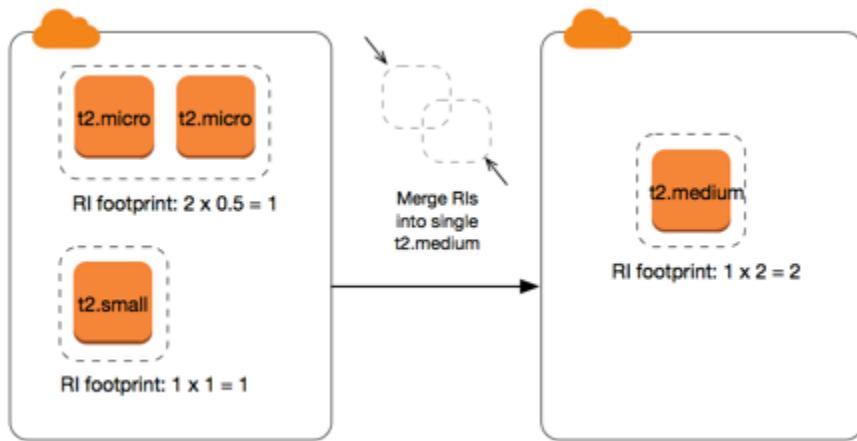

To calculate the instance size footprint of a Reserved Instance, multiply the number of instances by the normalization factor. In the Amazon EC2 console, the normalization factor is measured in units. The following table describes the normalization factor for the instance sizes in an instance family. For example, t2.medium has a normalization factor of 2, so a reservation for four t2.medium instances has a footprint of 8 units.

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48
8xlarge	64
9xlarge	72
10xlarge	80

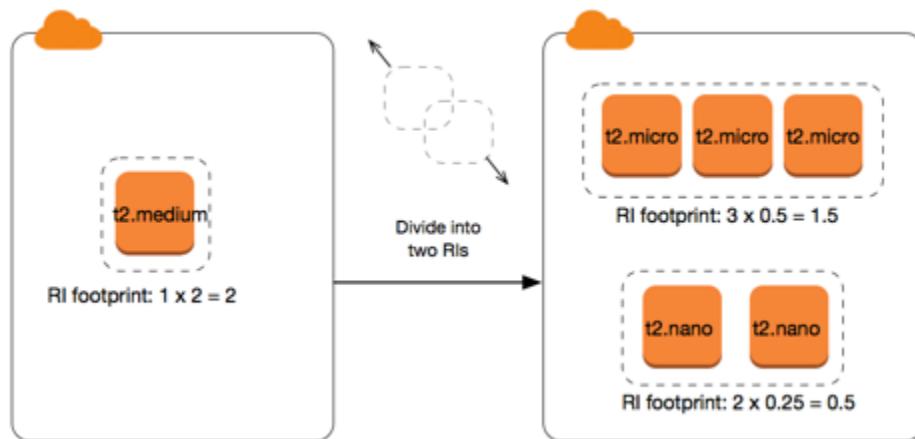

Instance size	Normalization factor
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
48xlarge	384
56xlarge	448
112xlarge	896

You can allocate your reservations into different instance sizes across the same instance family as long as the instance size footprint of your reservation remains the same. For example, you can divide a reservation for one `t2.large` (1 @ 4 units) instance into four `t2.small` (4 @ 1 unit) instances. Similarly, you can combine a reservation for four `t2.small` instances into one `t2.large` instance. However, you cannot change your reservation for two `t2.small` instances into one `t2.large` instance because the footprint of the new reservation (4 units) is larger than the footprint of the original reservation (2 units).

In the following example, you have a reservation with two `t2.micro` instances (1 unit) and a reservation with one `t2.small` instance (1 unit). If you merge both of these reservations to a single reservation with one `t2.medium` instance (2 units), the footprint of the new reservation equals the footprint of the combined reservations.

You can also modify a reservation to divide it into two or more reservations. In the following example, you have a reservation with a t2.medium instance (2 units). You can divide the reservation into two reservations, one with two t2.nano instances (.25 units) and the other with three t2.micro instances (1.5 units).

Normalization factors for bare metal instances

You can modify a reservation with `metal` instances using other sizes within the same instance family. Similarly, you can modify a reservation with instances other than bare metal instances using the `metal` size within the same instance family. Generally, a bare metal instance is the same size as the largest available instance size within the same instance family. For example, an `i3.metal` instance is the same size as an `i3.16xlarge` instance, so they have the same normalization factor.

The following table describes the normalization factor for the bare metal instance sizes in the instance families that have bare metal instances. The normalization factor for `metal` instances depends on the instance family, unlike the other instance sizes.

Instance size	Normalization factor
a1.metal	32
m5zn.metal z1d.metal	96
c6g.metal c6gd.metal i3.metal m6g.metal m6gd.metal r6g.metal r6gd.metal x2gd.metal	128
c5n.metal	144
c5.metal c5d.metal i3en.metal m5.metal m5d.metal m5dn.metal m5n.metal r5.metal r5b.metal r5d.metal r5dn.metal r5n.metal	192
u-* .metal	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance, you can divide the reservation as follows:

- An `i3.16xlarge` is the same size as an `i3.metal` instance, so its normalization factor is 128 (128/1). The reservation for one `i3.metal` instance can be modified into one `i3.16xlarge` instance.
- An `i3.8xlarge` is half the size of an `i3.metal` instance, so its normalization factor is 64 (128/2). The reservation for one `i3.metal` instance can be divided into two `i3.8xlarge` instances.
- An `i3.4xlarge` is a quarter the size of an `i3.metal` instance, so its normalization factor is 32 (128/4). The reservation for one `i3.metal` instance can be divided into four `i3.4xlarge` instances.

Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable [restrictions](#). Before you modify the instance size, calculate the total [instance size footprint](#) of the original

reservations that you want to modify and ensure that it matches the total instance size footprint of your new configurations.

New console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.
-  **Note**
If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.
3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration.
 - **Scope:** Choose whether the configuration applies to an Availability Zone or to the whole Region.
 - **Availability Zone:** Choose the required Availability Zone. Not applicable for regional Reserved Instances.
 - **Instance type:** Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
 - **Count:** Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.
 4. Choose **Continue**.
 5. To confirm your modification choices when you finish specifying your target configurations, choose **Submit modifications**.
 6. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.

- **active (*pending modification*)** — Transition state for original Reserved Instances
- **retired (*pending modification*)** — Transition state for original Reserved Instances while new Reserved Instances are being created
- **retired** — Reserved Instances successfully modified and replaced
- **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

Old console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.

 **Note**

If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.

3. The first entry in the modification table displays attributes of selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration, and then choose **Continue**:
 - **Scope:** Choose whether the configuration applies to an Availability Zone or to the whole Region.
 - **Availability Zone:** Choose the required Availability Zone. Not applicable for regional Reserved Instances.
 - **Instance Type:** Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
 - **Count:** Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can

change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. To confirm your modification choices when you finish specifying your target configurations, choose **Submit Modifications**.
5. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.
 - **active (*pending modification*)** — Transition state for original Reserved Instances
 - **retired (*pending modification*)** — Transition state for original Reserved Instances while new Reserved Instances are being created
 - **retired** — Reserved Instances successfully modified and replaced
 - **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

To modify your Reserved Instances using the command line

1. To modify your Reserved Instances, you can use one of the following commands:
 - [modify-reserved-instances](#) (AWS CLI)
 - [Edit-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)
2. To get the status of your modification request (processing, fulfilled, or failed), use one of the following commands:
 - [describe-reserved-instances-modifications](#) (AWS CLI)
 - [Get-EC2ReservedInstancesModification](#) (AWS Tools for Windows PowerShell)

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for

resubmitting another modification request. Ensure that you have read the applicable [restrictions](#) before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the **Reserved Instances** page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

Exchange Convertible Reserved Instances

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.

You can't exchange Standard Reserved Instances, but you can modify them. For more information, see [Modify Reserved Instances](#).

Contents

- [Requirements for exchanging Convertible Reserved Instances](#)

- [Calculate Convertible Reserved Instances exchanges](#)
- [Merge Convertible Reserved Instances](#)
- [Exchange a portion of a Convertible Reserved Instance](#)
- [Submit exchange requests](#)

Requirements for exchanging Convertible Reserved Instances

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:

- Active
- Not pending a previous exchange request
- Have at least 24 hours remaining before it expires

The following rules apply:

- Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.
- Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
- You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
- To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see [Exchange a portion of a Convertible Reserved Instance](#). For more information about modifying your Reserved Instances, see [Modify Reserved Instances](#).
- All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

 **Note**

If the total upfront payment required for the exchange (true-up cost) is less than \$0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is \$0.00 or more.

Note

If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.
- You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.
- You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.

Note

If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.
- If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see [Merge Convertible Reserved Instances](#).
- When Amazon EC2 exchanges a Convertible Reserved Instance, it retires the associated reservation, and transfers the end date to the new reservation. After the exchange, Amazon EC2 sets both the end date for the old reservation and the start date for the new reservation equal to the date of the exchange. For example, if you exchange a three-year reservation that had 16

months left in its term, the new reservation is a 16-month reservation with the same end date as the reservation from the Convertible Reserved Instance that you exchanged.

Calculate Convertible Reserved Instances exchanges

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.

Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x \$35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of \$10.

$$\$35/\$10 = 3.5$$

You can exchange your Convertible Reserved Instance for three \$10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

$$3.5 = 3 \text{ whole Convertible Reserved Instances} + 1 \text{ additional Convertible Reserved Instance}$$

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is \$500, and the new reservation would normally cost \$600 on a prorated basis, you are charged \$100.

$$\$600 \text{ prorated upfront cost of new reservations} - \$500 \text{ remaining upfront cost of old reservations} = \$100 \text{ difference}$$

Merge Convertible Reserved Instances

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the old Convertible Reserved Instances, or the highest of

the Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.

For example, you have the following Convertible Reserved Instances in your account:

Reserved Instance ID	Term	Expiration date
aaaa1111	1-year	2018-12-31
bbbb2222	1-year	2018-07-31
cccc3333	3-year	2018-06-30
dddd4444	3-year	2019-12-31

- You can merge bbbb2222 and cccc3333 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.
- You can merge cccc3333 and dddd4444 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

Exchange a portion of a Convertible Reserved Instance

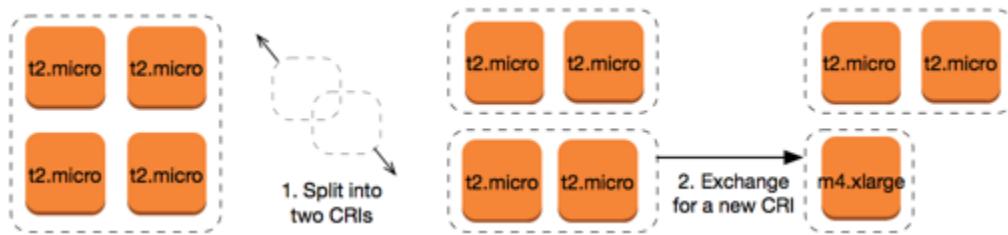

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

Example Example: Convertible Reserved Instance with multiple instances

In this example, you have a t2.micro Convertible Reserved Instance with four instances in the reservation. To exchange two t2.micro instances for an m4.xlarge instance:

1. Modify the t2.micro Convertible Reserved Instance by splitting it into two t2.micro Convertible Reserved Instances with two instances each.

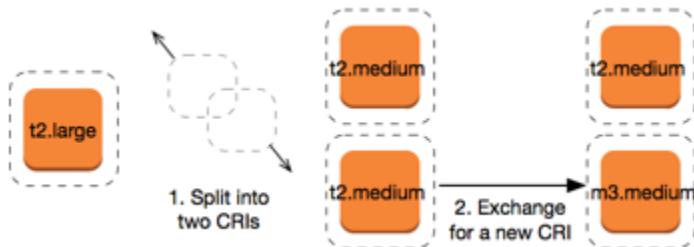

2. Exchange one of the new t2.micro Convertible Reserved Instances for an m4.xlarge Convertible Reserved Instance.

Example Example: Convertible Reserved Instance with a single instance

In this example, you have a t2.large Convertible Reserved Instance. To change it to a smaller t2.medium instance and a m3.medium instance:

1. Modify the t2.large Convertible Reserved Instance by splitting it into two t2.medium Convertible Reserved Instances. A single t2.large instance has the same instance size footprint as two t2.medium instances.
2. Exchange one of the new t2.medium Convertible Reserved Instances for an m3.medium Convertible Reserved Instance.

For more information, see [Support for modifying instance sizes](#) and [Submit exchange requests](#).

Submit exchange requests

You can exchange your Convertible Reserved Instances using the Amazon EC2 console or a command line tool.

Exchange a Convertible Reserved Instance using the console

You can search for Convertible Reserved Instances offerings and select your new configuration from the choices provided.

New console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find offering**.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose **Review**.
6. Choose **Exchange**, and then **Close**.

Old console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find Offering**.
4. Select a new Convertible Reserved Instance. The **Instance Count** column displays the number of Reserved Instances that you receive for the exchange. When you have selected a Convertible Reserved Instance that meets your needs, choose **Exchange**.

The Reserved Instances that were exchanged are retired, and the new Reserved Instances are displayed in the Amazon EC2 console. This process can take a few minutes to propagate.

Exchange a Convertible Reserved Instance using the command line interface

To exchange a Convertible Reserved Instance, first find a new Convertible Reserved Instance that meets your needs:

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (Tools for Windows PowerShell)

Get a quote for the exchange, which includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:

- [get-reserved-instances-exchange-quote](#) (AWS CLI)
- [GetEC2-ReservedInstancesExchangeQuote](#) (Tools for Windows PowerShell)

Finally, perform the exchange:

- [accept-reserved-instances-exchange-quote](#) (AWS CLI)
- [Confirm-EC2ReservedInstancesExchangeQuote](#) (Tools for Windows PowerShell)

Reserved Instance quotas

You can purchase new Reserved Instances each month. The number of new Reserved Instances that you can purchase each month is determined by your monthly quota, as follows:

Quota description	Default quota
New regional Reserved Instances	20 per Region per month
New zonal Reserved Instances	20 per Availability Zone per month

For example, in a Region with three Availability Zones, the default quota is 80 new Reserved Instances per month, calculated as follows:

- 20 regional Reserved Instances for the Region
- Plus 60 zonal Reserved Instances (20 for each of the three Availability Zones)

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

View the number of Reserved Instances you have purchased

The number of Reserved Instances that you purchase is indicated by the **Instance count** field (console) or the `InstanceCount` parameter (AWS CLI). When you purchase new Reserved Instances, the quota is measured against the total instance count. For example, if you purchase a

single Reserved Instance configuration with an instance count of 10, the purchase counts towards your quota as 10, not 1.

You can view how many Reserved Instances you have purchased by using the Amazon EC2 or the AWS CLI.

Console

To view the number of Reserved Instances you have purchased

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select a Reserved Instance configuration from the table, and check the **Instance count** field.

In the following screenshot, the selected line represents a single Reserved Instance configuration for a t3.micro instance type. The **Instance count** column in the table view and the **Instance count** field in the detail view (outlined in the screenshot) indicate that there are 10 Reserved Instances for this configuration.

The screenshot shows the Amazon EC2 Reserved Instances page. At the top, there is a search bar and a 'Purchase Reserved Instances' button. Below the search bar is a table with columns: Instance type, Scope, Availability Zone, Start, Expires, and Offering class. One row is selected, highlighted with a red box around the 'Instance count' cell, which contains the value '10'. Another row below it has an 'Instance count' of '4'. At the bottom of the table, it says '1 Reserved Instance selected'. Below the table, there is a 'Details' tab and a 'My Listings' tab. The 'Details' tab is active, showing a detailed view of a selected Reserved Instance. This view includes fields for Instance type (t3.micro), Scope (Region), Instance count (10, also outlined in a red box), Availability Zone (-), Start date (August 27, 2022), Expires date (August 27, 2023), Payment option (All upfront), Time left (around 50 weeks 6 days), Platform (Linux/UNIX), Upfront price (\$59.00), Usage price (\$0.00), State (Active), Hourly charges (\$0.00), Term (1 year), Offering class (Standard), and Tenancy (Default).

AWS CLI

To view the number of Reserved Instances you have purchased

Use the [describe-reserved-instances](#) CLI command and specify the ID of the Reserved Instance configuration.

```
aws ec2 describe-reserved-instances \
    --reserved-instances-ids 2fbf16dd-98b6-4a3a-955f-83f87790f04b \
    --output table
```

Example output – The InstanceCount field indicates that there are 10 Reserved Instances for this configuration.

Considerations

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by

purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional Reserved Instances, you will not be able to launch more instances because you have reached your On-Demand Instance limit.

Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches or exceeds the number of regional Reserved Instances you intend to own. If required, make sure you request an increase to your On-Demand Instance limit *before* purchasing more regional Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone—provides a capacity reservation as well as a discount. You *can exceed* your running On-Demand Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20 On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a total of 40 running instances.

View your Reserved Instance quotas and request a quota increase

The Amazon EC2 console provides quota information. You can also request an increase in your quotas. For more information, see [View your current quotas](#) and [Request an increase](#).

Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see [Amazon EC2 Spot Instances](#).

For a comparison of the different purchasing options for EC2 instances, see [Instance purchasing options](#).

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- *Spot capacity pool* – A set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone.
- *Spot price* – The current price of a Spot Instance per hour.
- *Spot Instance request* – Requests a Spot Instance. When capacity is available, Amazon EC2 fulfills your request. A Spot Instance request is either *one-time* or *persistent*. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is interrupted.
- *EC2 instance rebalance recommendation* – Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption.

This signal provides an opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.

- *Spot Instance interruption* – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

Key differences between Spot Instances and On-Demand Instances

The following table lists the key differences between Spot Instances and [On-Demand Instances](#).

	Spot Instances	On-Demand Instances
Launch time	Can only be launched immediately if the Spot Instance request is active and capacity is available.	Can only be launched immediately if you make a manual launch request and capacity is available.
Available capacity	If capacity is not available, the Spot Instance request continues to automatically make the launch request until capacity becomes available.	If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).
Hourly price	The hourly price for Spot Instances varies based on long-term supply and demand.	The hourly price for On-Demand Instances is static.
Rebalance recommendation	The signal that Amazon EC2 emits for a running Spot Instance when the instance is at an elevated risk of interruption.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).
Instance interruption	You can stop and start an Amazon EBS-backed Spot Instance. In addition, Amazon EC2 can interrupt an individual Spot Instance if capacity is no longer available.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).

How to get started

Best practices for EC2 Spot

Amazon EC2 Spot Instances are spare EC2 compute capacity in the AWS Cloud that are available to you at savings of up to 90% off compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notification, when Amazon EC2 needs the capacity back.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn't a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. They're also not recommended for workloads that are intolerant of occasional periods when the target capacity is not completely available. We strongly warn against using Spot Instances for these workloads or attempting to fail-over to On-Demand Instances to handle interruptions.

Regardless of whether you're an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

Spot best practices

- [Prepare individual instances for interruptions](#)
- [Be flexible about instance types and Availability Zones](#)
- [Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity](#)
- [Use the price and capacity optimized allocation strategy](#)
- [Use proactive capacity rebalancing](#)
- [Use integrated AWS services to manage your Spot Instances](#)
- [Which is the best Spot request method to use?](#)

Prepare individual instances for interruptions

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a signal that notifies you when a Spot Instance is at an elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this signal by using the Capacity Rebasing feature in Auto Scaling groups and EC2 Fleet. For more information, see [Use proactive capacity rebalancing](#).

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in [Amazon EventBridge](#) that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see [Monitor rebalance recommendation signals](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

For more information, see [EC2 instance rebalance recommendations](#) and [Spot Instance interruptions](#).

Be flexible about instance types and Availability Zones

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, `m5.large`) and Availability Zone (for example, `us-east-1a`). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for `c5.large` if you'd be willing to use larges from the `c4`, `m5`, and `m4` families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and EC2 Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or an EC2 Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide* and [Create an EC2 Fleet](#) in this user guide.

Use the price and capacity optimized allocation strategy

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the price-capacity-optimized strategy because this strategy automatically provisions instances from the most-available Spot capacity pools that also have the lowest possible price. You can also take advantage of the price-capacity-optimized allocation strategy in EC2 Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information about allocation strategies, see [Spot Instances](#) in the *Amazon EC2 Auto Scaling User Guide* and [When workloads have a high cost of interruption](#) in this user guide.

Use proactive capacity rebalancing

Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running Spot Instance receives the two-minute Spot Instance interruption notice. When Capacity Rebalancing is enabled, Auto Scaling or EC2 Fleet attempts to proactively replace Spot Instances that have received a rebalance recommendation, providing the opportunity to rebalance your workload to new Spot Instances that are not at elevated risk of interruption.

Capacity Rebalancing complements the price-capacity-optimized allocation strategy (which is designed to help find the most optimal spare capacity) and the mixed instances policy (which is designed to enhance availability by deploying instances across multiple instance types running in multiple Availability Zones).

For more information, see [Capacity Rebalancing](#).

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon Elastic Container Service, AWS Batch, Amazon Elastic Kubernetes Service, Amazon SageMaker, AWS Elastic Beanstalk, and Amazon GameLift. To learn more about Spot best practices with these services, see the [Amazon EC2 Spot Instances Workshops Website](#).

Which is the best Spot request method to use?

How Spot Instances work

To launch a Spot Instance, either you create a *Spot Instance request*, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see [Getting Started with Amazon EC2 Spot Instances](#). In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request by using the [launch instance wizard](#) in the Amazon EC2 console or the [run-instances](#) AWS CLI command. For more information, see [Create a Spot Instance request](#).
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see [Create an EC2 Fleet](#).
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see [Create a Spot Fleet request](#).

Your Spot Instance launches if there is available capacity.

Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a *Spot Instance interruption*).

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises or when the supply of Spot Instances decreases. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see [Spot Instance interruptions](#).

You can stop, start, reboot, or terminate an Amazon EBS-backed Spot Instance. The Spot service can stop, terminate, or hibernate a Spot Instance when it interrupts it.

Contents

- [Launch Spot Instances in a launch group](#)
- [Launch Spot Instances in an Availability Zone group](#)

- [Launch Spot Instances in a VPC](#)

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group, it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC

Amazon EC2 uses the Availability Zone for the specified subnet.

Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- [Default VPC] If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot Instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When your Spot request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

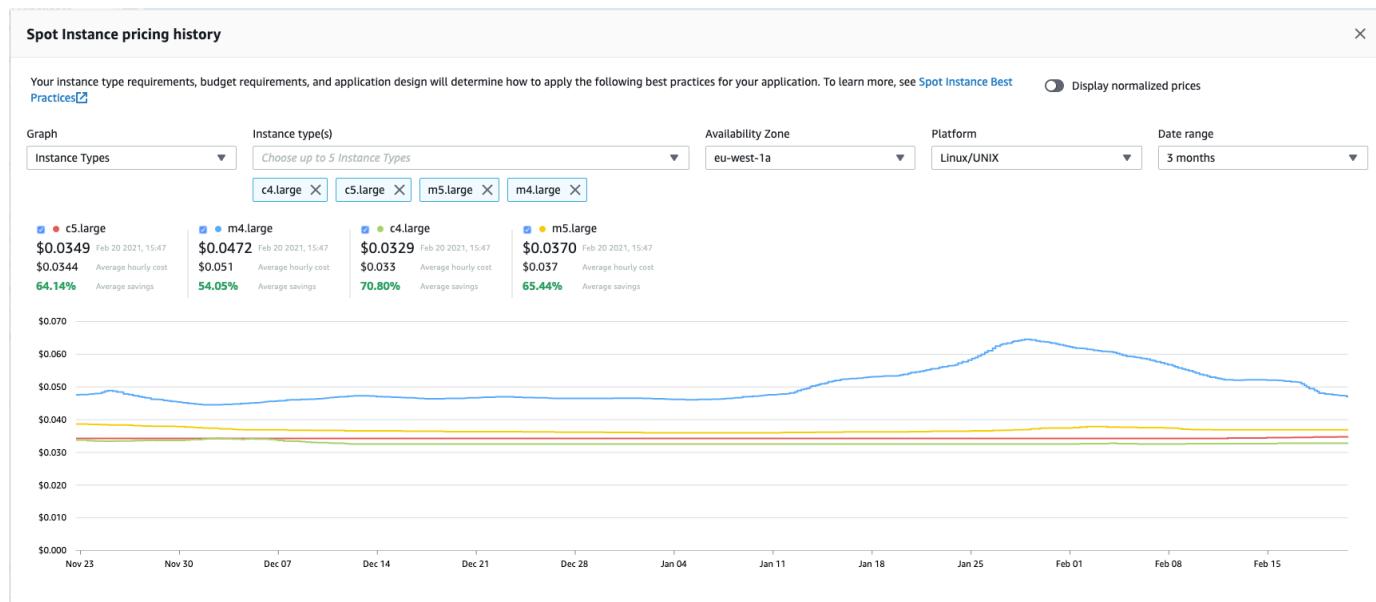

To view the current Spot prices

For the *current* Spot Instance prices, see [Amazon EC2 Spot Instances Pricing](#).

To view the Spot price history (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Pricing history**.
4. For **Graph**, choose to compare the price history by **Availability Zones** or by **Instance Types**.
 - If you choose **Availability Zones**, then choose the **Instance type**, operating system (**Platform**), and **Date range** for which to view the price history.
 - If you choose **Instance Types**, then choose up to five **Instance type(s)**, the **Availability Zone**, operating system (**Platform**), and **Date range** for which to view the price history.

The following screenshot shows a price comparison for different instance types.

5. Hover (move your pointer) over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.
6. To display the price per vCPU, toggle on **Display normalized prices**. To display the price for the instance type, toggle off **Display normalized prices**.

To view the Spot price history using the command line

You can use one of the following commands. For more information, see [Access Amazon EC2](#).

- [describe-spot-price-history](#) (AWS CLI)
- [Get-EC2SpotPriceHistory](#) (AWS Tools for Windows PowerShell)

Savings from purchasing Spot Instances

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the **Savings** section shows the Spot usage and savings information for a Spot Fleet.

Spot usage and savings

4 Spot Instances	266 vCPU-hours	700 Mem(GiB)-hours	\$9.55 On-Demand total	\$2.99 Spot total	69% Savings
				\$0.0112 Average cost per vCPU-hour	\$0.0043 Average cost per mem(GiB)-hour

Details

t3.medium (1)	2 vCPU hours	4 mem(GiB)-hours	\$0.01 total	70% savings
m4.large (1)	144 vCPU hours	576 mem(GiB)-hours	\$2.52 total	68% savings
t2.micro (2)	120 vCPU hours	120 mem(GiB)-hours	\$0.46 total	70% savings

You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per vCPU-hour = Spot total / vCPU-hours**.
- **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per mem(GiB)-hour = Spot total / Mem(GiB)-hours**.

- **Details table** – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

To view the savings information for a Spot Fleet (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.

Alternatively, select the check box next to the Spot Fleet request ID and choose the **Savings** tab.

4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

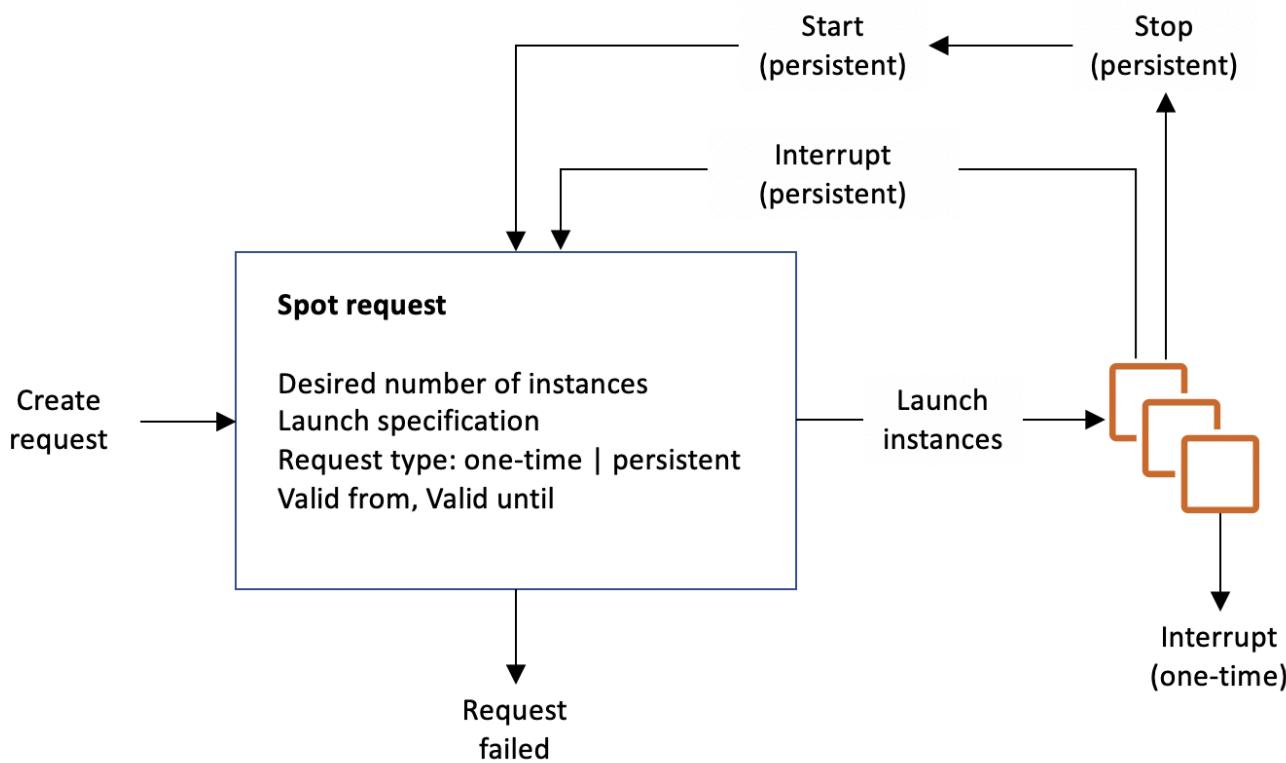

To view the savings information for all running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

Work with Spot Instances

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, and the Availability Zone. If capacity is available, Amazon EC2 fulfills your request immediately. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.

Spot Instance request states

A Spot Instance request can be in one of the following states:

- open – The request is waiting to be fulfilled.
- active – The request is fulfilled and has an associated Spot Instance.
- failed – The request has one or more bad parameters.
- closed – The Spot Instance was interrupted or terminated.
- disabled – You stopped the Spot Instance.
- cancelled – You canceled the request, or the request expired.

The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).

A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.

A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see [Stop a Spot Instance](#), [Start a Spot Instance](#), and [Terminate a Spot Instance](#).

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see [Spot request status](#).

Specify a tenancy for your Spot Instances

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see [Dedicated Instances](#) and the [Amazon EC2 Dedicated Instances](#) product page.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of dedicated when you create the Spot Instance request. For more information, see [Create a Spot Instance request](#).
- Request a Spot Instance in a VPC with an instance tenancy of dedicated. For more information, see [Create a VPC with a dedicated instance tenancy](#). You cannot request a Spot Instance with a tenancy of default if you request it in a VPC with an instance tenancy of dedicated.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see [Using Service-Linked Roles](#) in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf.

Permissions granted by AWSServiceRoleForEC2Spot

Amazon EC2 uses **AWSServiceRoleForEC2Spot** to complete the following actions:

- `ec2:DescribeInstances` – Describe Spot Instances
- `ec2:StopInstances` – Stop Spot Instances
- `ec2:StartInstances` – Start Spot Instances

Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2Spot** service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2Spot** role in your AWS account. For more information, see [A New Role Appeared in My Account](#) in the *IAM User Guide*.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

To create AWSServiceRoleForEC2Spot using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select type of trusted entity** page, choose **EC2, EC2 - Spot Instances**, **Next: Permissions**.
5. On the next page, choose **Next:Review**.
6. On the **Review** page, choose **Create role**.

To create AWSServiceRoleForEC2Spot using the AWS CLI

Use the [create-service-linked-role](#) command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```

If you no longer need to use Spot Instances, we recommend that you delete the **AWSServiceRoleForEC2Spot** role. After this role is deleted from your account, Amazon EC2 will create the role again if you request Spot Instances.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an [encrypted AMI](#) or an encrypted Amazon EBS snapshot for your Spot Instances and you use a customer managed key for encryption, you must grant the **AWSServiceRoleForEC2Spot** role permission to use the customer managed key so that Amazon EC2 can launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using Grants](#) and [Using Key Policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

To grant the **AWSServiceRoleForEC2Spot** role permissions to use the customer managed key

- Use the [create-grant](#) command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Spot** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the `key-id` parameter and the ARN of the customer managed key. The principal is specified by the `grantee-principal` parameter and the ARN of the **AWSServiceRoleForEC2Spot** service-linked role.

```
aws kms create-grant \
  --region us-east-1 \
  --key-id arn:aws:kms:us-
east-1:44445556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
  --grantee-principal arn:aws:iam::111122223333:role/aws-service-role/
spot.amazonaws.com/AWSServiceRoleForEC2Spot \
  --operations "Decrypt" "Encrypt" "GenerateDataKey"
  "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
  "ReEncryptTo"
```

Create a Spot Instance request

You can use the [launch instance wizard](#) in the Amazon EC2 console or the [run-instances](#) AWS CLI command to request a Spot Instance in the same way that you can launch an On-Demand Instance. This method is only recommended for the following reasons:

- You're already using the [launch instance wizard](#) or [run-instances](#) command to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter.
- You do not need multiple instances with different instance types.

This method is generally not recommended for launching Spot Instances because you can't specify multiple instance types, and you can't launch Spot Instances and On-Demand Instances in the same request. For the preferred methods for launching Spot Instances, which include launching a *fleet* that includes Spot Instances and On-Demand Instances with multiple instance types, see [Which is the best Spot request method to use?](#)

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests so that you can track the status of each request separately. For more information about tracking Spot Instance requests, see [Spot request status](#).

New console

To create a Spot Instance request using the launch instance wizard

Steps 1–9 are the same steps you'd use to launch an On-Demand Instance. At Step 10, you configure the Spot Instance request.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, you can name your instance, and tag the Spot Instance request, the instance, the volumes, and the elastic graphics. For information about tags, see [Tag your Amazon EC2 resources](#).
 - a. For **Name**, enter a descriptive name for your instance.

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.

- b. To tag the Spot Instance request, the instance, the volumes, and the elastic graphics, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

5. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance, and then select an AMI. For more information, see [Application and OS Images \(Amazon Machine Image\)](#).
6. Under **Instance type**, select the instance type that meets your requirements for the hardware configuration and size of your instance. For more information, see [Instance type](#).
7. Under **Key pair (login)**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

 **Important**

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

8. Under **Network settings**, use the default settings, or choose **Edit** to configure the network settings as necessary.

Security groups form part of the network settings, and define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance.

For more information, see [Network settings](#).

9. The AMI you selected includes one or more volumes of storage, including the root device volume. Under **Configure storage**, you can specify additional volumes to attach to the instance by choosing **Add new volume**. For more information, see [Configure storage](#).
10. Under **Advanced details**, configure the Spot Instance request as follows:

- a. Under **Purchasing option**, select the **Request Spot Instances** check box.
- b. You can either keep the default configuration for the Spot Instance request, or choose **Customize** (at the right) to specify custom settings for your Spot Instance request.

When you choose **Customize**, the following fields appear.

- i. **Maximum price:** You can request Spot Instances at the Spot price, capped at the On-Demand price, or you can specify the maximum amount you're willing to pay.

⚠️ Warning

If you specify a maximum price, your instances will be interrupted more frequently than if you choose **No maximum price**.

- **No maximum price:** Your Spot Instance will launch at the current Spot price. The price will never exceed the On-Demand price. (Recommended)
- **Set your maximum price (per instance/hour):** You can specify the maximum amount you're willing pay.
 - If you specify a maximum price that is less than the current Spot price, your Spot Instance will not launch.
 - If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
 - Regardless of the maximum price you specify, you will always be charged the current Spot price.

To review Spot price trends, see [Spot Instance pricing history](#).

- ii. **Request type:** The Spot Instance request type that you choose determines what happens if your Spot Instance is interrupted.
- **One-time:** Amazon EC2 places a one-time request for your Spot Instance. If your Spot Instance is interrupted, the request is not resubmitted.
 - **Persistent request:** Amazon EC2 places a persistent request for your Spot Instance. If your Spot Instance is interrupted, the request is resubmitted to replenish the interrupted Spot Instance.

If you do not specify a value, the default is a one-time request.

- iii. **Valid to:** The expiration date of a *persistent* Spot Instance request.

This field is not supported for one-time requests. A *one-time* request remains active until all the instances in the request launch or you cancel the request.

- **No request expiry date:** The request remains active until you cancel it.
 - **Set your request expiry date:** The persistent request remains active until the date that you specify, or until you cancel it.
- iv. **Interruption behavior:** The behavior that you choose determines what happens when a Spot Instance is interrupted.
- For persistent requests, valid values are **Stop** and **Hibernate**. When an instance is stopped, charges for EBS volume storage apply.

 **Note**

Spot Instances now use the same hibernation functionality as On-Demand Instances. To enable hibernation, you can either choose **Hibernate** here, or you can choose **Enable** from the **Stop - Hibernate behavior** field, which appears lower down in the launch instance wizard. For the hibernation prerequisites, see [Prerequisites for Amazon EC2 instance hibernation](#).

- For one-time requests, only **Terminate** is valid.

If you do not specify a value, the default is **Terminate**, which is not valid for a persistent Spot Instance request. If you keep the default and try to launch a persistent Spot Instance request, you'll get an error.

For more information, see [Interruption behavior](#).

11. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.

 **Note**

Amazon EC2 creates a separate request for each Spot Instance.

12. On the **Summary** panel, review the details of your instance, and make any necessary changes. After you submit your Spot Instance request, you can't change the parameters of the request. You can navigate directly to a section in the launch instance wizard by choosing its link in the **Summary** panel. For more information, see [Summary](#).
13. When you're ready to launch your instance, choose **Launch instance**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Old console

To create a Spot Instance request using the launch instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch Instance**.
4. On the **Choose an Amazon Machine Image (AMI)** page, choose an AMI. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\)](#).
5. On the **Choose an Instance Type** page , select the hardware configuration and size of the instance to launch, and then choose Next: Configure Instance Details. For more information, see [Step 2: Choose an Instance Type](#).
6. On the **Configure Instance Details** page, configure the Spot Instance request as follows:
 - **Number of instances:** Enter the number of instances to launch.

 **Note**

Amazon EC2 creates a separate request for each Spot Instance.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. When you choose this option, the following fields appear.
 - **Current price:** The current Spot price in each Availability Zone is displayed for the instance type that you selected.
 - (Optional) **Maximum price:** You can leave the field empty, or you can specify the maximum amount you're willing to pay.

⚠️ Warning

If you specify a maximum price, your instances will be interrupted more frequently than if you leave the field empty.

- If you specify a maximum price that is less than the Spot price, your Spot Instance will not launch.
- If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
- Regardless of the maximum price you specify, you will always be charged the current Spot price.
- If you leave the field empty, you'll pay the current Spot price.
- **Persistent request:** Choose **Persistent request** to resubmit the Spot Instance request if your Spot Instance is interrupted.
- **Interruption behavior:** By default, the Spot service terminates a Spot Instance when it is interrupted. If you choose **Persistent request**, you can then specify that the Spot service stops or hibernates your Spot Instance when it's interrupted. For more information, see [Interruption behavior](#).
- (Optional) **Request valid to:** Choose **Edit** to specify when the Spot Instance request expires.

For more information about configuring your Spot Instance, see [Step 3: Configure Instance Details](#).

7. The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. For more information, see [Step 4: Add Storage](#).
8. On the **Add Tags** page, specify [tags](#) by providing key and value combinations. For more information, see [Step 5: Add Tags](#).
9. On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see

[Amazon EC2 security groups for Linux instances](#).) Select or create a security group, and then choose **Review and Launch**. For more information, see [Step 6: Configure Security Group](#).

10. On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link. When you are ready, choose **Launch**. For more information, see [Step 7: Review Instance Launch and Select Key Pair](#).
11. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair that you created when getting set up. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

⚠ Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

12. To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

AWS CLI

To create a Spot Instance request using [run-instances](#)

Use the [run-instances](#) command and specify the Spot Instance options in the `--instance-market-options` parameter.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type t2.micro \
--count 5 \
--subnet-id subnet-08fc749671b2d077c \
--key-name MyKeyPair \
--security-group-ids sg-0b0384b66d7d692f9 \
--instance-market-options file://spot-options.json
```

The following is the data structure to specify in the JSON file for `--instance-market-options`. You can also specify `ValidUntil` and `InstanceInterruptionBehavior`. If you do not specify a field in the data structure, the default value is used.

The following example creates a persistent request.

```
{  
    "MarketType": "spot",  
    "SpotOptions": {  
        "SpotInstanceType": "persistent"  
    }  
}
```

To create a Spot Instance request using [request-spot-instances](#)

Note

We strongly discourage using the [request-spot-instances](#) command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use?](#)

Use the [request-spot-instances](#) command to create a one-time request.

```
aws ec2 request-spot-instances \  
  --instance-count 5 \  
  --type "one-time" \  
  --launch-specification file://specification.json
```

Use the [request-spot-instances](#) command to create a persistent request.

```
aws ec2 request-spot-instances \  
  --instance-count 5 \  
  --type "persistent" \  
  --launch-specification file://specification.json
```

For example launch specification files to use with these commands, see [Spot Instance request example launch specifications](#). If you download a launch specification file from the Spot

Requests console, you must use the [request-spot-fleet](#) command instead (the Spot Requests console specifies a Spot Instance request using a Spot Fleet).

Find running Spot Instances

Amazon EC2 launches a Spot Instance when capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself.

To find running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**. You can see both Spot Instance requests and Spot Fleet requests. If a Spot Instance request has been fulfilled, **Capacity** is the ID of the Spot Instance. For a Spot Fleet, **Capacity** indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose **Instances**.

Note

For Spot Instance requests that are created by a Spot Fleet, the requests are not tagged instantly with the system tag that indicates the Spot Fleet to which they belong, and for a period of time may appear separate from Spot Fleet request.

Alternatively, in the navigation pane, choose **Instances**. In the top right corner, choose the settings icon (

To find running Spot Instances (AWS CLI)

To enumerate your Spot Instances, use the [describe-spot-instance-requests](#) command with the --query option.

```
aws ec2 describe-spot-instance-requests \
--query "SpotInstanceRequests[*].{ID:InstanceId}"
```

The following is example output:

```
[  
  {  
    "ID": "i-1234567890abcdef0"  
  },  
  {  
    "ID": "i-0598c7d356eba48d7"  
  }  
]
```

Alternatively, you can enumerate your Spot Instances using the [describe-instances](#) command with the `--filters` option.

```
aws ec2 describe-instances \  
  --filters "Name=instance-lifecycle,Values=spot"
```

To describe a single Spot Instance instance, use the [describe-spot-instance-requests](#) command with the `--spot-instance-request-ids` option.

```
aws ec2 describe-spot-instance-requests \  
  --spot-instance-request-ids sir-08b93456
```

Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see [Tag your Amazon EC2 resources](#).

Contents

- [Prerequisites](#)
- [Tag a new Spot Instance request](#)
- [Tag an existing Spot Instance request](#)

- [View Spot Instance request tags](#)

Prerequisites

Grant the user the permission to tag resources. For more information about IAM policies and example policies, see [Example: Tag resources](#).

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

- If you use the launch instance wizard or `run-instances` to request Spot Instances, see [To grant a user the permission to tag resources when using the launch instance wizard or run-instances](#).
- If you use the `request-spot-instances` command to request Spot Instances, see [To grant a user the permission to tag resources when using request-spot-instances](#).

To grant a user the permission to tag resources when using the launch instance wizard or run-instances

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the user permission to launch an instance.
- For `Resource`, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For `Resource`, specify `*`. This allows users to tag all resources that are created during instance launch.

]
```

Note

When you use the `RunInstances` action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the `spot-instances-request` resource in the `RunInstances` statement.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the `RunInstances` statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the `RunInstances` statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use `RunInstances` to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use `RunInstances` to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the `RunInstances` allow statement, otherwise the call will fail.

- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the spot-instances-request resource or include a * wildcard in the CreateTags allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see [Work with Spot Instances](#).

To grant a user the permission to tag resources when using request-spot-instances

Create a IAM policy that includes the following:

- The ec2:RequestSpotInstances action. This grants the user permission to create a Spot Instance request.
- The ec2:CreateTags action. This grants the user permission to create tags.
- For Resource, specify spot-instances-request. This allows users to tag only the Spot Instance request.

Tag a new Spot Instance request

To tag a new Spot Instance request using the console

1. Follow the [Create a Spot Instance request](#) procedure.
2. To add a tag, on the **Add Tags** page, choose **Add Tag**, and enter the key and value for the tag. Choose **Add another tag** for each additional tag.

For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that **Instances**, **Volumes**, and **Spot Instance Requests** are selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.

3. Complete the required fields to create a Spot Instance request, and then choose **Launch**. For more information, see [Create a Spot Instance request](#).

To tag a new Spot Instance request using the AWS CLI

To tag a Spot Instance request when you create it, configure the Spot Instance request configuration as follows:

- Specify the tags for the Spot Instance request using the `--tag-specification` parameter.
- For `ResourceType`, specify `spot-instances-request`. If you specify another value, the Spot Instance request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Instance request is tagged with two tags: `Key=Environment` and `Value=Production`, and `Key=Cost-Center` and `Value=123`.

```
aws ec2 request-spot-instances \
  --instance-count 5 \
  --type "one-time" \
  --launch-specification file://specification.json \
  --tag-specification 'ResourceType=spot-instances-
request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]'
```

Tag an existing Spot Instance request

To tag an existing Spot Instance request using the console

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Spot Requests**.
2. Select your Spot Instance request.

3. Choose the **Tags** tab and choose **Create Tag**.

To tag an existing Spot Instance using the console

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see [Add and delete tags on an individual resource](#).

To tag an existing Spot Instance request or Spot Instance using the AWS CLI

Use the [create-tags](#) command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with Key=purpose and Value=test.

```
aws ec2 create-tags \
--resources sir-08b93456 i-1234567890abcdef0 \
--tags Key=purpose,Value=test
```

View Spot Instance request tags

To view Spot Instance request tags using the console

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Spot Requests**.
2. Select your Spot Instance request and choose the **Tags** tab.

To describe Spot Instance request tags

Use the [describe-tags](#) command to view the tags for the specified resource. In the following example, you describe the tags for the specified request.

```
aws ec2 describe-tags \
--filters "Name=resource-id,Values=sir-11112222-3333-4444-5555-66666EXAMPLE"
```

```
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-instances-request",
      "Value": "Production"
    },
  ]}
```

```
{  
    "Key": "Another key",  
    "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",  
    "ResourceType": "spot-instances-request",  
    "Value": "Another value"  
}  
]  
}
```

You can also view the tags of a Spot Instance request by describing the Spot Instance request.

Use the [describe-spot-instance-requests](#) command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```
aws ec2 describe-spot-instance-requests \  
  --spot-instance-request-ids sir-11112222-3333-4444-5555-66666EXAMPLE
```

Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are open, active, or disabled.

- Your Spot Instance request is open when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is active when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is disabled when you stop your Spot Instance.

If your Spot Instance request is active and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see [Terminate a Spot Instance](#).

To cancel a Spot Instance request (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests** and select the Spot Instance request.
3. Choose **Actions, Cancel request**.
4. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the **Cancel Spot request** dialog box, select **Terminate instances**, and then choose **Confirm**.

To cancel a Spot Instance request (AWS CLI)

- Use the [cancel-spot-instance-requests](#) command to cancel the specified Spot Instance request.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-ids sir-08b93456
```

Stop a Spot Instance

If you don't need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

Note

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.

We don't charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

- You can only stop a Spot Instance if the Spot Instance was launched from a persistent Spot Instance request.
- You can't stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.
- You can't stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.

Console

To stop a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Stop instance**.
4. When prompted for confirmation, choose **Stop**.

AWS CLI

To stop a Spot Instance (AWS CLI)

- Use the [stop-instances](#) command to manually stop one or more Spot Instances.

```
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

Start a Spot Instance

You can start a Spot Instance that you previously stopped. The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

Prerequisites

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.
- The Spot price is lower than your maximum price.

Limitations

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

Console

To start a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Start instance**.

AWS CLI

To start a Spot Instance (AWS CLI)

- Use the [start-instances](#) command to manually start one or more Spot Instances.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

Terminate a Spot Instance

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the open state so that a new Spot

Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an active Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a disabled Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For information about canceling a Spot Instance request, see [Cancel a Spot Instance request](#).

Console

To manually terminate a Spot Instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that **spot** appears in the **Instance lifecycle** column.
5. Select the instance, and choose **Instance state**, **Terminate instance**.
6. Choose **Terminate** when prompted for confirmation.

AWS CLI

To manually terminate a Spot Instance using the AWS CLI

- Use the [terminate-instances](#) command to manually terminate Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7
```

Spot Instance request example launch specifications

The following examples show launch configurations that you can use with the [request-spot-instances](#) command to create a Spot Instance request. For more information, see [Create a Spot Instance request](#).

Important

We strongly discourage using the [request-spot-instances](#) command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use?](#)

Examples

- [Example 1: Launch Spot Instances](#)
- [Example 2: Launch Spot Instances in the specified Availability Zone](#)
- [Example 3: Launch Spot Instances in the specified subnet](#)
- [Example 4: Launch a Dedicated Spot Instance](#)

Example 1: Launch Spot Instances

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 2: Launch Spot Instances in the specified Availability Zone

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "Placement": {  
        "AvailabilityZone": "us-west-2a"  
    },  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "SubnetId": "subnet-1a2b3c4d",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in the previous code block.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "InstanceType": "m5.medium",  
    "NetworkInterfaces": [  
        {
```

```
        "DeviceIndex": 0,
        "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
        "Groups": [ "sg-1a2b3c4d5e6f7g8h9" ],
        "AssociatePublicIpAddress": true
    },
],
"IamInstanceProfile": {
    "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
}
}
```

Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of dedicated. A Dedicated Spot Instance must be launched in a VPC.

```
{
    "ImageId": "ami-0abcdef1234567890",
    "KeyName": "my-key-pair",
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
    "InstanceType": "c5.8xlarge",
    "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
    "Placement": {
        "Tenancy": "dedicated"
    }
}
```

Spot request status

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn't fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

At each step of the process—also called the Spot request *lifecycle*—specific events determine successive request states.

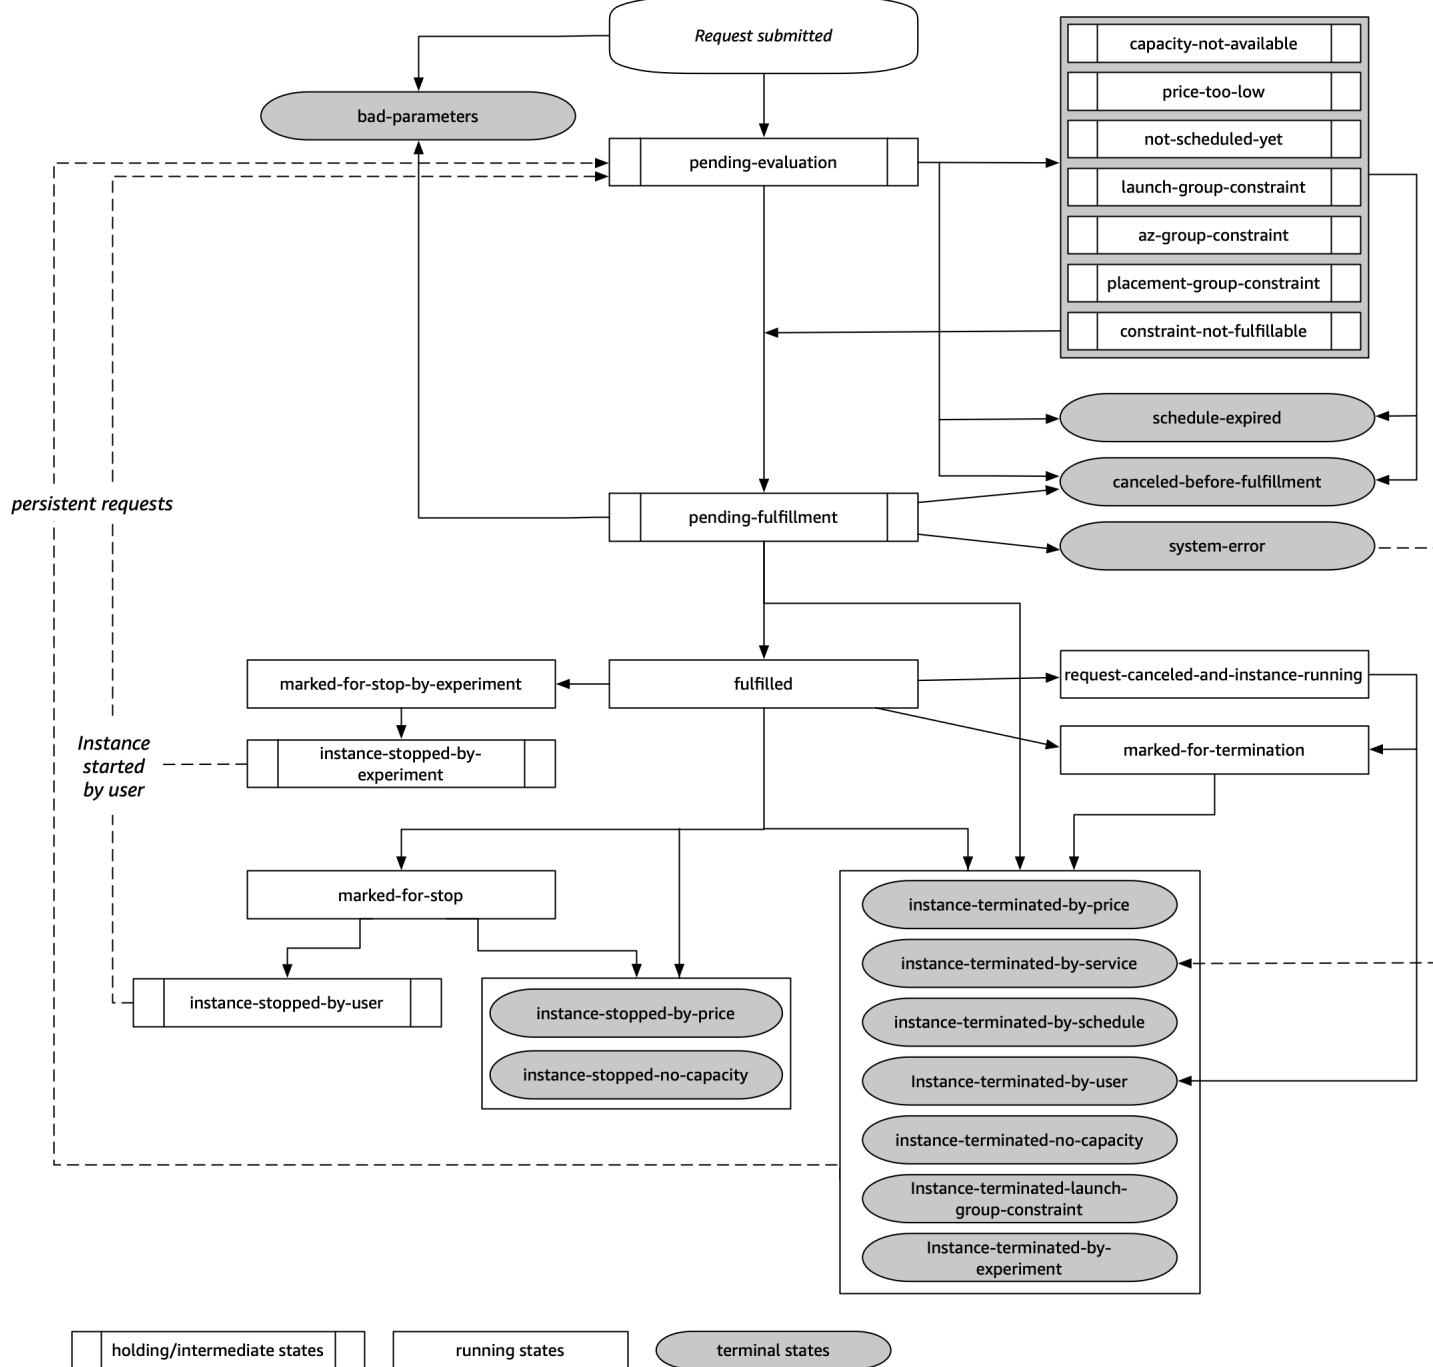

Contents

- [Lifecycle of a Spot request](#)
- [Get request status information](#)
- [Spot request status codes](#)

- [EC2 Spot Instance Request Fulfillment event](#)

Lifecycle of a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.

Pending evaluation

As soon as you create a Spot Instance request, it goes into the pending-evaluation state unless one or more request parameters are not valid (bad-parameters).

Status code	Request state	Instance state
pending-evaluation	open	Not applicable
bad-parameters	closed	Not applicable

Holding

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if there is no capacity, your request stays in a holding state until there is available capacity. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

Status code	Request state	Instance state
capacity-not-available	open	Not applicable
price-too-low	open	Not applicable
not-scheduled-yet	open	Not applicable
launch-group-constraint	open	Not applicable
az-group-constraint	open	Not applicable

Status code	Request state	Instance state
placement-group-constraint	open	Not applicable
constraint-not-fillable	open	Not applicable

Pending evaluation/fulfillment-terminal

Your Spot Instance request can go to a terminal state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

Status code	Request state	Instance state
schedule-expired	cancelled	Not applicable
canceled-before-fulfillment ¹	cancelled	Not applicable
bad-parameters	failed	Not applicable
system-error	closed	Not applicable

¹ If you cancel the request.

Pending fulfillment

When the constraints you specified (if any) are met, your Spot request goes into the pending-fulfillment state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

Status code	Request state	Instance state
pending-fulfillment	open	Not applicable

Fulfilled

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

Status code	Request state	Instance state
fulfilled	active	pending → running
fulfilled	active	stopped → running

If you stop a Spot Instance, your Spot request goes into the `marked-for-stop` or `instance-stopped-by-user` state until the Spot Instance can be started again or the request is cancelled.

Status code	Request state	Instance state
marked-for-stop	active	stopping
instance-stopped-by-user ¹	disabled or cancelled ²	stopped

¹ A Spot Instance goes into the `instance-stopped-by-user` state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the `pending-evaluation` state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

² The Spot request state is disabled if you stop the Spot Instance but do not cancel the request. The request state is cancelled if your Spot Instance is stopped and the request expires.

Fulfilled-terminal

Your Spot Instances continue to run as long as there is available capacity for your instance type, and you don't terminate the instance. If Amazon EC2 must terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.

Status code	Request state	Instance state
request-canceled-and-instance-running	cancelled	running
marked-for-stop	active	running
marked-for-termination	active	running
instance-stopped-by-price	disabled	stopped
instance-stopped-by-user	disabled	stopped
instance-stopped-no-capacity	disabled	stopped
instance-terminated-by-price	closed (one-time), open (persistent)	terminated
instance-terminated-by-schedule	closed	terminated
instance-terminated-by-service	cancelled	terminated
instance-terminated-by-user	closed or cancelled ¹	terminated
instance-terminated-no-capacity	closed (one-time), open (persistent)	running †

Status code	Request state	Instance state
instance-terminated-no-capacity	closed (one-time), open (persistent)	terminated
instance-terminate-d-launch-group-constraint	closed (one-time), open (persistent)	terminated

¹ The request state is *closed* if you terminate the instance but do not cancel the request. The request state is *cancelled* if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be *closed* or *cancelled*.

[†] When Amazon EC2 interrupts a Spot Instance if it needs the capacity back *and* the instance is configured to *terminate* on interruption, the status is immediately set to *instance-terminated-no-capacity* (it is not set to *marked-for-termination*). However, the instance remains in the *running* state for 2 minutes to reflect the 2-minute period when the instance receives the Spot Instance interruption notice. After 2 minutes, the instance state is set to *terminated*.

Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the pending-evaluation state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

Get request status information

You can get request status information using the AWS Management Console or a command line tool.

To get request status information (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests** and select the Spot request.
3. To check the status, on the **Description** tab, check the **Status** field.

To get request status information using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [describe-spot-instance-requests](#) (AWS CLI)
- [Get-EC2SpotInstanceRequest](#) (AWS Tools for Windows PowerShell)

Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

az-group-constraint

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

bad-parameters

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.

canceled-before-fulfillment

The user canceled the Spot request before it was fulfilled.

capacity-not-available

There is not enough capacity available for the instances that you requested.

constraint-not-fulfillable

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

fulfilled

The Spot request is active, and Amazon EC2 is launching your Spot Instances.

instance-stopped-by-price

Your instance was stopped because the Spot price exceeded your maximum price.

instance-stopped-by-user

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

instance-stopped-no-capacity

Your instance was stopped due to EC2 capacity management needs.

instance-terminated-by-price

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

instance-terminated-by-schedule

Your Spot Instance was terminated at the end of its scheduled duration.

instance-terminated-by-service

Your instance was terminated from a stopped state.

instance-terminated-by-user or spot-instance-terminated-by-user

You terminated a Spot Instance that had been fulfilled, so the request state is closed (unless it's a persistent request) and the instance state is terminated.

instance-terminated-launch-group-constraint

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

instance-terminated-no-capacity

Your instance was terminated due to standard capacity management processes.

launch-group-constraint

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

limit-exceeded

The limit on the number of EBS volumes or total volume storage was exceeded. For more information about these limits and how to request an increase, see [Amazon EBS Limits](#) in the [Amazon Web Services General Reference](#).

marked-for-stop

The Spot Instance is marked for stopping.

marked-for-termination

The Spot Instance is marked for termination.

not-scheduled-yet

The Spot request is not evaluated until the scheduled date.

pending-evaluation

After you make a Spot Instance request, it goes into the pending-evaluation state while the system evaluates the parameters of your request.

pending-fulfillment

Amazon EC2 is trying to provision your Spot Instances.

placement-group-constraint

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.

price-too-low

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains open.

request-canceled-and-instance-running

You canceled the Spot request while the Spot Instances are still running. The request is cancelled, but the instances remain running.

schedule-expired

The Spot request expired because it was not fulfilled before the specified date.

system-error

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 Spot Instance Request Fulfillment event

When a Spot Instance request is fulfilled, Amazon EC2 sends an EC2 Spot Instance Request Fulfillment event to Amazon EventBridge. You can create a rule to take an action whenever this event occurs, such as invoking a Lambda function or notifying an Amazon SNS topic.

The following is example data for this event.

```
{  
    "version": "0",  
    "id": "01234567-1234-0123-1234-012345678901",  
    "detail-type": "EC2 Spot Instance Request Fulfillment",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],  
    "detail": {  
        "spot-instance-request-id": "sir-1a2b3c4d",  
        "instance-id": "i-1234567890abcdef0"  
    }  
}
```

For more information, see the [Amazon EventBridge User Guide](#).

EC2 instance rebalance recommendations

An EC2 instance *rebalance recommendation* is a signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the [two-minute Spot Instance interruption notice](#), giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.

Rebalance recommendations are made available as a EventBridge event and as an item in the [instance metadata](#) on the Spot Instance. Events are emitted on a best effort basis.

Note

Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

- [Monitor rebalance recommendation signals](#)
- [Services that use the rebalance recommendation signal](#)

Rebalance actions you can take

These are some of the possible rebalancing actions that you can take:

Graceful shutdown

When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.

Prevent new work from being scheduled

When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances

You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see [Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions](#) in the *Amazon EC2 Auto Scaling User Guide*, and [Capacity Rebalancing](#) for EC2 Fleet and [Capacity Rebalancing](#) for Spot Fleet in this user guide.

Monitor rebalance recommendation signals

You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:

- [Use Amazon EventBridge](#)
- [Use instance metadata](#)

Use Amazon EventBridge

When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Instance Rebalance Recommendation",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],  
    "detail": {  
        "instance-id": "i-1234567890abcdef0"  
    }  
}
```

The following fields form the event pattern that is defined in the rule:

"detail-type": "EC2 Instance Rebalance Recommendation"

Identifies that the event is a rebalance recommendation event

"source": "aws.ec2"

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an `EC2 Instance Rebalance Recommendation` event, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:
 - a. Enter a **Name** for the rule, and, optionally, a description.

A rule can't have the same name as another rule in the same Region and on the same event bus.
 - b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
 - c. For **Rule type**, choose **Rule with an event pattern**.
 - d. Choose **Next**.
4. For **Build event pattern**, do the following:
 - a. For **Event source**, choose **AWS events or EventBridge partner events**.
 - b. For **Event pattern**, for this example you'll specify the following event pattern to match the `EC2 Instance Rebalance Recommendation` event, and then choose **Save**.

```
{  
  "source": ["aws.ec2"],  
  "detail-type": ["EC2 Instance Rebalance Recommendation"]  
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

- i. To use a template to create the event pattern, do the following:
 - A. Choose **Event pattern form**.
 - B. For **Event source**, choose **AWS services**.
 - C. For **AWS Service**, choose **EC2 Spot Fleet**.
 - D. For **Event type**, choose **EC2 Instance Rebalance Recommendation**.
 - E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.
- ii. (Alternative) To specify a custom event pattern, do the following:
 - A. Choose **Custom pattern (JSON editor)**.
 - B. In the **Event pattern** box, add the event pattern for this example.

c. Choose **Next**.

5. For **Select target(s)**, do the following:

- a. For **Target types**, choose **AWS service**.
- b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
- c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person \(A2P\) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.
- d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events](#) (step 16) in the *Amazon EventBridge User Guide*.
- e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:

- a. Review the details of the rule and modify them as necessary.
- b. Choose **Create rule**.

For more information, see [Amazon EventBridge rules](#) and [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*

Use instance metadata

The instance metadata category events/recommendations/rebalance provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

IMDSv2

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, events/recommendations/rebalance is not present and you receive an HTTP 404 error when you try to retrieve it.

Services that use the rebalance recommendation signal

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with

a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- [Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions](#) in the *Amazon EC2 Auto Scaling User Guide*
- [Capacity Rebalancing](#) in the EC2 Fleet topic in this user guide
- [Capacity Rebalancing](#) in the Spot Fleet topic in this user guide

Spot Instance interruptions

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a *Spot Instance interruption*.

When Amazon EC2 interrupts a Spot Instance, it either terminates, stops, or hibernates the instance, depending on what you specified when you created the Spot request.

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted.

An On-Demand Instance specified in an EC2 Fleet or Spot Fleet cannot be interrupted.

Reasons for interruption

The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

Capacity

Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.

Price

The Spot price is higher than your maximum price.

You can specify the maximum price in your Spot request. However, if you specify a maximum price, your instances will be interrupted more frequently than if you do not specify it.

Constraints

If your Spot request includes a constraint such as a launch group or an Availability Zone group, the Spot Instances are terminated as a group when the constraint can no longer be met.

You can see the historical interruption rates for your instance type in the [Spot Instance Advisor](#).

Interruption behavior

You can specify that Amazon EC2 must do one of the following when it interrupts a Spot Instance:

- [Stop interrupted Spot Instances](#)
- [Hibernate interrupted Spot Instances](#)
- [Terminate interrupted Spot Instances](#) (this is the default behavior)

Specify the interruption behavior

You can specify the interruption behavior when you create a Spot request. If you do not specify an interruption behavior, the default is that Amazon EC2 terminates Spot Instances when they are interrupted.

The way in which you specify the interruption behavior is different depending on how you request Spot Instances.

- If you request Spot Instances using the [launch instance wizard](#), you can specify the interruption behavior as follows: In the launch instance wizard, expand **Advanced details** and select the **Request Spot Instances** check box. Choose **Customize**. From **Interruption behavior**, choose an interruption behavior. If the interruption behavior is hibernation, you can alternatively choose **Enable for Stop - Hibernate behavior**.
- If you request Spot Instances using the [run-instances](#) CLI, you can specify the interruption behavior as follows: In the request configuration, (`--instance-market-options`), for `InstanceInterruptionBehavior`, specify an interruption behavior. If the interruption behavior is hibernate, you can alternatively enable hibernation using the `--hibernation-options Configured=true` parameter.
- If you configure Spot Instances in a [launch template](#), you can specify the interruption behavior as follows: In the launch template, expand **Advanced details** and select the **Request Spot Instances** check box. Choose **Customize** and then, from **Interruption behavior**, choose an interruption behavior.
- If you request Spot Instances using the [Spot console](#), you can specify the interruption behavior as follows: Select the **Maintain target capacity** check box and then, from **Interruption behavior**, choose an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [create-fleet](#) CLI, you can specify the interruption behavior as follows: For `InstanceInterruptionBehavior`, specify an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [request-spot-fleet](#) CLI, you can specify the interruption behavior as follows: For `InstanceInterruptionBehavior`, specify an interruption behavior.
- If you configure Spot Instances using the [request-spot-instances](#) CLI, you can specify the interruption behavior as follows: For `--instance-interruption-behavior`, specify an interruption behavior.

 **Note**

We strongly discourage using the [request-spot-fleet](#) and [request-spot-instances](#) commands to request Spot Instances because they are legacy APIs with no planned investment. For more information, see [Which is the best Spot request method to use?](#)

Stop interrupted Spot Instances

You can specify that Amazon EC2 stops your Spot Instances when they are interrupted. For more information, see [Specify the interruption behavior](#).

Considerations

- Only Amazon EC2 can restart an interrupted stopped Spot Instance.
- For a Spot Instance launched by a persistent Spot Instance request: Amazon EC2 restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance (the same launch specification must be used).
- For Spot Instances launched by an EC2 Fleet or Spot Fleet of type maintain: After a Spot Instance is interrupted, Amazon EC2 launches a replacement instance to maintain the target capacity. Amazon EC2 finds the best Spot capacity pools based on the specified allocation strategy (`lowestPrice`, `diversified`, or `InstancePoolsToUseCount`); it does not prioritize the pool with the earlier stopped instance. Later, if the allocation strategy leads to a pool containing the earlier stopped instance, Amazon EC2 restarts the stopped instance to meet the target capacity.

For example, consider a Spot Fleet with the `lowestPrice` allocation strategy. At initial launch, a `c3.large` pool meets the `lowestPrice` criteria for the launch specification. Later, when the `c3.large` instances are interrupted, Amazon EC2 stops the instances and replenishes capacity from another pool that fits the `lowestPrice` strategy. This time, the pool happens to be a `c4.large` pool and Amazon EC2 launches `c4.large` instances to meet the target capacity. Similarly, Spot Fleet could move to a `c5.large` pool the next time. In each of these transitions, Amazon EC2 does not prioritize pools with earlier stopped instances, but rather prioritizes purely on the specified allocation strategy. The `lowestPrice` strategy can lead back to pools with earlier stopped instances. For example, if instances are interrupted in the `c5.large` pool and the `lowestPrice` strategy leads it back to the `c3.large` or `c4.large` pools, the earlier stopped instances are restarted to fulfill target capacity.

- While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and Amazon EC2 attempts to start the Spot Instance, the instance will fail to start and Amazon EC2 will terminate the stopped instance.
- You can terminate a Spot Instance while it is stopped.
- If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, Amazon EC2 terminates any associated Spot Instances that are stopped.

- While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account. For more information about how you're charged when a Spot Instance is interrupted, see [Billing for interrupted Spot Instances](#).
- Make sure that you are familiar with the implications of stopping an instance. For information about what happens when an instance is stopped, see [Differences between reboot, stop, hibernate, and terminate](#).

Prerequisites

To stop an interrupted Spot Instance, the following prerequisites must be in place:

Spot request type

Spot Instance request type – Must be persistent. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be maintain.

Root volume type

Must be an EBS volume, not an instance store volume.

Hibernate interrupted Spot Instances

You can specify that Amazon EC2 hibernates your Spot Instances when they are interrupted. For more information, see [Hibernate your Amazon EC2 instance](#).

Amazon EC2 now offers the same hibernation experience for Spot Instances as is currently available for On-Demand Instances. It offers more extensive support, where the following is now supported for Spot Instance hibernation:

- [More supported AMIs](#)
- [More supported instance families](#)
- [User-initiated hibernation](#)

Terminate interrupted Spot Instances

When Amazon EC2 interrupts a Spot Instance, it terminates the instance by default, unless you specify a different interruption behavior, such as stop or hibernate. For more information, see [Specify the interruption behavior](#).

Prepare for interruptions

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

We recommend that you follow these best practices so that you're prepared for a Spot Instance interruption.

- Create your Spot request using an Auto Scaling group. If your Spot Instances are interrupted, the Auto Scaling group will automatically launch replacement instances. For more information, see [Auto Scaling groups with multiple instance types and purchase options](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at startup.
- Data on instance store volumes is lost when the instance is stopped or terminated. Back up any important data on instance store volumes to a more persistent storage, such as Amazon S3, Amazon EBS, or Amazon DynamoDB.
- Store important data regularly in a place that isn't affected if the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.
- Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.
- Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see [EC2 instance rebalance recommendations](#).
- Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see [Spot Instance interruption notices](#).

- While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance recommendation signals and interruption notices. You can do this by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.
- Run a controlled fault injection experiment with AWS Fault Injection Service to test how your application responds when your Spot Instance is interrupted. For more information, see the [Tutorial: Test Spot Instance interruptions using AWS FIS](#) in the *AWS Fault Injection Service User Guide*.

Initiate a Spot Instance interruption

You can select a Spot Instance request or a Spot Fleet request in the Amazon EC2 console and initiate a Spot Instance interruption so that you can test how the applications on your Spot Instances handle being interrupted. When you initiate a Spot Instance interruption, Amazon EC2 notifies you that your Spot Instance will be interrupted in two minutes, and then, after two minutes, the instance is interrupted.

The underlying service that performs the Spot Instance interruption is AWS Fault Injection Service (AWS FIS). For information about AWS FIS, see [AWS Fault Injection Service](#).

Note

Interruption behaviors are terminate, stop, and hibernate. If you set the interruption behavior to hibernate, when you initiate a Spot Instance interruption, the hibernation process will begin immediately.

Initiating a Spot Instance interruption is supported in all AWS Regions except Asia Pacific (Jakarta), Asia Pacific (Osaka), China (Beijing), China (Ningxia), and Middle East (UAE).

Initiate a Spot Instance interruption

You can use the EC2 console to quickly initiate a Spot Instance interruption. When you select a Spot Instance request, you can initiate the interruption of one Spot Instance. When you select a Spot Fleet request, you can initiate the interruption of multiple Spot Instances at once.

For more advanced experiments to test Spot Instance interruptions, you can create your own experiments using the AWS FIS console.

To initiate the interruption of one Spot Instance in a Spot Instance request using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Instance request, and then choose **Actions, Initiate interruption**. You can't select multiple Spot Instance requests to initiate an interruption.
4. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.
5. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption**.

To initiate the interruption of one or more Spot Instances in a Spot Fleet request using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Fleet request, and then choose **Actions, Initiate interruption**. You can't select multiple Spot Fleet requests to initiate an interruption.
4. In the **Specify number of Spot Instances** dialog box, for **Number of instances to interrupt**, enter the number of Spot Instances to interrupt, and then choose **Confirm**.

Note

The number can't exceed the number of Spot Instances in the fleet or your [quota](#) for the number of Spot Instances that AWS FIS can interrupt per experiment.

5. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.
6. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption**.

To create more advanced experiments to test Spot Instance interruptions using the AWS FIS console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Spot Requests**.
3. Choose **Actions, Create advanced experiments**.

The AWS FIS console opens. For more information, see [Tutorial: Test Spot Instance interruptions using AWS FIS in the AWS Fault Injection Service User Guide](#).

Verify the Spot Instance interruption

After you initiate the interruption, the following occurs:

- The Spot Instance receives an [instance rebalance recommendation](#).
- A [Spot Instance interruption notice](#) is issued two minutes before AWS FIS interrupts your instance.
- After two minutes, the Spot Instance is interrupted.
- A Spot Instance that was stopped by AWS FIS remains stopped until you restart it.

To verify that the instance was interrupted after you initiated the interruption

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, open **Spot Requests** and **Instances** in separate browser tabs or windows.
3. For **Spot Requests**, select the Spot Instance request or Spot Fleet request. The initial status is fulfilled. After the instance is interrupted, the status changes as follows, depending on the interruption behavior:
 - **terminate** – The status changes to `instance-terminated-by-experiment`.

- stop – The status changes to marked-for-stop-by-experiment and then instance-stopped-by-experiment.
4. For **Instances**, select the Spot Instance. The initial status is Running. Two minutes after you receive the Spot Instance interruption notice, the status changes as follows, depending on the interruption behavior:
- stop – The status changes to Stopping and then Stopped.
 - terminate – The status changes to Shutting-down and then Terminated.

Quotas

Your AWS account has the following default quota for the number of Spot Instances that AWS FIS can interrupt per experiment.

Name	Default	Adjustable	Description
Target SpotInstances for aws:ec2:send-spot-instance-interruptions	Each supported Region: 5	Yes	The maximum number of Spot Instances that aws :ec2:send-spot-ins tance-interruptions can target when you identify targets using tags, per experiment.

You can request a quota increase. For more information, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

To view all the quotas for AWS FIS, open the [Service Quotas console](#). In the navigation pane, choose **AWS services** and select **AWS Fault Injection Service**. You can also view all the [quotas for AWS Fault Injection Service](#) in the *AWS Fault Injection Service User Guide*.

Spot Instance interruption notices

A *Spot Instance interruption notice* is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior,

you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as a EventBridge event and as items in the [instance metadata](#) on the Spot Instance. Interruption notices are emitted on a best effort basis.

EC2 Spot Instance interruption notice

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon EventBridge. For more information about EventBridge events, see the [Amazon EventBridge User Guide](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

The following is an example of the event for Spot Instance interruption. The possible values for instance-action are hibernate, stop, or terminate.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Spot Instance Interruption Warning",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2a:instance/i-1234567890abcdef0"],  
    "detail": {  
        "instance-id": "i-1234567890abcdef0",  
        "instance-action": "action"  
    }  
}
```

Note

The ARN format of the Spot Instance interruption event is `arn:aws:ec2:availability-zone:instance/instance-id`. This format differs from the [EC2 resource ARN format](#).

instance-action

If your Spot Instance is marked to be stopped or terminated by Amazon EC2, the `instance-action` item is present in your [instance metadata](#). Otherwise, it is not present. You can retrieve the `instance-action` using Instance Metadata Service Version 2 (IMDSv2) as follows.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600"` \
& curl -H "X-aws-ec2-metadata-token: $TOKEN" http://169.254.169.254/latest/meta-data/spot/instance-action
```

The `instance-action` item specifies the action and the approximate time, in UTC, when the action will occur.

The following example output indicates the time at which this instance will be stopped.

```
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example output indicates the time at which this instance will be terminated.

```
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, `instance-action` is not present in the instance metadata and you receive an HTTP 404 error when you try to retrieve it.

termination-time

This item is maintained for backward compatibility; you should use `instance-action` instead.

If your Spot Instance is marked for termination by Amazon EC2 (either due to a Spot Instance interruption where the interruption behavior is set to terminate, or due to the cancellation of a persistent Spot Instance request), the `termination-time` item is present in your [instance metadata](#). Otherwise, it is not present. You can retrieve the `termination-time` using IMDSv2 as follows.

```
[ec2-user ~]$ TOKEN=`curl -X PUT "http://169.254.169.254/latest/api/token" -H "X-aws-ec2-metadata-token-ttl-seconds: 21600" `
```

```
[ec2-user ~]$ if curl -H "X-aws-ec2-metadata-token: $TOKEN" -s http://169.254.169.254/latest/meta-data/spot/termination-time | grep -q .*T.*Z; then echo termination_scheduled; fi
```

The `termination-time` item specifies the approximate time in UTC when the instance will receive the shutdown signal. The following is example output.

```
2015-01-05T18:02:00Z
```

If Amazon EC2 is not preparing to terminate the instance (either because there is no Spot Instance interruption or because your interruption behavior is set to stop or hibernate), or if you terminated the Spot Instance yourself, the `termination-time` item is either not present in the instance metadata (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to fulfilled. The `termination-time` value remains in the instance metadata with the original approximate time, which is now in the past.

Find interrupted Spot Instances

In the console, the **Instances** pane displays all instances, including Spot Instances. The instance lifecycle of a Spot Instance is spot. The instance state of a Spot Instance is either stopped or terminated, depending on the interruption behavior that you configured. For a hibernated Spot Instance, the instance state is stopped.

To find an interrupted Spot Instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Apply the following filter: **Instance lifecycle=spot**.
4. Apply the **Instance state=stopped** or **Instance state=terminated** filter depending on the interruption behavior that you configured.
5. For each Spot Instance, on the **Details** tab, under **Instance details**, find **State transition message**. The following codes indicate that the Spot Instance was interrupted.
 - `Server.SpotInstanceShutdown`
 - `Server.SpotInstanceTermination`

- For additional details about the reason for the interruption, check the Spot request status code. For more information, see [the section called “Spot request status”](#).

To find interrupted Spot Instances using the AWS CLI

You can list your interrupted Spot Instances using the [describe-instances](#) command with the `--filters` parameter. To list only the instance IDs in the output, include the `--query` parameter.

If the instance interruption behavior is to terminate the Spot Instances, use the following command:

```
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-
name,Values=terminated Name=state-reason-code,Values=Server.SpotInstanceTermination \
  --query "Reservations[*].Instances[*].InstanceId"
```

If the instance interruption behavior is to stop the Spot Instances, use the following command:

```
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-
name,Values=stopped Name=state-reason-code,Values=Server.SpotInstanceShutdown \
  --query "Reservations[*].Instances[*].InstanceId"
```

Determine whether Amazon EC2 terminated a Spot Instance

If a Spot Instance is terminated, you can use CloudTrail to see whether Amazon EC2 terminated the Spot Instance. In AWS CloudTrail, the event name `BidEvictedEvent` indicates that Amazon EC2 terminated the Spot Instance.

To view `BidEvictedEvent` events in CloudTrail

- Open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
- In the navigation pane, choose **Event history**.
- In the filter drop-down, choose **Event name**, and then in the filter field to the right, enter **BidEvictedEvent**.
- Choose **BidEvictedEvent** in the resulting list to view its details. Under **Event record**, you can find the instance ID.

For more information about using CloudTrail, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail](#).

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you're charged for instance and EBS volume usage, and you might incur other charges, as follows.

Instance usage

Who interrupts the Spot Instance	Operating system	Interrupted in the first hour	Interrupted in any hour after the first hour
If you stop or terminate the Spot Instance	Windows and Linux (excluding SUSE)	Charged for the seconds used	Charged for the seconds used
	SUSE	Charged for the full hour even if you used a partial hour	Charged for the full hours used, and charged a full hour for the interrupted partial hour
If the Amazon EC2 interrupts the Spot Instance	Windows and Linux (excluding SUSE)	No charge	Charged for the seconds used
	SUSE	No charge	Charged for the full hours used, but no charge for the interrupted partial hour

EBS volume usage

While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved.

With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.

Other charges

If your running Spot Instance incurs charges for other services, such as for data transfer, Elastic IP addresses, or usage of other AWS managed services, you will be billed for their usage. This is regardless of who interrupts the Spot Instance or when it was interrupted. Even if you're not charged for Spot Instance usage when Amazon EC2 interrupts your Spot Instance in the first hour, you can incur other charges.

For more information about other charges, see [Amazon EC2 On-Demand Pricing](#).

Spot placement score

The Spot placement score feature can recommend an AWS Region or Availability Zone based on your Spot capacity requirements. Spot capacity fluctuates, and you can't be sure that you'll always get the capacity that you need. A Spot placement score indicates how likely it is that a Spot request will succeed in a Region or Availability Zone.

Note

A Spot placement score does not provide any guarantees in terms of available capacity or risk of interruption. A Spot placement score serves only as a recommendation.

Benefits

You can use the Spot placement score feature for the following:

- To relocate and scale Spot compute capacity in a different Region, as needed, in response to increased capacity needs or decreased available capacity in the current Region.
- To identify the most optimal Availability Zone in which to run single-Availability Zone workloads.
- To simulate future Spot capacity needs so that you can pick an optimal Region for the expansion of your Spot-based workloads.
- To find an optimal combination of instance types to fulfill your Spot capacity needs.

Costs

There is no additional charge for using the Spot placement score feature.

How Spot placement score works

When you use the Spot placement score feature, you first specify your compute requirements for your Spot Instances, and then Amazon EC2 returns the top 10 Regions or Availability Zones where your Spot request is likely to succeed. Each Region or Availability Zone is scored on a scale from 1 to 10, with 10 indicating that your Spot request is highly likely to succeed, and 1 indicating that your Spot request is not likely to succeed.

To use the Spot placement score feature, follow these steps:

- [Step 1: Specify your Spot requirements](#)
- [Step 2: Filter the Spot placement score response](#)
- [Step 3: Review the recommendations](#)
- [Step 4: Use the recommendations](#)

Step 1: Specify your Spot requirements

First, you specify your desired target Spot capacity and your compute requirements, as follows:

1. Specify the target Spot capacity, and optionally the target capacity unit.

You can specify your desired target Spot capacity in terms of the number of instances or vCPUs, or in terms of the amount of memory in MiB. To specify the target capacity in number of vCPUs or amount of memory, you must specify the target capacity unit as `vcpu` or `memory-mib`. Otherwise, it defaults to number of instances.

By specifying your target capacity in terms of the number of vCPUs or the amount of memory, you can use these units when counting the total capacity. For example, if you want to use a mix of instances of different sizes, you can specify the target capacity as a total number of vCPUs. The Spot placement score feature then considers each instance type in the request by its number of vCPUs, and counts the total number of vCPUs rather than the total number of instances when totaling up the target capacity.

For example, say you specify a total target capacity of 30 vCPUs, and your instance type list consists of `c5.xlarge` (4 vCPUs), `m5.2xlarge` (8 vCPUs), and `r5.large` (2 vCPUs). To achieve a total of 30 vCPUs, you could get a mix of 2 `c5.xlarge` (2×4 vCPUs), 2 `m5.2xlarge` (2×8 vCPUs), and 3 `r5.large` (3×2 vCPUs).

2. Specify instance types or instance attributes.

You can either specify the instance types to use, or you can specify the instance attributes that you need for your compute requirements, and then let Amazon EC2 identify the instance types that have those attributes. This is known as attribute-based instance type selection.

You can't specify both instance types and instance attributes in the same Spot placement score request.

If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types.

For examples of different ways to specify your Spot requirements, see [Example configurations](#).

Step 2: Filter the Spot placement score response

Amazon EC2 calculates the Spot placement score for each Region or Availability Zone, and returns either the top 10 Regions or the top 10 Availability Zones where your Spot request is likely to succeed. The default is to return a list of scored Regions. If you plan to launch all of your Spot capacity into a single Availability Zone, then it's useful to request a list of scored Availability Zones.

You can specify a Region filter to narrow down the Regions that will be returned in the response.

You can combine the Region filter and a request for scored Availability Zones. In this way, the scored Availability Zones are confined to the Regions for which you've filtered. To find the highest-scored Availability Zone in a Region, specify only that Region, and the response will return a scored list of all of the Availability Zones in that Region.

Step 3: Review the recommendations

The Spot placement score for each Region or Availability Zone is calculated based on the target capacity, the composition of the instance types, the historical and current Spot usage trends, and the time of the request. Because Spot capacity is constantly fluctuating, the same Spot placement score request can yield different scores when calculated at different times.

Regions and Availability Zones are scored on a scale from 1 to 10. A score of 10 indicates that your Spot request is highly likely—but not guaranteed—to succeed. A score of 1 indicates that your Spot request is not likely to succeed at all. The same score might be returned for different Regions or Availability Zones.

If low scores are returned, you can edit your compute requirements and recalculate the score. You can also request Spot placement score recommendations for the same compute requirements at different times of the day.

Step 4: Use the recommendations

A Spot placement score is only relevant if your Spot request has exactly the same configuration as the Spot placement score configuration (target capacity, target capacity unit, and instance types or instance attributes), and is configured to use the capacity-optimized allocation strategy. Otherwise, the likelihood of getting available Spot capacity will not align with the score.

While a Spot placement score serves as a guideline, and no score guarantees that your Spot request will be fully or partially fulfilled, you can use the following information to get the best results:

- **Use the same configuration** – The Spot placement score is relevant only if the Spot request configuration (target capacity, target capacity unit, and instance types or instance attributes) in your Auto Scaling group, EC2 Fleet, or Spot Fleet is the same as what you entered to get the Spot placement score.

If you used attribute-based instance type selection in your Spot placement score request, you can use attribute-based instance type selection to configure your Auto Scaling group, EC2 Fleet, or Spot Fleet. For more information, see [Creating an Auto Scaling group with a set of requirements on the instance types used](#), [Attribute-based instance type selection for EC2 Fleet](#), and [Attribute-based instance type selection for Spot Fleet](#).

Note

If you specified your target capacity in terms of the number of vCPUs or the amount of memory, and you specified instance types in your Spot placement score configuration, note that you can't currently create this configuration in your Auto Scaling group, EC2 Fleet, or Spot Fleet. Instead, you must manually set the instance weighting by using the `WeightedCapacity` parameter.

- **Use the capacity-optimized allocation strategy** – Any score assumes that your fleet request will be configured to use all Availability Zones (for requesting capacity across Regions) or a single Availability Zone (if requesting capacity in one Availability Zone) and the capacity-optimized Spot allocation strategy for your request for Spot capacity to succeed. If you use other allocation

strategies, such as lowest-price, the likelihood of getting available Spot capacity will not align with the score.

- **Act on a score immediately** – The Spot placement score recommendation reflects the available Spot capacity at the time of the request, and the same configuration can yield different scores when calculated at different times due to Spot capacity fluctuations. While a score of 10 means that your Spot capacity request is highly likely—but not guaranteed—to succeed, for best results we recommend that you act on a score immediately. We also recommend that you get a fresh score each time you attempt a capacity request.

Limitations

- **Target capacity limit** – Your Spot placement score target capacity limit is based on your recent Spot usage, while accounting for potential usage growth. If you have no recent Spot usage, we provide you with a low default limit aligned with your Spot request limit.
- **Request configurations limit** – We can limit the number of new request configurations within a 24-hour period if we detect patterns not associated with the intended use of the Spot placement score feature. If you reach the limit, you can retry the request configurations that you've already used, but you can't specify new request configurations until the next 24-hour period.
- **Minimum number of instance types** – If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types. Instance types are considered different if they have a different name. For example, m5.8xlarge, m5a.8xlarge, and m5.12xlarge are all considered different.

Required IAM permission

By default, IAM identities (users, roles, or groups) don't have permission to use the Spot placement score feature. To allow IAM identities to use the Spot placement score feature, you must create an IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action. You then attach the policy to the IAM identities that require this permission.

The following is an example IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {
```

```
{  
    "Effect": "Allow",  
    "Action": "ec2:GetSpotPlacementScores",  
    "Resource": "*"  
}  
]  
}
```

For information about editing an IAM policy, see [Editing IAM policies](#) in the *IAM User Guide*.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

Calculate a Spot placement score

Calculate a Spot placement score by specifying instance attributes (console)

To calculate a Spot placement score by specifying instance attributes

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Spot placement score**.
4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify your compute requirements and let Amazon EC2 identify the optimal instance types with these requirements, choose **Specify instance attributes that match your compute requirements**.
7. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum**, **No maximum**, or both.
8. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum**, **No maximum**, or both.
9. For **CPU architecture**, select the required instance architecture.
10. (Optional) For **Additional instance attributes**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.
11. (Optional) To view the instance types with your specified attributes, expand **Preview matching instance types**. To exclude instance types from being used in the placement evaluation, select the instances and then choose **Exclude selected instance types**.
12. Choose **Load placement scores**, and review the results.
13. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
14. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.

15. (Optional) To edit your compute requirements and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate a Spot placement score by specifying instance types (console)

To calculate a Spot placement score by specifying instance types

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Spot placement score**.
4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify the instance types to use, choose **Manually select instance types**.
7. Choose **Select instance types**, select the instance types to use, and then choose **Select**. To quickly find instance types, you can use the filter bar to filter the instance types by different properties.
8. Choose **Load placement scores**, and review the results.
9. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
10. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
11. (Optional) To edit the list of instance types and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate the Spot placement score (AWS CLI)

To calculate the Spot placement score

1. (Optional) To generate all of the possible parameters that can be specified for the Spot placement score configuration, use the [get-spot-placement-scores](#) command and the --generate-cli-skeleton parameter.

```
aws ec2 get-spot-placement-scores \

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

- a. For TargetCapacity, enter your desired Spot capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).
- b. For TargetCapacityUnitType, enter the unit for the target capacity. If you omit this parameter, it defaults to units.

Valid values: units (which translates to number of instances) | vcpu | memory-mib

- c. For SingleAvailabilityZone, specify true for a response that returns a list of scored Availability Zones. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone. If you omit this parameter, it defaults to false, and the response returns a list of scored Regions.
- d. (Optional) For RegionNames, specify the Regions to use as a filter. You must specify the Region code, for example, us-east-1.

With a Region filter, the response returns only the Regions that you specify. If you specified true for SingleAvailabilityZone, the response returns only the Availability Zones in the specified Regions.

- e. You can include either InstanceTypes or InstanceRequirements, but not both in the same configuration.

Specify one of the following in your JSON configuration:

- To specify a list of instance types, specify the instance types in the InstanceTypes parameter. Specify at least three different instance types. If you specify only one or two instance types, Spot placement score returns a low score. For the list of instance types, see [Amazon EC2 Instance Types](#).
- To specify the instance attributes so that Amazon EC2 will identify the instance types that match those attributes, specify the attributes that are located in the InstanceRequirements structure.

You must provide values for VCpuCount, MemoryMiB, and CpuManufacturers.

You can omit the other attributes; when omitted, the default values are used. For a

description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

For example configurations, see [Example configurations](#).

3. To get the Spot placement score for the requirements that you specified in the JSON file, use the [get-spot-placement-scores](#) command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter.

```
aws ec2 get-spot-placement-scores \
--region us-east-1 \
--cli-input-json file://file_name.json
```

Example output if SingleAvailabilityZone is set to `false` or omitted (if omitted, it defaults to `false`) – a scored list of Regions is returned

```
"SpotPlacementScores": [
  {
    "Region": "us-east-1",
    "Score": 7
  },
  {
    "Region": "us-west-1",
    "Score": 5
  },
  ...
]
```

Example configurations

When using the AWS CLI, you can use the following example configurations.

Example configurations

- [Example: Specify instance types and target capacity](#)
- [Example: Specify instance types, and target capacity in terms of memory](#)
- [Example: Specify attributes for attribute-based instance type selection](#)
- [Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones](#)

Example: Specify instance types and target capacity

The following example configuration specifies three different instance types and a target Spot capacity of 500 Spot Instances.

```
{  
    "InstanceTypes": [  
        "m5.4xlarge",  
        "r5.2xlarge",  
        "m4.4xlarge"  
    ],  
    "TargetCapacity": 500  
}
```

Example: Specify instance types, and target capacity in terms of memory

The following example configuration specifies three different instance types and a target Spot capacity of 500,000 MiB of memory, where the number of Spot Instances to launch must provide a total of 500,000 MiB of memory.

```
{  
    "InstanceTypes": [  
        "m5.4xlarge",  
        "r5.2xlarge",  
        "m4.4xlarge"
```

```
],
  "TargetCapacity": 500000,
  "TargetCapacityUnitType": "memory-mib"
}
```

Example: Specify attributes for attribute-based instance type selection

The following example configuration is configured for attribute-based instance type selection, and is followed by a text explanation of the example configuration.

```
{
  "TargetCapacity": 5000,
  "TargetCapacityUnitType": "vcpu",
  "InstanceRequirementsWithMetadata": {
    "ArchitectureTypes": ["arm64"],
    "VirtualizationTypes": ["hvm"],
    "InstanceRequirements": {
      "VCpuCount": {
        "Min": 1,
        "Max": 12
      },
      "MemoryMiB": {
        "Min": 512
      }
    }
  }
}
```

InstanceRequirementsWithMetadata

To use attribute-based instance type selection, you must include the `InstanceRequirementsWithMetadata` structure in your configuration, and specify the desired attributes for the Spot Instances.

In the preceding example, the following required instance attributes are specified:

- `ArchitectureTypes` – The architecture type of the instance types must be `arm64`.
- `VirtualizationTypes` – The virtualization type of the instance types must be `hvm`.
- `VCpuCount` – The instance types must have a minimum of 1 and a maximum of 12 vCPUs.
- `MemoryMiB` – The instance types must have a minimum of 512 MiB of memory. By omitting the `Max` parameter, you are indicating that there is no maximum limit.

Note that there are several other optional attributes that you can specify. For the list of attributes, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

TargetCapacityUnitType

The TargetCapacityUnitType parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is vcpu, which together specify a desired target capacity of 5000 vCPUs, where the number of Spot Instances to launch must provide a total of 5000 vCPUs.

Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

The following example configuration is configured for attribute-based instance type selection. By specifying "SingleAvailabilityZone": true, the response will return a list of scored Availability Zones.

```
{  
    "TargetCapacity": 1000,  
    "TargetCapacityUnitType": "vcpu",  
    "SingleAvailabilityZone": true,  
    "InstanceRequirementsWithMetadata": {  
        "ArchitectureTypes": ["arm64"],  
        "VirtualizationTypes": ["hvm"],  
        "InstanceRequirements": {  
            "VCpuCount": {  
                "Min": 1,  
                "Max": 12  
            },  
            "MemoryMiB": {  
                "Min": 512  
            }  
        }  
    }  
}
```

Spot Instance data feed

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.

Data feed files arrive in your bucket typically once an hour, and each hour of usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2 can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

Note

You can create only one Spot Instance data feed per AWS account. If you don't have a Spot Instance running during a certain hour, you don't receive a data feed file for that hour.

Spot Instance data feed is supported in all AWS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US), and the [Regions that are disabled by default](#).

Contents

- [Data feed file name and format](#)
- [Amazon S3 bucket requirements](#)
- [Subscribe to your Spot Instance data feed](#)
- [Describe your Spot Instance data feed](#)
- [View the data in your data feed](#)
- [Delete your Spot Instance data feed](#)

Data feed file name and format

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-id.gz

For example, if your bucket name is **my-bucket-name** and your prefix is **my-prefix**, your file names are similar to the following:

my-bucket-name.s3.amazonaws.com/my-prefix/111122223333.2023-12-09-07.001.b959dbc6.gz

For more information about bucket names, see [Bucket naming rules](#) in the *Amazon S3 User Guide*.

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

Field	Description
Timestamp	The timestamp used to determine the price charged for this instance usage.
UsageType	The type of usage and instance type being charged for. For <code>m1.small</code> Spot Instances, this field is set to <code>SpotUsage</code> . For all other instance types, this field is set to <code>SpotUsage: {instance-type}</code> . For example, <code>SpotUsage:c1.medium</code> .
Operation	The product being charged for. For Linux Spot Instances, this field is set to <code>RunInstances</code> . For Windows Spot Instances, this field is set to <code>RunInstances:0002</code> . Spot usage is grouped according to Availability Zone.
InstanceID	The ID of the Spot Instance that generated this instance usage.
MyBidID	The ID for the Spot Instance request that generated this instance usage.
MyMaxPrice	The maximum price specified for this Spot request.
MarketPrice	The Spot price at the time specified in the <code>Timestamp</code> field.
Charge	The price charged for this instance usage.
Version	The data feed version. The possible version is 1.0.

Amazon S3 bucket requirements

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files.

Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have FULL_CONTROL permission to the bucket. If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.
- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account FULL_CONTROL permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket. For more information, see [Logs sent to Amazon S3](#) in the *Amazon CloudWatch Logs User Guide*.

 **Note**

If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.

- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has FULL_CONTROL permission to the data files. The AWS data feed account has read and write permissions.
- If you applied disabled ACLs for your buckets, add a bucket policy that allows users with full control to write to the bucket. For more information, see [Review and update bucket policies](#).
- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.
- You must use a customer managed key if you encrypt your Amazon S3 bucket using server-side encryption with a AWS KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see [Amazon S3 bucket server-side encryption](#) in the *Amazon CloudWatch Logs User Guide*.

 **Note**

For Spot Instance data feed, the resource that generates the S3 files is no longer Amazon CloudWatch Logs. Therefore, you must remove the aws:SourceArn section from the S3 bucket permission policy and from the KMS policy.

Subscribe to your Spot Instance data feed

To subscribe to your data feed, use the [create-spot-datafeed-subscription](#) command.

```
aws ec2 create-spot-datafeed-subscription \
--bucket my-bucket-name \
[--prefix my-prefix]
```

Example output

```
{  
    "SpotDatafeedSubscription": {  
        "OwnerId": "111122223333",  
        "Bucket": "my-bucket-name",  
        "Prefix": "my-prefix",  
        "State": "Active"  
    }  
}
```

Describe your Spot Instance data feed

To describe your data feed subscription, use the [describe-spot-datafeed-subscription](#) command.

```
aws ec2 describe-spot-datafeed-subscription
```

Example output

```
{  
    "SpotDatafeedSubscription": {  
        "OwnerId": "123456789012",  
        "Prefix": "spotdata",  
        "Bucket": "my-s3-bucket",  
        "State": "Active"  
    }  
}
```

View the data in your data feed

In the AWS Management Console, open AWS CloudShell. Use the following [s3 sync](#) command to get the .gz files from the S3 bucket for your data feed and store them the folder that you specify.

```
aws s3 sync s3://my-s3-bucket ./data-feed
```

To display the contents of a .gz file, change to the folder where you stored the contents of the S3 bucket.

```
cd data-feed
```

Use the **ls** command to view the names of the files. Use the **zcat** command with the name of the file to display the contents of the compressed file. The following is an example command.

```
zcat 111122223333.2023-12-09-07.001.b959dbc6.gz
```

The following is example output.

```
#Version: 1.0
#Fields: Timestamp UsageType Operation InstanceID MyBidID MyMaxPrice MarketPrice Charge
Version
2023-12-09 07:13:47 UTC USE2-SpotUsage:c7a.medium RunInstances:SV050
i-0c3e0c0b046e050df sir-pwq6nmfp 0.0510000000 USD 0.0142000000 USD
0.0142000000 USD 1
```

Delete your Spot Instance data feed

To delete your data feed, use the [delete-spot-datafeed-subscription](#) command.

```
aws ec2 delete-spot-datafeed-subscription
```

Spot Instance quotas

There are quotas for the number of running Spot Instances and pending Spot Instance requests per AWS account per Region. Once a pending Spot Instance request is fulfilled, the request no longer counts towards the quota because the running instance is counted towards the quota.

Spot Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU quota until Amazon EC2 detects the Spot Instance terminations and closes the requests.

We provide the following quota types for Spot Instances:

- All DL Spot Instance Requests
- All F Spot Instance Requests
- All G and VT Spot Instance Requests
- All Inf Spot Instance Requests
- All P Spot Instance Requests
- All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests
- All Trn Spot Instance Requests
- All X Spot Instance Requests

Each quota type specifies the maximum number of vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

You can launch any combination of instance types that meet your changing application needs. For example, with an All Standard Spot Instance Requests quota of 256 vCPUs, you could request 32 m5.2xlarge Spot Instances (32 x 8 vCPUs) or 16 c5.4xlarge Spot Instances (16 x 16 vCPUs).

Tasks

- [Monitor Spot Instance quotas and usage](#)
- [Request a quota increase](#)

Monitor Spot Instance quotas and usage

You can view and manage your Spot Instance quotas using the following:

- The Amazon EC2 [Services quotas page](#) in the Service Quotas console
- The [get-service-quota](#) AWS CLI

For more information, see [Amazon EC2 service quotas](#) in the *Amazon EC2 User Guide for Linux Instances* and [Viewing service quotas](#) in the *Service Quotas User Guide*.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Request a quota increase

Even though Amazon EC2 automatically increases your Spot Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more Spot Instances than your current quota allows, you can request a quota increase. You can also request a quota increase if you submit a Spot Instance request and you receive the error `Max spot instance count exceeded`. To request a quota increase, use the Service Quotas console described in [Amazon EC2 service quotas](#).

Burstable performance instances

The T instance types are [burstable performance instances](#). If you launch your Spot Instances using a burstable performance instance type, and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in [Standard mode](#) to avoid paying higher costs. If you launch burstable performance Spot Instances in [Unlimited mode](#) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see [When to use unlimited mode versus fixed CPU](#).

T2 instances, when configured in [Standard mode](#), get [launch credits](#). T2 instances are the only burstable performance instances that get launch credits. Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use [Unlimited mode](#) for T2 Spot Instances, or use an instance type with dedicated CPU.

Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server that is fully dedicated for your use. You can optionally choose to share the instance capacity with other AWS accounts. For more information, see [Work with shared Dedicated Hosts](#).

Dedicated Hosts provide visibility and control over instance placement and they support host affinity. This means that you can launch and run instances on specific hosts, and you can ensure

that instances run only on specific hosts. For more information, see [Understand auto-placement and affinity](#).

Dedicated Hosts provide comprehensive Bring Your Own License (BYOL) support. They allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, SQL Server, SUSE Linux Enterprise Server, Red Hat Enterprise Linux, or other software licenses that are bound to VMs, sockets, or physical cores, subject to your license terms.

If you require your instances to run on dedicated hardware, but you do not need visibility or control over instance placement, and you do not need to use per-socket or per-core software licenses, you can consider using Dedicated Instances instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Dedicated physical server	Physical server with instance capacity fully dedicated to your use.	Physical server that's dedicated to a single customer account.
Instance capacity sharing	Can share instance capacity with other accounts.	Not supported
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported

	Dedicated Host	Dedicated Instance
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Host recovery .	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information about Dedicated Instances, see [Dedicated Instances](#).

Instance capacity configurations

Dedicated Hosts support different configurations (physical cores, sockets, and VCPUs) that allow you to run instances of different families and sizes.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on a host depends on the configuration you choose.

Contents

- [Single instance type support](#)
- [Multiple instance type support](#)

Single instance type support

You can allocate a Dedicated Host that supports only one instance type. With this configuration, every instance that you launch on the Dedicated Host must be of the same instance type, which you specify when you allocate the host.

For example, you can allocate a host that supports only the `m5.4xlarge` instance type. In this case, you can run only `m5.4xlarge` instances on that host.

The number of instances that you can launch onto the host depends on the number of physical cores provided by the host, and the number of cores consumed by the specified instance type. For example, if you allocate a host for `m5.4xlarge` instances, the host provides 48 physical cores, and each `m5.4xlarge` instance consumes 8 physical cores. This means that you can launch up to 6 instances on that host ($48 \text{ physical cores} / 8 \text{ cores per instance} = 6 \text{ instances}$).

Multiple instance type support

You can allocate a Dedicated Host that supports multiple instance types within the same instance family. This allows you to run different instance types on the same host, as long as they're in the same instance family and the host has sufficient instance capacity.

For example, you can allocate a host that supports different instance types within the `R5` instance family. In this case, you can launch any combination of `R5` instance types, such as `r5.large`, `r5.xlarge`, `r5.2xlarge`, and `r5.4xlarge`, on that host, up to the host's physical core capacity.

The following instance families support Dedicated Hosts with multiple instance type support:

- **General purpose:** A1, M5, M5n, M6i, and T3
- **Compute optimized:** C5, C5n, and C6i
- **Memory optimized:** R5, R5n, and R6i

The number of instances you can run on the host depends on the number of physical cores provided by the host, and the number of cores consumed by each instance type that you run on the host. For example, if you allocate an R5 host, which provides 48 physical cores, and you run two `r5.2xlarge` instances (*4 cores x 2 instances*) and three `r5.4xlarge` instances (*8 cores x 3 instances*), those instances consume a total of 32 cores, and you can run any combination of R5 instances as long as they do not exceed the remaining 16 cores.

However, for each instance family, there is a limit on the number of instances that can be run for each instance size. For example, an R5 Dedicated Host supports a maximum of 2 `r5.8xlarge` instances, which uses 32 of the physical cores. In this case, additional R5 instances of smaller sizes can then be used to fill the host to core capacity. For the supported number of instance sizes for each instance family, see the [Dedicated Hosts Configuration Table](#).

The following table shows example instance type combinations:

Instance family	Example instance size combinations
R5	<ul style="list-style-type: none">• Example 1: 4 x <code>r5.4xlarge</code> + 4 x <code>r5.2xlarge</code>• Example 2: 1 x <code>r5.12xlarge</code> + 1 x <code>r5.4xlarge</code> + 1 x <code>r5.2xlarge</code> + 5 x <code>r5.xlarge</code> + 2 x <code>r5.large</code>
C5	<ul style="list-style-type: none">• Example 1: 1 x <code>c5.9xlarge</code> + 2 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code>• Example 2: 4 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code> + 2 x <code>c5.large</code>
M5	<ul style="list-style-type: none">• Example 1: 4 x <code>m5.4xlarge</code> + 4 x <code>m5.2xlarge</code>

Instance family	Example instance size combinations
	<ul style="list-style-type: none">• Example 2: 1 x m5.12xlarge + 1 x m5.4xlarge + 1 x m5.2xlarge + 5 x m5.xlarge + 2 x m5.large

Considerations

Keep the following in mind when working with Dedicated Hosts that support multiple instance types:

- With N-type Dedicated Hosts, such as C5n, M5n, and R5n, you can't mix smaller instance sizes (2xlarge and smaller) with larger instance sizes (4xlarge and larger, including meta1). If you require smaller and larger instance sizes on N-type Dedicated Hosts at the same time, you must allocate separate hosts for the smaller and larger instance sizes.
- We recommend that you launch larger instance types first, and then fill the remaining instance capacity with smaller instance types as needed.

Bring your own license

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment.
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the [VM Import/Export User Guide](#).
3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.

- When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server.

Note

To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see [Track configuration changes](#).

Pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options

- [On-Demand Dedicated Hosts](#)
- [Dedicated Host Reservations](#)
- [Savings Plans](#)
- [Pricing for Windows Server on Dedicated Hosts](#)

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see [Amazon EC2 Dedicated Hosts On-Demand Pricing](#).

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see [Release Dedicated Hosts](#).

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:

- **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.
- **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.
- **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (`m4.xlarge`, `m4.medium`, and `m4.large`) you can associate a single `m4` reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see [Amazon EC2 Dedicated Hosts Pricing](#).

Savings Plans

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the [AWS Savings Plans User Guide](#).

Note

Savings Plans are not supported with `u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal` Dedicated Hosts.

Pricing for Windows Server on Dedicated Hosts

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on current generation instance types only. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

Burstable T3 instances on Dedicated Hosts

Dedicated Hosts support burstable performance T3 instances. T3 instances provide a cost-efficient way of using your eligible BYOL license software on dedicated hardware. The smaller vCPU footprint of T3 instances enables you to consolidate your workloads on fewer hosts and maximize your per-core license utilization.

T3 Dedicated Hosts are best suited for running BYOL software with low to moderate CPU utilization. This includes eligible per-socket, per-core, or per-VM software licenses, such as Windows Server, Windows Desktop, SQL Server, SUSE Enterprise Linux Server, Red Hat Enterprise Linux, and Oracle Database. Examples of workloads suited for T3 Dedicated Hosts are small and medium databases, virtual desktops, development and test environments, code repositories, and product prototypes. T3 Dedicated Hosts are not recommended for workloads with sustained high CPU utilization or for workloads that experience correlated CPU bursts simultaneously.

T3 instances on Dedicated Hosts use the same credit model as T3 instances on shared tenancy hardware. However, they support the standard credit mode only; they do not support the unlimited credit mode. In standard mode, T3 instances on Dedicated Hosts *earn*, *spend*, and *accrue* credits in the same way as burstable instances on shared tenancy hardware. They provide a baseline CPU performance with the ability to burst above the baseline level. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. When the accrued credits are depleted, CPU utilization is lowered to the baseline level. For more information about standard mode, see [How standard burstable performance instances work](#).

T3 Dedicated Hosts support all of the features offered by Amazon EC2 Dedicated Hosts, including multiple instance sizes on a single host, Host resource groups, and BYOL.

Supported T3 instance sizes and configurations

T3 Dedicated Hosts run general purpose burstable T3 instances that share CPU resources of the host by providing a baseline CPU performance and the ability to burst to a higher level when needed. This enables T3 Dedicated Hosts, which have 48 cores, to support up to a maximum of 192 instances per host. In order to efficiently utilize the host's resources and to provide the best instance performance, the Amazon EC2 instance placement algorithm automatically calculates the supported number of instances and instance size combinations that can be launched on the host.

T3 Dedicated Hosts support multiple instance types on the same host. All T3 instance sizes are supported on Dedicated Hosts. You can run different combinations of T3 instances up to the CPU limit of the host.

The following table lists the supported instance types, summarizes the performance of each instance type, and indicates the maximum number of instances of each size that can be launched.

Instance type	vCPUs	Memory (GiB)	Baseline CPU utilization per vCPU	Network burst bandwidth (Gbps)	Amazon EBS burst bandwidth (Mbps)	Max number of instances per Dedicated Host
t3.nano	2	0.5	5%	5	Up to 2,085	192
t3.micro	2	1	10%	5	Up to 2,085	192
t3.small	2	2	20%	5	Up to 2,085	192
t3.medium	2	4	20%	5	Up to 2,085	192
t3.large	2	8	30%	5	2,780	96
t3.xlarge	4	16	40%	5	2,780	48
t3.2xlarge	8	32	40%	5	2,780	24

Monitor CPU utilization for T3 Dedicated Hosts

You can use the `DedicatedHostCPUUtilization` Amazon CloudWatch metric to monitor the vCPU utilization of a Dedicated Host. The metric is available in the EC2 namespace and Per-Host-Metrics dimension. For more information, see [Dedicated Host metrics](#).

Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL, SUSE Linux, and SQL Server on Dedicated Hosts, you must bring your own AMIs. RHEL, SUSE Linux, and SQL Server AMIs that are offered by AWS or that are available on AWS Marketplace can't be used with Dedicated Hosts. For more information on how to create your own AMI, see [Bring your own license](#).

This restriction does not apply to hosts allocated for high memory instances (u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- There is a limit on the number of running Dedicated Hosts per instance family per AWS account per Region. Quotas apply to running instances only. If your instance is pending, stopping, or stopped, it does not count towards your quota. To view the quotas for your account, or to request a quota increase, use the [Service Quotas console](#).
- The instances that run on a Dedicated Host can only be launched in a VPC.
- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see [Create a launch template using advanced settings](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Amazon RDS instances are not supported.
- The AWS Free Usage tier is not available for Dedicated Hosts.
- Instance placement control refers to managing instance launches onto Dedicated Hosts. You cannot launch Dedicated Hosts into placement groups.
- If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal.

Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

Work with Dedicated Hosts

To use a Dedicated Host, you first allocate hosts for use in your account. You then launch instances onto the hosts by specifying *host* tenancy for the instance. You must select a specific host for the instance to launch on to, or you can allow it to launch on to any host that has auto-placement enabled and matches its instance type. When an instance is stopped and restarted, the *Host affinity* setting determines whether it's restarted on the same, or a different, host.

If you no longer need an On-Demand host, you can stop the instances running on the host, direct them to launch on a different host, and then *release* the host.

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see [Host Resource Groups in the AWS License Manager User Guide](#).

Allocate Dedicated Hosts

To begin using Dedicated Hosts, you must allocate Dedicated Hosts in your account using the Amazon EC2 console or the command line tools. After you allocate the Dedicated Host, the Dedicated Host capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on the host depends on the configuration you choose. For more information see [Instance capacity configurations](#).

Console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts** and then choose **Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
 - To configure the Dedicated Host to support multiple instance types in the selected instance family, for **Support multiple instance types**, choose **Enable**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.xlarge and m5.4xlarge instances onto the Dedicated Host.
 - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.
5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity](#).

7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see [Host recovery](#).
8. For **Quantity**, enter the number of Dedicated Hosts to allocate.
9. (Optional) Choose **Add new tag** and enter a tag key and a tag value.
10. Choose **Allocate**.

AWS CLI

To allocate a Dedicated Host

Use the [allocate-hosts](#) AWS CLI command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
aws ec2 allocate-hosts --instance-family "m5" --availability-zone "us-east-1a" --auto-placement "off" --host-recovery "on" --quantity 1
```

The following command allocates a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enables host recovery, and applies a tag with a key of purpose and a value of production.

```
aws ec2 allocate-hosts --instance-type "m4.large" --availability-zone "eu-west-1a" --auto-placement "on" --host-recovery "on" --quantity 1 --tag-specifications 'ResourceType=dedicated-host,Tags=[{Key=purpose,Value=production}]'
```

PowerShell

To allocate a Dedicated Host

Use the [New-EC2Host](#) AWS Tools for Windows PowerShell command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
PS C:\> New-EC2Host -InstanceFamily m5 -AvailabilityZone us-east-1a -AutoPlacement Off -HostRecovery On -Quantity 1
```

The following commands allocate a Dedicated Host that supports *untargeted m4.large* instance launches in the *eu-west-1a* Availability Zone, enable host recovery, and apply a tag with a key of *purpose* and a value of *production*.

The `TagSpecification` parameter used to tag a Dedicated Host on creation requires an object that specifies the type of resource to be tagged, the tag key, and the tag value. The following commands create the required object.

```
PS C:\> $tag = @{ Key="purpose"; Value="production" }
PS C:\> $tagspec = new-object Amazon.EC2.Model.TagSpecification
PS C:\> $tagspec.ResourceType = "dedicated-host"
PS C:\> $tagspec.Tags.Add($tag)
```

The following command allocates the Dedicated Host and applies the tag specified in the `$tagspec` object.

```
PS C:\> New-EC2Host -InstanceType m4.large -AvailabilityZone eu-west-1a -
AutoPlacement On -HostRecovery On -Quantity 1 -TagSpecification $tagspec
```

Launch instances onto a Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with host tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

Tip

For Dedicated Hosts that support multiple instance sizes, we recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

Before you launch your instances, take note of the limitations. For more information, see [Dedicated Hosts restrictions](#).

You can launch an instance onto a Dedicated Host using the following methods.

Console

To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions, Launch Instance(s) onto host**.
4. In the **Application and OS Images** section, select an AMI from the list.

 **Note**

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

5. In the **Instance type** section, select the instance type to launch.

 **Note**

If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.

If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. In the **Key pair** section, select the key pair to associate with the instance.
7. In the **Advanced details** section, for **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity](#).

Note

The **Tenancy** and **Host** options are pre-configured based on the host that you selected.

8. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters](#).
9. Choose **Launch instance**.

To launch an instance onto a Dedicated Host using the Launch Instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances, Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

Note

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:
 - a. For **Tenancy**, select **Dedicated Host**.
 - b. For **Target host by**, select **Host ID**.
 - c. For **Target host ID**, select the host onto which to launch the instance.
 - d. For **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity](#).

7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters](#).
8. Choose **Launch instance**.

AWS CLI

To launch an instance onto a Dedicated Host

Use the [run-instances](#) AWS CLI command and specify the instance affinity, tenancy, and host in the Placement request parameter.

PowerShell

To launch an instance onto a Dedicated Host

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command and specify the instance affinity, tenancy, and host in the Placement request parameter.

Launch instances into a host resource group

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not have a host with available instance capacity, Amazon EC2 automatically allocates a new host in the host resource group, and then launches the instance onto that host. For more information, see [Host Resource Groups in the AWS License Manager User Guide](#).

Requirements and limits

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

You can launch an instance into a host resource group using the following methods.

Console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances, Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

 **Note**

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:
 - a. For **Tenancy**, select **Dedicated Host**.
 - b. For **Target host by**, select **Host resource group**.
 - c. For **Tenancy host resource group**, select the host resource group into which to launch the instance.
 - d. For **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity](#).

7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters](#).
8. Choose **Launch instance**.

AWS CLI

To launch an instance into a host resource group

Use the [run-instances](#) AWS CLI command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

PowerShell

To launch an instance into a host resource group

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

Understand auto-placement and affinity

Placement control for Dedicated Hosts happens on both the instance level and host level.

Auto-placement

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When the auto-placement of a Dedicated Host is *disabled*, it only accepts *Host* tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When the auto-placement of a Dedicated Host is *enabled*, it accepts any untargeted instance launches that match its instance type configuration.

When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific HostId enables it to launch on any Dedicated Host that has auto-placement *enabled* and that matches its instance type.

Host affinity

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to Host, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to Default, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

Modify Dedicated Host auto-placement

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account, using one of the following methods.

Console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select a host and choose **Actions, Modify host**.
4. For **Instance auto-placement**, choose **Enable** to enable auto-placement, or clear **Enable** to disable auto-placement. For more information, see [Understand auto-placement and affinity](#).
5. Choose **Save**.

AWS CLI

To modify the auto-placement of a Dedicated Host

Use the [modify-hosts](#) AWS CLI command. The following example enables auto-placement for the specified Dedicated Host.

```
aws ec2 modify-hosts --auto-placement on --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the auto-placement of a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command. The following example enables auto-placement for the specified Dedicated Host.

```
PS C:\> Edit-EC2Host --AutoPlacement 1 --HostId h-012a3456b7890cdef
```

Modify the supported instance types

Support for multiple instance types on the same Dedicated Host is available for the following instance families: C5, M5, R5, C5n, R5n, M5n, and T3. Other instance families support only a single instance type on the same Dedicated Host.

You can allocate a Dedicated Host using the following methods.

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the pending state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the pending state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the m5 instance family to support only m5.large instances, the Dedicated Host must either have no running instances, or it must have only m5.large instances running on it.

If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal. Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

You can modify the supported instance types using one of the following methods.

Console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions, Modify host**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
 - If the Dedicated Host currently supports a specific instance type, **Support multiple instance types** is not enabled, and **Instance type** lists the supported instance type. To

modify the host to support multiple types in the current instance family, for **Support multiple instance types**, choose **Enable**.

You must first stop all instances running on the host before modifying it to support multiple instance types.

- If the Dedicated Host currently supports multiple instance types in an instance family, **Enabled** is selected for **Support multiple instance types**. To modify the host to support a specific instance type, for **Support multiple instance types**, clear **Enable**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the [modify-hosts](#) AWS CLI command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
aws ec2 modify-hosts --instance-family m5 --host-ids h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
aws ec2 modify-hosts --instance-type m5.xlarge --instance-family --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the supported instance types for a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
PS C:\> Edit-EC2Host --InstanceFamily m5 --HostId h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
PS C:\> Edit-EC2Host --InstanceType m5.xlarge --HostId h-012a3456b7890cdef
```

Modify instance tenancy and affinity

You can change the tenancy of an instance after you have launched it. You can also modify the affinity for your instance to target a specific host or allow it to launch on any available dedicated host with matching attributes in your account. To modify either instance tenancy or affinity, the instance must be in the stopped state.

The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see [Tenancy conversion](#) in the *License Manager User Guide*.

Note

For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of host. For T3 instances, you can't change the tenancy from host to dedicated or default. Attempting to make one of these unsupported tenancy changes results in an InvalidRequest error code.

You can modify an instance's tenancy and affinity using the following methods.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances**, and select the instance to modify.
3. Choose **Instance state, Stop**.
4. With the instance selected, choose **Actions, Instance settings, Modify instance placement**.
5. On the **Modify instance placement** page, configure the following:
 - **Tenancy**—Choose one of the following:
 - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see [Dedicated Instances](#).

- Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.
- **Affinity**—Choose one of the following:
 - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
 - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for **Target Host**.
- **Target Host**—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

For more information, see [Understand auto-placement and affinity](#).

6. Choose **Save**.

AWS CLI

To modify instance tenancy or affinity

Use the [modify-instance-placement](#) AWS CLI command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
aws ec2 modify-instance-placement --instance-id i-1234567890abcdef0 --affinity host
--tenancy host --host-id h-012a3456b7890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the [Edit-EC2InstancePlacement](#) AWS Tools for Windows PowerShell command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
PS C:\> Edit-EC2InstancePlacement -InstanceId i-1234567890abcdef0 -Affinity host -
Tenancy host -HostId h-012a3456b7890cdef
```

View Dedicated Hosts

You can view details about a Dedicated Host and the individual instances on it using the following methods.

Console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select a host.
4. For information about the host, choose **Details**.

Available vCPUs indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose **Running instances**.

AWS CLI

To view the capacity of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command.

The following example uses the [describe-hosts](#) (AWS CLI) command to view the available instance capacity for a Dedicated Host that supports multiple instance types within the c5 instance family. The Dedicated Host already has two c5.4xlarge instances and four c5.2xlarge instances running on it.

```
$ aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

```
"AvailableInstanceCapacity": [  
    { "AvailableCapacity": 2,  
      "InstanceType": "c5.xlarge",  
      "TotalCapacity": 18 },  
    { "AvailableCapacity": 4,
```

```
"InstanceType": "c5.large",
"TotalCapacity": 36
],
"AvailableVCpus": 8
```

PowerShell

To view the instance capacity of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

Tag Dedicated Hosts

You can assign custom tags to your existing Dedicated Hosts to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host based on the custom tags that you assigned. Dedicated Host tags can also be used for cost allocation tracking.

You can also apply tags to Dedicated Hosts at the time of creation. For more information, see [Allocate Dedicated Hosts](#).

You can tag a Dedicated Host using the following methods.

Console

To tag a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host to tag, and then choose **Actions, Manage tags**.
4. In the **Manage tags** screen, choose **Add tag**, and then specify the key and value for the tag.
5. (Optional) Choose **Add tag** to add additional tags to the Dedicated Host.
6. Choose **Save changes**.

AWS CLI

To tag a Dedicated Host

Use the [create-tags](#) AWS CLI command.

The following command tags the specified Dedicated Host with Owner=TeamA.

```
aws ec2 create-tags --resources h-abc12345678909876 --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag object, which specifies the key and value pair to be used for the Dedicated Host tag. The following commands create a Tag object named \$tag, with a key and value pair of Owner and TeamA respectively.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag  
PS C:\> $tag.Key = "Owner"  
PS C:\> $tag.Value = "TeamA"
```

The following command tags the specified Dedicated Host with the \$tag object.

```
PS C:\> New-EC2Tag -Resource h-abc12345678909876 -Tag $tag
```

Monitor Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Locate the Dedicated Host in the list and review the value in the **State** column.

AWS CLI

To view the state of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command and then review the state property in the hostSet response element.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

PowerShell

To view the state of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command and then review the state property in the hostSet response element.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

The following table explains the possible Dedicated Host states.

State	Description
available	AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.
released	The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.
under-assessment	AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.
pending	The Dedicated Host cannot be used for new instance launches. It is either being modified to support multiple instance types , or a host recovery is in progress.
permanent-failure	An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might continue to run. If you stop or terminate all instances on a Dedicated Host, the host ID becomes available again.

State	Description
retired	Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.
released-permanent-failure	AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.

Release Dedicated Hosts

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

You can release a Dedicated Host using the following methods.

Console

To release a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions, Release host**.
5. To confirm, choose **Release**.

AWS CLI

To release a Dedicated Host

Use the [release-hosts](#) AWS CLI command.

```
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

PowerShell

To release a Dedicated Host

Use the [Remove-EC2Hosts](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Remove-EC2Hosts -HostId h-012a3456b7890cdef
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to released, and you are not able to launch any instances onto that host.

Note

If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience `LimitExceeded` errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their host tenancy setting.

Purchase Dedicated Host Reservations

You can purchase reservations using the following methods:

Console

To purchase reservations

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts**, **Dedicated Host Reservations**, **Purchase Dedicated Host Reservation**.
3. On the **Find offerings** screen, do the following:
 - a. For **Instance family**, select the instance family of the Dedicated Host for which to purchase the Dedicated Host Reservation.
 - b. For **Payment option**, select and configure your preferred payment option.
4. Choose **Next**.
5. Select the Dedicated Hosts with which to associate the Dedicated Host Reservation, and then choose **Next**.

6. *(Optional)* Assign tags to the Dedicated Host Reservation.
7. Review your order and choose **Purchase**.

AWS CLI

To purchase reservations

1. Use the [describe-host-reservation-offerings](#) AWS CLI command to list the available offerings that match your needs. The following example lists the offerings that support instances in the m4 instance family and have a one-year term.

 **Note**

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
aws ec2 describe-host-reservation-offerings --filter Name=instance-family,Values=m4 --max-duration 31536000
```

The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the [purchase-host-reservation](#) AWS CLI command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of purpose and a value of production.

```
aws ec2 purchase-host-reservation --offering-id hro-03f707bf363b6b324 --host-id-set h-013abcd2a00cbd123 --tag-specifications 'ResourceType=host-reservation,Tags=[Key=purpose,Value=production]'
```

PowerShell

To purchase reservations

1. Use the [Get-EC2HostReservationOffering](#) AWS Tools for Windows PowerShell command to list the available offerings that match your needs. The following examples list the offerings that support instances in the m4 instance family and have a one-year term.

 **Note**

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
PS C:\> $filter = @{"Name="instance-family"; Value="m4"}
```

```
PS C:\> Get-EC2HostReservationOffering -filter $filter -MaxDuration 31536000
```

The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the [New-EC2HostReservation](#) AWS Tools for Windows PowerShell command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

```
PS C:\> New-EC2HostReservation -OfferingId hro-03f707bf363b6b324 -  
HostIdSet h-013abcd2a00cbd123
```

View Dedicated Host reservations

You can view information about the Dedicated Hosts that are associated with your reservation, including:

- The term of the reservation
- The payment option
- The start and end dates

You can view details of your Dedicated Host reservations using the following methods.

Console

To view the details of a Dedicated Host reservation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, choose **Dedicated Host Reservations**, and then select the reservation from the list provided.
4. Choose **Details** for information about the reservation.
5. Choose **Hosts** for information about the Dedicated Hosts with which the reservation is associated.

AWS CLI

To view the details of a Dedicated Host reservation

Use the [describe-host-reservations](#) AWS CLI command.

```
aws ec2 describe-host-reservations
```

PowerShell

To view the details of a Dedicated Host reservation

Use the [Get-EC2HostReservation](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2HostReservation
```

Tag Dedicated Host Reservations

You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host Reservation based on the custom tags that you assigned.

You can tag a Dedicated Host Reservation using the command line tools only.

AWS CLI

To tag a Dedicated Host Reservation

Use the [create-tags](#) AWS CLI command.

```
aws ec2 create-tags --resources hr-1234563a4ffc669ae --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host Reservation

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag parameter, which specifies the key and value pair to be used for the Dedicated Host Reservation tag. The following commands create the Tag parameter.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag  
PS C:\> $tag.Key = "Owner"  
PS C:\> $tag.Value = "TeamA"
```

```
PS C:\> New-EC2Tag -Resource hr-1234563a4ffc669ae -Tag $tag
```

Work with shared Dedicated Hosts

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (*owner*) shares it with other AWS accounts (*consumers*). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Prerequisites for sharing Dedicated Hosts

- To share a Dedicated Host, you must own it in your AWS account. You can't share a Dedicated Host that has been shared with you.
- To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Limitations for sharing Dedicated Hosts

You can't share Dedicated Hosts that have been allocated for the following instance types: u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal.

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an Availability Zone ID for the us-east-1 Region and it is the same location in every AWS account.

To view the Availability Zone IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.
2. The Availability Zone IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Dedicated Host

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

Important

Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.

To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

 **Note**

After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

You can share a Dedicated Host that you own by using one of the following methods.

Amazon EC2 console

To share a Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to share and choose **Actions, Share host**.
4. Select the resource share to which to add the Dedicated Host and choose **Share host**.

It could take a few minutes for consumers to get access to the shared host.

AWS RAM console

To share a Dedicated Host that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

AWS CLI

To share a Dedicated Host that you own using the AWS CLI

Use the [create-resource-share](#) command.

Unshare a shared Dedicated Host

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:

- Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
- Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for [retirement](#). Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is reshared with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share. You can do this by using one of the following methods.

Amazon EC2 console

To unshare a shared Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to unshare and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose **Remove host from resource share**.

AWS RAM console

To unshare a shared Dedicated Host that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

Command line

To unshare a shared Dedicated Host that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify a shared Dedicated Host

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

Amazon EC2 console

To identify a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The **Owner** column shows the AWS account ID of the Dedicated Host owner.

Command line

To identify a shared Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you.

View instances running on a shared Dedicated Host

Owners and consumers can view the instances running on a shared Dedicated Host at any time using one of the following methods.

Amazon EC2 console

To view the instances running on a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to view the instances and choose **Instances**. The tab lists the instances that are running on the host. Owners see all of the instances running on the host, including instances launched by consumers. Consumers only see running instances that they launched onto the host. The **Owner** column shows the AWS account ID of the account that launched the instance.

Command line

To view the instances running on a shared Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command. The command returns the instances running on each Dedicated Host. Owners see all of the instances running on the host. Consumers only see running instances that they launched on the shared hosts. InstanceOwnerId shows the AWS account ID of the instance owner.

Shared Dedicated Host permissions

Permissions for owners

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can't take any action on running instances that were launched by consumers.

Permissions for consumers

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can't modify the shared Dedicated Host in any way, and they can't view or modify instances that were launched by other consumers or the Dedicated Host owner.

Billing and metering

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.

Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see [Host recovery](#).

Dedicated Hosts on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to your premises. By providing local access to AWS managed infrastructure, AWS Outposts enables you to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can allocate Dedicated Hosts on Outposts that you own in your account. This makes it easier for you to bring your existing software licenses and workloads that require a dedicated physical server to AWS Outposts. You can also target specific hardware assets on an Outpost to help minimize latency between your workloads.

Dedicated Hosts allow you to use your eligible software licenses on Amazon EC2, so that you get the flexibility and cost effectiveness of using your own licenses. Other software licenses that are bound to virtual machines, sockets, or physical cores, can also be used on Dedicated Hosts, subject to their license terms. While Outposts have always been a single-tenant environments that are

eligible for BYOL workloads, Dedicated Hosts allows you to limit the needed licenses to a single host as opposed to the entire Outpost deployment.

Additionally, using Dedicated Hosts on an Outpost gives you greater flexibility in instance type deployment, and more granular control over instance placement. You can target a specific host for instance launches and use host affinity to ensure that the instance always runs on that host, or you can use auto-placement to launch an instance onto any available host that has matching configurations and available capacity.

Contents

- [Prerequisites](#)
- [Supported features](#)
- [Considerations](#)
- [Allocate and use a Dedicated Host on an Outpost](#)

Prerequisites

You must have an Outpost installed at your site. For more information, see [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

Supported features

- The following instance families are supported: C5, M5, R5, C5d, M5d, R5d, G4dn, and i3en.
- Dedicated Hosts on Outposts can be configured to support multiple instance sizes. Support for multiple instance sizes is available for the following instance families: C5, M5, R5, C5d, M5d, and R5d. For more information, see [Instance capacity configurations](#).
- Dedicated Hosts on Outposts support auto-placement and targeted instance launches. For more information, see [Understand auto-placement and affinity](#).
- Dedicated Hosts on Outposts support host affinity. For more information, see [Understand auto-placement and affinity](#).
- Dedicated Hosts on Outposts support sharing with AWS RAM. For more information, see [Work with shared Dedicated Hosts](#).

Considerations

- Dedicated Host Reservations are not supported on Outposts.

- Host resource groups and AWS License Manager are not supported on Outposts.
- Dedicated Hosts on Outposts do not support burstable T3 instances.
- Dedicated Hosts on Outposts do not support host recovery.
- Simplified automatic recovery is not supported for instances with Dedicated Host tenancy on Outposts.

Allocate and use a Dedicated Host on an Outpost

You allocate and use Dedicated Hosts on Outposts in the same way that would with Dedicated Hosts in an AWS Region.

Prerequisites

Create a subnet on the Outpost. For more information, see [Create a subnet](#) in the *AWS Outposts User Guide*.

To allocate a Dedicated Host on an Outpost, use one of the following methods:

AWS Outposts console

1. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
2. In the navigation pane, choose **Outposts**. Select the Outpost and then choose **Actions**, **Allocate Dedicated Host**.
3. Configure the Dedicated Host as needed. For more information, see [Allocate Dedicated Hosts](#).

 **Note**

Availability Zone and **Outpost ARN** should be pre-populated with the Availability Zone and ARN of the selected Outpost.

4. Choose **Allocate**.

Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**, and then choose **Allocate Dedicated Host**.

3. For **Availability Zone**, select the Availability Zone associated with the Outpost.
4. For **Outpost ARN**, enter the ARN of the Outpost.
5. To target specific hardware assets on the Outpost, for **Target specific hardware assets on Outpost**, select **Enable**. For each hardware asset to target, choose **Add asset ID**, and then enter the ID of the hardware asset.

 **Note**

The value that you specify for **Quantity** must be equal to the number of asset IDs that you specify. For example, if you specify 3 asset IDs, then Quantity must also be 3.

6. Configure the remaining Dedicated Host settings as needed. For more information, see [Allocate Dedicated Hosts](#).
7. Choose **Allocate**.

AWS CLI

Use the [**allocate-hosts**](#) AWS CLI command. For **--availability-zone**, specify the Availability Zone associated with the Outpost. For **--outpost-arn**, specify the ARN of the Outpost. Optionally, for **--asset-ids**, specify the IDs of the Outpost hardware assets to target.

```
aws ec2 allocate-hosts --availability-zone "us-east-1a" --outpost-arn  
"arn:aws:outposts:us-east-1a:111122223333:outpost/op-4fe3dc21baEXAMPLE" --asset-  
ids asset_id --instance-family "m5" --auto-placement "off" --quantity 1
```

To launch an instance onto a Dedicated Host on an Outpost

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**. Select the Dedicated Host that you allocated in the previous step and choose **Actions, Launch instance onto host**.
3. Configure the instance as needed and then launch the instance. For more information, see [Launch instances onto a Dedicated Host](#).

Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure concerning system power or network connectivity events. Other Dedicated Host issues will require manual intervention to recover from.

Host recovery basics

Dedicated Hosts and the host resource groups recovery process use host-level health checks to assess Dedicated Host availability and to detect underlying system failures. The type of Dedicated Host failure determines if Dedicated Host auto recovery is possible. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

 **Important**

Dedicated Host auto recovery does not occur when the host is scheduled for retirement.

Dedicated Host auto recovery

When a system power or network connectivity failure is detected on your Dedicated Host, Dedicated Host auto recovery is initiated and Amazon EC2 **automatically allocates a replacement Dedicated Host**. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings
- Reservation

When the replacement Dedicated Host is allocated, the **instances are recovered on to the replacement Dedicated Host**. The recovered instances retain the same attributes as the original instances, including:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

Additionally, the built-in integration with AWS License Manager automates the tracking and management of your licenses.

 **Note**

AWS License Manager integration is supported only in Regions in which AWS License Manager is available.

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.

When all of the instances have been recovered on to the replacement Dedicated Host, **the impaired Dedicated Host is released**, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification (if notification settings have been configured for AWS License Manager). If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see [Using License Configurations](#) and [Settings in License Manager](#) in the [AWS License Manager User Guide](#).

Scenarios without Dedicated Host auto recovery

Dedicated Host auto recovery does not occur when the host is scheduled for retirement. You will receive a retirement notification in the AWS Health Dashboard, an Amazon CloudWatch event, and the AWS account owner email address receives a message regarding the Dedicated Host failure. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the instances on the retiring host.

Stopped instances are not recovered on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.

Instances with instance storage are not recovered on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

Supported instance types

Host recovery is supported for the following instance families: A1, C3, C4, C5, C5n, C6a, C6g, C6i, Inf1, G3, G5g, M3, M4, M5, M5n, M5zn, M6a, M6g, M6i, P2, P3, R3, R4, R5, R5b, R5n, R6g, R6i, T3, X1, X1e, X2iezn, u-6tb1, u-9tb1, u-12tb1, u-18tb1, and u-24tb1.

To recover instances that are not supported, see [Manually recover unsupported instances](#).

Note

Dedicated Host auto recovery of supported metal [instance types](#) will take longer to detect and recover from than non-metal instance types.

Configure host recovery

You can configure host recovery at the time of Dedicated Host allocation, or after allocation using the Amazon EC2 console or AWS Command Line Interface (CLI).

Contents

- [Enable host recovery](#)
- [Disable host recovery](#)
- [View the host recovery configuration](#)

Enable host recovery

You can enable host recovery at the time of Dedicated Host allocation or after allocation.

For more information about enabling host recovery at the time of Dedicated Host allocation, see [Allocate Dedicated Hosts](#).

To enable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to enable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Enable**, and then choose **Save**.

To enable host recovery after allocation using the AWS CLI

Use the [modify-hosts](#) command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery on --host-ids h-012a3456b7890cdef
```

Disable host recovery

You can disable host recovery at any time after the Dedicated Host has been allocated.

To disable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to disable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Disable**, and then choose **Save**.

To disable host recovery after allocation using the AWS CLI

Use the [modify-hosts](#) command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery off --host-ids h-012a3456b7890cdef
```

View the host recovery configuration

You can view the host recovery configuration for a Dedicated Host at any time.

To view the host recovery configuration for a Dedicated Host using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host Recovery** field.

To view the host recovery configuration for a Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command.

```
$ aws ec2 describe-hosts --host-ids h-012a3456b7890cdef
```

The HostRecovery response element indicates whether host recovery is enabled or disabled.

Host recovery states

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the under-assessment state, and all of the instances enter the impaired state. You can't launch instances on to the impaired Dedicated Host while it is in the under-assessment state.

After the replacement Dedicated Host is allocated, it enters the pending state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the pending state. Recovered instances on the replacement Dedicated Host remain in the impaired state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the available state, and the recovered instances return to the running state. You can launch instances on to the replacement Dedicated Host after it enters the available state. The original impaired Dedicated Host is permanently released and it enters the released-permanent-failure state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the permanent-failure state.

Manually recover unsupported instances

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.

Warning

Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

Manually recover EBS-backed instances

For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more

information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see [Stop and start Amazon EC2 instances](#).

Manually recover instance store-backed instances

For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.
3. Terminate the original instance on the impaired Dedicated Host.

Related services

Dedicated Host integrates with the following services:

- **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

Pricing

There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.

If the impaired Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Host maintenance

With host maintenance, your Amazon EC2 instances on the degraded Dedicated Host are automatically rebooted on a replacement Dedicated Host during a scheduled maintenance event. This helps reduce application downtime and offloads the undifferentiated heavy-lift of maintenance to AWS. Host maintenance is also performed for planned and routine Amazon EC2 maintenance.

Host maintenance is supported on all new Dedicated Host allocations made through Amazon EC2 console. For any Dedicated Host in your AWS account or any new Dedicated Host allocated through [AllocateHosts](#) API, you can configure host maintenance for supported Dedicated Hosts. For more information, see [the section called “Configuring host maintenance”](#).

Host maintenance basics

When degradation is detected on a Dedicated Host, a new Dedicated Host is allocated. Degradation can be caused by degradation of the underlying hardware or detection of certain problematic conditions. Your instances on the degraded Dedicated Host are scheduled to be automatically rebooted on the replacement Dedicated Host.

The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host. These attributes include the following.

- Auto placement settings
- Availability Zone
- Reservation
- Host affinity
- Host maintenance settings
- Host recovery settings
- Instance type
- Tags

Host maintenance is available in all AWS Regions for all supported Dedicated Hosts. For more information about Dedicated Hosts where host maintenance is not supported, see [the section called “Limitations”](#).

Your degraded Dedicated Host is released after all of your instances have been rebooted to a new Dedicated Host or stopped. You can access your instances on the degraded Dedicated Host before the scheduled maintenance event, but launching instances on the degraded Dedicated Host is not supported.

You can use the replacement Dedicated Host to launch new instances on the host before the scheduled maintenance event. However, some instance capacity on the replacement host is reserved for the instances that must be migrated from the degraded host. You can't launch new instances into this reserved capacity. For more information, see [the section called “Instances on Dedicated Host”](#).

Limitations

- Host maintenance is not supported in AWS Outposts, AWS Local Zones, and AWS Wavelength Zones.
- Host maintenance cannot be turned on or off for hosts already within a host resource group. Hosts added to a host resource group retain their host maintenance setting. For more information, see [Host resource groups](#).
- Host maintenance is only supported on specific instance types. For more information, see [the section called “Supported instance types”](#).

Host maintenance versus host recovery

The following table shows the main differences between host recovery and host maintenance.

	Host recovery	Host maintenance
Accessibility	Unreachable	Reachable
State	under-assessment	permanent-failure
Action	Recovery is immediate	Maintenance is scheduled
Scheduling flexibility	Cannot be rescheduled	Can be rescheduled

	Host recovery	Host maintenance
Host Resource Group	Supported	Not supported

For more information about host recovery, see [Host recovery](#).

Supported instance types

Host maintenance is supported for the following instance families:

- General purpose: A1 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | M6in | M7a | M7g | M7i | T3
- Compute optimized: C4 | C5 | C5a | C5n | C6a | C6g | C6gn | C6i | C6in | C7g | C7gn | C7i
- Memory optimized: R4 | R5 | R5a | R5b | R5n | R6a | R6g | R6i | R6in | R7a | R7g | R7iz | u-12tb1 | u-18tb1 | u-24tb1 | u-3tb1 | u-6tb1 | u-9tb1 | X2iezn
- Accelerated computing: G3 | G5g | Inf1 | P2 | P3

Instances on Dedicated Host

Amazon EC2 automatically reserves capacity on the replacement host for the instances that will be automatically migrated from the degraded host. Amazon EC2 does not reserve capacity on the replacement host for instances that can't be automatically migrated, such as instances with instance store root volumes. The reserved capacity can't be used to launch new instances.

Note

The Amazon EC2 console shows the reserved capacity as used capacity. It could appear that the instances are running on both the degraded host and the replacement host. However, the instances will continue to run only on the degraded host until they are stopped or they are migrated into the reserved capacity on the replacement host.

If you manually stop an instance on the degraded host that can be automatically migrated, the capacity that was reserved for that instance on the replacement host is released and becomes available for use.

During the scheduled maintenance event, the instances on the degraded host are rebooted and migrated into the reserved capacity on the replacement Dedicated Host. The migrated instances retain the same attributes as the ones on your degraded host, including the following.

- Amazon EBS volume attachments
- Elastic IP addresses
- Instance ID
- Instance metadata
- Private IP address

You can **stop and start an instance** on the degraded host at any point before the scheduled maintenance event is initiated. Doing this reboots your instance on to another host, and your instance won't undergo scheduled maintenance. You must update your instance's host affinity to the new host where you want to reboot your instance. If you stop all instances on the degraded host before the maintenance event is initiated, the degraded host is released and the maintenance event is canceled. For more information, see [Stop and start Amazon EC2 instances](#).

 **Note**

The data on any local store volume is not preserved when you stop and start your instance.

Instances with an **instance store volume** as the root device are terminated after the specified termination date. Any data on the instance store volumes is deleted when the instances are terminated. Terminated instances are permanently deleted, and cannot be started again. For instances with instance store volumes as the root device, we recommend launching replacement instances on a different Dedicated Host using the most recent Amazon Machine Image, and migrating all available data to the replacement instances before the specified termination date. For more information, see [Instance retirement](#).

Instances that **cannot be rebooted** automatically are stopped after the specified date. You can start these instances again on a different host. Instances using an Amazon EBS volume as a root device continue to use the same Amazon EBS volume after being started on a new host.

You can set the **order of instance reboot** by rescheduling the start time of an instance reboot in <https://console.aws.amazon.com/ec2/>.

Configuring host maintenance

You can configure host maintenance for all supported Dedicated Hosts via AWS Management Console or AWS CLI. See the following table for more details.

AWS Management Console

To enable host maintenance for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select **on** in the **Host maintenance** field.

To disable host maintenance for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select **off** in the **Host maintenance** field.

To view the host maintenance configuration for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host maintenance** field.

AWS CLI

To enable or disable host maintenance for your new Dedicated Host during allocation using AWS CLI.

Use the [allocate-hosts](#) command.

Enable

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --  
availability-zone us-east-1b --host-maintenance on
```

Disable

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --availability-zone us-east-1b --host-maintenance off
```

To enable or disable host maintenance for your existing Dedicated Host using AWS CLI.

Use the [modify-hosts](#) command.

Enable

```
aws ec2 modify-hosts --region us-east-1 --host-maintenance on --host-ids h-0d123456bbf78910d
```

Disable

```
aws ec2 modify-hosts --region us-east-1 --host-maintenance off --host-ids h-0d123456bbf78910d
```

To view the host maintenance configuration for your Dedicated Host using AWS CLI.

Use the [describe-hosts](#) command.

```
aws ec2 describe-hosts --region us-east-1 --host-ids h-0d123456bbf78910d
```

Note

If you disable host maintenance, you receive an email notification to evict the degraded host and manually migrate your instances to another host within 28 days. A replacement host is allocated if you have Dedicated Host reservation. After 28 days, the instances running on the degraded host are terminated, and the host is released automatically.

Maintenance event

On detection of degradation, a maintenance event is scheduled 14 days later, to reboot your instances on a new Dedicated Host. You receive an email notification providing details about the degraded host, scheduled maintenance event, and maintenance time slots. For more information, see [View scheduled events](#).

You can reschedule the maintenance event for any day up to seven days after the date of the scheduled event. For more information about rescheduling, see [Reschedule a scheduled event](#).

The maintenance event usually takes a few minutes to complete. In the rare case of unsuccessful event, you receive an email notification to evict the instances on the degraded host within a specified time frame.

Host maintenance states

Your Dedicated Host is set to permanent-failure state when degradation is detected. You cannot launch instances on a Dedicated Host in the state of permanent-failure. On completion of maintenance event, the degraded host is released and put in the state of released, permanent-failure.

After detecting degradation on a Dedicated Host and before scheduling a maintenance event, host maintenance automatically allocates a replacement Dedicated Host in your account. This replacement host stays in a pending state until a maintenance event is scheduled. Once the maintenance event is scheduled, the replacement Dedicated Host moves to the available state.

You can use the replacement Dedicated Host to launch new instances on the host before the scheduled maintenance event. However, some instance capacity on the replacement host is reserved for the instances that must be migrated from the degraded host. You can't launch new instances into this reserved capacity. For more information, see [the section called “Instances on Dedicated Host”](#).

Related services

Dedicated Host integrates with **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

You must have sufficient licenses in your AWS account for your new Dedicated Host. The licenses associated with your degraded host are released when the host is released after the completion of the scheduled maintenance event.

Pricing

There are no additional charges for using host maintenance, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host maintenance is initiated, you are no longer billed for the degraded Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.

If the degraded Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the degraded Dedicated Host had an active Dedicated Host Reservation, it is transferred to the new Dedicated Host.

Track configuration changes

You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When **On**, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.
- **Host recording status**—When **Enabled**, the configuration information for Dedicated Hosts is recorded.
- **Instance recording status**—When **Enabled**, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the **Edit Config Recording** button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three are enabled, the icon is green. To edit the settings, choose **Edit Config Recording**. You are directed to the **Set up AWS Config** page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see [Setting up AWS Config using the Console](#) in the *AWS Config Developer Guide*.

Note

AWS Config records your resources after it discovers them, which might take several minutes.

After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you

have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- By using the AWS Config console. For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see [Viewing Configuration Details in the AWS Config Console](#) in the *AWS Config Developer Guide*.
- By running AWS CLI commands. First, you can use the [list-discovered-resources](#) command to get a list of all hosts and instances. Then, you can use the [get-resource-config-history](#) command to get the configuration details of a host or instance for a specific time interval. For more information, see [View Configuration Details Using the CLI](#) in the *AWS Config Developer Guide*.
- By using the AWS Config API in your applications. First, you can use the [ListDiscoveredResources](#) action to get a list of all hosts and instances. Then, you can use the [GetResourceConfigHistory](#) action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.

```
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --  
resource-id i-1234567890abcdef0
```

To manage AWS Config settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Dedicated Hosts** page, choose **Edit Config Recording**.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see [Setting up AWS Config using the Console](#).

For more information, see [Viewing Configuration Details in the AWS Config Console](#).

To activate AWS Config using the command line or API

- AWS CLI: [Viewing Configuration Details \(AWS CLI\)](#) in the *AWS Config Developer Guide*.
- Amazon EC2 API: [GetResourceConfigHistory](#).

Dedicated Instances

By default, EC2 instances run on shared tenancy hardware. This means that multiple AWS accounts might share the same physical hardware.

Dedicated Instances are EC2 instances that run on hardware that's dedicated to a single AWS account. This means that Dedicated Instances are physically isolated at the host hardware level from instances that belong to other AWS accounts, even if those accounts are linked to a single payer account. However, Dedicated Instances might share hardware with other instances from the same AWS account that are not Dedicated Instances.

Dedicated Instances provide no visibility or control over instance placement, and they do not support host affinity. If you stop and start a Dedicated Instance, it might not run on the same host. Similarly, you cannot target a specific host on which to launch or run an instance. Additionally, Dedicated Instances provide limited support for Bring Your Own License (BYOL).

If you require visibility and control over instance placement and more comprehensive BYOL support, consider using a Dedicated Host instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Dedicated physical server	Physical server with instance capacity fully dedicated to your use.	Physical server that's dedicated to a single customer account.

	Dedicated Host	Dedicated Instance
Instance capacity sharing	Can share instance capacity with other accounts.	Not supported
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Host recovery .	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

Dedicated Instance basics

A VPC can have a tenancy of either default or dedicated. By default, your VPCs have default tenancy and instances launched into a default tenancy VPC have default tenancy. To launch Dedicated Instances, do the following:

- Create a VPC with a tenancy of dedicated, so that all instances in the VPC run as Dedicated Instances. For more information, see [Create a VPC with a dedicated instance tenancy](#).
- Create a VPC with a tenancy of default and manually specify a tenancy of dedicated for the instances to run as Dedicated Instances. For more information, see [Launch Dedicated Instances into a VPC](#).

Supported features

Dedicated Instances support the following features and AWS service integrations:

Topics

- [Reserved Instances](#)
- [Automatic scaling](#)
- [Automatic recovery](#)
- [Dedicated Spot Instances](#)
- [Burstable performance instances](#)

Reserved Instances

To reserve capacity for your Dedicated Instances, you can purchase Dedicated Reserved Instances or Capacity Reservations. For more information, see [Reserved Instances](#) and [On-Demand Capacity Reservations](#).

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance into a VPC at a much reduced usage fee; the price break in the usage charge applies only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with default tenancy; it does not apply to a running instance with dedicated tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

Automatic scaling

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see [Launching Auto Scaling Instances in a VPC](#) in the *Amazon EC2 Auto Scaling User Guide*.

Automatic recovery

You can configure automatic recovery for a Dedicated Instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see [Recover your instance](#).

Dedicated Spot Instances

You can run a Dedicated Spot Instance by specifying a tenancy of dedicated when you create a Spot Instance request. For more information, see [Specify a tenancy for your Spot Instances](#).

Burstable performance instances

You can leverage the benefits of running on dedicated tenancy hardware with [the section called "Burstable performance instances"](#). T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see [the section called "Key concepts"](#).

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short-term variability if you launch multiple T3 Dedicated Instances

that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

Dedicated Instances limitations

Keep the following in mind when using Dedicated Instances:

- Some AWS services or their features are not supported with a VPC with the instance tenancy set to dedicated. Refer to the respective service's documentation to confirm if there are any limitations.
- Some instance types can't be launched into a VPC with the instance tenancy set to dedicated. For more information about supported instance types, see [Amazon EC2 Dedicated Instances](#).
- When you launch a Dedicated Instance backed by Amazon EBS, the EBS volume doesn't run on single-tenant hardware.

Pricing for Dedicated Instances

Pricing for Dedicated Instances is different from pricing for On-Demand Instances. For more information, see the [Amazon EC2 Dedicated Instances product page](#).

Work with Dedicated Instances

You can create a VPC with an instance tenancy of dedicated to ensure that all instances launched into the VPC are Dedicated Instances. Alternatively, you can specify the tenancy of the instance during launch.

Topics

- [Create a VPC with a dedicated instance tenancy](#)
- [Launch Dedicated Instances into a VPC](#)

Create a VPC with a dedicated instance tenancy

When you create a VPC, you have the option of specifying its instance tenancy. If you launch an instance into a VPC that has an instance tenancy of dedicated, the instance will always run as a Dedicated Instance on hardware that's dedicated for your use.

For more information about creating a VPC and choosing the tenancy options, see [Create a VPC](#) in the *Amazon VPC User Guide*.

Launch Dedicated Instances into a VPC

You can launch a Dedicated Instance using the Amazon EC2 launch instance wizard.

Console

To launch a Dedicated Instance into a default tenancy VPC using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances, Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.
4. In the **Instance type** section, select the instance type to launch.

 **Note**

Ensure that you choose an instance type that's supported as a Dedicated Instance. For more information, see [Amazon EC2 Dedicated Instances](#).

5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, for **Tenancy**, select **Dedicated**.
7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters](#).
8. Choose **Launch instance**.

Command line

To set the tenancy option for an instance during launch using the command line

- [run-instances](#) (AWS CLI)

- [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

For more information about launching an instance with a tenancy of host, see [Launch instances onto a Dedicated Host](#).

Display tenancy information

Console

To display tenancy information for your VPC using the console

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Your VPCs**.
3. Check the instance tenancy of your VPC in the **Tenancy** column.
4. If the **Tenancy** column isn't displayed, choose settings () in the top-right corner, turn on **Tenancy**, and choose **Confirm**.

To display tenancy information for your instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Check the tenancy of your instance in the **Tenancy** column.
4. If the **Tenancy** column isn't displayed, do one of the following:
 - Choose settings () in the top-right corner, turn on **Tenancy**, and choose **Confirm**.
 - Select the instance. On the **Details** tab near the bottom of the page, under **Host and placement group**, check the value for **Tenancy**.

Command line

To describe the tenancy of your VPC using the command line

- [describe-vpcs](#) (AWS CLI)

- [Get-EC2Vpc](#) (AWS Tools for Windows PowerShell)

To describe the tenancy of your instance using the command line

- [describe-instances](#) (AWS CLI)
- [Get-EC2Instance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance offering using the command line

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (AWS Tools for Windows PowerShell)

Change the tenancy of an instance

You can change the tenancy of a stopped instance after launch. The changes that you make take effect the next time the instance starts.

The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see [Tenancy conversion](#) in the *License Manager User Guide*.

Note

For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of host. You can't change the tenancy from host to dedicated or default. Attempting to make one of these unsupported tenancy changes results in an InvalidRequest error code.

Console

To change the tenancy of an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select your instance.
3. Choose **Instance state, Stop instance, Stop**.
4. Choose **Actions, Instance settings, Modify instance placement**.
5. For **Tenancy**, choose whether to run your instance on dedicated hardware or on a Dedicated Host. Choose **Save**.

Command line

To modify the tenancy value of an instance using the command line

- [modify-instance-placement](#) (AWS CLI)
- [Edit-EC2InstancePlacement](#) (AWS Tools for Windows PowerShell)

Change the tenancy of a VPC

You can change the instance tenancy of a VPC from dedicated to default after you create it. Modifying the instance tenancy of the VPC does not affect the tenancy of any existing instances in the VPC. The next time you launch an instance in the VPC, it has a tenancy of default, unless you specify otherwise during launch.

Note

You cannot change the instance tenancy of a VPC from default to dedicated after it is created.

You can modify the instance tenancy of a VPC using the AWS CLI, an AWS SDK, or the Amazon EC2 API only.

Command line

To modify the instance tenancy attribute of a VPC using the AWS CLI

Use the [modify-vpc-tenancy](#) command and specify the ID of the VPC and instance tenancy value. The only supported value is default.

```
aws ec2 modify-vpc-tenancy --vpc-id vpc-1a2b3c4d --instance-tenancy default
```

Capacity Reservations

Capacity Reservations allow you to reserve compute capacity for Amazon EC2 instances in a specific Availability Zone. There are two types of Capacity Reservations serving different use cases.

Types of Capacity Reservations

- On-Demand Capacity Reservations
- Capacity Blocks for ML

The following are some common use cases for On-Demand Capacity Reservations:

- **Scaling events** – Create On-Demand Capacity Reservations ahead of your business-critical events to ensure that you can scale when you need to.
- **Regulatory requirements and disaster recovery** – Use On-Demand Capacity Reservations to satisfy regulatory requirements for high availability, and reserve capacity in a different Availability Zone or Region for disaster recovery.

The following are some common use cases for Capacity Blocks for ML:

- **Machine learning (ML) model training and fine-tuning** – Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.
- **ML experiments and prototypes** – Run experiments and build prototypes that require GPU instances for short durations.

When to use On-Demand Capacity Reservation

Use On-Demand Capacity Reservations if you have strict capacity requirements, and are running business-critical workloads that require capacity assurance. With On-Demand Capacity Reservations, you can ensure that you'll always have access to the Amazon EC2 capacity you've reserved for as long as you need it.

When to use Capacity Blocks for ML

Use Capacity Blocks for ML when you need to ensure that you have uninterrupted access to GPU instances for a defined period of time starting on a future date. Capacity Blocks are ideal for training and fine-tuning ML models, short experimentation runs, and handling temporary surges in inference demand in the future. With Capacity Blocks, you can ensure that you'll have access to GPU resources on a specific date to run your ML workloads.

On-Demand Capacity Reservations

On-Demand Capacity Reservations enable you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. Capacity Reservations mitigate against the risk of being unable to get On-Demand capacity in case there are capacity constraints. If you have strict capacity requirements, and are running business-critical workloads that require a certain level of long or short-term capacity assurance, we recommend that you create a Capacity Reservation to ensure that you always have access to Amazon EC2 capacity when you need it, for as long as you need it.

You can create Capacity Reservations at any time, without entering into a one-year or three-year term commitment. The capacity becomes available and billing starts as soon as the Capacity Reservation is provisioned in your account. When you no longer need the capacity assurance, cancel the Capacity Reservation to release the capacity and to stop incurring charges. You can also use the billing discounts offered by Savings Plans and Regional Reserved Instances to reduce the cost of a Capacity Reservation.

When you create a Capacity Reservation, you specify:

- The Availability Zone in which to reserve the capacity
- The number of instances for which to reserve capacity
- The instance attributes, including the instance type, tenancy, and platform/OS

Capacity Reservations can only be used by instances that match their attributes. By default, they are automatically used by running instances that match the attributes. If you don't have any running instances that match the attributes of the Capacity Reservation, it remains unused until you launch an instance with matching attributes.

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Term	No commitment required. Can be created and canceled as needed.	Requires a fixed one-year or three-year commitment		
Capacity benefit	Capacity reserved in a specific Availability Zone.		No capacity reserved.	
Billing discount	No billing discount. †	Provides a billing discount.		

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Instance Limits	Your On-Demand Instance limits per Region apply.	Default is 20 per Availability Zone. You can request a limit increase.	Default is 20 per Region. You can request a limit increase.	No limit.

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- [Reserved Instances](#)
- [Savings Plans User Guide](#)

Supported platforms

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following platforms:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- RHEL with SQL Server Standard
- RHEL with SQL Server Enterprise
- RHEL with SQL Server Web
- RHEL with HA
- RHEL with HA and SQL Server Standard
- RHEL with HA and SQL Server Enterprise

- Ubuntu Pro

When you purchase a Capacity Reservation, you must specify the *platform* that represents the operating system for your instance.

- For SUSE Linux and RHEL distributions, excluding BYOL, you must choose the specific platform. For example, the **SUSE Linux** or **Red Hat Enterprise Linux** platform.
- For all other Linux distributions (including Ubuntu), choose the **Linux/UNIX** platform.
- If you bring your existing RHEL subscription (BYOL), you must choose the **Linux/UNIX** platform.

For more information about the supported Windows platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Windows Instances*.

Quotas

The number of instances for which you are allowed to reserve capacity is based on your account's On-Demand Instance quota. You can reserve capacity for as many instances as that quota allows, minus the number of instances that are already running.

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

Limitations

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.
- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see [Work with shared Capacity Reservations](#).
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can be created in cluster placement groups. Spread and partition placement groups are not supported.
- Capacity Reservations can't be used with Dedicated Hosts. Capacity Reservations can be used with Dedicated Instances.
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.

Capacity Reservation pricing and billing

Topics

- [Pricing](#)
- [Billing](#)
- [Billing discounts](#)
- [Viewing your bill](#)

Pricing

Capacity Reservations are charged at the equivalent On-Demand rate whether you run instances in reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your Amazon EC2 bill. When you run an instance that matches the attributes of a reservation, you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 m4.large Linux instances and run 15 m4.large Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. For more information, see [Billing discounts](#).

For more information, see [Amazon EC2 Pricing](#).

Billing

Billing starts as soon as the Capacity Reservation is provisioned in your account, and it continues while the Capacity Reservation remains provisioned in your account.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a Capacity Reservation remains provisioned in your account for 24 hours and 15 minutes, you are billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one m4.large Linux instance, which has an On-Demand rate of \$0.10 per usage hour. In this example, the Capacity Reservation is provisioned in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the m4.large

instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an m4.large instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the m4.large instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the m4.large instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the m4.large instance type.

Hour	1	2	3	4	5	6	Total cost
Unused Capacity Reservation	\$0.10	\$0.00	\$0.00	\$0.00	\$0.00	\$0.00	\$0.10
On-demand Instance Usage	\$0.00	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.50
Hourly cost	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.60

Billing discounts

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- [Reserved Instances](#)
- [Savings Plans User Guide](#)
- [Billing and purchase options](#)

Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details**, expand the **Elastic Compute Cloud** section and the Region to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see [Capacity Reservation Line Items](#) in the *AWS Billing and Cost Management User Guide*.

Work with Capacity Reservations

To start using Capacity Reservations, you create the capacity reservation in the required Availability Zone. Then, you can launch instances into the reserved capacity, view its capacity utilization in real time, and increase or decrease its capacity as needed.

By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, and Availability Zone). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This enables you to explicitly control which instances are allowed to run in that reserved capacity.

You can specify how the reservation ends. You can choose to cancel the Capacity Reservation or end it automatically at a specified time. If you specify an end time, the Capacity Reservation is canceled within an hour of the specified time. For example, if you specify 5/31/2019, 13:30:55, the Capacity Reservation is guaranteed to end between 13:30:55 and 14:30:55 on 5/31/2019. After a reservation ends, you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you cannot restart them until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation.

Create a Capacity Reservation

If your request to create a Capacity Reservation succeeds, the capacity is available immediately. The capacity remains reserved for your use as long as the Capacity Reservation is active, and you can launch instances into it at any time. If the Capacity Reservation is open, new instances and existing instances that have matching attributes automatically run in the capacity of the Capacity Reservation. If the Capacity Reservation is targeted, instances must specifically target it to run in the reserved capacity.

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller request. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas](#).

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the Create a Capacity Reservation page, configure the following settings in the **Instance details** section. The instance type, platform, and Availability Zone of the instances that you launch must match the instance type, platform, and Availability Zone that you specify here or the Capacity Reservation is not applied. For example, if an open Capacity Reservation doesn't match, an instance launch that targets that Capacity Reservation explicitly will fail.
 - a. **Instance Type**—The type of instance to launch into the reserved capacity.
 - b. **Launch EBS-optimized instances**—Specify whether to reserve the capacity for EBS-optimized instances. This option is selected by default for some instance types. For more information, see [the section called "EBS optimization"](#).
 - c. **Platform**—The operating system for your instances. For more information, see [Supported platforms](#). For more information about the supported Windows platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Windows Instances*.
 - d. **Availability Zone**—The Availability Zone in which to reserve the capacity.
 - e. **Tenancy**—Specify whether to run on shared hardware (default) or a dedicated instance.
 - f. **(Optional) Placement group ARN**—The ARN of the cluster placement group in which to create the Capacity Reservation.

For more information, see [Capacity Reservations in cluster placement groups](#).

- g. **Quantity**—The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the request is denied.

4. Configure the following settings in the **Reservation details** section:
 - a. **Reservation Ends**—Choose one of the following options:
 - **Manually**—Reserve the capacity until you explicitly cancel it.
 - **Specific time**—Cancel the capacity reservation automatically at the specified date and time.
 - b. **Instance eligibility**—Choose one of the following options:
 - **open**—(Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, and Availability Zone). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
 - **targeted**—The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, and Availability Zone), and that explicitly target the reservation.
5. Choose **Request reservation**.

To create a Capacity Reservation using the AWS CLI

Use the [create-capacity-reservation](#) command. For more information, see [Supported platforms](#). For more information about the supported Windows platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Windows Instances*.

For example, the following command creates a Capacity Reservation that reserves capacity for three m5.2xlarge instances running Red Hat Enterprise Linux AMIs in the us-east-1a Availability Zone.

```
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Red Hat Enterprise Linux --availability-zone us-east-1a --instance-count 3
```

Launch instances into an existing Capacity Reservation

When you launch an instance, you can specify whether to launch the instance into any open Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations. You can only launch an instance into a Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and sufficient capacity. Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an open Capacity Reservation that has matching attributes and available capacity.

Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.

To launch instances into an existing Capacity Reservation using the console

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.
2. Expand **Advanced details** and do the following:
 - a. For **Placement group**, select the cluster placement group in which to launch the instance.
 - b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:
 - **None** – Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
 - **Open** – Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
 - **Target by ID** – Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
 - **Target by group** – Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

To launch an instance into an existing Capacity Reservation using the AWS CLI

Use the [run-instances](#) command and specify the `--capacity-reservation-specification` parameter.

The following example launches a `t2.micro` instance into any open Capacity Reservation that has matching attributes and available capacity:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro  
--key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-  
specification CapacityReservationPreference=open
```

The following example launches a `t2.micro` instance into a targeted Capacity Reservation:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro  
--key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-  
specification CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

The following example launches a `t2.micro` instance into a Capacity Reservation group:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1  
--instance-type t2.micro --key-name MyKeyPair --subnet-  
id subnet-1234567890abcdef1 --capacity-reservation-specification  
CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-  
groups:us-west-1:123456789012:group/my-cr-group}
```

Modify a Capacity Reservation

You can change the attributes of an active Capacity Reservation after you have created it. You cannot modify a Capacity Reservation after it has expired or after you have explicitly canceled it.

When modifying a Capacity Reservation, you can only increase or decrease the quantity and change the way in which it is released. You cannot change the instance type, EBS optimization, platform, Availability Zone, or instance eligibility of a Capacity Reservation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.

If you specify a new quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

To modify a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.

3. Modify the **Quantity** or **Reservation ends** options as needed, and choose **Save changes**.

To modify a Capacity Reservation using the AWS CLI

Use the [modify-capacity-reservation](#) command:

For example, the following command modifies a Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0 --  
instance-count 8
```

Modify an instance's Capacity Reservation settings

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

To modify an instance's Capacity Reservation settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances** and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose **Actions, Modify Capacity Reservation Settings**.
4. For **Capacity Reservation**, choose one of the following options:
 - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
 - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.

- **Specify Capacity Reservation** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
- **Specify Capacity Reservation group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

To modify an instance's Capacity Reservation settings using the AWS CLI

Use the [modify-instance-capacity-reservation-attributes](#) command.

For example, the following command changes an instance's Capacity Reservation setting to open or none.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationPreference=none|open
```

For example, the following command modifies an instance to target a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

For example, the following command modifies an instance to target a specific Capacity Reservation group.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

View a Capacity Reservation

Capacity Reservations have the following possible states:

- **active**—The capacity is available for use.

- **expired**—The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
- **cancelled**—The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.
- **pending**—The Capacity Reservation request was successful but the capacity provisioning is still pending.
- **failed**—The Capacity Reservation request has failed. A request can fail due to request parameters that are not valid, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.

 **Note**

Due to the [eventual consistency](#) model followed by the Amazon EC2 APIs, after you create a Capacity Reservation, it can take up to 5 minutes for the console and the [describe-capacity-reservations](#) response to indicate that the Capacity Reservation is in the active state. During this time, the console and the `describe-capacity-reservations` response might indicate that the Capacity Reservation is in the pending state. However, the Capacity Reservation might already be available for use and you can attempt to launch instances into it.

To view your Capacity Reservations using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations** and select a Capacity Reservation to view.
3. Choose **View launched instances for this reservation**.

To view your Capacity Reservations using the AWS CLI

Use the [describe-capacity-reservations](#) command:

For example, the following command describes all Capacity Reservations.

```
aws ec2 describe-capacity-reservations
```

Example output.

```
{  
    "CapacityReservations": [  
        {

}
```

Cancel a Capacity Reservation

You can cancel a Capacity Reservation at any time if you no longer need the reserved capacity. When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.

You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plan or Regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see [Modify an instance's Capacity Reservation settings](#).

To cancel a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations** and select the Capacity Reservation to cancel.
3. Choose **Cancel reservation, Cancel reservation**.

To cancel a Capacity Reservation using the AWS CLI

Use the [cancel-capacity-reservation](#) command:

For example, the following command cancels a Capacity Reservation with an ID of cr-1234567890abcdef0.

```
aws ec2 cancel-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0
```

Work with Capacity Reservation groups

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called *resource groups*. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. For more information about resource groups, see [What are resource groups?](#) in the [AWS Resource Groups User Guide](#).

You can include Capacity Reservations that you own in your account, and Capacity Reservations that are shared with you by other AWS accounts in a single resource group. You can also include

Capacity Reservations that have different attributes (instance type, platform, and Availability Zone) in a single resource group.

When you create resource groups for Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, and Availability Zone) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation.

To do this, set **Instance eligibility to targeted** (old console) or **Only instances that specify this reservation** (new console) when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

Create a Capacity Reservation group

To create a group for Capacity Reservations

Use the [create-group](#) AWS CLI command. For name, provide a descriptive name for the group, and for configuration, specify two Type request parameters:

- AWS::EC2::CapacityReservationPool to ensure that the resource group can be targeted for instance launches
- AWS::ResourceGroups::Generic with allowed-resource-types set to AWS::EC2::CapacityReservation to ensure that the resource group accepts Capacity Reservations only

For example, the following command creates a group named MyCRGroup.

```
$ aws resource-groups create-group --name MyCRGroup --configuration
'{"Type":"AWS::EC2::CapacityReservationPool"}'
'{"Type":"AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-resource-
types", "Values": ["AWS::EC2::CapacityReservation"]}]}'
```

The following shows example output.

```
{
    "GroupConfiguration": {
        "Status": "UPDATE_COMPLETE",
        "Configuration": [
            {
                "Type": "AWS::EC2::CapacityReservationPool"
            },
            {
                "Type": "AWS::ResourceGroups::Generic",
                "Parameters": [
                    {
                        "Values": [
                            "AWS::EC2::CapacityReservation"
                        ],
                        "Name": "allowed-resource-types"
                    }
                ]
            }
        ],
        "Group": {
            "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
            "Name": "MyCRGroup"
        }
    }
}
```

```
}
```

Add a Capacity Reservation to a group

If you add a Capacity Reservation that is shared with you to a group, and that Capacity Reservation is unshared, it is automatically removed from the group.

To add a Capacity Reservation to a group

Use the [group-resources](#) AWS CLI command. For `group`, specify the name of the group to which to add the Capacity Reservations, and for `resources`, specify ARNs of the Capacity Reservations to add. To add multiple Capacity Reservations, separate the ARNs with a space. To get the ARNs of the Capacity Reservations to add, use the [describe-capacity-reservations](#) AWS CLI command and specify the IDs of the Capacity Reservations.

For example, the following command adds two Capacity Reservations to a group named `MyCRGroup`.

```
$ aws resource-groups group-resources --group MyCRGroup --resource-arns arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1 arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

The following shows example output.

```
{
  "Failed": [],
  "Succeeded": [
    "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1",
    "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"
  ]
}
```

View Capacity Reservations in a group

To view the Capacity Reservations in a specific group

Use the [list-group-resources](#) AWS CLI command. For `group`, specify the name of the group.

For example, the following command lists the Capacity Reservations in a group named `MyCRGroup`.

```
$ aws resource-groups list-group-resources --group MyCRGroup
```

The following shows example output.

```
{  
    "QueryErrors": [],  
    "ResourceIdentifiers": [  
        {  
            "ResourceType": "AWS::EC2::CapacityReservation",  
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-1234567890abcdef1"  
        },  
        {  
            "ResourceType": "AWS::EC2::CapacityReservation",  
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-54321abcdef567890"  
        }  
    ]  
}
```

 **Note**

The command output includes Capacity Reservations that you own and Capacity Reservations that are shared with you.

View the groups to which a Capacity Reservation belongs

AWS CLI

To view the groups to which a specific Capacity Reservation has been added

Use the [get-groups-for-capacity-reservation](#) AWS CLI command.

For example, the following command lists the groups to which Capacity Reservation cr-1234567890abcdef1 has been added.

```
$ aws ec2 get-groups-for-capacity-reservation --capacity-reservation-  
id cr-1234567890abcdef1
```

The following shows example output.

```
{  
    "CapacityReservationGroups": [  
        {  
            "OwnerId": "123456789012",  
            "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/  
MyCRGroup"  
        }  
    ]  
}
```

 Note

If you specify a Capacity Reservation that is shared with you, the command returns only Capacity Reservation groups that you own.

Amazon EC2 console

To view the groups to which a specific Capacity Reservation has been added

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**, select the Capacity Reservation to view, and then choose **View**.

The groups to which the Capacity Reservation has been added are listed in the **Groups** card.

 Note

If you choose a Capacity Reservation that is shared with you, the console displays only Capacity Reservation groups that you own.

Remove a Capacity Reservation from a group

To remove a Capacity Reservation from a group

Use the [ungroup-resources](#) AWS CLI command. For **group**, specify the ARN of the group from which to remove the Capacity Reservation, and for **resources** specify the ARNs of the Capacity

Reservations to remove. To remove multiple Capacity Reservations, separate the ARNs with a space.

The following example removes two Capacity Reservations from a group named MyCRGroup.

```
$ aws resource-groups ungroup-resources --group MyCRGroup --resource-arns arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

The following shows example output.

```
{  
    "Failed": [],  
    "Succeeded": [  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd",  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"  
    ]  
}
```

Delete a Capacity Reservation group

To delete a group

Use the [delete-group](#) AWS CLI command. For group, provide the name of the group to delete.

For example, the following command deletes a group named MyCRGroup.

```
$ aws resource-groups delete-group --group MyCRGroup
```

The following shows example output.

```
{  
    "Group": {  
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",  
        "Name": "MyCRGroup"  
    }  
}
```

Capacity Reservations in cluster placement groups

You can create Capacity Reservations in a cluster placement group to reserve Amazon EC2 compute capacity for your workloads. Cluster placement groups offer the benefit of low network latency and high network throughput.

Creating a Capacity Reservation in a cluster placement group ensures that you have access to compute capacity in your cluster placement groups when you need it, for as long as you need it. This is ideal for reserving capacity for high-performance (HPC) workloads that require compute scaling. It allows you to scale your cluster down while ensuring that the capacity remains available for your use so that you can scale back up when needed.

Topics

- [Limitations](#)
- [Work with Capacity Reservations in cluster placement groups](#)

Limitations

Keep the following in mind when creating Capacity Reservations in cluster placement groups:

- If an existing Capacity Reservation is not in a placement group, you can't modify the Capacity Reservation to reserve capacity in a placement group. To reserve capacity in a placement group, you must create the Capacity Reservation in the placement group.
- After you create a Capacity Reservation in a placement group, you can't modify it to reserve capacity outside of the placement group.
- You can increase your reserved capacity in a placement group by modifying an existing Capacity Reservation in the placement group, or by creating additional Capacity Reservations in the placement group. However, you increase your chances of getting an insufficient capacity error.
- You can't share Capacity Reservations that have been created in a cluster placement group.
- You can't delete a cluster placement group that has active Capacity Reservations. You must cancel all Capacity Reservations in the cluster placement group before you can delete it.

Work with Capacity Reservations in cluster placement groups

To start using Capacity Reservations with cluster placement groups, perform the following steps.

Note

If you want to create a Capacity Reservation in an existing cluster placement group, skip Step 1. Then for Steps 2 and 3, specify the ARN of the existing cluster placement group. For information about how to find the ARN of your existing cluster placement group, see [View placement group information](#).

Topics

- [Step 1: \(Conditional\) Create a cluster placement group for use with a Capacity Reservation](#)
- [Step 2: Create a Capacity Reservation in a cluster placement group](#)
- [Step 3: Launch instances into the cluster placement group](#)

Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation

Perform this step only if you need to create a new cluster placement group. To use an existing cluster placement group, skip this step and then for Steps 2 and 3, use the ARN of that cluster placement group. For information about how to find the ARN of your existing cluster placement group, see [View placement group information](#).

You can create the cluster placement group using one of the following methods.

Console**To create a cluster placement group using the console**

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Placement Groups**, and then choose **Create placement group**.
3. For **Name**, specify a descriptive name for the placement group.
4. For **Placement strategy**, choose **Cluster**.
5. Choose **Create group**.
6. In the **Placement groups** table, in the **Group ARN** column, make a note of the ARN of the cluster placement group that you created. You'll need it for the next step.

AWS CLI

To create a cluster placement group using the AWS CLI

Use the [create-placement-group](#) command. For `--group-name`, specify a descriptive name for the placement group, and for `--strategy`, specify `cluster`.

The following example creates a placement group named `MyPG` that uses the `cluster` placement strategy.

```
$ aws ec2 create-placement-group \
  --group-name MyPG \
  --strategy cluster
```

Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

Step 2: Create a Capacity Reservation in a cluster placement group

You create a Capacity Reservation in a cluster placement group in the same way that you create any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Create a Capacity Reservation](#).

Considerations

- The specified cluster placement group must be in the `available` state. If the cluster placement group is in the `pending`, `deleting`, or `deleted` state, the request fails.
- The Capacity Reservation and the cluster placement group must be in the same Availability Zone. If the request to create the Capacity Reservation specifies an Availability Zone that is different from that of the cluster placement group, the request fails.
- You can create Capacity Reservations only for instance types that are supported by cluster placement groups. If you specify an unsupported instance type, the request fails. For more information, see [Cluster placement group rules and limitations](#).
- If you create an open Capacity Reservation in a cluster placement group and there are existing running instances that have matching attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy), those instances automatically run in the Capacity Reservation.

- Your request to create a Capacity Reservation could fail if one of the following is true:
 - Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your workload is flexible across instance types and sizes, try different instance attributes.
 - The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas](#).

You can create the Capacity Reservation in the cluster placement group using one of the following methods.

Console

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the **Create a Capacity Reservation** page, specify the instance type, platform, Availability Zone, Tenancy, quantity, and end date as needed.
4. For **Placement group**, select the ARN of the cluster placement group in which to create the Capacity Reservation.
5. Choose **Create**.

For more information, see [Create a Capacity Reservation](#).

AWS CLI

To create a Capacity Reservation using the AWS CLI

Use the [create-capacity-reservation](#) command. For **--placement-group-arn**, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
$ aws ec2 create-capacity-reservation \
  --instance-type instance_type \
  --instance-platform platform \
  --availability-zone az \
  --instance-count quantity \
  --placement-group-arn placement_group_ARN
```

For more information, see [Create a Capacity Reservation](#).

Step 3: Launch instances into the cluster placement group

You launch an instance into a Capacity Reservation in a cluster placement group in the same way that you launch an instance into any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to launch the instance. For more information, see [Create a Capacity Reservation](#).

Considerations

- If the Capacity Reservation is open, you do not need to specify the Capacity Reservation in the instance launch request. If the instance has attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy) that match a Capacity Reservation in the specified placement group, the instance automatically runs in the Capacity Reservation.
- If the Capacity Reservation accepts only targeted instance launches, you must specify the target Capacity Reservation in addition to the cluster placement group in the request.
- If the Capacity Reservation is in a Capacity Reservation group, you must specify the target Capacity Reservation group in addition to the cluster placement group in the request. For more information, see [Work with Capacity Reservation groups](#).

You can launch an instance into a Capacity Reservation in a cluster placement group using one of the following methods.

Console

To launch instances into an existing Capacity Reservation using the console

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.
2. Expand **Advanced details** and do the following:
 - a. For **Placement group**, select the cluster placement group in which to launch the instance.
 - b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:

- **Open** – To launch the instances into any open Capacity Reservation in the cluster placement group that has matching attributes and sufficient capacity.
 - **Target by ID** – To launch the instances into a Capacity Reservation that accepts only targeted instance launches.
 - **Target by group** – To launch the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

For more information, see [Launch instances into an existing Capacity Reservation](#).

AWS CLI

To launch instances into an existing Capacity Reservation using the AWS CLI

Use the [run-instances](#) command. If you need to target a specific Capacity Reservation or a Capacity Reservation group, specify the `--capacity-reservation-specification` parameter. For `--placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

The following command launches an instance into a targeted Capacity Reservation in a cluster placement group.

```
$ aws ec2 run-instances \
  --image-id ami_id \
  --count quantity \
  --instance-type instance_type \
  --key-name key_pair_name \
  --subnet-id subnetid \
  --capacity-reservation-specification
CapacityReservationTarget={CapacityReservationId=capacity_reservation_id} \
  --placement "GroupName=cluster_placement_group_name"
```

For more information, see [Launch instances into an existing Capacity Reservation](#).

Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.

By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see [AWS Local Zones FAQs](#).

Considerations

You can't use Capacity Reservation groups in a Local Zone.

To use a Capacity Reservation in a Local Zone

1. Enable the Local Zone for use in your AWS account. For more information, see [Opt in to Local Zones](#).
2. Create a Capacity Reservation in the Local Zone. For **Availability Zone**, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a. For more information, see [Create a Capacity Reservation](#).
3. Create a subnet in the Local Zone. For **Availability Zone**, choose the Local Zone. For more information, see [Create a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Local Zone (for example subnet-123abc | us-west-2-lax-1a), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Local Zone. For more information, see [Launch instances into an existing Capacity Reservation](#).

Capacity Reservations in Wavelength Zones

AWS *Wavelength* enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see [AWS Wavelength Zones](#).

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Developer Guide*.

Considerations

You can't use Capacity Reservation groups in a Wavelength Zone.

To use a Capacity Reservation in a Wavelength Zone

1. Enable the Wavelength Zone for use in your AWS account. For more information, see [Enable Wavelength Zones](#) in the *Amazon EC2 User Guide for Linux Instances*.
2. Create a Capacity Reservation in the Wavelength Zone. For **Availability Zone**, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1. For more information, see [Create a Capacity Reservation](#).
3. Create a subnet in the Wavelength Zone. For **Availability Zone**, choose the Wavelength Zone. For more information, see [Create a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Wavelength Zone (for example subnet-123abc | us-east-1-wl1-bos-wlz-1), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Wavelength. For more information, see [Launch instances into an existing Capacity Reservation](#).

Capacity Reservations on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see [Work with shared Capacity Reservations](#).

Prerequisite

You must have an Outpost installed at your site. For more information, see [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

Considerations

- You can't use Capacity Reservation groups on an Outpost.

To use a Capacity Reservation on an Outpost

1. Create a subnet on the Outpost. For more information, see [Create a subnet](#) in the *AWS Outposts User Guide*.
2. Create a Capacity Reservation on the Outpost.
 - a. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
 - b. In the navigation pane, choose **Outposts**, and then choose **Actions, Create Capacity Reservation**.
 - c. Configure the Capacity Reservation as needed and then choose **Create**. For more information, see [Create a Capacity Reservation](#).

Note

The **Instance Type** drop-down lists only instance types that are supported by the selected Outpost, and the **Availability Zone** drop-down lists only the Availability Zone with which the selected Outpost is associated.

3. Launch an instance into the Capacity Reservation. For **Subnet** choose the subnet that you created in Step 1, and for **Capacity Reservation**, select the Capacity Reservation that you created in Step 2. For more information, see [Launch an instance on the Outpost](#) in the *AWS Outposts User Guide*.

Work with shared Capacity Reservations

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.

A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

- [Stop sharing a Capacity Reservation](#)
- [Identify and view a shared Capacity Reservation](#)
- [View shared Capacity Reservation usage](#)
- [Shared Capacity Reservation permissions](#)
- [Billing and metering](#)
- [Instance limits](#)

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.
- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an AZ ID for the us-east-1 Region and it is the same location in every AWS account.

To view the AZ IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.
2. The AZ IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the CapacityReservationPreference parameter set to open, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
- If consumers launch instances that have matching attributes (instance type, platform, and Availability Zone) and have the CapacityReservationPreference parameter set to open, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the [AWS RAM console](#).

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are granted access to the shared Capacity Reservation if the [prerequisites for sharing](#) are met. If the Capacity Reservation is shared with external accounts, they receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the [describe-capacity-reservations](#) AWS CLI command. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instances will launch into On-Demand capacity.

You can share a Capacity Reservation that you own using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To share a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Choose the Capacity Reservation to share and choose **Actions, Share reservation**.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

It could take a few minutes for consumers to get access to the shared Capacity Reservation.

To share a Capacity Reservation that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

To share a Capacity Reservation that you own using the AWS CLI

Use the [create-resource-share](#) command.

Stop sharing a Capacity Reservation

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:

- Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability.
- Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share. You can do this using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To stop sharing a Capacity Reservation that you own using the Amazon EC2 console

- Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
- In the navigation pane, choose **Capacity Reservations**.
- Select the Capacity Reservation and choose the **Sharing** tab.
- The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

To stop sharing a Capacity Reservation that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

To stop sharing a Capacity Reservation that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify and view a shared Capacity Reservation

Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the AWS CLI. If you can view the shared Capacity Reservation in the

console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instance will launch into On-Demand capacity.

Owners and consumers can identify and view shared Capacity Reservations using the Amazon EC2 console and AWS CLI.

To identify a shared Capacity Reservation using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**. The screen lists Capacity Reservations that you own and Capacity Reservations that are shared with you. The **Owner** column shows the AWS account ID of the Capacity Reservation owner. (me) next to the AWS account ID indicates that you are the owner.

To identify a shared Capacity Reservation using the AWS CLI

Use the [describe-capacity-reservations](#) command. The command returns the Capacity Reservations that you own and Capacity Reservations that are shared with you. OwnerId shows the AWS account ID of the Capacity Reservation owner.

View shared Capacity Reservation usage

The owner of a shared Capacity Reservation can view its usage at any time using the Amazon EC2 console and the AWS CLI.

To view Capacity Reservation usage using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation for which to view the usage and choose the **Usage** tab.

The **AWS account ID** column shows the account IDs of the consumers currently using the Capacity Reservation. The **Launched instances** column shows the number of instances each consumer currently has running in the reserved capacity.

To view Capacity Reservation usage using the AWS CLI

Use the [get-capacity-reservation-usage](#) command. AccountId shows the account ID of the account using the Capacity Reservation. UsedInstanceCount shows the number of instances the consumer currently has running in the reserved capacity.

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

The Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity. Consumers are billed for the instances that they run inside the shared Capacity Reservation.

If the Capacity Reservation owner belongs to a different payer account and the Capacity Reservation is covered by a Regional Reserved Instance or a Savings Plan, the Capacity Reservation owner continues to be billed for the Regional Reserved Instance or Savings Plan. In these cases, the Capacity Reservation owner pays for the Regional Reserved Instance or Savings Plan, and consumers are billed for the instances that they run in the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

Capacity Reservation Fleets

An *On-Demand Capacity Reservation Fleet* is a group of Capacity Reservations.

A Capacity Reservation Fleet request contains all of the configuration information that's needed to launch a Capacity Reservation Fleet. Using a single request, you can reserve large amounts of Amazon EC2 capacity for your workload across multiple instance types, up to a target capacity that you specify.

After you create a Capacity Reservation Fleet, you can manage the Capacity Reservations in the fleet collectively by modifying or canceling the Capacity Reservation Fleet.

How Capacity Reservation Fleets work

When you create a Capacity Reservation Fleet, the Fleet attempts to create individual Capacity Reservations to meet the total target capacity that you specified in the Fleet request.

The number of instances for which the Fleet reserves capacity depends on the [*total target capacity*](#) and the [*instance type weights*](#) that you specify. The instance type for which it reserves capacity depends on the [*allocation strategy*](#) and [*instance type priorities*](#) that you use.

If there is insufficient capacity at the time the Fleet is created, and it is unable to immediately meet its total target capacity, the Fleet asynchronously attempts to create Capacity Reservations until it has reserved the requested amount of capacity.

When the Fleet reaches its total target capacity, it attempts to maintain that capacity. If a Capacity Reservation in the Fleet is cancelled, the Fleet automatically creates one or more Capacity Reservations, depending on your Fleet configuration, to replace the lost capacity and to maintain its total target capacity.

The Capacity Reservations in the Fleet can't be managed individually. They must be managed collectively by modifying the Fleet. When you modify a Fleet, the Capacity Reservations in the Fleet are automatically updated to reflect the changes.

Currently, Capacity Reservation Fleets support the open instance matching criteria, and all Capacity Reservations launched by a Fleet automatically use this instance matching criteria. With this criteria, new instances and existing instances that have matching attributes (instance type, platform, and Availability Zone) automatically run in the Capacity Reservations created by a Fleet. Capacity Reservation Fleets do not support target instance matching criteria.

Considerations

Keep the following in mind when working with Capacity Reservation Fleets:

- A Capacity Reservation Fleet can be created, modified, viewed, and cancelled using the AWS CLI and AWS API.
- The Capacity Reservations in a Fleet can't be managed individually. They must be managed collectively by modifying or cancelling the Fleet.
- A Capacity Reservation Fleet can't span across Regions.
- A Capacity Reservation Fleet can't span across Availability Zones.
- Capacity Reservations created by a Capacity Reservation Fleet are automatically tagged with the following AWS generated tag:
 - Key — `aws:ec2-capacity-reservation-fleet`
 - Value — `fleet_id`

You can use this tag to identify Capacity Reservations that were created by a Capacity Reservation Fleet.

Pricing

There are no additional charges for using Capacity Reservation Fleets. You are billed for the individual Capacity Reservations that are created by your Capacity Reservation Fleets. For more

information about how Capacity Reservations are billed, see [Capacity Reservation pricing and billing](#).

Capacity Reservation Fleet concepts

This topic describes some of the concepts of Capacity Reservation Fleets.

Topics

- [Total target capacity](#)
- [Allocation strategy](#)
- [Instance type weight](#)
- [Instance type priority](#)

Total target capacity

The *total target capacity* defines the total amount of compute capacity that the Capacity Reservation Fleet reserves. You specify the total target capacity when you create the Capacity Reservation Fleet. After the Fleet has been created, Amazon EC2 automatically creates Capacity Reservations to reserve capacity up to the total target capacity.

The number of instances for which the Capacity Reservation Fleet reserves capacity is determined by the total target capacity and the *instance type weight* that you specify for each instance type in the Capacity Reservation Fleet ($\text{total target capacity}/\text{instance type weight} = \text{number of instances}$).

You can assign a total target capacity based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign the total target capacity based on the number of vCPUs required. If your workload requires 2048 vCPUs, specify a total target capacity of 2048 and then assign instance type weights based on the number of vCPUs provided by the instance types in the Fleet. For an example, see [Instance type weight](#).

Allocation strategy

The allocation strategy for your Capacity Reservation Fleet determines how it fulfills your request for reserved capacity from the instance type specifications in the Capacity Reservation Fleet configuration.

Currently, only the prioritized allocation strategy is supported. With this strategy, the Capacity Reservation Fleet creates Capacity Reservations using the priorities that you have assigned to each

of the instance type specifications in the Capacity Reservation Fleet configuration. Lower priority values indicate higher priority for use. For example, say you create a Capacity Reservation Fleet that uses the following instance types and priorities:

- m4.16xlarge — priority = 1
- m5.16xlarge — priority = 3
- m5.24xlarge — priority = 2

The Fleet first attempts to create Capacity Reservations for m4.16xlarge. If Amazon EC2 has insufficient m4.16xlarge capacity, the Fleet attempts to create Capacity Reservations for m5.24xlarge. If Amazon EC2 has insufficient m5.24xlarge capacity, the Fleet creates Capacity Reservations for m5.16xlarge.

Instance type weight

The *instance type weight* is a weight that you assign to each instance type in the Capacity Reservation Fleet. The weight determines how many units of capacity each instance of that specific instance type counts toward the Fleet's *total target capacity*.

You can assign weights based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign weights based on the number of vCPUs provided by each instance type in the Capacity Reservation Fleet. In this case, if you create a Capacity Reservation Fleet using m4.16xlarge and m5.24xlarge instances, you would assign weights that correspond to the number of vCPUs for each instance as follows:

- m4.16xlarge — 64 vCPUs, weight = 64 units
- m5.24xlarge — 96 vCPUs, weight = 96 units

The instance type weight determines the number of instances for which the Capacity Reservation Fleet reserves capacity. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types and weights in the preceding example, the Fleet could reserve capacity for 6 m4.16xlarge instances ($384 \text{ total target capacity} / 64 \text{ instance type weight} = 6$ instances), or 4 m5.24xlarge instances ($384 / 96 = 4$).

If you do not assign instance type weights, or if you assign an instance type weight of 1, the total target capacity is based purely on instance count. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types in the preceding example, but omits

the weights or specifies a weight of 1 for both instance types, the Fleet could reserve capacity for either 384 m4.16xlarge instances or 384 m5.24xlarge instances.

Instance type priority

The *instance type priority* is a value that you assign to the instance types in the Fleet. The priorities are used to determine which of the instance types specified for the Fleet should be prioritized for use.

Lower priority values indicate a higher priority for use.

Before you begin

Before you create a Capacity Reservation Fleet:

1. Determine the amount of compute capacity that is needed by your workload.
2. Decide on the instance types and Availability Zones that you want to use.
3. Assign each instance type a priority based on your needs and preferences. For more information, see [Instance type priority](#).
4. Create a capacity weighting system that makes sense for your workload. Assign a weight to each instance type and determine your total target capacity. For more information, see [Instance type weight](#) and [Total target capacity](#).
5. Determine whether you need the Capacity Reservation indefinitely or only for a specific period of time.

Capacity Reservation Fleet states

A Capacity Reservation Fleet can be in one of the following states:

- submitted — The Capacity Reservation Fleet request has been submitted and Amazon EC2 is preparing to create the Capacity Reservations.
- modifying — The Capacity Reservation Fleet is being modified. The Fleet remains in this state until the modification is complete.
- active — The Capacity Reservation Fleet has fulfilled its total target capacity and it is attempting to maintain this capacity. The Fleet remains in this state until it is modified or deleted.
- partially_fulfilled — The Capacity Reservation Fleet has partially fulfilled its total target capacity. There is insufficient Amazon EC2 capacity to fulfill the total target capacity. The Fleet is attempting to asynchronously fulfill its total target capacity.
- expiring — The Capacity Reservation Fleet has reached its end date and it is in the process of expiring. One or more of its Capacity Reservations might still be active.
- expired — The Capacity Reservation Fleet has reached its end date. The Fleet and its Capacity Reservations are expired. The Fleet can't create new Capacity Reservations.
- cancelling — The Capacity Reservation Fleet is in the process of being cancelled. One or more of its Capacity Reservations might still be active.
- cancelled — The Capacity Reservation Fleet has been manually cancelled. The Fleet and its Capacity Reservations are cancelled and the Fleet can't create new Capacity Reservations.
- failed — The Capacity Reservation Fleet failed to reserve capacity for the specified instance types.

Create a Capacity Reservation Fleet

When you create a Capacity Reservation Fleet it automatically creates Capacity Reservations for the instance types specified in the Fleet request, up to the specified total target capacity. The number of instances for which the Capacity Reservation Fleet reserves capacity depends on the total target capacity and instance type weights that you specify in the request. For more information, see [Instance type weight](#) and [Total target capacity](#).

When you create the Fleet, you must specify the instance types to use and a priority for each of those instance types. For more information, see [Allocation strategy](#) and [Instance type priority](#).

Note

The **AWSServiceRoleForEC2CapacityReservationFleet** service-linked role is automatically created in your account the first time that you create a Capacity Reservation Fleet. For more information, see [Using service-linked roles for Capacity Reservation Fleet](#).

Currently, Capacity Reservation Fleets support the open instance matching criteria only.

You can create a Capacity Reservation Fleet using the command line only.

To create a Capacity Reservation Fleet

Use the [create-capacity-reservation-fleet](#) AWS CLI command.

```
$ aws ec2 create-capacity-reservation-fleet \
--total-target-capacity capacity_units \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy dedicated/default \
--end-date yyyy-mm-ddThh:mm:ss.000Z \

Modify a Capacity Reservation Fleet

You can modify the total target capacity and date of a Capacity Reservation Fleet at any time. When you modify the total target capacity of a Capacity Reservation Fleet, the Fleet automatically creates new Capacity Reservations, or modifies or cancels existing Capacity Reservations in the Fleet to meet the new total target capacity. When you modify the end date for the Fleet, the end dates for all of the individual Capacity Reservations are updated accordingly.

After you modify a Fleet, its status transitions to modifying. You can't attempt additional modifications to a Fleet while it is in the modifying state.

You can't modify the tenancy, Availability Zone, instance types, instance platforms, priorities, or weights used by a Capacity Reservation Fleet. If you need to change any of these parameters, you might need to cancel the existing Fleet and create a new one with the required parameters.

You can modify a Capacity Reservation Fleet using the command line only.

To modify a Capacity Reservation Fleet

Use the [modify-capacity-reservation-fleet](#) AWS CLI command.

Note

You can't specify `--end-date` and `--remove-end-date` in the same command.

```
$ aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id cr_fleet_ids \
--total-target-capacity capacity_units \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--remove-end-date
```

Expected output

```
{
```

```
"Return": true  
}
```

Example: Modify total target capacity

```
$ aws ec2 modify-capacity-reservation-fleet \  
--capacity-reservation-fleet-id crf-01234567890abcdef \  
--total-target-capacity 160
```

Example: Modify end date

```
$ aws ec2 modify-capacity-reservation-fleet \  
--capacity-reservation-fleet-id crf-01234567890abcdef \  
--end-date 2021-07-04T23:59:59.000Z
```

Example: Remove end date

```
$ aws ec2 modify-capacity-reservation-fleet \  
--capacity-reservation-fleet-id crf-01234567890abcdef \  
--remove-end-date
```

Example output

```
{  
    "Return": true  
}
```

Cancel a Capacity Reservation Fleet

When you no longer need a Capacity Reservation Fleet and the capacity it reserves, you can cancel it. When you cancel a Fleet, its status changes to `cancelled` and it can no longer create new Capacity Reservations. Additionally, all of the individual Capacity Reservations in the Fleet are cancelled and the instances that were previously running in the reserved capacity continue to run normally in shared capacity.

You can cancel a Capacity Reservation Fleet using the command line only.

To cancel a Capacity Reservation Fleet

Use the [cancel-capacity-reservation-fleet](#) AWS CLI command.

```
$ aws ec2 cancel-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

Expected output

      ]
    }
  ]
}
```

Example: Successful cancellation

```
$ aws ec2 cancel-capacity-reservation-fleets \

Example Capacity Reservation Fleet configurations

Topics

- [Example 1: Reserve capacity based on vCPUs](#)

Example 1: Reserve capacity based on vCPUs

The following example creates a Capacity Reservation Fleet that uses two instance types: m5.4xlarge and m5.12xlarge.

It uses a weighting system based on the number of vCPUs provided by the specified instance types. The total target capacity is 480 vCPUs. The m5.4xlarge provides 16 vCPUs and gets a weight of 16, while the m5.12xlarge provides 48 vCPUs and gets a weight of 48. This weighting system configures the Capacity Reservation Fleet to reserve capacity for either 30 m5.4xlarge instances ($480/16=30$), or 10 m5.12xlarge instances ($480/48=10$).

The Fleet is configured to prioritize the m5.12xlarge capacity and gets priority of 1, while the m5.4xlarge gets a lower priority of 2. This means that the fleet will attempt to reserve the m5.12xlarge capacity first, and only attempt to reserve the m5.4xlarge capacity if Amazon EC2 has insufficient m5.12xlarge capacity.

The Fleet reserves the capacity for Windows instances and the reservation automatically expires on October 31, 2021 at 23:59:59 UTC.

```
$ aws ec2 create-capacity-reservation-fleet \
--total-target-capacity 480 \
--allocation-strategy prioritized \
--instance-match-criteria open \

Using service-linked roles for Capacity Reservation Fleet

On-Demand Capacity Reservation Fleet uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Capacity Reservation Fleet. Service-linked roles are predefined by Capacity Reservation Fleet and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Capacity Reservation Fleet easier because you don't have to manually add the necessary permissions. Capacity Reservation Fleet defines the permissions of its service-linked roles, and unless defined otherwise, only Capacity Reservation Fleet can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Capacity Reservation Fleet resources because you can't inadvertently remove permission to access the resources.

Service-linked role permissions for Capacity Reservation Fleet

Capacity Reservation Fleet uses the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to create, describe, modify, and cancel Capacity Reservations that were previously created by a Capacity Reservation Fleet, on your behalf.

The `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role trusts the following entity to assume the role: `capacity-reservation-fleet.amazonaws.com`.

The role uses the **AWSEC2CapacityReservationFleetRolePolicy** policy, which includes the following permissions:

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Create a service-linked role for Capacity Reservation Fleet

You don't need to manually create a service-linked role. When you create a Capacity Reservation Fleet using the `create-capacity-reservation-fleet` AWS CLI command or the `CreateCapacityReservationFleet` API, the service-linked role is automatically created for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Capacity Reservation Fleet, Capacity Reservation Fleet creates the service-linked role for you again.

Edit a service-linked role for Capacity Reservation Fleet

Capacity Reservation Fleet does not allow you to edit the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Delete a service-linked role for Capacity Reservation Fleet

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete the resources for your service-linked role before you can manually delete it.

Note

If the Capacity Reservation Fleet service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role

1. Use the `delete-capacity-reservation-fleet` AWS CLI command or the `DeleteCapacityReservationFleet` API to delete the Capacity Reservation Fleets in your account.
2. Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Supported Regions for Capacity Reservation Fleet service-linked roles

Capacity Reservation Fleet supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and Endpoints](#).

Monitoring Capacity Reservations

You can use the following features to monitor your Capacity Reservations:

Topics

- [Monitor Capacity Reservations using CloudWatch metrics](#)
- [Monitor Capacity Reservations using EventBridge](#)
- [Utilization notifications](#)

Monitor Capacity Reservations using CloudWatch metrics

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

On-Demand Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see [Using Amazon CloudWatch Metrics](#). For more information about creating alarms, see [Creating Amazon CloudWatch Alarms](#).

Capacity Reservation usage metrics

The AWS/EC2CapacityReservations namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

Metric	Description
UsedInstanceCount	The number of instances that are currently in use. Unit: Count
AvailableInstanceCount	The number of instances that are available. Unit: Count
TotalInstanceCount	The total number of instances you have reserved. Unit: Count
InstanceUtilization	The percentage of reserved capacity instances that are currently in use. Unit: Percent

Capacity Reservation metric dimensions

You can use the following dimensions to refine the metrics listed in the previous table.

Dimension	Description
CapacityReservationId	This globally unique dimension filters the data you request for the identified capacity reservation only.

View CloudWatch metrics for Capacity Reservations

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

To view Capacity Reservation metrics using the CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see [Regions and Endpoints](#).
3. In the navigation pane, choose **Metrics**.
4. For **All metrics**, choose **EC2 Capacity Reservations**.
5. Choose the metric dimension **By Capacity Reservation**. Metrics will be grouped by CapacityReservationId.
6. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric.

To view Capacity Reservation metrics (AWS CLI)

Use the following [list-metrics](#) command:

```
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

Monitor Capacity Reservations using EventBridge

AWS Health sends events to Amazon EventBridge when a Capacity Reservation in your account is below 20 percent usage over certain periods. With EventBridge, you can establish rules that trigger programmatic actions in response to such events. For example, you can create a rule that

automatically cancels a Capacity Reservation when its utilization drops below 20 percent utilization over a 7-day period.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*.

For more information, see the [Amazon EventBridge User Guide](#).

This feature is not supported in AWS GovCloud (US).

Create an EventBridge rule

To receive email notifications when your Capacity Reservation utilization drops below 20 percent, create an Amazon SNS topic, and then create an EventBridge rule for the AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION event.

To create the Amazon SNS topic

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Topics**, and then choose **Create topic**.
3. For **Type**, choose **Standard**.
4. For **Name**, enter a name for the new topic.
5. Choose **Create topic**.
6. Choose **Create subscription**.

7. For **Protocol**, choose **Email**, and then for **Endpoint**, enter the email address that receives the notifications.
8. Choose **Create subscription**.
9. The email address entered above will receive email message with the following subject line: **AWS Notification - Subscription Confirmation**. Follow the directions to confirm your subscription.

To create the EventBridge rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**, and then choose **Create rule**.
3. For **Name**, enter a name for the new rule.
4. For **Rule type**, choose **Rule with an event pattern**.
5. Choose **Next**.
6. In the **Event pattern**, do the following:
 - a. For **Event source**, choose **AWS services**.
 - b. For **AWS service**, choose **AWS Health**.
 - c. For **Event type**, choose **EC2 ODCR Underutilization Notification**.
7. Choose **Next**.
8. For **Target 1**, do the following:
 - a. For **Target types**, choose **AWS service**.
 - b. For **Select a target**, choose **SNS topic**.
 - c. For **Topic**, choose the topic that you created earlier.
9. Choose **Next** and then **Next** again.
10. Choose **Create rule**.

Utilization notifications

AWS Health sends the following email and AWS Health Dashboard notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.

- Individual notifications for each newly created Capacity Reservation that has been below 20 percent utilization over the last 24-hour period.

- A summary notification for all Capacity Reservations that have been below 20 percent utilization over the last 7-day period.

The email notifications and AWS Health Dashboard notifications are sent to the email address associated with the AWS account that owns the Capacity Reservations. The notifications include the following information:

- The ID of the Capacity Reservation.
- The Availability Zone of the Capacity Reservation.
- The average utilization rate for the Capacity Reservation.
- The instance type and platform (operating system) of the Capacity Reservation.

Additionally, when capacity utilization for a Capacity Reservation in your account drops below 20 percent over a 24-hour and 7-day period, AWS Health sends events to EventBridge. With EventBridge, you can create rules that activate automatic actions, such as sending email notifications or triggering AWS Lambda functions, in response to such events. For more information, see [Monitor Capacity Reservations using EventBridge](#).

Capacity Blocks for ML

Capacity Blocks for ML allow you to reserve highly sought-after GPU instances on a future date to support your short duration machine learning (ML) workloads. Instances that run inside a Capacity Block are automatically placed close together inside [Amazon EC2 UltraClusters](#), for low-latency, petabit-scale, nonblocking networking.

With Capacity Blocks, you can see when GPU instance capacity is available on future dates, and you can schedule a Capacity Block to start at a time that works best for you. When you reserve a Capacity Block, you get predictable capacity assurance for GPU instances while paying only for the amount of time that you need. We recommend Capacity Blocks when you need GPUs to support your ML workloads for days or weeks at a time and don't want to pay for a reservation while your GPU instances aren't in use.

The following are some common use cases for Capacity Blocks.

- **ML model training and fine-tuning** – Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.

- **ML experiments and prototypes** – Run experiments and build prototypes that require GPU instances for short durations.

Capacity Blocks are currently available for p5.48xlarge and p4d.24xlargeinstances. The p5.48xlarge instances are available in the US East (Ohio) and US East (N. Virginia) Regions. The p4d.24xlargeinstances are available in the US East (Ohio) and the US West (Oregon) Regions. You can reserve a Capacity Block with a reservation start time up to eight weeks in the future.

You can use Capacity Blocks to reserve p5 and p4d instances with the following reservation duration and instance quantity options.

- Reservation durations for **1-day increments up 14 days total**
- Reservation instance quantity options of **1, 2, 4, 8, 16, 32, or 64 instances**

To reserve a Capacity Block, you start by specifying your capacity needs, including the instance type, the number of instances, amount of time, earliest start date, and latest end date that you need. Then, you can see an available Capacity Block offering that meets your specifications. The Capacity Block offering includes details such as start time, Availability Zone, and reservation price. The price of a Capacity Block offering depends on available supply and demand at the time the offering was delivered. After you reserve a Capacity Block, the price doesn't change. For more information, see [Capacity Blocks pricing and billing](#).

When you purchase a Capacity Block offering, your reservation is created for the date and number of instances that you selected. When your Capacity Block reservation begins, you can target instance launches by specifying the reservation ID in your launch requests.

You can use all the instances you reserved until 30 minutes before the end time of the Capacity Block. With 30 minutes left in your Capacity Block reservation, we begin terminating any instances that are running in the Capacity Block. We use this time to clean up your instances before delivering the Capacity Block to the next customer. The last 30 minutes of the reservation are not charged in the price of the Capacity Block. We emit an event through EventBridge 10 minutes before the termination process begins. For more information, see [Monitor Capacity Blocks with EventBridge](#).

Supported platforms

Capacity Blocks for ML currently support p5.48xlarge and p4d.24xlarge instances with default tenancy. When you use the AWS Management Console to purchase a Capacity Block, the default platform option is Linux/UNIX. When you use the AWS Command Line Interface (AWS CLI) or AWS SDK to purchase a Capacity Block, the following platform options are available:

- Linux/Unix
- Red Hat Enterprise Linux
- RHEL with HA
- SUSE Linux
- Ubuntu Pro

Considerations

Before you use Capacity Blocks, consider the following details and limitations.

- Capacity Blocks start and end at 11:30AM Coordinated Universal Time (UTC).
- The termination process for instances running in a Capacity Block begins at 11:00AM Coordinated Universal Time (UTC) on the final day of the reservation.
- Capacity Blocks can be reserved with a start time up to 8 weeks in the future.
- Capacity Block modifications and cancellations aren't allowed.
- Capacity Blocks can't be shared across AWS accounts or within your AWS Organization.
- Capacity Blocks can't be used in a capacity reservation group.
- The total number of instances that can be reserved in Capacity Blocks across all accounts in your AWS Organization can't exceed 64 instances on a particular date.
- To use a Capacity Block, instances must specifically target the reservation ID.
- Instances in a Capacity Block don't count against your On-Demand Instances limits.

Related resources

After you create a Capacity Block, you can do the following with the Capacity Block:

- Launch instances into the Capacity Block. See [Launch instances into Capacity Blocks](#).
- Create an Amazon EC2 Auto Scaling group. See [Use Capacity Blocks for machine learning workloads](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Create an Amazon EKS self-managed node group. See [Capacity Blocks for ML](#) in the *Amazon EKS User Guide*.

If you use Amazon EC2 Auto Scaling or Amazon EKS, you can schedule scaling to run at the start of the Capacity Block reservation. With scheduled scaling, AWS automatically handles retries for you, so you don't need to worry about implementing retry logic to handle transient failures.

Capacity Blocks pricing and billing

Topics

- [Pricing](#)
- [Billing](#)

Pricing

With Amazon EC2 Capacity Blocks for ML, you pay only for what you reserve. The price of a Capacity Block depends on available supply and demand for Capacity Blocks at the time of purchase. You can view the price of a Capacity Block offering before you reserve it. The price of the Capacity Block is charged up front at the time the reservation is made. When you search for a Capacity Block across a range of dates, we return the lowest-priced Capacity Block offering available. After you've reserved a Capacity Block, the price doesn't change.

When you use a Capacity Block, you pay for the operating system you use when your instances are running. For more information about operating system prices, see [Amazon EC2 Capacity Blocks for ML Pricing](#).

Billing

The price of a Capacity Block offering is charged up front. Payment is billed to your AWS account within 12 hours after you purchase a Capacity Block. While your payment is processing, your Capacity Block reservation resource remains in a state of payment-pending. If your payment can't

be processed within 12 hours, your Capacity Block is released and the reservation state changes to payment-failed.

After your payment is processed successfully, the Capacity Block resource state changes from payment-pending to scheduled. You receive an invoice that reflects the one-time upfront payment. In the invoice, you can associate the paid amount with the Capacity Block reservation ID.

When your Capacity Block reservation begins, you are billed based only on the operating system you use while your instances are running in the reservation. You can view your usage and associated charges in your anniversary bill for the month of usage in your AWS Cost and Usage Report.

Note

Savings Plans and Reserved Instance discounts don't apply to Capacity Blocks.

Viewing your bill

You can view your bill in the AWS Billing and Cost Management console. The upfront payment for your Capacity Block appears in the month that you purchased the reservation.

After your reservation begins, your bill shows separate lines for the block reservation used and unused time. You can use these line items to see how much time was used in your reservation. You will see only a usage charge in the line for used time if you use a premium operating system. For more information, see [Pricing](#). There is no additional charge for unused time.

For more information, see [Viewing your bill](#) in the *AWS Billing and Cost Management User Guide*.

If your Capacity Block starts in a different month than the month you purchased your reservation, the upfront price and reservation usage show up under separate billing months. In your AWS Cost and Usage Report, the Capacity Block reservation ID is listed in the reservation/ReservationARN line item of your upfront fee and the lineitem/ResourceId in your anniversary bill so that you can associate the usage to the corresponding upfront price.

Work with Capacity Blocks

To start using Capacity Blocks, you first find and purchase an available Capacity Block that matches your reservation size, duration, and timing needs. Then, when the reservation begins, you can use

the Capacity Block by launching instances that target the reservation ID. Thirty minutes before the reservation expires, we begin to terminate any instances that are still running in the Capacity Block.

Capacity Blocks are delivered as targeted Capacity Reservations in a single Availability Zone. To run instances in a Capacity Block, you must specify the reservation ID when launching your instances. If you stop instances on your own and the Capacity Block expires, you can't restart them until you target another Capacity Block in the active state.

By default, Capacity Blocks deliver low-latency, high-throughput network connectivity between the instances inside the Capacity Block, so there is no need to use a cluster placement group with a Capacity Block.

Prerequisites

You must use the corresponding AWS Region for the instance type that you want to use. For more information, see [Regions](#).

Capacity Blocks with p5.48xlarge instances are available in following AWS Regions.

Region name	Region code
US East (Ohio)	us-east-2
US East (N. Virginia)	us-east-1

Capacity Blocks with p4d.24xlarge instances are available in following AWS Regions.

Region name	Region code
US East (Ohio)	us-east-2

Region name	Region code
US West (Oregon)	us-west-2

 **Note**

Capacity Block sizes of 64 instances are not supported for all instance types in all AWS Regions.

Find and purchase Capacity Blocks

To reserve a Capacity Block, you first need to find a block of time when capacity is available that matches your needs. To find a Capacity Block that is available to reserve, you specify:

- The number of instances that you need
- The duration of time you need the instances
- The date range that you need your reservation

To search for an available Capacity Block offering, you specify a reservation duration and instance count. You must select one of the following options.

- **For reservation duration** – Up to 14 days in 1-day increments
- **For instance count** – 1, 2, 4, 8, 16, 32, or 64 instances

If a Capacity Block is available that matches your specifications, we return the details of a single Capacity Block offering. The offering details include the start time of the reservation, the Availability Zone for the reservation, and the price of the reservation. For more information, see [Pricing](#).

You can purchase the Capacity Block offering you are shown, or you can modify your search criteria to see the other options that are available. There is no predefined expiration time for the offering, but offerings are only available on a first-come, first-served basis.

When you purchase a Capacity Block offering, you get an immediate response confirming that your Capacity Block was reserved. After confirmation, you will see a new Capacity Reservation in your account with a reservation type of `capacity-block` and a `start-date` set to the start

time of the offering that you purchased. Your Capacity Block reservation is created with a state of payment-pending. After the upfront payment is successfully processed, the reservation state changes to scheduled. For more information, see [Billing](#).

You can use one of the following methods to find and purchase a Capacity Block.

Console

To find and purchase a Capacity Block using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select an AWS Region. This choice is important because Capacity Block sizes of 64 instances are not supported for all instance types in all Regions.
3. In the navigation pane, choose **Capacity Reservations, Purchase Capacity Blocks**.
4. Under **Capacity attributes**, you can define your Capacity Block search parameters. By default, the platform is Linux. If you want to select a different operating system, use the AWS CLI. For more information, see [Supported platforms](#).
5. Under **Total capacity**, select the number of instances you want to reserve.
6. Under **Duration**, enter the number of days you need the reservation for.
7. Under **Date range to search for Capacity Blocks**, enter the earliest possible start date and latest acceptable end date for your reservation.
8. Choose **Find Capacity Blocks**.
9. If a Capacity Block is available that meets your specifications, you see an offering under **Recommended Capacity Blocks**. If there are multiple offerings that meet your specifications, the lowest priced Capacity Block offering available is shown. To view other Capacity Block offerings, adjust your search inputs and choose **Find Capacity Blocks** again.
10. When you find a Capacity Block offering that you want to purchase, choose **Next**.
11. (Optional) On the **Add tags** page, choose **Add new tag**.
12. The **Review and purchase** page lists the start and end date, duration, total number of instances, and price.

 **Note**

Capacity Blocks can't be modified or canceled after you reserve them.

13. In the popup window **Purchase a Capacity Block**, type confirm, then choose **Purchase**.

AWS CLI

To find a Capacity Block using the AWS CLI

Use the `describe-capacity-block-offerings` command.

The following example searches for a Capacity Block that has 16 p5.48xlarge instances with a date range starting 2023-08-14 and ending 2023-10-22 with a duration of 48 hours. The instance count must be an integer from a predefined set of options 1, 2, 4, 8, 16, 32, 64. The capacity duration must be an integer that is a multiple of 24 between 24 and 336 indicating the number of days in hours.

```
aws ec2 describe-capacity-block-offerings --instance-type p5.48xlarge \
--instance-count 16 --start-date-range 2023-08-14T00:00:00Z \
--end-date-range 2023-10-22-T00:00:00Z --capacity-duration 48
```

To purchase a Capacity Block using the AWS CLI

Use the `purchase-capacity-block` command and specify the offering ID of the Capacity Block that you want to purchase and the instance platform.

```
aws ec2 purchase-capacity-block \
--capacity-block-offering-id cbr-0123456789abcdefg \
--instance-platform Linux/UNIX
```

Launch instances into Capacity Blocks

After you reserve a Capacity Block, you can view the Capacity Block reservation in your AWS account. You can view the start-date and end-date to see when your reservation will begin and end. Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available in your Capacity Block by the tag value for the tag key `aws:ec2capacityreservation:incrementalRequestedQuantity`.

When a Capacity Block reservation begins, the reservation state changes from scheduled to active. We emit an event through Amazon EventBridge to notify you that the Capacity Block is available to use. For more information, see [Monitor Capacity Blocks](#).

To use your Capacity Block, you must specify the Capacity Block reservation ID when launching instances. Launching an instance into a Capacity Block reduces the available capacity by the number of instances launched. For example, if your purchased instance capacity is eight instances and you launch four instances, the available capacity is reduced by four.

If you terminate an instance running in the Capacity Block before the reservation ends, you can launch a new instance in its place. When you stop or terminate an instance in a Capacity Block, it takes several minutes to clean up your instance before you can launch another instance to replace it. During this time, your instance will be in a stopping or shutting-down state. After this process is complete, your instance state will change to stopped or terminated. Then, the available capacity in your Capacity Block will update to show another instance available to use.

The following steps explain how to launch instances into a Capacity Block in the active state using the AWS Management Console or the AWS CLI.

For information about how to set up an EKS node group to automatically use a Capacity Block when it begins, see [Capacity Blocks for ML](#) in the Amazon EKS User Guide.

For information about how to launch instances into a Capacity Block using EC2 Fleet, see [Tutorial: Launch instances into Capacity Blocks](#).

For information about how to create a Launch Template targeting a Capacity Block, see [Launch an instance from a launch template](#).

You can use one of the following methods to launch instances into a Capacity Block.

Console

To launch instances into a Capacity Block using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select the Region for your Capacity Block reservation.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, you can name your instance and tag the instance. For information about tags, see [Tag your Amazon EC2 resources](#)
5. Under **Application and OS Images**, select an Amazon Machine Image (AMI).
6. Under **Instance type**, select the instance type that matches your Capacity Block reservation.

7. Under **Key pair (login)**, choose an existing key pair or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).
8. Under **Network settings**, use the default settings, or choose **Edit** to configure the network settings as necessary.

⚠️ Important

Your instance can't launch in a subnet in a different Availability Zone from the Availability Zone where your Capacity Block is located.

9. Under **Advanced details**, configure the instance as follows.
 - a. Under **Purchasing option (market type)**, select **Capacity Blocks**.
 - b. Under **Capacity Reservation**, select **Target by ID**.
 - c. Select the Capacity Reservation ID of your Capacity Block reservation.
10. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.
11. Choose **Launch instance**.

AWS CLI

To launch instances into a Capacity Block using the AWS CLI

- Use the `run-instances` command and specify a `MarketType` of `capacity-block` in the `instance-market-options` structure. You must also specify the `capacity-reservation-specification` parameter.

The following example launches a single p5.48xlarge instance into an active Capacity Block that has matching attributes and available capacity.

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 \
--instance-type p5.48xlarge --key-name MyKeyPair \
--subnet-id subnet-1234567890abcdef1 \
--instance-market-options MarketType='capacity-block'
--capacity-reservation-specification
CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

View Capacity Blocks

Capacity Blocks have the following states:

- **payment-pending** – The upfront payment hasn't been processed yet.
- **payment-failed**—The payment couldn't be processed in the 12 hour time frame. Your Capacity Block was released.
- **scheduled** – The payment was processed and the Capacity Block reservation hasn't started yet.
- **active** – The reserved capacity is available for your use.
- **expired** – The Capacity Block reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.

You can use one of the following methods to view your Capacity Block reservation.

Console

To view Capacity Blocks using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. On the **Capacity Reservations overview** page, you see a resource table with details about all of your Capacity Reservation resources. To find your Capacity Blocks reservations, select **Capacity Blocks** from the dropdown list above **Capacity Reservation ID**. In the table, you can see information about your Capacity Blocks such as start and end dates, duration, and status.
4. For more details about a Capacity Block, select the reservation ID for the Capacity Block that you want to view. The **Capacity Reservation details** page displays all the properties of the reservation and the number of instances in use and available in the Capacity Block.

Note

Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available when the Capacity Block reservation starts by using the following tag value for the tag key:
`aws:ec2capacityreservation:incrementalRequestedQuantity`.

AWS CLI

To view Capacity Blocks using the AWS CLI

By default, when you use the [describe-capacity-reservations](#) command both On-Demand Capacity Reservations and Capacity Block reservations are listed. To view only your Capacity Block reservations, filter using `capacity-block` for the `capacity-reservation-type` parameter.

For example, the following command describes one or more of your Capacity Block reservations in your current AWS Region.

```
aws ec2 describe-capacity-reservations --reservation-type capacity-block
```

Example output.

Monitor Capacity Blocks with EventBridge

When your Capacity Block reservation starts, Amazon EC2 will emit an event through EventBridge that indicates your capacity is ready to use. Forty minutes before your Capacity Block reservation ends, you receive another EventBridge event that tells you that any instances running in the reservation will begin to terminate in 10 minutes. For more information about EventBridge events, see [Amazon EventBridge Events](#).

The following event structures for events emitted for Capacity Blocks:

Capacity Block Delivered

The following example shows an event for Capacity Block Delivered.

Logging Capacity Blocks API calls with AWS CloudTrail

Capacity Blocks is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Capacity Blocks. CloudTrail captures API calls for Capacity Blocks as events. The calls captured include calls from the Capacity Blocks console and code calls to the Capacity Blocks API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Capacity Blocks. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Capacity Blocks, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

Capacity Blocks information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Capacity Blocks, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail Event history](#).

For an ongoing record of events in your AWS account, including events for Capacity Blocks, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for creating a trail](#)

- [CloudTrail supported services and integrations](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

All Capacity Blocks actions are logged by CloudTrail and are documented in the Amazon EC2 API Reference. For example, calls to the CapacityBlockScheduled, and CapacityBlockActive actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity element](#).

Understanding Capacity Blocks log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following examples show CloudTrail log entries for:

- [TerminateCapacityBlocksInstances](#)
- [CapacityBlockPaymentFailed](#)
- [CapacityBlockScheduled](#)
- [CapacityBlockActive](#)
- [CapacityBlockFailed](#)
- [CapacityBlockExpired](#)

Instance lifecycle

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states. Notice that you can't stop and start an instance store-backed instance. For more information about instance store-backed instances, see [Storage for the root device](#).

The following table provides a brief description of each instance state and indicates whether instance usage is billed. Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the *AWS Billing User Guide*.

Instance launch

When you launch an instance, it enters the pending state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the running state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the running state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

For more information, see [Launch your instance](#) and [Connect to your Linux instance](#).

Instance stop and start (Amazon EBS-backed instances only)

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the stopping state, and then the stopped state. You are not charged for usage or data transfer fees for your instance when it is stopped. Charges are incurred for the storage of any Amazon EBS volumes. While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the pending state, and the instance is moved to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes attached to the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface remains associated with your instance. If your instance has an IPv6 address, it retains the IPv6 address.

Each time you transition an instance from stopped to running, you are charged per second when the instance is running, with a minimum of one minute per instance start.

For more details about stopping and starting an instance, see [Stop and start Amazon EC2 instances](#).

Instance hibernate (Amazon EBS-backed instances only)

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the stopping state, and then the stopped state. We don't charge usage for a hibernated instance when it is in the stopped state, but we do charge while it is in the stopping state, unlike when you [stop an instance](#) without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see [Hibernate your Amazon EC2 instance](#).

Instance reboot

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see [Reboot your instance](#).

Instance termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the `InstanceInitiatedShutdownBehavior` attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself (for example, by using the `shutdown` command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the `DeleteOnTermination` attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see [Terminate Amazon EC2 instances](#).

Differences between reboot, stop, hibernate, and terminate

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
Host computer	The instance stays on the same host computer	We move the instance to a new host computer (though in some cases, it remains on the current host).	We move the instance to a new host computer (though in some cases, it remains on the current host).	None
Private and public IPv4 addresses	These addresses stay the same	The instance keeps its private IPv4 address. The instance gets a new public IPv4 address, unless it has an Elastic IP address, which doesn't change during a stop/start.	The instance keeps its private IPv4 address. The instance gets a new public IPv4 address, unless it has an Elastic IP address, which doesn't change during a stop/start.	None
Elastic IP addresses (IPv4)	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address is disassociated from the instance
IPv6 address	The instance keeps its IPv6 address	The instance keeps its IPv6 address	The instance keeps its IPv6 address	None
Instance store volumes	The data is preserved	The data is erased	The data is erased	The data is erased

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
Root device volume	The volume is preserved	The volume is preserved	The volume is preserved	The volume is deleted by default
RAM (contents of memory)	The RAM is erased	The RAM is erased	The RAM is saved to a file on the root volume	The RAM is erased
Billing	The instance billing hour doesn't change	You stop incurring charges for an instance as soon as its state changes to stopping. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance. Launch your instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you sign up for AWS, you can get started with Amazon EC2 for free using the [AWS Free Tier](#). You can use the free tier to launch and use a t2.micro instance for free for 12 months (in Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier). If you launch an instance that is not within the free tier, you incur the standard Amazon EC2 usage fees for the instance. For more information, see [Amazon EC2 pricing](#).

You can launch an instance using the following methods.

Method	Documentation
[Amazon EC2 console] Use the launch instance wizard to specify the launch parameters.	Launch an instance using the old launch instance wizard
[Amazon EC2 console] Create a launch template and launch the instance from the launch template.	Launch an instance from a launch template
[Amazon EC2 console] Use an existing instance as the base.	Launch an instance using parameters from an existing instance

[AWS CLI] Use an AMI that you select.	Using Amazon EC2 through the AWS CLI
[AWS Tools for Windows PowerShell] Use an AMI that you select.	Amazon EC2 from the AWS Tools for Windows PowerShell
[AWS CLI] Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchase models.	EC2 Fleet

Method	Documentation
[AWS CloudFormation] Use a AWS CloudFormation template to specify an instance.	AWS::EC2::Instance in the <i>AWS CloudFormation User Guide</i>
[AWS SDK] Use a language-specific AWS SDK to launch an instance.	AWS SDK for .NET AWS SDK for C++ AWS SDK for Go AWS SDK for Java AWS SDK for JavaScript AWS SDK for PHP V3 AWS SDK for Python AWS SDK for Ruby V3

 **Note**

To launch an EC2 instance into an IPv6-only subnet, you must use [Instances built on the AWS Nitro System](#).

 **Note**

When launching an IPv6-only instance, it is possible that DHCPv6 may not immediately provide the instance with the IPv6 DNS name server. During this initial delay, the instance may not be able to resolve public domains.

For instances running on Amazon Linux 2, if you want to immediately update the /etc/resolv.conf file with the IPv6 DNS name server, run the following [cloud-init directive](#) at launch:

```
#cloud-config
bootcmd:
```

```
- /usr/bin/sed -i -E 's,^nameserver\s+[\.\[[:digit:]\]]+\$,nameserver  
fd00:ec2::253,' /etc/resolv.conf
```

Another option is to change the configuration file and re-image your AMI so that the file has the IPv6 DNS name server address immediately on booting.

When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone - This option is the default.
- A Local Zone - To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see [Local Zones](#)
- A Wavelength Zone - To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see [Get started with AWS Wavelength](#) in the *AWS Wavelength Developer Guide*.
- An Outpost - To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see [Get Started with AWS Outposts](#) in the *AWS Outposts User Guide*.

After you launch your instance, you can connect to it and use it. To begin, the instance state is pending. When the instance state is running, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch.

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance. For more information about connecting to your instance, see [Connect to your Linux instance](#).

When you are finished with an instance, be sure to terminate it. For more information, see [Terminate Amazon EC2 instances](#).

Launch an instance using the new launch instance wizard

You can launch an instance using the new launch instance wizard. The launch instance wizard specifies the launch parameters that are required for launching an instance. Where the launch

instance wizard provides a default value, you can accept the default or specify your own value. If you accept the default values, then it's possible to launch an instance by selecting only a key pair.

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

Topics

- [Launch an instance using defined parameters](#)
- [Launch an instance using the old launch instance wizard](#)

Quickly launch an instance

To set up an instance quickly for testing purposes, follow these steps. You'll select the operating system and your key pair, and accept the default values. For information about all of the parameters in the launch instance wizard, see [Launch an instance using defined parameters](#).

To quickly launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
5. Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, and then choose the operating system (OS) for your instance.
6. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
7. In the **Summary** panel, choose **Launch instance**.

Launch an instance using defined parameters

Except for the key pair, the launch instance wizard provides default values for all of the parameters. You can accept any or all of the defaults, or configure an instance by specifying your own values for each parameter. The parameters are grouped in the launch instance wizard. The following instructions take you through each parameter group.

Parameters for instance configuration

- [Initiate instance launch](#)
- [Name and tags](#)
- [Application and OS Images \(Amazon Machine Image\)](#)
- [Instance type](#)
- [Key pair \(login\)](#)
- [Network settings](#)
- [Configure storage](#)
- [Advanced details](#)
- [Summary](#)

Initiate instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, volumes, and network interfaces. For Spot Instances, you can tag the Spot Instance request only. For information about tags, see [Tag your Amazon EC2 resources](#).

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch instance wizard without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI by using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see [Use a Systems Manager parameter to find an AMI](#).
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.
- Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device](#).
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information, see [Linux AMI virtualization types](#).
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Boot modes](#).
- Choose an AMI that meets your needs, and then choose **Select**.

Warning when changing the AMI

If you modify the configuration of any volumes or security groups associated with the selected AMI, and then you choose a different AMI, a window opens to warn you that some of your current settings will be changed or removed. You can review the changes to the security groups and volumes. Furthermore, you can either view which volumes will be added and deleted, or view only the volumes that will be added.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Amazon EC2 instance types](#).

- For **Instance type**, select the instance type for the instance.

Free Tier – If your AWS account is less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier, it is labeled **Free tier eligible**. For more information about t2.micro and t3.micro, see [Burstable performance instances](#).

- **Compare instance types:** You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.
- **Get advice:** You can get guidance and suggestions for instance types from the Amazon Q EC2 instance type selector. For more information, see [Get instance type recommendations for a new workload](#).

Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Network settings

Configure the network settings, as necessary.

- **VPC:** Choose an existing VPC for your instance. You can choose the default VPC or a VPC that you created. For more information, see [the section called “Virtual private clouds”](#).
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you

are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in an IPv6-only subnet, the instance must be [built on the Nitro System](#).

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address, and instances in a nondefault subnet don't. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses](#).
- **Firewall (security groups):** Use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for Linux instances](#).

If you add a network interface, you must specify the same security group in the network interface.

Select or create a security group as follows:

- To select an existing security group for your VPC, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group for your VPC, choose **Create security group**. The launch instance wizard automatically defines the **launch-wizard-x** security group and provides the following check boxes for quickly adding security group rules:

Allow SSH traffic from – Creates an inbound rule to allow you to connect to your instance over SSH (port 22). Specify whether the traffic comes from **Anywhere**, **Custom**, or **My IP**.

Allow HTTPS traffic from the internet – Creates an inbound rule that opens port 443 (HTTPS) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

Allow HTTP traffic from the internet – Creates an inbound rule that opens port 80 (HTTP) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

You can edit these rules and add rules to suit your needs.

To edit or add a rule, choose **Edit** (at top right). To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source type**, select the source type. To let the launch instance wizard add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (`0.0.0.0/0`) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration** – Available only if you choose a subnet.

Network interface

- **Device index:** The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.
- **Network interface:** Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description:** (Optional) A description for the new network interface.
- **Subnet:** The subnet in which to create the new network interface. For the primary network interface (`eth0`), this is the subnet in which the instance is launched. If you've entered an existing network interface for `eth0`, the instance is launched in the subnet in which the network interface is located.
- **Security groups:** One or more security groups in your VPC with which to associate the network interface.
- **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP:** One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- **(IPv6-only) IPv6 IPs:** An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **IPv4 Prefixes:** The IPv4 prefixes for the network interface.
- **IPv6 Prefixes:** The IPv6 prefixes for the network interface.
- **(Dual-stack and IPv6-only) Assign Primary IPv6 IP:** (Optional) If you're launching an instance into a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if this instance relies on its IPv6 address not changing. When you launch the instance, AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
- **Delete on termination:** Whether the network interface is deleted when the instance is deleted.
- **Elastic Fabric Adapter:** Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).
- **ENA Express:** ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD technology uses a packet spraying mechanism to distribute load and avoid network congestion. Enabling ENA Express allows supported instances to communicate using SRD on top of regular TCP traffic when possible. The launch instance wizard does not include ENA Express configuration for the instance unless you select **Enable** or **Disable** from the list.
- **ENA Express UDP:** If you've enabled ENA Express, you can optionally use it for UDP traffic. The launch instance wizard does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

Choose **Add network interface** to add additional network interfaces. Additional network interfaces can reside in a different subnet of the same VPC or in a subnet in a different VPC that you own (as long as the subnet is in the same Availability Zone as your instance). If you choose to add an additional network interface residing in another VPC subnet, you'll see the **Multi-VPC subnets** option when you select a subnet. If you select a subnet in another VPC, the **Multi-VPC** label appears next to the network interface you've added. This enables you to create multi-

homed instances across VPCs with different networking and security configurations. Note that if you attach an additional ENI from another VPC, you must choose a security group for the ENI from that VPC.

For more information, see [Elastic network interfaces](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch](#).

Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of the volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

By using the **Advanced** view, you can configure each volume as follows:

- **Storage type:** Select Amazon EBS or instance store volumes to associate with your instance. The volume types available in the list depend on the instance type that you've chosen. For more information, see [Amazon EC2 instance store](#) and [Amazon EBS volumes](#).
- **Device name:** Select from the list of available device names for the volume.
- **Snapshot:** Select the snapshot from which to restore the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB):** For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage.
- **Volume type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types](#) in the *Amazon EBS User Guide*.
- **IOPS:** If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on termination:** For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see [Preserve data when an instance is terminated](#).

- **Encrypted:** If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*.
- **KMS key:** If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.
- **File systems:** Mount an Amazon EFS or Amazon FSx file system to the instance. For more information about mounting an Amazon EFS file system, see [Use Amazon EFS with Amazon EC2](#). For more information about mounting an Amazon FSx file system, see [Use Amazon FSx with Amazon EC2](#)

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, Amazon EC2 launches an On-Demand Instance by default. For more information, see [Create a Spot Instance request](#).
- **Domain join directory:** Select the AWS Directory Service directory (domain) to which your Linux instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see [Seamlessly join a Linux EC2 instance to your AWS Managed Microsoft AD directory](#).
- **IAM instance profile:** Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2](#).
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types](#).
- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types](#).

- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior](#).
- **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is available only if your instance meets the hibernation prerequisites. For more information, see [Hibernate your Amazon EC2 instance](#).
- **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection](#).
- **Stop protection:** To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection](#).
- **Detailed CloudWatch monitoring:** Choose **Enable** to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch](#).
- **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

 **Note**

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

- **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for **T** instances. Additional charges may apply. For more information, see [Burstable performance instances](#).
- **Placement group name:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types support launching an instance in a placement group. For more information, see [Placement groups](#).
- **EBS-optimized instance:** An instance that's optimized for Amazon EBS uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, choose **Enable** to enable it. Additional charges apply. For more information, see [the section called "EBS optimization"](#).

- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances](#) and [Dedicated Hosts](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.
- **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the *AWS License Manager User Guide*.
- **Metadata accessible:** You can enable or disable access to the instance metadata. For more information, see [Configure instance metadata options for new instances](#).
- **Metadata transport:** Enable the instance to reach the link local IMDSv2 IPv6 address (`fd00:ec2::254`) to retrieve instance metadata. This option is only available if you are launching [instances built on the AWS Nitro System](#) into an [IPv6-only subnet](#). For more information about retrieving instance metadata, see [Retrieve instance metadata](#).
- **Metadata version:** If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).
- **Metadata response hop limit:** If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances](#).
- **Allow tags in metadata:** If you select **Enable**, the instance will allow access to all of its tags from its metadata. If no value is specified, then by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata](#).

- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Linux instance at launch](#).

Summary

Use the **Summary** panel to specify the number of instances to launch, to review your instance configuration, and to launch your instances.

- **Number of instances:** Enter the number of instances to launch. All of the instances will launch with the same configuration.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) If you specify more than one instance, to help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **consider EC2 Auto Scaling** to create a launch template and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- Review the details of your instance, and make any necessary changes. You can navigate directly to a section by choosing its link in the **Summary** panel.
- When you're ready to launch your instance, choose **Launch instance**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

(Optional) You can create a billing alert for the instance. On the confirmation screen, under **Next Steps**, choose **Create billing alerts** and follow the directions. Billing alerts can also be created after you launch the instance. For more information, see [Creating a billing alarm to monitor your estimated AWS charges](#) in the *Amazon CloudWatch User Guide*.

Launch an instance using the old launch instance wizard

You can launch an instance using the old launch instance wizard only if your Region supports the old launch experience. The launch instance wizard specifies all the launch parameters required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. You must specify an AMI and a key pair to launch an instance.

For the instructions to use the *new* launch instance wizard, see [Launch an instance using the new launch instance wizard](#).

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

Steps to launch an instance:

- [Initiate instance launch](#)
- [Step 1: Choose an Amazon Machine Image \(AMI\)](#)
- [Step 2: Choose an Instance Type](#)
- [Step 3: Configure Instance Details](#)
- [Step 4: Add Storage](#)
- [Step 5: Add Tags](#)
- [Step 6: Configure Security Group](#)
- [Step 7: Review Instance Launch and Select Key Pair](#)

Initiate instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current Region is displayed (for example, US East (Ohio)). Select a Region for the instance that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

Step 1: Choose an Amazon Machine Image (AMI)

When you launch an instance, you must select a configuration, known as an Amazon Machine Image (AMI). An AMI contains the information required to create a new instance. For example, an AMI might contain the software required to act as a web server, such as Linux, Apache, and your website.

When you launch an instance, you can either select an AMI from the list, or you can select a Systems Manager parameter that points to an AMI ID. For more information, see [Using a Systems Manager parameter to find an AMI](#).

On the **Choose an Amazon Machine Image (AMI)** page, use one of two options to choose an AMI. Either [search the list of AMIs](#), or [search by Systems Manager parameter](#).

By searching the list of AMIs

1. Select the type of AMI to use in the left pane:

Quick Start

A selection of popular AMIs to help you get started quickly. To select an AMI that is eligible for the free tier, choose **Free tier only** in the left pane. These AMIs are marked **Free tier eligible**.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you. To view AMIs that are shared with you, choose **Shared with me** in the left pane.

AWS Marketplace

An online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance](#).

Community AMIs

The AMIs that AWS community members have made available for others to use. To filter the list of AMIs by operating system, choose the appropriate check box under **Operating system**. You can also filter by architecture and root device type.

2. Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need, either ebs (backed by Amazon EBS) or instance-store (backed by instance store). For more information, see [Storage for the root device](#).
3. Check the **Virtualization type** listed for each AMI. Notice which AMIs are the type that you need, either hvm or paravirtual. For example, some instance types require HVM. For more information, see [Linux AMI virtualization types](#).
4. Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need, either legacy-bios or uefi. For more information, see [Boot modes](#).
5. Choose an AMI that meets your needs, and then choose **Select**.

By Systems Manager parameter

1. Choose **Search by Systems Manager parameter** (at top right).
2. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
3. Choose **Search**. The AMIs that match the AMI ID appear in the list.
4. Select the AMI from the list, and choose **Select**.

Step 2: Choose an Instance Type

On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information, see [Amazon EC2 instance types](#).

To remain eligible for the free tier, choose the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier,

it is labeled **Free tier eligible**. For more information about t2.micro and t3.micro, see [Burstable performance instances](#).

By default, the wizard displays current generation instance types, and selects the first available instance type based on the AMI that you selected. To view previous generation instance types, choose **All generations** from the filter list.

Note

To set up an instance quickly for testing purposes, choose **Review and Launch** to accept the default configuration settings, and launch your instance. Otherwise, to configure your instance further, choose **Next: Configure Instance Details**.

Step 3: Configure Instance Details

On the **Configure Instance Details** page, change the following settings as necessary (expand **Advanced Details** to see all the settings), and then choose **Next: Add Storage**:

- **Number of instances:** Enter the number of instances to launch.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks

the instance as unhealthy. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. This adds and removes options from this page. You can optionally set your maximum price (not recommended), and optionally change the request type, interruption behavior, and request validity. For more information, see [Create a Spot Instance request](#).
- **Network:** Select the VPC or to create a new VPC, choose **Create new VPC** to go the Amazon VPC console. When you have finished, return to the launch instance wizard and choose **Refresh** to load your VPC in the list.
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone or Outpost.

To launch the instance in an Availability Zone, select the subnet into which to launch your instance. You can select **No preference** to let AWS choose a default subnet in any Availability Zone. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose **Refresh** to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with an Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet don't. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses](#).
- **Auto-assign IPv6 IP:** Specify whether your instance receives an IPv6 address from the range of the subnet. Select **Enable** or **Disable** to override the subnet's default setting. This option is only available if you've associated an IPv6 CIDR block with your VPC and subnet. For more information, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types](#).
- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types](#).

- **Domain join directory:** Select the AWS Directory Service directory (domain) to which your Linux instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see [Seamlessly join a Linux EC2 instance to your AWS Managed Microsoft AD directory](#).
- **Placement group:** A placement group determines the placement strategy of your instances. Select an existing placement group, or create a new one. This option is only available if you've selected an instance type that supports placement groups. For more information, see [Placement groups](#).
- **Capacity Reservation:** Specify whether to launch the instance into shared capacity, any open Capacity Reservation, a specific Capacity Reservation, or a Capacity Reservation group. For more information, see [Launch instances into an existing Capacity Reservation](#).
- **IAM role:** Select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see [IAM roles for Amazon EC2](#).
- **CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior](#).
- **Stop - Hibernate behavior:** To enable hibernation, select this check box. This option is only available if your instance meets the hibernation prerequisites. For more information, see [Hibernate your Amazon EC2 instance](#).
- **Enable termination protection:** To prevent accidental termination, select this check box. For more information, see [Enable termination protection](#).
- **Enable stop protection:** To prevent accidental stopping, select this check box. For more information, see [Enable stop protection](#).
- **Monitoring:** Select this check box to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch](#).
- **EBS-optimized instance:** An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see [Amazon EBS-optimized instances](#).

- **Tenancy:** If you are launching your instance into a VPC, you can choose to run your instance on isolated, dedicated hardware (**Dedicated**) or on a Dedicated Host (**Dedicated host**). Additional charges may apply. For more information, see [Dedicated Instances](#) and [Dedicated Hosts](#).
- **T2/T3 Unlimited:** Select this check box to enable applications to burst beyond the baseline for as long as needed. Additional charges may apply. For more information, see [Burstable performance instances](#).
- **File systems:** To create a new file system to mount to your instance, choose **Create new file system**, enter a name for the new file system, and then choose **Create**. The file system is created using Amazon EFS Quick Create, which applies the service recommended settings. The security groups required to enable access to the file system are automatically created and attached to the instance and the mount targets of the file system. You can also choose to manually create and attach the required security groups. To mount one or more existing Amazon EFS file systems to your instance, choose **Add file system** and then choose the file systems to mount and the mount points to use. For more information, see [Use Amazon EFS with Amazon EC2](#).
- **Network interfaces:** If you selected a specific subnet, you can specify up to two network interfaces for your instance:
 - For **Network Interface**, select **New network interface** to let AWS create a new interface, or select an existing, available network interface.
 - For **Primary IP**, enter a private IPv4 address from the range of your subnet, or leave **Auto-assign** to let AWS choose a private IPv4 address for you.
 - For **Secondary IP addresses**, choose **Add IP** to assign more than one private IPv4 address to the selected network interface.
 - (IPv6-only) For **IPv6 IPs**, choose **Add IP**, and enter an IPv6 address from the range of the subnet, or leave **Auto-assign** to let AWS choose one for you.
 - **Network Card Index:** The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.
 - Choose **Add Device** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch](#).

- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific kernel.
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.
- **Enclave:** Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.
- **Metadata accessible:** You can enable or disable access to the Instance Metadata Service (IMDS). For more information, see [Use IMDSv2](#).
- **Metadata transport:** Enable the instance to reach the link local IMDSv2 IPv6 address (`fd00:ec2::254`) to retrieve instance metadata. This option is only available if you are launching [instances built on the AWS Nitro System](#) into an [IPv6-only subnet](#). For more information about retrieving instance metadata, see [Retrieve instance metadata](#).
- **Metadata version:** If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).
- **Metadata token response hop limit:** If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the **As file** option and browse for the file to attach.

Step 4: Add Storage

The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. Configure each volume as follows, and then choose **Next: Add Tags**.

- **Type:** Select instance store or Amazon EBS volumes to associate with your instance. The types of volume available in the list depend on the instance type you've chosen. For more information, see [Amazon EC2 instance store](#) and [Amazon EBS volumes](#).
- **Device:** Select from the list of available device names for the volume.
- **Snapshot:** Enter the name or ID of the snapshot from which to restore a volume. You can also search for available shared and public snapshots by typing text into the **Snapshot** field. Snapshot descriptions are case-sensitive.

- **Size:** For EBS volumes, you can specify a storage size. Even if you have selected an AMI and instance that are eligible for the free tier, to stay within the free tier, you must stay under 30 GiB of total storage.
- **Volume Type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types](#) in the *Amazon EBS User Guide*.
- **IOPS:** If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on Termination:** For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see [Preserve data when an instance is terminated](#).
- **Encrypted:** If the instance type supports EBS encryption, you can specify the encryption state of the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or disable encryption. For more information, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*.

Step 5: Add Tags

On the **Add Tags** page, specify [tags](#) by providing key and value combinations. You can tag the instance, the volumes, or both. For Spot Instances, you can tag the Spot Instance request only. Choose **Add another tag** to add more than one tag to your resources. Choose **Next: Configure Security Group** when you are done.

Step 6: Configure Security Group

On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for Linux instances](#).) Select or create a security group as follows, and then choose **Review and Launch**.

- To select an existing security group, choose **Select an existing security group**, and select your security group. You can't edit the rules of an existing security group, but you can copy them to a new group by choosing **Copy to new**. Then you can add rules as described in the next step.
- To create a new security group, choose **Create a new security group**. The wizard automatically defines the **launch-wizard-x** security group and creates an inbound rule to allow you to connect to your instance over SSH (port 22).
- You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add Rule**, select the protocol to open to network traffic, and then specify the source. Choose **My IP** from the **Source** list to let the wizard add your computer's public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (`0.0.0.0/0`) to access your instance over SSH or RDP are acceptable for this short exercise, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

Step 7: Review Instance Launch and Select Key Pair

On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch**.

In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair you created when getting set up. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

(Optional) You can create a status check alarm for the instance (additional fees may apply). On the confirmation screen, choose **Create status check alarms** and follow the directions. Status check alarms can also be created after you launch the instance. For more information, see [Create and edit status check alarms](#).

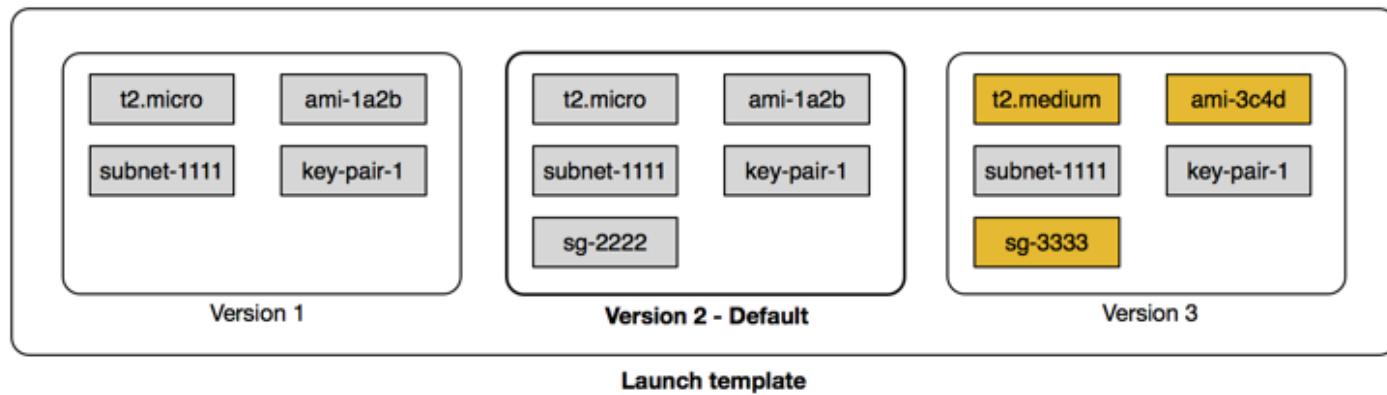

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Launch an instance from a launch template

You can use a *launch template* to store instance launch parameters so that you do not have to specify them every time you launch an instance. For example, you can create a launch template with the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template instead of entering the parameters again.

For each launch template, you can create one or more numbered *launch template versions*. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you do not specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it's the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.

Launch template restrictions

The following rules apply to launch templates and launch template versions:

- **Quotas** – To view the quotas for your launch templates and launch template versions, open the [Service Quotas](#) console or use the [list-service-quotas](#) AWS CLI command. Each AWS account can have up to a maximum of 5,000 launch templates per Region and up to 10,000 versions per launch template. Your accounts might have different quotas based on their age and usage history.
- **Parameters are optional** – Launch template parameters are optional. However, you must ensure that your request to launch an instance includes all the required parameters. For example, if your launch template does not include an AMI ID, you must specify both the launch template and an AMI ID when you launch an instance.
- **Parameters not validated** – Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values for parameters, or if you do not use supported parameter combinations, no instances can launch using this launch template. Ensure that you specify the correct values for the parameters and that you use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.
- **Tags** – You can tag a launch template, but you cannot tag a launch template version.
- **Immutable** – Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
- **Version numbers** – Launch template versions are numbered in the order in which they are created. When you create a launch template version, you cannot specify the version number yourself.

Control access to launch templates with IAM permissions

You can use IAM permissions to control which launch template actions users can perform, such as viewing, creating, or deleting launch templates.

When you grant users permission to create launch templates and launch template versions, you can't use resource-level permissions to restrict the resources that they can specify in a launch template. Therefore, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

You must grant anyone that will use a launch template the permissions required to create and access the resources that are specified in the launch template. For example:

- To launch an instance from a shared private Amazon Machine Image (AMI), the user must have launch permission for the AMI.
- To create EBS volumes with tags from existing snapshots, the user must have read access to the snapshots, and permissions to create and tag volumes.

ec2:CreateLaunchTemplate

To create a launch template in the console or by using the APIs, the principal must have the `ec2:CreateLaunchTemplate` permission in an IAM policy. Whenever possible, use tags to help you control access to the launch templates in your account.

For example, the following IAM policy statement gives the principal permission to create launch templates only if the template uses the specified tag (*purpose=testing*).

```
{  
    "Sid": "IAMPolicyForCreatingTaggedLaunchTemplates",  
    "Action": "ec2:CreateLaunchTemplate",  
    "Effect": "Allow",  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:ResourceTag/purpose        }  
    }  
}
```

Principals who create launch templates might need some related permissions, such as:

- **ec2:CreateTags** – To add tags to the launch template during the CreateLaunchTemplate operation, the CreateLaunchTemplate caller must have the ec2:CreateTags permission in an IAM policy.
- **ec2:RunInstances** – To launch EC2 instances from the launch template that they created, the principal must also have the ec2:RunInstances permission in an IAM policy.

For resource-creating actions that apply tags, users must have the ec2:CreateTags permission. The following IAM policy statement uses the ec2:CreateAction condition key to allow users to create tags only in the context of CreateLaunchTemplate. Users cannot tag existing launch templates or any other resources. For more information, see [Grant permission to tag resources during creation](#).

```
{  
    "Sid": "IAMPolicyForTaggingLaunchTemplatesOnCreation",  
    "Action": "ec2:CreateTags",  
    "Effect": "Allow",  
    "Resource": "arn:aws:ec2:<region>:<account-id>:launch-template/*",  
    "Condition": {  
        "StringEquals": {  
            "ec2:CreateAction": "CreateLaunchTemplate"  
        }  
    }  
}
```

The IAM user who creates a launch template doesn't automatically have permission to use the launch template that they created. Like any other principal, the launch template creator needs to get permission through an IAM policy. If an IAM user wants to launch an EC2 instance from a launch template, they must have the ec2:RunInstances permission. When granting these permissions, you can specify that users can only use launch templates with specific tags or specific IDs. You can also control the AMI and other resources that anyone using launch templates can reference and use when launching instances by specifying resource-level permissions for the RunInstances call. For example policies, see [Launch templates](#).

ec2:DescribeLaunchTemplates

To list launch templates in the account, the principal must have the ec2:DescribeLaunchTemplates permission in an IAM policy. Because Describe actions do not

support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be "*".

For example, the following IAM policy statement gives the principal permission to list all launch templates in the account.

```
{  
    "Sid": "IAMPolicyForDescribingLaunchTemplates",  
    "Action": "ec2:DescribeLaunchTemplates",  
    "Effect": "Allow",  
    "Resource": "*"  
}
```

ec2:DescribeLaunchTemplateVersions

Principals who view launch templates should also have the ec2:DescribeLaunchTemplateVersions permission to retrieve the entire set of attributes that make up the launch templates.

To list launch template versions in the account, the principal must have the ec2:DescribeLaunchTemplateVersions permission in an IAM policy. Because Describe actions do not support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be "*".

For example, the following IAM policy statement gives the principal permission to list all launch template versions in the account.

```
{  
    "Sid": "IAMPolicyForDescribingLaunchTemplateVersions",  
    "Effect": "Allow",  
    "Action": "ec2:DescribeLaunchTemplateVersions",  
    "Resource": "*"  
}
```

ec2:DeleteLaunchTemplate

Important

Use caution when giving principals permission to delete a resource. Deleting a launch template might cause a failure in an AWS resource that relies on the launch template.

To delete a launch template, the principal must have the `ec2:DeleteLaunchTemplate` permission in an IAM policy. Whenever possible, use tag-based condition keys to limit the permissions.

For example, the following IAM policy statement gives the principal permission to delete launch templates only if the template uses the specified tag (`purpose=testing`).

```
{  
    "Sid": "IAMPolicyForDeletingLaunchTemplates",  
    "Action": "ec2:DeleteLaunchTemplate",  
    "Effect": "Allow",  
    "Resource": "*",  
    "Condition": {  
        "StringEquals": {  
            "aws:ResourceTag/purpose": "testing"  
        }  
    }  
}
```

Alternatively, you can use ARNs to identify the launch template that the IAM policy applies to.

A launch template has the following ARN.

```
"Resource": "arn:aws:ec2:region:account-id:launch-template/lt-09477bcd97b0d310e"
```

You can specify multiple ARNs by enclosing them in a list, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to delete any launch template in the account.

Control versioning permissions

For trusted administrators, you can grant access for creating and deleting versions of a launch template, and for changing the default version of a launch template, by using IAM policies similar to the following examples.

Important

Be cautious when giving principals permission to create launch template versions or modify launch templates.

- When you create a launch template version, you affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with the Latest version.
- When you modify a launch template, you can change which version is the Default and therefore affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with this modified version.

You also need to be cautious in how you handle AWS resources that interact with the Latest or Default launch template version, such as EC2 Fleet and Spot Fleet. When a different launch template version is used for Latest or Default, Amazon EC2 does not re-check user permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity because there is no user interaction with the AWS resource. By granting a user permission to call the `CreateLaunchTemplateVersion` and `ModifyLaunchTemplate` APIs, the user is effectively also granted the `iam:PassRole` permission if they point the fleet to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. You can manage this risk by being careful when granting permissions to who can create and manage launch template versions.

ec2:CreateLaunchTemplateVersion

To create a new version of a launch template, the principal must have the `ec2:CreateLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to create launch template versions only if the version uses the specified tag (`environment=production`). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a Resource value of "*" without the Condition element to allow the principal to create versions of any launch template in the account.

```
{  
    "Sid": "IAMPolicyForCreatingLaunchTemplateVersions",  
    "Action": "ec2:CreateLaunchTemplateVersion",  
    "Effect": "Allow",  
    "Resource": "*",  
    "Condition": {
```

```
        "StringEquals": {
            "aws:ResourceTag/environment
```

ec2:DeleteLaunchTemplateVersion

Important

As always, you should exercise caution when giving principals permission to delete a resource. Deleting a launch template version might cause a failure in an AWS resource that relies on the launch template version.

To delete a launch template version, the principal must have the `ec2:DeleteLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to delete launch template versions only if the version uses the specified tag (`environment=production`).

Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of `"*"` without the `Condition` element to allow the principal to delete versions of any launch template in the account.

```
{
    "Sid": "IAMPolicyForDeletingLaunchTemplateVersions",
    "Action": "ec2:DeleteLaunchTemplateVersion",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/environment
```

ec2:ModifyLaunchTemplate

To change the `Default` version that is associated with a launch template, the principal must have the `ec2:ModifyLaunchTemplate` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to modify launch templates only if the launch template uses the specified tag (*environment=production*). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a Resource value of "*" without the Condition element to allow the principal to modify any launch template in the account.

```
{  
    "Sid": "IAMPolicyForModifyingLaunchTemplates",  
    "Action": "ec2:ModifyLaunchTemplate",  
    "Effect": "Allow",  
    "Resource": "*"  
    "Condition": {  
        "StringEquals": {  
            "aws:ResourceTag/environment        }  
    }  
}
```

Control access to tags on launch templates

You can use condition keys to limit tagging permissions when the resource is a launch template. For example, the following IAM policy allows removing only the tag with the *temporary* key from launch templates in the specified account and Region.

```
{  
    "Sid": "IAMPolicyForDeletingTagsOnLaunchTemplates",  
    "Action": "ec2:DeleteTags",  
    "Effect": "Allow",  
    "Resource": "arn:aws:ec2:region:account-id:launch-template/*",  
    "Condition": {  
        "ForAllValues:StringEquals": {  
            "aws:TagKeys": ["temporary"]  
        }  
    }  
}
```

For more information about conditions keys that you can use to control the tag keys and values that can be applied to Amazon EC2 resources, see [Control access to specific tags](#).

Use launch templates to control launching instances

You can specify that users can only launch instances if they use a launch template, and that they can only use a specific launch template. You can also control who can create, modify, describe, and delete launch templates and launch template versions.

Use launch templates to control launch parameters

A launch template can contain all or some of the parameters to launch an instance. When you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

Note

You cannot remove launch template parameters during launch (for example, you can't specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, users must have permissions to use the `ec2:RunInstances` action. Users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the `ec2:RunInstances` action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see [Launch templates](#).

Control the use of launch templates

By default, users do not have permissions to work with launch templates. You can create a policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user's ability to use specific resources for those actions. For more information, see the following example policies: [Example: Work with launch templates](#).

Take care when granting users permissions to use the `ec2>CreateLaunchTemplate` and `ec2>CreateLaunchTemplateVersion` actions. You cannot use resource-level permissions to

control which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

Important security concerns when using launch templates with EC2 Fleet or Spot Fleet

To use launch templates, you must grant your users permissions to create, modify, describe, and delete launch templates and launch template versions. You can control who can create launch templates and launch template versions by controlling access to the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You can also control who can modify launch templates by controlling access to the `ec2:ModifyLaunchTemplate` action.

Important

If an EC2 Fleet or Spot Fleet is configured to use the Latest or Default launch template version, the fleet is not aware if Latest or Default are later changed to point to a different launch template version. When a different launch template version is used for Latest or Default, Amazon EC2 does not re-check permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity. This is an important consideration when granting permissions to who can create and manage launch template versions, particularly the `ec2:ModifyLaunchTemplate` action that allows a user to change the Default launch template version.

By granting a user permission to use the EC2 actions for the launch template APIs, the user is effectively also granted the `iam:PassRole` permission if they create or update an EC2 Fleet or Spot Fleet to point to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. For more information and an example IAM policy, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

For more information, see [Control the use of launch templates](#) and [Example: Work with launch templates](#).

Create a launch template

Create a launch template using parameters that you define, or use an existing launch template or an instance as the basis for a new launch template.

Tasks

- [Create a launch template from parameters](#)
- [Create a launch template from an existing launch template](#)
- [Create a launch template from an instance](#)
- [Use a Systems Manager parameter instead of an AMI ID](#)

Create a launch template from parameters

To create a launch template, you must specify the launch template name and at least one instance configuration parameter.

Console directions

To create a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. The launch template parameters are grouped. For details about each group see the sections below.
4. Use the **Summary** panel to review your launch template configuration. You can navigate to any section by choosing its link and then make any necessary changes.
5. When you're ready to create your launch template, choose **Create launch template**.

Launch template name, description, and tags

1. For **Launch template name**, enter a descriptive name for the launch template.
2. For **Template version description**, provide a brief description of this version of the launch template.
3. To [tag](#) the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair. Choose **Add tag** again for each additional tag to add.

Note

To tag the resources that are created when an instance is launched, you must specify the tags under **Resource tags**. For more information, see [Resource tags](#).

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch template without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see [Use a Systems Manager parameter to find an AMI](#).
- To specify a Systems Manager parameter that will resolve to an AMI at the time an instance is launched from the launch template, choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**. For more information, see [Use a Systems Manager parameter instead of an AMI ID](#).
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.
- Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device](#).
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information, see [Linux AMI virtualization types](#).
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Boot modes](#).
- Choose an AMI that meets your needs, and then choose **Select**.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see the [Amazon EC2 instance types](#).

For **Instance type**, you can either select an instance type, or you can specify instance attributes and let Amazon EC2 identify the instance types with those attributes.

 **Note**

Specifying instance attributes is supported only when using Auto Scaling groups, EC2 Fleet, and Spot Fleet to launch instances. For more information, see [Creating an Auto Scaling group using attribute-based instance type selection](#), [Attribute-based instance type selection for EC2 Fleet](#), and [Attribute-based instance type selection for Spot Fleet](#).

If you plan to use the launch template in the [launch instance wizard](#) or with the [RunInstances API](#), you must select an instance type.

- **Instance type:** Ensure that the instance type is compatible with the AMI that you've specified. For more information, see [Amazon EC2 instance types](#).
- **Compare instance types:** You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.
- **Get advice:** You can get guidance and suggestions for instance types from the Amazon Q EC2 instance type selector. For more information, see [Get instance type recommendations for a new workload](#).
- **Advanced:** To specify instance attributes and let Amazon EC2 identify the instance types with those attributes, choose **Advanced**, and then choose **Specify instance type attributes**.
 - **Number of vCPUs:** Enter the minimum and maximum number of vCPUs for your compute requirements. To indicate no limits, enter a minimum of **0**, and leave the maximum blank.
 - **Amount of memory (MiB):** Enter the minimum and maximum amount of memory, in MiB, for your compute requirements. To indicate no limits, enter a minimum of **0**, and leave the maximum blank.
 - Expand **Optional instance type attributes** and choose **Add attribute** to express your compute requirements in more detail. For information about each attribute, see [InstanceRequirementsRequest](#) in the *Amazon EC2 API Reference*.
 - **Resulting instance types:** You can preview the instance types that match the specified attributes. To exclude instance types, choose **Add attribute**, and from the **Attribute** list, choose **Excluded instance types**. From the **Attribute value** list, select the instance types to exclude.

Key pair (login)

The key pair for the instance.

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

Network settings

Configure the network settings, as necessary.

- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Firewall (security groups):** Use one or more security groups to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for Linux instances](#).

If you add a network interface, you must specify the same security groups in the network interface.

Select or create a security group as follows:

- To select an existing security group, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group, choose **Create security group**.

You can add rules to suit your needs. For example, if your instance will be a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source**

type, select the source type. To let the launch template add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (`0.0.0.0/0`) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration**

Network interface

- **Device index:** The device number for the network interface, for example, `eth0` for the primary network interface. If you leave the field blank, AWS creates the primary network interface.
- **Network interface:** Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description:** (Optional) A description for the new network interface.
- **Subnet:** The subnet in which to create the new network interface. For the primary network interface (`eth0`), this is the subnet in which the instance is launched. If you've entered an existing network interface for `eth0`, the instance is launched in the subnet in which the network interface is located.
- **Security groups:** One or more security groups in your VPC with which to associate the network interface.
- **Auto-assign public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses](#).
- **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP:** One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- **(IPv6-only) IPv6 IPs:** An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **IPv4 Prefixes:** The IPv4 prefixes for the network interface.
- **IPv6 Prefixes:** The IPv6 prefixes for the network interface.
- **(Optional) Assign Primary IPv6 IP:** If you're launching an instance into a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if this instance relies on its IPv6 address not changing. When you launch the instance, AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
- **Delete on termination:** Whether the network interface is deleted when the instance is deleted.
- **Elastic Fabric Adapter:** Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).
- **Network card index:** The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.
- **ENA Express:** ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD technology uses a packet spraying mechanism to distribute load and avoid network congestion. Enabling ENA Express allows supported instances to communicate using SRD on top of regular TCP traffic when possible. The launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.
- **ENA Express UDP:** If you've enabled ENA Express, you can optionally use it for UDP traffic. The launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

Choose **Add network interface** to add more network interfaces. The number of network interfaces that you can add depends on the number that is supported by the selected instance type. Additional network interfaces can reside in a different subnet of the same VPC or in a subnet in a different VPC that you own (as long as the subnet is in the same Availability Zone as

your instance). If you select a subnet in another VPC, the **Multi-VPC** label appears next to the network interface you've added. This enables you to create multi-homed instances across VPCs with different networking and security configurations. Note that if you attach an additional ENI from another VPC, you must choose a security group for the ENI from that VPC.

For more information, see [Elastic network interfaces](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch](#).

Configure storage

If you specify an AMI for the launch template, the AMI includes one or more volumes of storage, including the root volume (**Volume 1 (AMI Root)**). You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

To add a new volume, choose **Add new volume**.

By using the **Advanced** view, you can configure each volume as follows:

- **Storage type:** The type of volume (EBS or ephemeral) to associate with your instance. The instance store (ephemeral) volume type is only available if you select an instance type that supports it. For more information, see [Amazon EC2 instance store](#) and [Amazon EBS volumes](#).
- **Device name:** Select from the list of available device names for the volume.
- **Snapshot:** Select the snapshot from which to create the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB):** For EBS volumes, you can specify a storage size. If you have selected an AMI and instance type that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage.
- **Volume type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types](#) in the *Amazon EBS User Guide*.
- **IOPS:** If you have selected a Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp3) volume type, then you can enter the number of I/O operations per second (IOPS) that the

volume can support. This is required for io1, io2, and gp3 volumes. It is not supported for gp2, st1, sc1, or standard volumes. If you omit this parameter for the launch template, you must specify a value for it when you launch an instance from the launch template.

- **Delete on termination:** For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see [Preserve data when an instance is terminated](#).
- **Encrypted:** If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption](#) in the *Amazon EBS User Guide*.
- **KMS key:** If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.

Resource tags

To [tag](#) the resources that are created when an instance is launched, under **Resource tags**, choose **Add tag**, and then enter a tag key and value pair. For **Resource types**, specify the resources to tag on creation. You can specify the same tag for all the resources, or specify different tags for different resources. Choose **Add tag** again for each additional tag to add.

You can specify tags for the following resources that are created when a launch template is used:

- Instances
- Volumes
- Spot Instance requests
- Network interfaces

Note

To tag the launch template itself, you must specify the tags under **Template tags**. For more information, see [Launch template name, description, and tags](#).

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see [Spot Instances](#).
- **IAM instance profile:** Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2](#).
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types](#).
- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior](#).
- **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is only valid for instances that meet the hibernation prerequisites. For more information, see [Hibernate your Amazon EC2 instance](#).
- **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection](#).
- **Stop protection:** To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection](#).
- **Detailed CloudWatch monitoring:** Choose **Enable** to enable detailed monitoring of the instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch](#).
- **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

Note

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

- **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for T instances. Additional charges may apply. For more information, see [Burstable performance instances](#).
- **Placement group name:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types can be launched in a placement group. For more information, see [Placement groups](#).
- **EBS-optimized instance:** Select **Enable** to provide additional, dedicated capacity for Amazon EBS I/O. Not all instance types support this feature. Additional charges apply. For more information, see [the section called “EBS optimization”](#).
- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances](#) and [Dedicated Hosts](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.

- **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the AWS License Manager User Guide.
- **Specify CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options](#).
- **Metadata transport:** You can enable or disable the access method to the Instance Metadata Service (IMDS) that's available for this EC2 instance based on the IP address type (IPv4, IPv6, or IPv4 and IPv6) of the instance. For more information, see [Retrieve instance metadata](#).
- **Metadata accessible:** You can enable or disable access to the IMDS. For more information, see [Configure instance metadata options for new instances](#).
- **Metadata version:** If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).
- **Metadata response hop limit:** If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances](#).
- **Allow tags in metadata:** If you select **Enable**, the instance will allow access to all of its instance's tags from its metadata. If you do not include this setting in the template, by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Linux instance at launch](#).

AWS CLI example

The following example uses the [create-launch-template](#) command to create a launch template with the specified name and instance configuration.

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForWebServer \
    --version-description WebVersion1 \
    --tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
    --launch-template-data file://template-data.json
```

The following is example JSON that specifies the launch template data for the instance configuration. Save the JSON to a file and include it in the --launch-template-data parameter as shown in the example command.

```
{  
    "NetworkInterfaces": [  
        {"AssociatePublicIpAddress": true,  
         "DeviceIndex": 0,  
         "Ipv6AddressCount": 1,  
         "SubnetId": "subnet-7b16de0c"  
    ]},  
    "ImageId": "ami-8c1be5f6",  
    "InstanceType": "r4.4xlarge",  
    "TagSpecifications": [  
        {"ResourceType": "instance",  
         "Tags": [  
             {"Key": "Name",  
              "Value": "webserver"  
         ]]  
    ]},  
    "CpuOptions": {  
        "CoreCount": 4,  
        "ThreadsPerCore": 2  
    }  
}
```

The following is example output.

```
{  
    "LaunchTemplate": {  
        "LatestVersionNumber": 1,  
        "LaunchTemplateId": "lt-01238c059e3466abc",  
        "LaunchTemplateName": "TemplateForWebServer",  
        "DefaultVersionNumber": 1,  
        "CreatedBy": "arn:aws:iam::123456789012:root",  
        "CreateTime": "2017-11-27T09:13:24.000Z"  
    }  
}
```

AWS Tools for Windows PowerShell example

The following example uses the [New-EC2LaunchTemplate](#) cmdlet to create a launch template with the specified name and instance configuration.

```
$launchTemplateData = [Amazon.EC2.Model.RequestLaunchTemplateData]@{
    ImageId = 'ami-8c1be5f6'
    InstanceType = 'r4.4xlarge'
    NetworkInterfaces = @(
        [Amazon.EC2.Model.LaunchTemplateInstanceNetworkInterfaceSpecificationRequest]@{
            AssociatePublicIpAddress = $true
            DeviceIndex = 0
            Ipv6AddressCount = 1
            SubnetId = 'subnet-7b16de0c'
        }
    )
    TagSpecifications = @(
        [Amazon.EC2.Model.LaunchTemplateTagSpecificationRequest]@{
            ResourceType = 'instance'
            Tags = [Amazon.EC2.Model.Tag]@{
                Key = 'Name'
                Value = 'webserver'
            }
        }
    )
    CpuOptions = [Amazon.EC2.Model.LaunchTemplateCpuOptionsRequest]@{
        CoreCount = 4
        ThreadsPerCore = 2
    }
}
$tagSpecificationData = [Amazon.EC2.Model.TagSpecification]@{
    ResourceType = 'launch-template'
    Tags = [Amazon.EC2.Model.Tag]@{
        Key = 'purpose'
        Value = 'production'
    }
}
New-EC2LaunchTemplate -LaunchTemplateName 'TemplateForWebServer' -VersionDescription
'WebVersion1' -LaunchTemplateData $launchTemplateData -TagSpecification
$tagSpecificationData
```

The following is example output.

```

```

Create a launch template from an existing launch template

You can clone an existing launch template and then adjust the parameters to create a new launch template. However, you can only do this when using the Amazon EC2 console; the AWS CLI does not support cloning a template.

Console

To create a launch template from an existing launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. To tag the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair.
6. Expand **Source template**, and for **Launch template name** choose a launch template on which to base the new launch template.
7. For **Source template version**, choose the launch template version on which to base the new launch template.
8. Adjust any launch parameters as required, and then choose **Create launch template**.

Create a launch template from an instance

Console

To create a launch template from an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Actions, Create template from instance**.
4. Provide a name, description, and tags, and adjust the launch parameters as required.

Note

When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.

5. Choose **Create launch template**.

AWS CLI

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.

To get launch template data from an instance

- Use the [get-launch-template-data](#) command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level LaunchTemplateData object, which cannot be specified in your launch template data. Use the --query option to exclude this object.

```
aws ec2 get-launch-template-data \
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData"
```

The following is example output.

```
{  
    "Monitoring": {},
```

```
"ImageId": "ami-8c1be5f6",
"BlockDeviceMappings": [
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "DeleteOnTermination": true
        }
    }
],
"EbsOptimized": false,
"Placement": {
    "Tenancy": "default",
    "GroupName": "",
    "AvailabilityZone": "us-east-1a"
},
"InstanceType": "t2.micro",
"NetworkInterfaces": [
    {
        "Description": "",
        "NetworkInterfaceId": "eni-35306abc",
        "PrivateIpAddresses": [
            {
                "Primary": true,
                "PrivateIpAddress": "10.0.0.72"
            }
        ],
        "SubnetId": "subnet-7b16de0c",
        "Groups": [
            "sg-7c227019"
        ],
        "Ipv6Addresses": [
            {
                "Ipv6Address": "2001:db8:1234:1a00::123"
            }
        ],
        "PrivateIpAddress": "10.0.0.72"
    }
]
}
```

You can write the output directly to a file, for example:

```
aws ec2 get-launch-template-data \
```

```
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData" >> instance-data.json
```

To create a launch template using launch template data

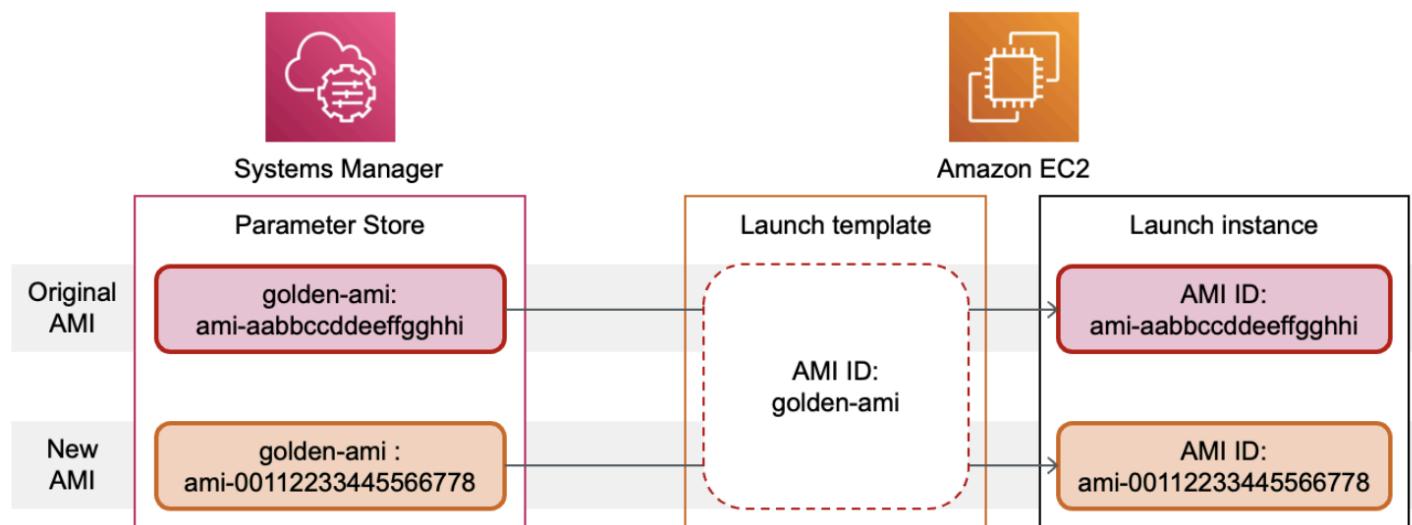

- Use the [create-launch-template](#) command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see [Create a launch template from parameters](#).

Use a Systems Manager parameter instead of an AMI ID

Instead of specifying an AMI ID in your launch templates, you can specify an AWS Systems Manager parameter. If the AMI ID changes, you can update the AMI ID in one place by updating the Systems Manager parameter in the Systems Manager Parameter Store. Parameters can also be shared with other AWS accounts. You can centrally store and manage AMI parameters in one account and share them with every other account that needs to reference them. By using a Systems Manager parameter, all your launch templates can be updated in a single action.

A Systems Manager parameter is a user-defined key-value pair that you create in the Systems Manager Parameter Store. The Parameter Store provides a central place to store your application configuration values. For more information, see [AWS Systems Manager Parameter Store](#) in the [AWS Systems Manager User Guide](#).

In the following diagram, the `golden-ami` parameter is first mapped to the original AMI `ami-aabbccddeeffgghhi` in the Parameter Store. In the launch template, the value for the AMI ID is `golden-ami`. When an instance is launched using this launch template, the AMI ID resolves to `ami-aabbccddeeffgghhi`. Later, the AMI is updated resulting in a new AMI ID. In the Parameter Store, the `golden-ami` parameter is mapped to the new `ami-00112233445566778`. *The launch template remains unchanged*. When an instance is launched using this launch template, the AMI ID resolves to the new `ami-00112233445566778`.

Systems Manager parameter format for AMI IDs

Launch templates require that user-defined Systems Manager parameters adhere to the following format when used in place of an AMI ID:

- Parameter type: String
- Parameter data type: aws:ec2:image – This ensures that Parameter Store validates that the value you enter is in the proper format for an AMI ID.

For more information about creating a valid parameter for an AMI ID, see [Creating Systems Manager parameters](#) in the *AWS Systems Manager User Guide*.

Systems Manager parameter format in launch templates

To use a Systems Manager parameter in place of an AMI ID in a launch template, you must use one of the following formats when specifying the parameter in the launch template:

To reference a public parameter:

- `resolve:ssm:public-parameter`

To reference a parameter stored in the same account:

- `resolve:ssm:parameter-name`
- `resolve:ssm:parameter-name:version-number` – The version number itself is a default label

- `resolve:ssm:parameter-name:label`

To reference a parameter shared from another AWS account:

- `resolve:ssm:parameter-ARN`
- `resolve:ssm:parameter-ARN:version-number`
- `resolve:ssm:parameter-ARN:label`

Parameter versions

Systems Manager parameters are versioned resources. When you update a parameter, you create new, successive versions of the parameter. Systems Manager supports [parameter labels](#) that you can map to specific versions of a parameter.

For example, the `golden-ami` parameter can have three versions: 1, 2, and 3. You can create a parameter label `beta` that maps to version 2, and a parameter label `prod` that maps to version 3.

In a launch template, you can specify version 3 of the `golden-ami` parameter by using either of the following formats:

- `resolve:ssm:golden-ami:3`
- `resolve:ssm:golden-ami:prod`

Specifying the version or label is optional. If a version or label is not specified, the latest version of the parameter is used.

Specify a Systems Manager parameter in a launch template

You can specify a Systems Manager parameter in a launch template instead of an AMI ID when you create a launch template or a new version of a launch template.

Console

To specify a Systems Manager parameter in a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.

3. For **Launch template name**, enter a descriptive name for the launch template.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**.
6. In the **Specify custom value or Systems Manager parameter** dialog box, do the following:
 - a. For **AMI ID or Systems Manager parameter string**, enter the Systems Manager parameter name using one of the following formats:

To reference a public parameter:

- **resolve:ssm:*public-parameter***

To reference a parameter stored in the same account:

- **resolve:ssm:*parameter-name***
- **resolve:ssm:*parameter-name:version-number***
- **resolve:ssm:*parameter-name:label***

To reference a parameter shared from another AWS account:

- **resolve:ssm:*parameter-ARN***
- **resolve:ssm:*parameter-ARN:version-number***
- **resolve:ssm:*parameter-ARN:label***

- b. Choose **Save**.
7. Specify any other launch template parameters as needed, and then choose **Create launch template**.

For more information, see [Create a launch template from parameters](#).

AWS CLI

To specify a Systems Manager parameter in a launch template

- Use the [create-launch-template](#) command to create the launch template. To specify the AMI to use, enter the Systems Manager parameter name using one of the following formats:

To reference a public parameter:

- **resolve:ssm:*public-parameter***

To reference a parameter stored in the same account:

- **resolve:ssm:*parameter-name***
- **resolve:ssm:*parameter-name:version-number***
- **resolve:ssm:*parameter-name:label***

To reference a parameter shared from another AWS account:

- **resolve:ssm:*parameter-ARN***
- **resolve:ssm:*parameter-ARN:version-number***
- **resolve:ssm:*parameter-ARN:label***

The following example creates a launch template that specifies the following:

- A name for the launch template (*TemplateForWebServer*)
- A tag for the launch template (*purpose=production*)
- The data for the instance configuration, specified in a JSON file:
 - The AMI to use (`resolve:ssm:golden-ami`)
 - The instance type to launch (*m5.4xlarge*)
 - A tag for the instance (*Name=webserver*)

```
aws ec2 create-launch-template \
    --launch-template-name TemplateForWebServer \
    --tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
    --launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data for the instance configuration. The value for `ImageId` is the Systems Manager parameter name, entered in the required format `resolve:ssm:golden-ami`.

```
{"LaunchTemplateData": {  
    "ImageId": "resolve:ssm:golden-ami",  
    "InstanceType": "m5.4xlarge",  
    "TagSpecifications": [{  
        "ResourceType": "instance",  
        "Tags": [{  
            "Key": "Name",  
            "Value": "webserver"  
        }]  
    }]  
}
```

Verify that a launch template gets the correct AMI ID

To resolve the Systems Manager parameter to the actual AMI ID

Use the [describe-launch-template-versions](#) command and include the `--resolve-alias` parameter.

```
aws ec2 describe-launch-template-versions \  
--launch-template-name my-launch-template \  
--versions $Default \  
--resolve-alias
```

The response includes the AMI ID for ImageId. In this example, when an instance is launched using this launch template, the AMI ID resolves to ami-0ac394d6a3example.

```
{  
    "LaunchTemplateVersions": [  
        {  
            "LaunchTemplateId": "lt-089c023a30example",  
            "LaunchTemplateName": "my-launch-template",

}
```

```
        }
    ]
}
```

Limitations

- Currently, EC2 Fleets and Spot Fleets do not support using a launch template that has a Systems Manager parameter specified in place of an AMI ID. For EC2 Fleets and Spot Fleets, if you specify an AMI in the launch template, you must specify the AMI ID.
- Amazon EC2 Auto Scaling provides other restrictions. For more information, see [Use AWS Systems Manager parameters instead of AMI IDs in launch templates](#) in the *Amazon EC2 Auto Scaling User Guide*.

Modify a launch template (manage launch template versions)

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.

You can create different versions of a launch template, set the default version, describe a launch template version, and delete versions that you no longer require.

Tasks

- [Create a launch template version](#)
- [Set the default launch template version](#)
- [Describe a launch template version](#)

- [Delete a launch template version](#)

Create a launch template version

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For more information about the launch parameters, see [Create a launch template](#).

Console

To create a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select a launch template, and then choose **Actions, Modify template (Create new version)**.
4. For **Template version description**, enter a description for this version of the launch template.
5. (Optional) Expand **Source template** and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required, and choose **Create launch template**.

AWS CLI

To create a launch template version

- Use the [create-launch-template-version](#) command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `--launch-template-data`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```
aws ec2 create-launch-template-version \
    --launch-template-id lt-0abcd290751193123 \
    --version-description WebVersion2 \
    --source-version 1 \
    --launch-template-data "ImageId=ami-c998b6b2"
```

Set the default launch template version

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

Console

To set the default launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Set default version**.
4. For **Template version**, select the version number to set as the default version and choose **Set as default version**.

AWS CLI

To set the default launch template version

- Use the [modify-launch-template](#) command and specify the version that you want to set as the default.

```
aws ec2 modify-launch-template \
--launch-template-id lt-0abcd290751193123 \
--default-version 2
```

Describe a launch template version

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI, you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

Console

To describe a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
 - To view a version of a launch template: Select the launch template. On the **Versions** tab, from **Version**, select a version to view its details.
 - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose **Latest version**, and then choose a version number.
 - To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose **Default version**, and then choose a version number.

AWS CLI

To describe a launch template version

- Use the [describe-launch-template-versions](#) command and specify the version numbers. In the following example, versions **1** and **3** are specified.

```
aws ec2 describe-launch-template-versions \
    --launch-template-id lt-0abcd290751193123 \
    --versions 1 3
```

To describe all the latest and default launch template versions in your account

- Use the [describe-launch-template-versions](#) command and specify **\$Latest**, **\$Default**, or both. You must omit the launch template ID and name in the call. You cannot specify version numbers.

```
aws ec2 describe-launch-template-versions \
    --versions "$Latest,$Default"
```

Delete a launch template version

If you no longer require a launch template version, you can delete it.

Considerations

- You can't replace the version number after you delete it.
- You can't delete the default version of the launch template; you must first assign a different version as the default. If the default version is the only version for the launch template, you must [delete the entire launch template](#).
- When using the console, you can delete one launch template version at a time. When using the AWS CLI, you can delete up to 200 launch template versions in a single request. To delete more than 200 versions in a single request, you can [delete the launch template](#), which also deletes all of its versions.

Console

To delete a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template version**.
4. Select the version to delete and choose **Delete**.

AWS CLI

To delete a launch template version

- Use the [delete-launch-template-versions](#) command and specify the version numbers to delete. You can specify up to 200 launch template versions to delete in a single request.

```
aws ec2 delete-launch-template-versions \
    --launch-template-id lt-0abcd290751193123 \
    --versions 1
```

Delete a launch template

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions. To delete a specific version of a launch template, see [Delete a launch template version](#).

When you delete a launch template, it doesn't affect any instances that you've launched from the launch template.

Console

To delete a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template**.
4. Enter **Delete** to confirm deletion, and then choose **Delete**.

AWS CLI

To delete a launch template

- Use the [delete-launch-template](#) (AWS CLI) command and specify the launch template.

```
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

Launch instances from a launch template

Launch templates are supported by several instance launch services. This topic describes how to use a launch template when launching an instance using the EC2 launch instance wizard, Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet.

Topics

- [Launch an instance from a launch template](#)
- [Use launch templates with Amazon EC2 Auto Scaling](#)
- [Use launch templates with EC2 Fleet](#)
- [Use launch templates with Spot Fleet](#)

Launch an instance from a launch template

You can use the parameters contained in a launch template to launch an instance. You have the option to override or add launch parameters before you launch the instance.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You cannot remove or edit these tags.

Console

To launch an instance from a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Launch instance from template**.
4. For **Source template version**, select the launch template version to use.
5. For **Number of instances**, specify the number of instances to launch.
6. (Optional) You can override or add launch template parameters by changing and adding parameters in the **Instance details** section.
7. Choose **Launch instance from template**.

AWS CLI

To launch an instance from a launch template using the AWS CLI

- Use the [run-instances](#) command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
aws ec2 run-instances \
  --launch-template LaunchTemplateId=lt-0abcd290751193123,Version=1
```

- To override a launch template parameter, specify the parameter in the [run-instances](#) command. The following example overrides the instance type that's specified in the launch template (if any).

```
aws ec2 run-instances \
  --launch-template LaunchTemplateId=lt-0abcd290751193123 \
```

```
--instance-type t2.small
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag *Owner=TeamA* as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of *Owner*, the value is replaced with *TeamA*.

```
aws ec2 run-instances \
--launch-template LaunchTemplateId=lt-0abcd290751193123 \
--tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
```

In the following example, the instance is launched with a volume with the device name */dev/xvdb* as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for */dev/xvdb*, its values are replaced with the specified values.

```
aws ec2 run-instances \
--launch-template LaunchTemplateId=lt-0abcd290751193123 \
--block-device-mappings "DeviceName=/dev/
xvdb,Ebs={VolumeSize=20,VolumeType=gp2}"
```

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

PowerShell

To launch an instance from a launch template using the AWS Tools for PowerShell

- Use the [New-EC2Instance](#) command and specify the -LaunchTemplate parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification - 
        Property @{
```

```
        LaunchTemplateId = 'lt-0abcd290751193123';
        Version          = '4'
    }
)
```

- To override a launch template parameter, specify the parameter in the [New-EC2Instance](#) command. The following example overrides the instance type that's specified in the launch template (if any).

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -InstanceType t4g.small ` 
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification - 
Property @{
        LaunchTemplateId = 'lt-0abcd290751193123';
        Version          = '4'
    }
)
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag *Owner=TeamA* as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of *Owner*, the value is replaced with *TeamA*.

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -InstanceType t4g.small ` 
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification - 
Property @{
        LaunchTemplateId = 'lt-0abcd290751193123';
        Version          = '4'
    }
)
` 
-TagSpecification (
    New-Object -TypeName Amazon.EC2.Model.TagSpecification -Property @{
        ResourceType = 'instance';
        Tags         = @(

```

```
        @{key = "Owner"; value = "TeamA" },
        @{key = "Department"; value = "Operations" }
    )
}
)
```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```
Import-Module AWS.Tools.EC2
New-EC2Instance `-
    -InstanceType t4g.small `-
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -`-
        Property @{
            LaunchTemplateId = 'lt-0abcd290751193123';
            Version          = '4'
        }
    ) `-
    -BlockDeviceMapping (
        New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping -Property @{
            DeviceName = '/dev/xvdb';
            EBS       = (
                New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice -Property @{
                    VolumeSize = 25;
                    VolumeType = 'gp3'
                }
            )
        }
    )
)
```

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Use launch templates with Amazon EC2 Auto Scaling

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch

parameters defined in the associated launch template. For more information, see [Create a launch template for an Auto Scaling group](#) and [Create a launch template using advanced settings](#) in the *Amazon EC2 Auto Scaling User Guide*.

Before you can create an Auto Scaling group using a launch template, you must create a launch template that includes the parameters required to launch an instance in an Auto Scaling group, such as the ID of the AMI. The console provides guidance to help you create a template that you can use with Amazon EC2 Auto Scaling.

To create a launch template to use with Auto Scaling using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. Under **Auto Scaling guidance**, select the check box to have Amazon EC2 provide guidance to help create a template to use with Auto Scaling.
6. Modify the launch parameters as required. Because you selected Auto Scaling guidance, some fields are required and some fields are not available. For information about how to configure the launch parameters for Amazon EC2 Auto Scaling, see [Create a launch template for an Auto Scaling group](#) and [Create a launch template using advanced settings](#) in the *Amazon EC2 Auto Scaling User Guide*.
7. Choose **Create launch template**.
8. (Optional) To create an Auto Scaling group using this launch template, on the **Next steps** page, choose **Create Auto Scaling group**.

For examples that show how to use the AWS CLI to create launch templates with various parameter combinations, see [Examples for creating and managing launch templates with the AWS Command Line Interface \(AWS CLI\)](#) in the *Amazon EC2 Auto Scaling User Guide*.

To create or update an Auto Scaling group with a launch template using the AWS CLI

- Use the [create-auto-scaling-group](#) or the [update-auto-scaling-group](#) command and specify the --launch-template parameter.

For more information about creating or updating an Auto Scaling group using a launch template, see the following topics in the *Amazon EC2 Auto Scaling User Guide*.

- [Create Auto Scaling groups using launch templates](#)
- [Update an Auto Scaling group](#)

Use launch templates with EC2 Fleet

You can create an EC2 Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create an EC2 Fleet](#).

To create an EC2 Fleet with a launch template using the AWS CLI

- Use the [create-fleet](#) command. Use the `--launch-template-configs` parameter to specify the launch template and any overrides for the launch template.

Use launch templates with Spot Fleet

You can create a Spot Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create a Spot Fleet request](#).

To create a Spot Fleet request with a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Request Spot Instances**.
4. Under **Launch parameters**, choose **Use a launch template**.
5. For **Launch template**, choose a launch template, and then, from the field to the right, choose the launch template version.

6. Configure your Spot Fleet by selecting different options on this screen. For more information about the options, see [Create a Spot Fleet request using defined parameters \(console\)](#).
7. When you're ready to create your Spot Fleet, choose **Launch**.

To create a Spot Fleet request with a launch template using the AWS CLI

- Use the [request-spot-fleet](#) command. Use the LaunchTemplateConfigs parameter to specify the launch template and any overrides for the launch template.

Launch an instance using parameters from an existing instance

The Amazon EC2 console provides a **Launch more like this** option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch instance wizard with certain configuration details from the selected instance.

Considerations

- We do not clone your instances; we only replicate some of the configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI. Create a [launch template](#) to ensure that you launch your instances using the same launch details.
- The current instance must be in the `running` state.

Copied details

The following configuration details are copied from the selected instance into the launch instance wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address - regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see [Public IPv4 addresses](#).
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)

- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance

Details not copied

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- Number of network interfaces – The default is one network interface, which is the primary network interface (eth0).
- Storage – The default storage configuration is determined by the AMI and the instance type.

To launch more instances like an existing instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions, Images and templates, Launch more like this**.
4. The launch instance wizard opens. You can make any necessary changes to the instance configuration by selecting different options on this screen.

When you are ready to launch your instance, choose **Launch instance**.

5. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Launch an AWS Marketplace instance

You can subscribe to an AWS Marketplace product and launch an instance from the product's AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see [Paid AMIs](#). To

cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see [Manage your AWS Marketplace subscriptions](#).

New console

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Amazon EC2 console dashboard, choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**, and then choose the **AWS Marketplace AMIs** tab. Find a suitable AMI by browsing the categories or using the search functionality. To choose a product, choose **Select**.
5. A window opens with an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose one of the following buttons:
 - **Subscribe on instance launch** – Your subscription starts when you choose **Launch instance** (at Step 10).
 - **Subscribe now** – Your subscription starts immediately. While the subscription is underway, you can configure the instance by continuing with the steps in this procedure. If there are any problems with your credit card details, you will be asked to update your account details.

 **Note**

You're not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type when you select an instance type. Additional taxes might also apply to the product.

6. For **Instance type**, select an instance type for your instance. The instance type defines the hardware configuration and size of the instance to launch.
7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
8. Under **Network settings, Firewall (security groups)**, take note of the new security group that was created according to the vendor's specifications for the product. The security group might include rules that allow all IPv4 addresses ($0.0.0.0/0$) access on SSH (port

- 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.
9. You can use the other fields on the screen to configure your instance, add storage, and add tags. For information about the different options that you can configure, see [Launch an instance using defined parameters](#).
 10. In the **Summary** panel, under **Software Image (AMI)**, check the details of the AMI from which you're about to launch the instance. Also check the other configuration details that you specified. When you're ready to launch your instance, choose **Launch instance**.
 11. Depending on the product you've subscribed to, the instance might take a few minutes or more to launch. If you chose **Subscribe on instance launch** at Step 5, you are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View all instances** to go to the **Instances** page.

 **Note**

You are charged the subscription price as long as your instance is in the **running** state, even if it is idle. If your instance is stopped, you might still be charged for storage.

12. When your instance is in the **running** state, you can connect to it. To do this, select your instance in the list, choose **Connect**, and choose a connection option. For more information about connecting to your instance, see [Connect to your Linux instance](#).

 **Important**

Check the vendor's usage instructions carefully, as you might need to use a specific user name to connect to your instance. For information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions](#).

13. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Old console

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Amazon EC2 dashboard, choose **Launch instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the **AWS Marketplace** category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Choose **Select** to choose your product.
4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose **Continue**.

 **Note**

You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard. Additional taxes may also apply to the product.

5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. When you're done, choose **Next: Configure Instance Details**.
6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see [Launch an instance using the old launch instance wizard](#). Choose **Next** until you reach the **Configure Security Group** page.

The wizard creates a new security group according to the vendor's specifications for the product. The security group may include rules that allow all IPv4 addresses (`0.0.0.0/0`) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

When you are ready, choose **Review and Launch**.

7. On the **Review Instance Launch** page, check the details of the AMI from which you're about to launch the instance, as well as the other configuration details you set up in the wizard. When you're ready, choose **Launch** to select or create a key pair, and launch your instance.

8. Depending on the product you've subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View Instances** to go to the Instances page.

 **Note**

You are charged the subscription price as long as your instance is running, even if it is idle. If your instance is stopped, you may still be charged for storage.

9. When your instance is in the `running` state, you can connect to it. To do this, select your instance in the list and choose **Connect**. Follow the instructions in the dialog. For more information about connecting to your instance, see [Connect to your Linux instance](#).

 **Important**

Check the vendor's usage instructions carefully, as you may need to use a specific user name to log in to the instance. For more information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions](#).

10. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

Launch an AWS Marketplace AMI instance using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

Method	Documentation
AWS CLI	Use the run-instances command, or see the following topic for more information: Launching an Instance .
AWS Tools for Windows PowerShell	Use the New-EC2Instance command, or see the following topic for more information: Launch an Amazon EC2 Instance Using Windows PowerShell

Method	Documentation
Query API	Use the RunInstances request.

Stop and start Amazon EC2 instances

You can stop and start your instance if it has an Amazon EBS volume as its root device. When you stop an instance, it shuts down. When you start an instance, it is typically migrated to a new underlying host computer and assigned a new public IPv4 address.

When you stop an instance, it is not deleted. If you decide that you no longer need an instance, you can terminate it. For more information, see [Terminate Amazon EC2 instances](#). If you want to hibernate an instance to save the contents from the instance memory (RAM), see [Hibernate your Amazon EC2 instance](#). For distinctions between instance lifecycle actions, see [Differences between reboot, stop, hibernate, and terminate](#).

How instance stop and start works

When you stop an instance, changes are registered at the OS level of the instance, some resources are lost, and some resources persist. When you start an instance, changes are registered at the instance level.

The following diagram shows what is lost and what persists when an Amazon EC2 instance is stopped. When an instance stops, it loses any attached instance store volumes and the data stored on those volumes, the data stored on the instance RAM, and the assigned public IPv4 address if an Elastic IP address is not associated with the instance. An instance retains assigned private IPv4 addresses, Elastic IP addresses associated with the instance, any IPv6 addresses, and any attached Amazon EBS volumes and the data on those volumes.

What happens when you stop an instance

Changes registered at the OS level

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not cleanly shut down within a few minutes, a hard shutdown is performed.
- The instance stops running.
- The instance status changes to stopping and then stopped.
- **[Auto Scaling]** If your instance is in an Auto Scaling group, when the instance is in any Amazon EC2 state other than running, or if its status for the status checks becomes impaired, Amazon EC2 Auto Scaling considers the instance to be unhealthy and replaces it. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

Resources lost

- Data stored on the RAM.
- Data stored on the instance store volumes.

- The public IPv4 address that Amazon EC2 automatically assigned to the instance upon launch or start. To retain a public IPv4 address that never changes, you can associate an [Elastic IP address](#) with your instance.

Resources that persist

- Any attached Amazon EBS volumes.
- Data stored on the attached Amazon EBS volumes.
- Private IPv4 addresses.
- IPv6 addresses.
- Elastic IP addresses associated with the instance. Note that when the instance is stopped, you are [charged for the associated Elastic IP addresses](#).

For information about what happens when you stop a Mac instance, see [Stop and terminate your Mac instance](#).

What happens when you start an instance

Changes registered at the OS level

- In most cases, the instance is migrated to a new underlying host computer (though in some cases, such as when an instance is allocated to a host in a [Dedicated Host](#) configuration, it remains on the current host).
- Amazon EC2 assigns a new public IPv4 address to the instance if the instance is configured to receive a public IPv4 address. To retain a public IPv4 address that never changes, you can associate an [Elastic IP address](#) with your instance.

Test application response to stop and start

You can use AWS Fault Injection Service to test how your application responds when your instance is stopped and started. For more information, see the [AWS Fault Injection Service User Guide](#).

Costs related to instance stop and start

The following costs are associated with stopping and starting an instance.

Stopping — As soon as the state of an instance changes to shutting-down or terminated, charges are no longer incurred for the instance. You are not charged for usage or data transfer fees for a stopped instance. Charges are incurred to store Amazon EBS storage volumes.

Starting — Each time you start a stopped instance, you are charged for a minimum of one minute of usage. After one minute, you are charged for only the seconds you use. For example, if you run an instance for 20 seconds and then stop it, you are charged for a minute of usage. If you run an instance for 3 minutes and 40 seconds, you are charged for 3 minutes and 40 seconds of usage.

Manually stop and start your instances

You can stop and start your Amazon EBS-backed instances (instances with EBS root devices). You can't stop and start instances with instance store root device.

Warning

When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from the instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

Console

To stop and start an Amazon EBS-backed instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**, and then select the instance.
3. On the **Storage** tab, verify that **Root device type** is **EBS**. Otherwise, you can't stop the instance.
4. Choose **Instance state, Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
5. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
6. To start a stopped instance, select the instance, and choose **Instance state, Start instance**.
7. It can take a few minutes for the instance to enter the **running** state.
8. If you stopped an Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance](#).

Command line

Prerequisites

Verify that the root device of the instance is an EBS volume. For example, run the [describe-instances](#) AWS CLI command and verify that RootDeviceType is ebs, not instance-store.

To stop and start an Amazon EBS-backed instance

Use one of the following commands:

- **AWS CLI**—[stop-instances](#) and [start-instances](#).
- **AWS Tools for PowerShell**—[Stop-EC2Instance](#) and [Start-EC2Instance](#).
- **OS commands**—You can initiate a shutdown using the **shutdown** or **poweroff** commands. When you use an OS command, the instance stops by default. You can change this behavior so that it terminates instead. For more information, see [Change the instance initiated shutdown behavior](#).

Note that using the OS **halt** command from an instance does not initiate a shutdown. If you use the **halt** command, the instance does not terminate; instead, it places the CPU into HLT, which suspends CPU operation. The instance remains running.

Automatically stop and start your instances

You can automate stopping and starting instances with the following services:

Instance Scheduler on AWS

You can use Instance Scheduler on AWS to automate the starting and stopping of EC2 instances. For more information, see [How do I use Instance Scheduler with CloudFormation to schedule EC2 instances?](#) Note that [additional charges apply](#).

AWS Lambda and an Amazon EventBridge rule

You can use Lambda and an EventBridge rule to stop and start your instances on a schedule. For more information, see [How do I stop and start Amazon EC2 instances at regular intervals using Lambda?](#)

Amazon EC2 Auto Scaling

To ensure you have the correct number of Amazon EC2 instances available to handle the load for an application, create Auto Scaling groups. Amazon EC2 Auto Scaling ensures that your application always has the right capacity to handle the traffic demand, and saves costs by launching instances only when they are needed. Note that Amazon EC2 Auto Scaling terminates, rather than stops, unneeded instances. To set up Auto Scaling groups, see [Get started with Amazon EC2 Auto Scaling](#).

Find all running and stopped instances

You can find all of your running and stopped instances across all AWS Regions on a single page using [Amazon EC2 Global View](#). This capability is especially useful for taking inventory and finding forgotten instances. For information about how to use Global View, see [Amazon EC2 Global View](#).

Enable stop protection for your instance

To prevent an instance from being accidentally stopped, you can enable stop protection for the instance. Stop protection also protects your instance from accidental termination.

The `DisableApiStop` attribute of the Amazon EC2 [ModifyInstanceAttribute](#) API controls whether the instance can be stopped by using the Amazon EC2 console, the AWS CLI, or the Amazon EC2 API. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped.

Considerations

- Enabling stop protection does not prevent you from accidentally stopping an instance by initiating a shutdown from the instance using an operating system command such as `shutdown` or `poweroff`.
- Enabling stop protection does not prevent AWS from stopping the instance when there is a [scheduled event](#) to stop the instance.
- Enabling stop protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an Auto Scaling group can terminate a particular instance when scaling in by using [instance scale-in protection](#).
- Stop protection not only prevents your instance from being accidentally stopped, but also from accidental termination when using the console, AWS CLI, or API. However, it

does not automatically set the `DisableApiTermination` attribute. Note that when the `DisableApiStop` attribute is set to `false`, the `DisableApiTermination` attribute setting determines whether the instance can be terminated using the console, AWS CLI, or API. For more information see [Terminate Amazon EC2 instances](#).

- You can't enable stop protection for instance store-backed instances.
- You can't enable stop protection for Spot Instances.
- The Amazon EC2 API follows an eventual consistency model when you enable or disable stop protection. This means that the result of running commands to set the stop protection attribute might not be immediately visible to all subsequent commands you run. For more information, see [Eventual consistency](#) in the *Amazon EC2 Developer Guide*.

Stop protection tasks

- [Enable stop protection for an instance at launch](#)
- [Enable stop protection for a running or stopped instance](#)
- [Disable stop protection for a running or stopped instance](#)

Enable stop protection for an instance at launch

You can enable stop protection for an instance when launching the instance using one of the following methods.

Console

To enable stop protection for an instance at launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the dashboard, choose **Launch instance**.
3. Configure your instance in the [new launch instance wizard](#).
4. In the wizard, enable stop protection by choosing **Enable** for **Stop protection** under **Advanced details**.

AWS CLI

To enable stop protection for an instance at launch

Use the [run-instances](#) AWS CLI command to launch the instance, and specify the disable-api-stop parameter.

```
aws ec2 run-instances \
--image-id ami-a1b2c3d4e5example \
--instance-type t3.micro \
--key-name MyKeyPair \
--disable-api-stop \
...
```

Enable stop protection for a running or stopped instance

You can enable stop protection for an instance while the instance is running or stopped using one of the following methods.

Console

To enable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions>Instance settings>Change stop protection**.
4. Select the **Enable** check box, and then choose **Save**.

AWS CLI

To enable stop protection for a running or stopped instance

Use the [modify-instance-attribute](#) AWS CLI command and specify the disable-api-stop parameter.

```
aws ec2 modify-instance-attribute \
--instance-id i-1234567890abcdef0 \
--disable-api-stop
```

Disable stop protection for a running or stopped instance

You can disable stop protection for a running or stopped instance using one of the following methods.

Console

To disable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions, Instance settings, Change stop protection**.
4. Clear the **Enable** check box, and then choose **Save**.

AWS CLI

To disable stop protection for a running or stopped instance

Use the [modify-instance-attribute](#) AWS CLI command and specify the no-disable-api-stop parameter.

```
aws ec2 modify-instance-attribute \
--instance-id i-1234567890abcdef0 \
--no-disable-api-stop
```

Hibernate your Amazon EC2 instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When your instance is started:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID

You can hibernate an instance only if it's [enabled for hibernation](#) and it meets the [hibernation prerequisites](#).

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

You're not charged for instance usage for a hibernated instance when it is in the stopped state or for data transfer when the contents of the RAM are transferred to the EBS root volume. You are charged for storage of any EBS volumes, including storage for the RAM contents.

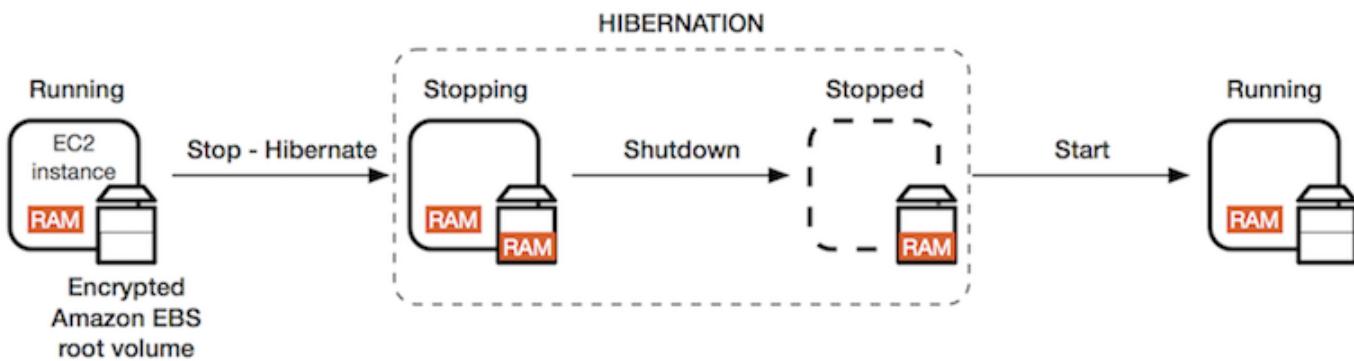

If you no longer need an instance, you can terminate it at any time, including when it is in a stopped (hibernated) state. For more information, see [Terminate Amazon EC2 instances](#).

How Amazon EC2 instance hibernation works

The following diagram shows a basic overview of the hibernation process for EC2 instances.

What happens when you hibernate an instance

When you hibernate an instance, the following happens:

- The instance moves to the stopping state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the stopped state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type or size.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When the instance is started, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When the instance is started, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When the instance is started, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance.

For information about how hibernation differs from reboot, stop, and terminate, see [Differences between reboot, stop, hibernate, and terminate](#).

Limitations

- When you hibernate an instance, the data on any instance store volumes is lost.
- (Linux instances) You can't hibernate a Linux instance that has more than 150 GB of RAM.
- (Windows instances) You can't hibernate a Windows instance that has more than 16 GB of RAM.
- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI or from an AMI that was created from the snapshot.
- (Spot Instances only) If Amazon EC2 hibernates your Spot Instance, only Amazon EC2 can resume your instance. If you hibernate your Spot Instance ([user-initiated hibernation](#)), you can resume your instance. A hibernated Spot Instance can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.
- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.
- You can't hibernate an instance that is configured to boot in UEFI mode with [UEFI Secure Boot](#) enabled.
- If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.
- You can't hibernate an instance that uses a kernel below 5.10 if Federal Information Processing Standard (FIPS) mode is enabled.
- We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.
- We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.

Considerations for hibernating a Spot Instance

- If you hibernate your Spot Instance, you can restart it provided capacity is available and the Spot price is less than or equal to your specified maximum price.
- If Amazon EC2 hibernates your Spot Instance:
 - Only Amazon EC2 can resume your instance.
 - Amazon EC2 resumes the hibernated Spot Instance when capacity becomes available with a Spot price that is less than or equal to your specified maximum price.
 - Before Amazon EC2 hibernates your Spot Instance, you'll receive an interruption notice two minutes before hibernation starts.

For more information, see [Spot Instance interruptions](#).

- There are several ways in which you can enable hibernation for a Spot Instance. For more information, see [Specify the interruption behavior](#).

Prerequisites for Amazon EC2 instance hibernation

You can enable hibernation support for an On-Demand Instance or a Spot Instance when you launch it. You can't enable hibernation on an existing instance, whether it is running or stopped.

For more information, see [Enable instance hibernation](#).

Ubuntu 16.04 LTS (Xenial Xerus) AMI ^{2 3 4} (<u>Additional configuration</u> is required)	Supported	Supported

¹ For CentOS, Fedora, and Red Hat Enterprise Linux, hibernation is supported on Nitro-based instances only.

² We recommend disabling KASLR on instances with Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa), Ubuntu 18.04 LTS (Bionic Beaver), and Ubuntu 16.04 LTS (Xenial Xerus). For more information, see [Disable KASLR on an instance \(Ubuntu only\)](#).

³ For the Ubuntu 16.04 LTS (Xenial Xerus) AMI, hibernation is not supported on t3.nano instance types. No patch will be made available because Ubuntu (Xenial Xerus) ended support in April 2021. If you want to use t3.nano instance types, we recommend that you upgrade to the Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa) AMI, or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

⁴ Support for Ubuntu 18.04 LTS (Bionic Beaver) and Ubuntu 16.04 LTS (Xenial Xerus) has reached end of life.

To configure your own AMI to support hibernation, see [Configure a Linux AMI to support hibernation](#).

Support for other versions of Ubuntu and other operating systems is coming soon.

Windows AMIs

- Windows Server 2022 AMI released 2023.09.13 or later
- Windows Server 2019 AMI released 2019.09.11 or later
- Windows Server 2016 AMI released 2019.09.11 or later
- Windows Server 2012 R2 AMI released 2019.09.11 or later
- Windows Server 2012 AMI released 2019.09.11 or later

Instance families

You must use an instance family that supports hibernation.

- General purpose: M3, M4, M5, M5a, M5ad, M5d, M6i, M6id, M7i, M7i-flex, T2, T3, T3a
- Compute optimized: C3, C4, C5, C5d, C6i, C6id, C7a, C7i
- Memory optimized: R3, R4, R5, R5a, R5ad, R5d, R7a, R7i, R7iz
- Storage optimized: I3, I3en

Nitro instances – Bare metal instances are not supported.

To see the available instance types that support hibernation in a specific Region

The available instance types vary by Region. To see the available instance types that support hibernation in a Region, use the [describe-instance-types](#) command with the `--region` parameter. Include the `--filters` parameter to scope the results to the instance types that support hibernation and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types --filters Name=hibernation-supported,Values=true --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Example output

```
c3.2xlarge  
c3.4xlarge
```

```
c3.8xlarge  
c3.large  
c3.xlarge  
c4.2xlarge  
c4.4xlarge  
c4.8xlarge  
...
```

Instance RAM size

Linux instances – Must be less than 150 GB.

Windows instances – Can be up to 16 GB. For hibernating a T3 or T3a Windows instance, we recommend at least 1 GB of RAM.

Root volume type

The root volume must be an EBS volume, not an instance store volume.

Root volume size

The root volume must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.

Root volume encryption

The root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Encryption by default](#).
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs](#).
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI

and request encryption. For more information, see [Encrypt an unencrypted image during copy](#) and [Copy an AMI](#).

EBS volume type

The EBS volumes must use one of the following EBS volume types:

- General Purpose SSD (gp2 and gp3)
- Provisioned IOPS SSD (io1 and io2)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see [Amazon EBS volume types](#) in the *Amazon EBS User Guide*.

Spot Instance requests

For Spot Instances, the following requirements apply:

- The Spot Instance request type must be persistent.
- You can't specify a launch group in the Spot Instance request.

Configure a Linux AMI to support hibernation

The following Linux AMIs support hibernation, but to hibernate an instance that was launched with one of these AMIs, additional configuration is required before you can hibernate the instance.

Additional configuration required for:

- [Amazon Linux 2 minimal AMI released 2019.08.29 or later](#)
- [Amazon Linux 2 released before 2019.08.29](#)
- [Amazon Linux released before 2018.11.16](#)
- [CentOS version 8 or later](#)
- [Fedora version 34 or later](#)
- [Red Hat Enterprise Linux version 8 or 9](#)
- [Ubuntu 20.04 LTS \(Focal Fossa\) released before serial number 20210820](#)
- [Ubuntu 18.04 \(Bionic Beaver\) released before serial number 20190722.1](#)
- [Ubuntu 16.04 \(Xenial Xerus\)](#)

For more information, see [Update instance software on your Amazon Linux instance](#).

No additional configuration is required for the following AMIs because they're already configured to support hibernation:

- AL2023 AMI released 2023.09.20 or later
- Amazon Linux 2 full AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI released with serial number 20230303 or later
- Ubuntu 20.04 LTS (Focal Fossa) AMI released with serial number 20210820 or later
- Ubuntu 18.04 LTS (Bionic Beaver) AMI released with serial number 20190722.1 or later

Amazon Linux 2 minimal AMI released 2019.08.29 or later

To configure an Amazon Linux 2 minimal AMI released 2019.08.29 or later to support hibernation

1. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

2. Restart the service.

```
[ec2-user ~]$ sudo systemctl start hibinit-agent
```

Amazon Linux 2 released before 2019.08.29

To configure an Amazon Linux 2 AMI released before 2019.08.29 to support hibernation

1. Update the kernel to 4.14.138-114.102 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.14.138-114.102 or later.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see [Create a Linux AMI from an instance](#).

Amazon Linux released before 2018.11.16

To configure an Amazon Linux AMI released before 2018.11.16 to support hibernation

1. Update the kernel to 4.14.77-70.59 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.14.77-70.59 or greater.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see [Create a Linux AMI from an instance](#).

CentOS version 8 or later

To configure a CentOS version 8 or later AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
```

3. Install the ec2-hibernate-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibernate-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibernate-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Fedora version 34 or later

To configure a Fedora version 34 or later AMI to support hibernation

1. Update the kernel to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibernate-agent package from the repositories.

```
[ec2-user ~]$ sudo dnf install ec2-hibernate-agent
```

3. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibernate-agent.service
```

4. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

5. Confirm that the kernel version is updated to 5.12.10-300.fc34.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Red Hat Enterprise Linux version 8 or 9

To configure a Red Hat Enterprise Linux 8 or 9 AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

RHEL version 8:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-8.noarch.rpm
```

RHEL version 9:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-9.noarch.rpm
```

3. Install the ec2-hibernate-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibernate-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibernate.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 20.04 LTS (Focal Fossa) released before serial number 20210820

To configure an Ubuntu 20.04 LTS (Focal Fossa) AMI released before serial number 20210820 to support hibernation

1. Update the linux-aws-kernel to 5.8.0-1038.40 or later, and grub2 to 2.04-1ubuntu26.13 or later.

```
[ec2-user ~]$ sudo apt update  
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

3. Confirm that the kernel version is updated to 5.8.0-1038.40 or later.

```
[ec2-user ~]$ uname -a
```

4. Confirm that the grub2 version is updated to 2.04-1ubuntu26.13 or later.

```
[ec2-user ~]$ dpkg --list | grep grub2-common
```

Ubuntu 18.04 (Bionic Beaver) released before serial number 20190722.1

To configure an Ubuntu 18.04 LTS AMI released before serial number 20190722.1 to support hibernation

1. Update the kernel to 4.15.0-1044 or later.

```
[ec2-user ~]$ sudo apt update  
[ec2-user ~]$ sudo apt dist-upgrade
```

2. Install the ec2-hibernate-agent package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibernate-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.15.0-1044 or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 16.04 (Xenial Xerus)

To configure Ubuntu 16.04 LTS to support hibernation, you need to install the `linux-aws-hwe` kernel package version 4.15.0-1058-aws or later and the `ec2-hibinit-agent`.

Important

The `linux-aws-hwe` kernel package is supported by Canonical. The standard support for Ubuntu 16.04 LTS ended in April 2021, and the package no longer receives regular updates. However, it will receive additional security updates until the Extended Security Maintenance support ends in 2024. For more information, see [Amazon EC2 Hibernation for Ubuntu 16.04 LTS now available](#) on the Canonical Ubuntu Blog.

We recommend that you upgrade to the Ubuntu 20.04 LTS (Focal Fossa) AMI or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

To configure an Ubuntu 16.04 LTS AMI to support hibernation

1. Update the kernel to 4.15.0-1058-aws or later.

```
[ec2-user ~]$ sudo apt update  
[ec2-user ~]$ sudo apt install linux-aws-hwe
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.15.0-1058-aws or later.

```
[ec2-user ~]$ uname -a
```

Enable hibernation for an Amazon EC2 instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

Important

You can't enable or disable hibernation for an instance after you launch it.

Enable hibernation for On-Demand Instances

Use one the following methods to enable hibernation for your On-Demand Instances.

New console

To enable hibernation for an On-Demand Instance

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:
 - a. Under **Application and OS Images (Amazon Machine Image)**, select an AMI that supports hibernation. For more information, see [AMIs](#).
 - b. Under **Instance type**, select a supported instance type. For more information, see [Instance families](#).
 - c. Under **Configure storage**, choose **Advanced** (at the right), and specify the following information for the root volume:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume type**, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).

- For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.
- For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Prerequisites for Amazon EC2 instance hibernation](#).

- d. Expand **Advanced details**, and for **Stop - Hibernate behavior**, choose **Enable**.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

Old console

To enable hibernation for an On-Demand Instance

1. Follow the [Launch an instance using the old launch instance wizard](#) procedure.
2. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI that supports hibernation. For more information about supported AMIs, see [Prerequisites for Amazon EC2 instance hibernation](#).
3. On the **Choose an Instance Type** page, select a supported instance type, and choose **Next: Configure Instance Details**. For information about supported instance types, see [Prerequisites for Amazon EC2 instance hibernation](#).
4. On the **Configure Instance Details** page, for **Stop - Hibernate Behavior**, select the **Enable hibernation as an additional stop behavior** check box.
5. On the **Add Storage** page, for the root volume, specify the following information:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume Type**, select a supported EBS volume type, General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
 - For **Encryption**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Prerequisites for Amazon EC2 instance hibernation](#).

6. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the old launch instance wizard](#).

AWS CLI

To enable hibernation for an On-Demand Instance

Use the [run-instances](#) command to launch an instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type m5.large \
--block-device-mappings file://mapping.json \
--hibernation-options Configured=true \
--count 1 \
--key-name MyKeyPair
```

Specify the following in `mapping.json`.

```
[  
  {  
    "DeviceName": "/dev/xvda",  
    "Ebs": {  
      "VolumeSize": 30,  
      "VolumeType": "gp2",  
      "Encrypted": true  
    }  
  }  
]
```

Note

The value for `DeviceName` must match the root device name that's associated with the AMI. To find the root device name, use the [describe-images](#) command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

PowerShell

To enable hibernation for an On-Demand Instance using the AWS Tools for Windows PowerShell

Use the [New-EC2Instance](#) command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the `-BlockDeviceMappings` parameter. Enable hibernation using the `-HibernationOptions_Configured $true` parameter.

```
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true

PS C:\> New-EC2Instance ` 
    -ImageId ami-0abcdef1234567890 ` 
    -InstanceType m5.large ` 
    -BlockDeviceMappings $ebs_encrypt ` 
    -HibernationOptions_Configured $true ` 
    -MinCount 1 ` 
    -MaxCount 1 ` 
    -KeyName MyKeyPair
```

Note

The value for `DeviceName` must match the root device name associated with the AMI. To find the root device name, use the [Get-EC2Image](#) command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit Encrypted = \$true from the block device mapping.

Enable hibernation for Spot Instances

Use one of the following methods to enable hibernation for your Spot Instances. For more information about hibernating a Spot Instance on interruption, see [Spot Instance interruptions](#).

Console

You can use the launch instance wizard in the Amazon EC2 console to enable hibernation for a Spot Instance.

To enable hibernation for a Spot Instance

1. Follow the procedure to [request a Spot Instance using the launch instance wizard](#), but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:
 - a. Under **Application and OS Images (Amazon Machine Image)**, select an AMI that supports hibernation. For more information, see [AMIs](#).
 - b. Under **Instance type**, select a supported instance type. For more information, see [Instance families](#).
 - c. Under **Configure storage**, choose **Advanced** (at the right), and specify the following information for the root volume:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume type**, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
 - For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.
 - For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

- For more information about the prerequisites for the root volume, see [Prerequisites for Amazon EC2 instance hibernation](#).
- d. Expand **Advanced details**, and, in addition to the fields for configuring a Spot Instance, do the following:
 - i. For **Request type**, choose **Persistent**.
 - ii. For **Interruption behavior**, choose **Hibernate**. Alternatively, for **Stop - Hibernate behavior**, choose **Enable**. Both fields enable hibernation on your Spot Instance. You need only configure one of them.
 3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

AWS CLI

You can enable hibernation for a Spot Instance using the [run-instances](#) AWS CLI command.

To enable hibernation for a Spot Instance using the **hibernation-options** parameter

Use the [run-instances](#) command to request a Spot Instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter. The Spot request type (`SpotInstanceType`) must be persistent.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type c4.xlarge \
--block-device-mappings file://mapping.json \
--hibernation-options Configured=true \
--count 1 \
--key-name MyKeyPair
--instance-market-options
{
    "MarketType": "spot",
    "SpotOptions": {
        "MaxPrice": "1",
        "SpotInstanceType": "persistent"
    }
}
```

}

Specify the EBS root volume parameters in mapping.json as follows.

```
[  
 {  
     "DeviceName": "/dev/xvda",  
     "Ebs": {  
         "VolumeSize": 30,  
         "VolumeType": "gp2",  
         "Encrypted": true  
     }  
 }  
 ]
```

Note

The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the [describe-images](#) command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

PowerShell

To enable hibernation for a Spot Instance using the AWS Tools for Windows PowerShell

Use the [New-EC2Instance](#) command to request a Spot Instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the -BlockDeviceMappings parameter. Enable hibernation using the -HibernationOptions_Configured \$true parameter.

```
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping  
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"  
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice  
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30  
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
```

```
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true  
  
PS C:\> New-EC2Instance  
    -ImageId ami-0abcdef1234567890  
    -InstanceType m5.large  
    -BlockDeviceMappings $ebs_encrypt  
    -HibernationOptions_Configured $true  
    -MinCount 1  
    -MaxCount 1  
    -KeyName MyKeyPair  
    -InstanceMarketOption @(  
        MarketType = spot;  
        SpotOptions @{  
            MaxPrice = 1;  
            SpotInstanceType = persistent}  
    )
```

Note

The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the [Get-EC2Image](#) command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit Encrypted = \$true from the block device mapping.

There are several ways in which you can enable hibernation for a Spot Instance. For more information, see [Specify the interruption behavior](#).

View if an instance is enabled for hibernation

Use the following instructions to view whether an instance is enabled for hibernation.

Console

To view if an instance is enabled for hibernation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.

3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **Stop-hibernate behavior**. **Enabled** indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation

Use the [describe-instances](#) command and specify the `--filters "Name=hibernation-options.configured,Values=true"` parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \
--filters "Name=hibernation-options.configured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
    "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the `-Filter @{ Name="hibernation-options.configured"; Value="true"}` parameter to filter instances that are enabled for hibernation.

```
(Get-EC2Instance -Filter @{Name="hibernation-options.configured";
Value="true"}).Instances
```

The output lists the EC2 instances that are enabled for hibernation.

Disable KASLR on an instance (Ubuntu only)

To run hibernation on a newly launched instance with Ubuntu 16.04 LTS (Xenial Xerus), Ubuntu 18.04 LTS (Bionic Beaver) released with serial number 20190722.1 or later, or Ubuntu 20.04 LTS

(Focal Fossa) released with serial number 20210820 or later, we recommend disabling KASLR (Kernel Address Space Layout Randomization). On Ubuntu 16.04 LTS, Ubuntu 18.04 LTS, or Ubuntu 20.04 LTS, KASLR is enabled by default.

KASLR is a standard Linux kernel security feature that helps to mitigate exposure to and ramifications of yet-undiscovered memory access vulnerabilities by randomizing the base address value of the kernel. With KASLR enabled, there is a possibility that the instance might not resume after it has been hibernated.

To learn more about KASLR, see [Ubuntu Features](#).

To disable KASLR on an instance launched with Ubuntu

1. Connect to your instance using SSH. For more information, see [Connect to your Linux instance from Linux or macOS using SSH](#).
2. Open the /etc/default/grub.d/50-cloudimg-settings.cfg file in your editor of choice. Edit the GRUB_CMDLINE_LINUX_DEFAULT line to append the nokaslr option to its end, as shown in the following example.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0  
nvme_core.io_timeout=4294967295 nokaslr"
```

3. Save the file and exit your editor.
4. Run the following command to rebuild the grub configuration.

```
[ec2-user ~]$ sudo update-grub
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Run the following command to confirm that nokaslr has been added.

```
[ec2-user ~]$ cat /proc/cmdline
```

The output of the command should include the nokaslr option.

Hibernate an Amazon EC2 instance

You can initiate hibernation on an On-Demand Instance or Spot Instance if the instance is an EBS-backed instance, is [enabled for hibernation](#), and meets the [hibernation prerequisites](#). If an instance cannot hibernate successfully, a normal shutdown occurs.

Console

To hibernate an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and choose **Instance state**, **Hibernate instance**. If **Hibernate instance** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see [Prerequisites for Amazon EC2 instance hibernation](#).
4. When prompted for confirmation, choose **Hibernate**. It can take a few minutes for the instance to hibernate. The instance state first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

AWS CLI

To hibernate an EBS-backed instance

Use the [stop-instances](#) command and specify the --hibernate parameter.

```
aws ec2 stop-instances \
--instance-ids i-1234567890abcdef0 \
--hibernate
```

PowerShell

To hibernate an instance using the AWS Tools for Windows PowerShell

Use the [Stop-EC2Instance](#) command and specify the -Hibernate \$true parameter.

```
Stop-EC2Instance ` 
-InstanceId i-1234567890abcdef0 ` 
-Hibernate $true
```

Console

To view if hibernation was initiated on an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, check the value for **State transition message**.

Client.UserInitiatedHibernate: User initiated hibernate indicates that you initiated hibernation on the On-Demand Instance or Spot Instance.

AWS CLI

To view if hibernation was initiated on an instance

Use the [describe-instances](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \
--filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the On-Demand Instance or Spot Instance.

```
"StateReason": {
    "Code": "Client.UserInitiatedHibernate"
}
```

PowerShell

To view if hibernation was initiated on an instance using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance
```

```
-Filter @{Name="state-reason-code";Value="Client.UserInitiatedHibernate"}
```

The output lists the EC2 instances on which hibernation was initiated.

Start a hibernated Amazon EC2 instance

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

Note

For Spot Instances, if Amazon EC2 hibernated the instance, then only Amazon EC2 can resume it. You can only resume a hibernated Spot Instance if *you* hibernated it. Spot Instances can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.

Console

To start a hibernated instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the running state. During this time, the instance [status checks](#) show the instance in a failed state until the instance has started.

AWS CLI

To start a hibernated instance

Use the [start-instances](#) command.

```
aws ec2 start-instances \
--instance-ids i-1234567890abcdef0
```

PowerShell

To start a hibernated instance using the AWS Tools for Windows PowerShell

Use the [Start-EC2Instance](#) command.

```
Start-EC2Instance  
-InstanceId i-1234567890abcdef0
```

Troubleshoot Amazon EC2 instance hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

Hibernation issues

- [Can't hibernate immediately after launch](#)
- [Takes too long to transition from stopping to stopped, and memory state not restored after start](#)
- [Instance "stuck" in the stopping state](#)
- [Can't start Spot Instance immediately after hibernate](#)
- [Resume Spot Instances failed](#)

Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about two minutes for Linux instances and about five minutes for Windows instances after launch before hibernating.

Takes too long to transition from stopping to stopped, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the stopping state to stopped, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see [Prerequisites for Amazon EC2 instance hibernation](#). If you used your own Linux AMI, make sure that you followed the instructions for [Configure a Linux AMI to support hibernation](#).

Linux instances

Check the instance system log and look for messages that are related to hibernation. To access the system log, [connect](#) to the instance or use the [get-console-output](#) command. Find the log lines from the hibinit-agent. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough: hibinit-agent: Insufficient disk space. Cannot create setup for hibernation. Please allocate a larger root device.

If the last log line from the hibinit-agent is hibinit-agent: Running: swapoff /swap, hibernation was successfully configured.

Windows Server 2016 and later

Check the EC2 launch log and look for messages that are related to hibernation. To access the EC2 launch log, [connect](#) to the instance and open the C:\ProgramData\Amazon\EC2-Windows\Launch\Log\Ec2Launch.log file in a text editor. If you're using EC2Launch v2, open C:\ProgramData\Amazon\EC2Launch\log\agent.log.

Note

By default, Windows hides files and folders under C:\ProgramData. To view EC2 Launch directories and files, enter the path in Windows Explorer or change the folder properties to show hidden files and folders.

Find the log lines for hibernation. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that hibernation failed to configure: Message: Failed to enable hibernation. If the error message includes decimal ASCII values, you can convert the ASCII values to plain text in order to read the full error message.

If the log line contains HibernationEnabled: true, hibernation was successfully configured.

Windows Server 2012 R2 and earlier

Check the EC2 config log and look for messages that are related to hibernation. To access the EC2 config log, [connect](#) to the instance and open the C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt file in a text editor. Find the log lines for

`SetHibernateOnSleep`. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough: `SetHibernateOnSleep: Failed to enable hibernation: Hibernation failed with the following error: There is not enough space on the disk.`

If the log line is `SetHibernateOnSleep: HibernationEnabled: true`, hibernation was successfully configured.

Windows instance size

If you're using a T3 or T3a Windows instance with less than 1 GB of RAM, try increasing the size of the instance to one that has at least 1 GB of RAM.

Instance "stuck" in the stopping state

If you hibernated your instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance](#).

Can't start Spot Instance immediately after hibernate

If you try to start a Spot Instance within two minutes of hibernating it, you might get the following error:

You failed to start the Spot Instance because the associated Spot Instance request is not in an appropriate state to support start.

Wait for about two minutes for Linux instances and about five minutes for Windows instances and then retry starting the instance.

Resume Spot Instances failed

If your Spot Instance was hibernated successfully but failed to resume, and instead rebooted (a fresh restart where the hibernated state is not retained), it might be because the user data contained the following script:

```
/usr/bin/enable-ec2-spot-hibernation
```

Remove this script from the **User data** field in the launch template, and then request a new Spot Instance.

Note that even if the instance failed to resume, without the hibernated state preserved, the instance can still be started in the same way as starting from the stopped state.

Reboot your instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance.

When you reboot an instance, it keeps the following:

- Public DNS name (IPv4)
- Private IPv4 address
- Public IPv4 address
- IPv6 address (if applicable)
- Any data on its instance store volumes

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike [stopping and starting](#) your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see [Scheduled events for your instances](#).

We recommend that you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance instead of running the operating system reboot command from your instance. If you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance, we perform a hard reboot if the instance does not cleanly shut down within a few minutes. If you use AWS CloudTrail, then using Amazon EC2 to reboot your instance also creates an API record of when your instance was rebooted.

Console

To reboot an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state, Reboot instance**.

Alternatively, select the instance and choose **Actions, Manage instance state**. In the screen that opens, choose **Reboot**, and then **Change state**.

4. Choose **Reboot** when prompted for confirmation.

The instance remains in the `running` state.

Command line

To reboot an instance

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [reboot-instances](#) (AWS CLI)
- [Restart-EC2Instance](#) (AWS Tools for Windows PowerShell)

To run a controlled fault injection experiment

You can use AWS Fault Injection Service to test how your application responds when your instance is rebooted. For more information, see the [AWS Fault Injection Service User Guide](#).

Terminate Amazon EC2 instances

You can delete your instance when you no longer need it. This is referred to as *terminating* your instance. As soon as the state of an instance changes to `shutting-down` or `terminated`, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop or hibernate an instance, see [Stop and start Amazon EC2 instances](#) or [Hibernate your Amazon EC2 instance](#). For more information, see [Differences between reboot, stop, hibernate, and terminate](#).

Contents

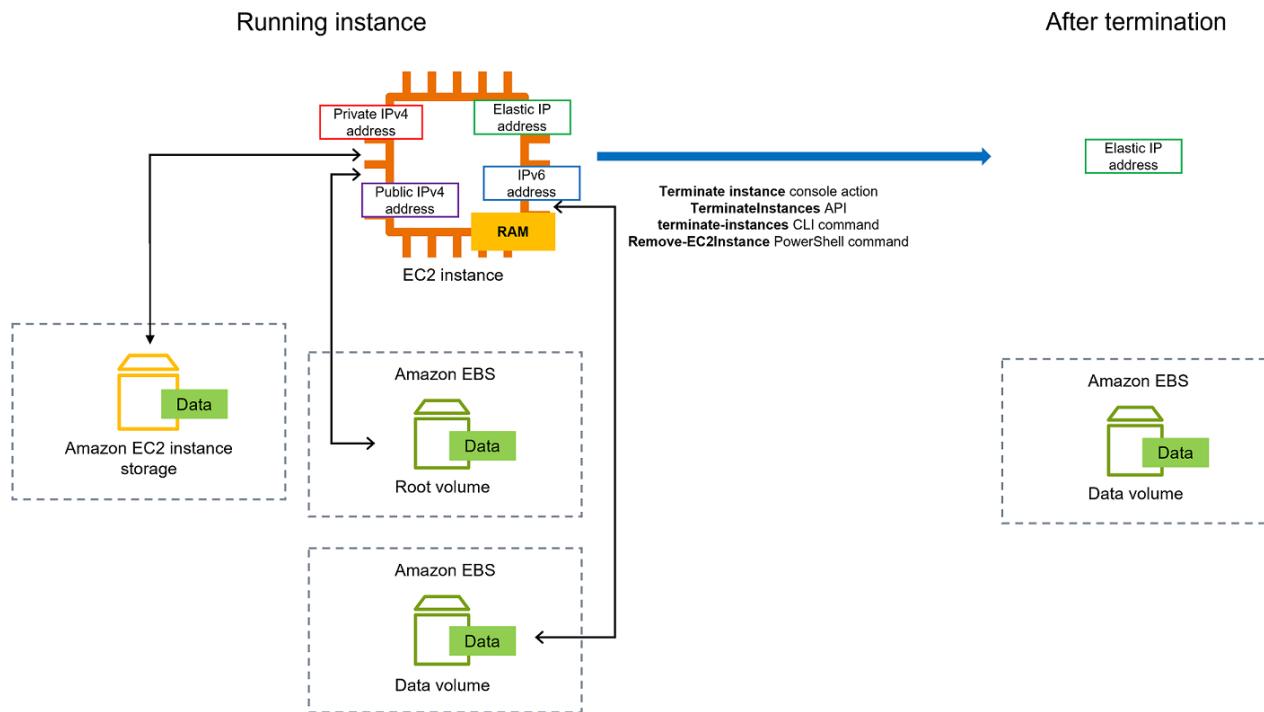

- [How instance termination works](#)
- [Terminate an instance](#)
- [Troubleshoot instance termination](#)
- [Enable termination protection](#)

- [Change the instance initiated shutdown behavior](#)
- [Preserve data when an instance is terminated](#)

How instance termination works

When you terminate an instance, changes are registered at the OS level of the instance, some resources are lost, and some resources persist.

The following diagram shows what is lost and what persists when an Amazon EC2 instance is terminated. When an instance terminates, the data on any instance store volumes and the data stored in the instance RAM is erased. Any Elastic IP addresses associated with the instance are detached. For Amazon EBS volumes and the data on those volumes, the outcome depends on the **Delete on termination** setting for the volume. By default, the root volume is deleted and the data volumes are preserved.

Considerations

- When an instance terminates, the data on any instance store volumes associated with that instance is deleted.
- By default, Amazon EBS root device volumes are automatically deleted when the instance terminates. However, any additional EBS volumes that you attach at launch, or any EBS volumes

that you attach to an existing instance persist even after the instance terminates. For more information, see [Preserve data when an instance is terminated](#).

Note

Any volumes that are not deleted upon termination of the instance will continue to incur charges.

- To prevent an instance from being accidentally terminated by someone, [enable termination protection](#).
- To control whether an instance stops or terminates when shutdown is initiated from the instance, change the [instance initiated shutdown behavior](#).
- If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

What happens when you terminate an instance

Changes registered at the OS level

- The API request will send a button press event to the guest.
- Various system services will be stopped as a result of the button press event. In Linux, `systemd` handles a graceful shutdown of the system. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown will be initiated.
- The instance will shut down when the graceful shutdown process exits. There is no configurable OS shutdown time. The instance remains visible in the console for a short time, then the entry is automatically deleted.

Resources lost

- Data stored on an instance store volume.
- Data stored on Amazon EBS root device volumes if the `DeleteOnTermination` attribute is set to true.

Resources that persist

- Data stored on additional Amazon EBS volumes attached at launch or after launch of an instance.

Test application response to instance termination

You can use AWS Fault Injection Service to test how your application responds when your instance is terminated. For more information, see the [AWS Fault Injection Service User Guide](#).

Terminate an instance

You can terminate an instance at any time.

Console

To terminate an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.
5. After you terminate an instance, it remains visible for a short while, with a state of terminated.

If termination fails or if a terminated instance is visible for more than a few hours, see [Terminated instance still displayed](#).

Command line

To terminate an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [terminate-instances](#) (AWS CLI)
- [Remove-EC2Instance](#) (AWS Tools for Windows PowerShell)

Troubleshoot instance termination

If you terminate your instance and another instance starts, most likely you have configured automatic scaling through a feature like EC2 Fleet or Amazon EC2 Auto Scaling. For more information, see [Instances automatically launched or terminated](#).

If your instance is in the shutting-down state for longer than usual, it should be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see [Delayed instance termination](#).

Enable termination protection

To prevent your instance from being accidentally terminated, you can enable *termination protection* for the instance. The `DisableApiTermination` attribute controls whether the instance can be terminated using the AWS Management Console, AWS Command Line Interface (AWS CLI), or API. By default, termination protection is disabled for your instance which means that your instance can be terminated using the AWS Management Console, AWS CLI, or API. You can set the value of this attribute when you launch an instance, while the instance is running, or while the instance is stopped (for Amazon EBS backed instances).

The `DisableApiTermination` attribute doesn't prevent you from terminating an instance by initiating shutdown from the instance (using an operating system command for system shutdown) when the `InstanceInitiatedShutdownBehavior` attribute is set. For more information, see [Change the instance initiated shutdown behavior](#).

Considerations

- Enabling termination protection does not prevent AWS from terminating the instance when there is a [scheduled event](#) to terminate the instance.
- Enabling termination protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an Auto Scaling group can terminate a particular instance when scaling using [instance scale-in protection](#). You can control whether an Auto Scaling group can terminate unhealthy instances by [suspending the ReplaceUnhealthy scaling process](#).
- You can't enable termination protection for Spot Instances.

To enable termination protection for an instance at launch time

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. On the dashboard, choose **Launch Instance** and follow the directions in the wizard.
3. On the **Configure Instance Details** page, select the **Enable termination protection** check box.

To enable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Enable**.

To disable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Disable**.

To enable or disable termination protection using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Terminate multiple instances with termination protection

If you terminate multiple instances across multiple Availability Zones in the same request, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

Example

Suppose that you have the following four instances across two Availability Zones.

Instance	Availability Zone	Terminate protection
Instance 1	AZ A	Disabled
Instance 2		Disabled
Instance 3	AZ B	Enabled
Instance 4		Disabled

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance 1** and **Instance 2** are successfully terminated because neither instance is enabled for termination protection.
- **Instance 3** and **Instance 4** fail to terminate because **Instance 3** is enabled for termination protection.

Change the instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS backed instance (using a command such as **shutdown** or **poweroff**), the instance stops. You can change this behavior so that the instance terminates instead by changing the `InstanceInitiatedShutdownBehavior` attribute for the instance. You can change this attribute while the instance is running or stopped.

The **halt** command doesn't initiate a shutdown. If used, the instance doesn't terminate; instead, it places the CPU into HLT and the instance continues to run.

Note

The `InstanceInitiatedShutdownBehavior` attribute only applies when you perform a shutdown from the operating system of the instance itself. It doesn't apply when you stop an instance using the `StopInstances` API or the Amazon EC2 console.

You can change the `InstanceInitiatedShutdownBehavior` attribute using the Amazon EC2 console or the command line.

Console

To change the instance initiated shutdown behavior

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions, Instance settings, Change shutdown behavior**.

Shutdown behavior displays the current behavior.

5. To change the behavior, for **Shutdown behavior**, choose **Stop or Terminate**.
6. Choose **Save**.

Command line

To change the instance initiated shutdown behavior

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Preserve data when an instance is terminated

Depending on your use case, you might want to preserve the data on your instance store volume or Amazon EBS volume when the Amazon EC2 instance is terminated. The data on an instance store volume doesn't persist when an instance is terminated. If you need to preserve the data stored on an instance store volume beyond the lifetime of the instance, you must manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system. For more information, see [Storage options for your Amazon EC2 instances](#).

For data on Amazon EBS volumes, Amazon EC2 uses the value of the `DeleteOnTermination` attribute for each attached Amazon EBS volume to determine whether to preserve or delete the volume.

The default value for the `DeleteOnTermination` attribute differs depending on whether the volume is the root volume of the instance or a non-root volume attached to the instance.

Root volume

By default, when you launch an instance the `DeleteOnTermination` attribute for the root volume of an instance is set to `true`. Therefore, the default is to delete the root volume of the instance when the instance terminates.

Non-root volume

By default, when you attach a non-root EBS volume to an instance, its `DeleteOnTermination` attribute is set to `false`. Therefore, the default is to preserve these volumes.

Note

After the instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. You must delete a volume to avoid incurring further charges.

The `DeleteOnTermination` attribute can be set by the creator of an AMI as well as by the person who launches an instance. When the attribute is changed by the creator of an AMI or by the person who launches an instance, the new setting overrides the original AMI default setting. We recommend that you verify the default setting for the `DeleteOnTermination` attribute after you launch an instance with an AMI.

To verify if an Amazon EBS volume will be deleted on instance termination, view the details for volume on the instance's details pane. On the **Storage** tab, under **Block devices**, scroll right to view the **Delete on termination** setting for the volume.

- If **Yes**, the volume will be deleted when the instance is terminated.
- If **No**, the volume will not be deleted when the instance is terminated. Any volumes that are not deleted upon termination of the instance will continue to incur charges.

Change the root volume to persist at launch

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

Use one of the following methods to change the root volume to persist at launch.

Console

To change the root volume of an instance to persist at launch using the console

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to change the root volume to persist.
2. Under **Storage (volumes)**, expand the information under the root volume.
3. For **Delete on termination**, choose **No**.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

Command line

To change the root volume of an instance to persist at launch using the command line

When you launch an EBS-backed instance, you can use one of the following commands to change the root device volume to persist. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [run-instances](#) (AWS CLI)
- [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

In the block device mappings for the volumes that you want to persist, include `--DeleteOnTermination`, and specify `false`.

For example, to persist a volume add the following option to your `run-instances` command:

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for `--DeleteOnTermination`, specify `false`.

```
[  
 {  
   "DeviceName": "device_name",  
   "Ebs": {  
     "DeleteOnTermination": false  
   }  
 }]
```

Change the root volume of a running instance to persist

You can use one of the following commands to change the root device volume of a running EBS-backed instance to persist. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

For example, use the following command:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

In `mapping.json`, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for `--DeleteOnTermination`, specify `false`.

```
[  
  {  
    "DeviceName": "device_name",  
    "Ebs": {  
      "DeleteOnTermination": false  
    }  
  }  
]
```

Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS.

- If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.

- If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information about the types of instance events, see [Scheduled events for your instances](#).

- [Actions to take for instance-store backed instances scheduled for retirement](#)

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement using the Amazon EC2 console or the command line.

Important

If an instance is scheduled for retirement, we recommend that you take action as soon as possible because the instance might be unreachable. (The email notification you receive states the following: "Due to this degradation your instance could already be unreachable.") For more information about the recommended action you should take, see [Check if your instance is reachable](#).

Ways to identify instances scheduled for retirement

- [Email notification](#)
- [Console identification](#)

Email notification

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date.

The email is sent to the primary account holder and the operations contact. For more information, see [Adding, changing, or removing alternate contacts](#) in the *AWS Billing User Guide*.

Console identification

If you use an email account that you do not check regularly for instance retirement notifications, you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **EC2 Dashboard**. Under **Scheduled events**, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.

The screenshot shows the 'Scheduled events' section of the EC2 Dashboard. At the top, it says 'US East (N. Virginia)'. Below that, there are two bullet points: '7 instance(s) have scheduled events' and '1 volume(s) are impaired'. A large 'C' icon is in the top right corner of the dashboard area.

3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.
4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.
5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

To identify instances scheduled for retirement using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- [describe-instance-status](#) (AWS CLI)
- [Get-EC2InstanceState](#) (AWS Tools for Windows PowerShell)

Actions to take for EBS-backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

If you are not sure whether your instance is backed by EBS or instance store, see [Determine the root device type of your instance](#).

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either [connecting](#) to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see [Stop and start Amazon EC2 instances](#). Note that data on instance store volumes is lost when you stop and start your instance.
- If your instance is unreachable, you should take immediate action and perform a [stop/start](#) to recover your instance.
- Alternatively, if you want to [terminate](#) your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

Create a backup of your instance

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see [Create an Amazon EBS-backed Linux AMI](#).

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose **Actions, Launch**. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the new launch instance wizard](#).

Actions to take for instance-store backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

Warning

If your instance store-backed instance passes its retirement date, it is terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if the volumes are attached to an EBS-backed instance.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either [connecting](#) to or pinging your instance.
- If your instance is unreachable, there is likely very little that can be done to recover your instance. For more information, see [Troubleshoot an unreachable instance](#). AWS will terminate your instance on the scheduled retirement date, so, for an unreachable instance, you can immediately [terminate](#) the instance yourself.

Launch a replacement instance

Create an instance store-backed AMI from your instance using the AMI tools, as described in [Create an instance store-backed Linux AMI](#). From the Amazon EC2 console, select your new AMI and then choose **Actions, Launch**. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the new launch instance wizard](#).

Convert your instance to an EBS-backed instance

Transfer your data to an EBS volume, take a snapshot of the volume, and then create AMI from the snapshot. You can launch a replacement instance from your new AMI. For more information, see [Convert your instance store-backed AMI to an Amazon EBS-backed AMI](#).

Recover your instance

To automatically recover an instance when a system status check failure occurs, you can use the default configuration of the instance or create an Amazon CloudWatch alarm. If an instance becomes unreachable because of an underlying hardware failure or a problem that requires AWS involvement to repair, the instance is automatically recovered.

A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata. If the impaired instance has a public IPv4 address, the instance retains the public IPv4 address after recovery. If the impaired instance is in a placement group, the recovered instance runs in the placement group. During instance recovery, the instance is migrated as part of an instance reboot, and any data that is in-memory is lost.

Examples of problems that require instance recovery:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

Simplified automatic recovery based on instance configuration

Instances that support simplified automatic recovery are configured by default to recover a failed instance. The default configuration applies to new instances that you launch and existing instances that you previously launched. Simplified automatic recovery is initiated in response to system status check failures. Simplified automatic recovery doesn't take place during Service Health Dashboard events, or any other events that impact the underlying hardware. For more information, see [the section called "Troubleshoot instance recovery failures"](#).

When a simplified automatic recovery event succeeds, you are notified by an AWS Health Dashboard event. When a simplified automatic recovery event fails, you are notified by an AWS

Health Dashboard event and by email. You can also use Amazon EventBridge rules to monitor for simplified automatic recovery events using the following event codes:

- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS — successful events
- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE — failed events

For more information, see [Amazon EventBridge rules](#).

Topics

- [Requirements](#)
- [Limitations](#)
- [Set the recovery behavior](#)

Requirements

Simplified automatic recovery is supported by an instance if the instance has the following characteristics:

- It uses default or dedicated instance tenancy.
- It does not use an Elastic Fabric Adapter.
- It uses one of the following instance types:
 - **General purpose:** A1 | M3 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | M6in | M7a | M7g | M7i | M7i-flex | T1 | T2 | T3 | T3a | T4g
 - **Compute optimized:** C3 | C4 | C5 | C5a | C5n | C6a | C6g | C6gn | C6i | C6in | C7a | C7g | C7gn | C7i
 - **Memory optimized:** R3 | R4 | R5 | R5a | R5b | R5n | R6a | R6g | R6i | R6in | R7a | R7g | R7i | R7iz | u-3tb1 | u-6tb1 | u-9tb1 | u-12tb1 | u-18tb1 | u-24tb1 | X1 | X1e | X2iezn
 - **Accelerated computing:** G3 | G3s | G5g | Inf1 | P2 | P3 | VT1
 - **High-performance computing** Hpc6a | Hpc7a | Hpc7g
- It does not have instance store volumes. If a Nitro instance type has instance store volumes, or if a Xen-based instance has mapped instance store volumes in the AMI being used, the instance can't be automatically recovered.

Important

If an instance has instance store volumes attached, stopping and starting the instance will cause any data on the instance store volumes to be lost. You should regularly backup your instance store volume data to more persistent storage, such as Amazon EBS, Amazon S3, or Amazon EFS. In the event of a system status check failure, you can stop and start instances with instance store volumes and then restore the instance store volumes using the backed-up data.

Limitations

- Instances with instance store volumes and metal instance types are not supported by simplified automatic recovery.
- Simplified automatic recovery is not initiated for instances in an Auto Scaling group. If your instance is part of an Auto Scaling group with health checks enabled, then the instance is replaced when it becomes impaired.
- Simplified automatic recovery applies to unplanned events only. It does not apply to scheduled events.
- Terminated or stopped instances can't be recovered.

Set the recovery behavior

You can set the automatic recovery behavior to disabled or default during or after launching the instance. The default configuration does not enable simplified automatic recovery for an unsupported instance type.

Console

To disable simplified automatic recovery during instance launch

- Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
- In the navigation pane, choose **Instances**, and then choose **Launch instance**.
- In the **Advanced details** section, for **Instance auto-recovery**, select **Disabled**.
- Configure the remaining instance launch settings as needed and then launch the instance.

To disable simplified automatic recovery for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.
4. Choose **Off**, and then choose **Save**.

To set the automatic recovery behavior to default for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.
4. Choose **Default (On)**, and then choose **Save**.

AWS CLI

To disable simplified automatic recovery at launch

Use the [run-instances](#) command.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type t2.micro \
--key-name MyKeyPair \
--maintenance-options AutoRecovery=Disabled \
[...]
```

To disable simplified automatic recovery for a running or stopped instance

Use the [modify-instance-maintenance-options](#) command.

```
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery disabled
```

To set the automatic recovery behavior to default for a running or stopped instance

Use the [modify-instance-maintenance-options](#) command.

```
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery default
```

Amazon CloudWatch action based recovery

Use Amazon CloudWatch action based recovery if you want to customize when to recover your instance.

When the StatusCheckFailed_System alarm is triggered, and the recovery action is initiated, you're notified by the Amazon SNS topic that you selected when you created the alarm and associated the recovery action. When the recovery action is complete, information is published to the Amazon SNS topic you configured for the alarm. Anyone who is subscribed to this Amazon SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. As a last step in the recovery action, the recovered instance reboots.

You can use Amazon CloudWatch alarms to recover an instance even if simplified automatic recovery is not disabled. For information about creating an Amazon CloudWatch alarm to recover an instance, see [Add recover actions to Amazon CloudWatch alarms](#).

Supported instance types

All of the instance types [supported by simplified automatic recovery](#) are also supported by Amazon CloudWatch action based recovery. Additionally, CloudWatch action based recovery supports bare metal variants of the supported instance types. The following instance families are also supported in addition to those supported by simplified automatic recovery:

- **Memory optimized:** X2idn | X2iedn

Important

For supported instance types that have instance store volumes, any data on these volumes will be lost during a recovery. Stopping and starting the instance will also cause any data on the instance store volume to be lost. You should regularly backup your instance store volume data to more persistent storage, such as Amazon EBS, Amazon S3, or Amazon EFS.

In the event of a system status check failure, you can stop and start instances with instance store volumes and then restore the instance store volumes using the backed-up data.

CloudWatch action based recovery does not support recovery for instances with Dedicated Host tenancy. For Amazon EC2 Dedicated Hosts, you can use [Dedicated Host Auto Recovery](#) to automatically recover unhealthy instances.

You can use the AWS Management Console or the AWS CLI to view the instance types that support CloudWatch action based recovery.

Console

To view the instance types that support Amazon CloudWatch action based recovery

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, enter **Auto Recovery support: true**. Alternatively, as you enter the characters and the filter name appears, you can select it.

The **Instance types** table displays all the instance types that support Amazon CloudWatch action based recovery.

AWS CLI

To view the instance types that support Amazon CloudWatch action based recovery

Use the [describe-instance-types](#) command.

```
aws ec2 describe-instance-types --filters Name=auto-recovery-supported,Values=true  
--query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Troubleshoot instance recovery failures

The following issues can cause the recovery of your instance to fail:

- During Service Health Dashboard events, simplified automatic recovery might not recover your instance. You might not receive recovery failure notifications for such events. Any ongoing Service Health Dashboard events might also prevent CloudWatch action based recovery from

successfully recovering an instance. For the latest service availability information, see <http://status.aws.amazon.com/>.

- Temporary, insufficient capacity of replacement hardware.
- The instance has reached the maximum daily allowance of three recovery attempts.

The automatic recovery process attempts to recover your instance for up to three separate failures per day. If the instance system status check failure persists, we recommend that you manually stop and start the instance. Data on instance store volumes is lost when the instance is stopped. For more information, see [Stop and start Amazon EC2 instances](#).

Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

Connect

This section of the *Amazon EC2 User Guide for Linux Instances* provides information to help you connect to your Linux instance after you launch it. It also provides information to help you connect your Linux instance to another AWS resource.

For information about how to connect to a **Windows instance**, see [Connect to your Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

Topics

- [Connect to your Linux instance](#)
- [Connect to your instances without requiring a public IPv4 address using EC2 Instance Connect Endpoint](#)

Connect to your Linux instance

There are many ways to connect to your Linux instance. Some vary depending on the operating system of the local machine that you connect from. Others, like EC2 Instance Connect or AWS Systems Manager Session Manager, don't vary. In this section, you can learn how to connect to your Linux instance and transfer files between your local computer and your instance. For information about how to connect to a **Windows instance**, see [Connect to your Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

Before you connect to your Linux instance, complete the following prerequisites.

- [Get information about your instance](#)
- [Locate the private key and set permissions](#)
- [\(Optional\) Get the instance fingerprint](#)

Then, choose from one of the following options to connect to your Linux instance.

Options to connect based on your local operating system

- [Connect from a Linux or macOS local machine using SSH](#)
- [Connect from a Windows local machine](#)

Options to connect from any local operating system

- [Connect to your Linux instance with AWS Systems Manager Session Manager](#)
- [Connect to your Linux instance with EC2 Instance Connect.](#)

 **Note**

For instance connection troubleshooting tips, see [Troubleshoot connecting to your instance](#).

To troubleshoot boot, network configuration, and other issues for instances built on the [AWS Nitro System](#), you can use the [EC2 Serial Console for Linux instances](#).

Get information about your instance

To prepare to connect to an instance, get the following information from the Amazon EC2 console or by using the AWS CLI.

The screenshot shows the Amazon EC2 console interface. On the left, there's a navigation sidebar with various links like EC2 Dashboard, EC2 Global View, Events, Tags, Limits, Instances (which is selected and highlighted with a red circle), Instance Types, Launch Templates, Spot Requests, Savings Plans, Reserved Instances, Dedicated Hosts, Scheduled Instances, Capacity Reservations, Images, AMIs, AMI Catalog, Elastic Block Store, Volumes, Snapshots, Lifecycle Manager, Network & Security, and Security Groups.

The main area displays the 'Instances (1/8) Info' table. The columns include Name, Instance ID (which is also circled in red), Instance state, Instance type, Status check, Alarm status, Availability Zone, and Public IPv4 DNS. One row is selected, showing an instance named 'Windows' with an Instance ID of 'i-05e1...', which is also circled in red. The Public IPv4 DNS value is 'ec2-172-31-10-198.compute-1.amazonaws.com'. Below the table, a detailed view for 'Instance: i-05e1...' is shown under the 'Details' tab. In this detailed view, the 'Public IPv4 DNS' field is also circled in red.

- **Get the public DNS name of the instance.**

You can get the public DNS for your instance from the Amazon EC2 console. Check the **Public IPv4 DNS** column of the **Instances** pane. If this column is hidden, choose the settings icon (

) in the top-right corner of the screen, and select **Public IPv4 DNS**. You can also find the public DNS in the instance information section of the **Instances** pane. When you select the instance in the **Instances** pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the **Details** tab, look for **Public IPv4 DNS**.

If you prefer, you can use the [describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) commands.

If no **Public IPv4 DNS** is displayed, verify that the **Instance state** is **Running**, and that you have not launched the instance in a private subnet. If you launched your instance using the [launch instance wizard](#), you may have edited the **Auto-assign public IP** field under **Network settings** and changed the value to **Disable**. If you disable the **Auto-assign public IP** option, the instance is not assigned a public IP address when it is launched.

- **(IPv6 only) Get the IPv6 address of the instance.**

If you assigned an IPv6 address to your instance, you can optionally connect to the instance using its IPv6 address instead of a public IPv4 address or public IPv4 DNS hostname. Your local computer must have an IPv6 address and must be configured to use IPv6. You can get the IPv6 address of your instance from the Amazon EC2 console. Check the **IPv6 IPs** column of the **Instances** pane. Or, you can find the IPv6 address in the instance information section. When you select the instance in the **Instances** pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the **Details** tab, look for **IPv6 address**.

If you prefer, you can use the [describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) commands. For more information about IPv6, see [IPv6 addresses](#).

- **Get the user name for your instance.**

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- **Get the username for your user account.**

For more information about how to create a user account, see [Manage users on your Linux instance](#).

- **Get the default username for the AMI that you used to launch your instance:**

AMI used to launch instance	Default username
AL2023	ec2-user
Amazon Linux 2	
Amazon Linux	
CentOS	centos or ec2-user
Debian	admin
Fedora	fedora or ec2-user
RHEL	ec2-user or root
SUSE	ec2-user or root

AMI used to launch instance	Default username
Ubuntu	ubuntu
Oracle	ec2-user
Bitnami	bitnami
Rocky Linux	rocky
Other	Check with the AMI provider

Locate the private key and set permissions

You must know the location of your private key file to connect to your instance. For SSH connections, you must set the permissions so that only you can read the file.

For information about how key pairs work when using Amazon EC2, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

- **Locate the private key**

Get the fully-qualified path to the location on your computer of the . pem file for the key pair that you specified when you launched the instance. For more information, see [Identify the public key specified at launch](#). If you can't find your private key file, see [I've lost my private key. How can I connect to my Linux instance?](#)

If you are connecting to your instance using Putty and need to convert the . pem file to . ppk, see [Convert your private key using PuTTYgen](#) in the [Connect to your Linux instance from Windows with PuTTY](#) topic in this section.

- **Set the permissions of your private key so that only you can read it**

- **Connect from macOS or Linux**

If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
chmod 400 key-pair-name.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see [Error: Unprotected private key file](#).

- **Connect from Windows**

Open File Explorer and right-click on the . pem file. Select **Properties > Security tab** and choose **Advanced**. Choose **Disable inheritance**. Remove access to all users except for the current user.

(Optional) Get the instance fingerprint

To protect yourself from man-in-the-middle attacks, you can verify the authenticity of the instance you're about to connect to by verifying the fingerprint that is displayed. Verifying the fingerprint is useful if you launched your instance from a public AMI provided by a third party.

Task overview

First, get the instance fingerprint from the instance. Then, when you connect to the instance and are prompted to verify the fingerprint, compare the fingerprint you obtained in this procedure with the fingerprint that is displayed. If the fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, you can confidently connect to your instance.

Prerequisites to get the instance fingerprint

- The instance must not be in the pending state. The fingerprint is available only after the first boot of the instance is complete.
- You must be the instance owner to get the console output.
- There are various ways to get the instance fingerprint. If you want to use the AWS CLI, it must be installed on your local computer. For information about installing the AWS CLI, see [Installing the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

To get the instance fingerprint

In Step 1, you get the console output, which includes the instance fingerprint. In Step 2, you find the instance fingerprint in the console output.

1. Get the console output using one of the following methods.

Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the left navigator, choose **Instances**.
3. Select your instance, and then choose **Actions, Monitor and troubleshoot, Get system log**.

AWS CLI

On your local computer (not on the instance you're connecting to), use the [get-console-output](#) (AWS CLI) command. If the output is large, [you can pipe it to a text file](#), where it might be easier to read. Note that you must specify an AWS Region when you use the AWS CLI, either explicitly or by setting a default Region. For information about how to set or specify a Region, see [Configuration basics](#) in the *AWS Command Line Interface User Guide*.

```
aws ec2 get-console-output --instance-id instance_id --query Output --output text > temp.txt
```

2. In the console output, find the instance (host) fingerprint, which is located under BEGIN SSH HOST KEY FINGERPRINTS. There might be several instance fingerprints. When you connect to your instance, it will display only one of the fingerprints.

The exact output can vary by operating system, AMI version, and whether AWS created the key pairs. The following is example output.

```
ec2:#####
ec2: -----BEGIN SSH HOST KEY FINGERPRINTS-----
ec2: 256 SHA256:14UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY no comment (ECDSA)
ec2: 256 SHA256:kpEa+rw/Uq3zxaYZN8KT501iBtJ0IdHG52dFi66EEfQ no comment (ED25519)
ec2: 2048 SHA256:L8l6pepcA7iqW/jBecQjVZC1UrKY+o2cHLI0iHerbVc no comment (RSA)
ec2: -----END SSH HOST KEY FINGERPRINTS-----
ec2: #####
```

Note

You'll reference this fingerprint when you connect to the instance.

Connect to your Linux instance from Linux or macOS using SSH

You can use Secure Shell (SSH) to connect to your Linux instance from a local machine that runs a Linux or macOS operating system, or you can use a platform independent connection tool, such as EC2 Instance Connect or AWS Systems Manager Session Manager. For more information about platform independent tools, see [Connect to your Linux instance](#).

This page explains how to connect to your instance with an SSH client. To connect to your Linux instance from Windows, see [Connect from Windows](#).

Note

If you receive an error while attempting to connect to your instance, make sure that your instance meets all of the [SSH connection prerequisites](#). If it meets all of the prerequisites, and you're still not able to connect to your Linux instance, see [Troubleshoot connecting to your instance](#).

Contents

- [SSH connection prerequisites](#)
- [Connect to your Linux instance using an SSH client](#)
- [Transfer files to Linux instances using an SCP client](#)

SSH connection prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Check your instance status

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the **Instances** page.

Get the public DNS name and user name to connect to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see [Get information about your instance](#).

Locate the private key and set the permissions

To locate the private key that is required to connect to your instance, and to set the key permissions, see [Locate the private key and set permissions](#).

Install an SSH client on your local computer as needed

Your local computer might have an SSH client installed by default. You can verify this by typing `ssh` at the command line. If your computer doesn't recognize the command, you can install an SSH client.

- Recent versions of Windows Server 2019 and Windows 10 – OpenSSH is included as an installable component. For more information, see [OpenSSH in Windows](#).
- Earlier versions of Windows – Download and install OpenSSH. For more information, see [Win32-OpenSSH](#).
- Linux and macOS X – Download and install OpenSSH. For more information, see <https://www.openssh.com>.

Connect to your Linux instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

Connect to your instance using SSH

- In a terminal window, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (. pem), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set permissions](#) and [Get information about your instance](#). To connect to your instance, use one of the following commands.
 - (Public DNS) To connect using your instance's public DNS name, enter the following command.

```
ssh -i /path/key-pair-name.pem instance-user-name@instance-public-dns-name
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.

```
ssh -i /path/key-pair-name.pem instance-user-name@instance-IPv6-address
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)'  
can't be established.  
ECDSA key fingerprint is 14UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.  
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint](#). If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.
3. Enter **yes**.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to  
the list of known hosts.
```

Transfer files to Linux instances using an SCP client

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- **Verify the general prerequisites for transferring files to your instance.**

Before you transfer files between your local machine and your instance, take the following actions to ensure that you have all of the information you need.

- [Get information about your instance](#)
- [Locate the private key and set permissions](#)
- [\(Optional\) Get the instance fingerprint](#)
- **Install an SCP client**

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see <https://www.openssh.com>.

The following procedure steps you through using SCP to transfer a file using the instance's public DNS name, or the IPv6 address if your instance has one.

To use SCP to transfer files between your computer and your instance

1. Determine the location of the source file on your computer and the destination path on the instance. In the following examples, the name of the private key file is key-pair-name.pem, the file to transfer is my-file.txt, the user name for the instance is ec2-user, the public DNS name of the instance is instance-public-dns-name, and the IPv6 address of the instance is instance-IPv6-address.
 - (Public DNS) To transfer a file to the destination on the instance, enter the following command from your computer.

```
scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@instance-public-dns-name:path/
```

- (IPv6) To transfer a file to the destination on the instance if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@\[instance-IPv6-address\]:path/
```

2. If you haven't already connected to the instance using SSH, you see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.  
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.  
Are you sure you want to continue connecting (yes/no)?
```

(Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see [\(Optional\) Get the instance fingerprint](#).

Enter **yes**.

3. If the transfer is successful, the response is similar to the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)
          to the list of known hosts.
```

```
my-file.txt          100%   480      24.4KB/s  00:00
```

4. To transfer a file in the other direction (from your Amazon EC2 instance to your computer), reverse the order of the host parameters. For example, you can transfer `my-file.txt` from your EC2 instance to the a destination on your local computer as `my-file2.txt`, as shown in the following examples.

- (Public DNS) To transfer a file to a destination on your computer, enter the following command from your computer.

```
scp -i /path/key-pair-name.pem ec2-user@instance-public-dns-name:path/my-
file.txt path/my-file2.txt
```

- (IPv6) To transfer a file to a destination on your computer if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/key-pair-name.pem ec2-user@\[instance-IPv6-address\]:path/my-
file.txt path/my-file2.txt
```

Connect to your Linux instance from Windows

You can use the following methods to connect to your Linux instance from a local machine that has a Windows operating system.

- [OpenSSH](#)
- [PuTTY](#)
- [Windows Subsystem for Linux](#)

Connect to your Linux instance from Windows with OpenSSH

The following procedures show you how to connect to your Linux instance from Windows using OpenSSH, an open source connectivity tool for remote login with the SSH protocol. OpenSSH is supported on Windows Server 2019 and later operating systems.

Contents

- [Prerequisites](#)
- [Install OpenSSH for Windows using PowerShell](#)
- [Connect to your Linux instance from Windows using OpenSSH](#)
- [Uninstall OpenSSH from Windows using PowerShell](#)

Prerequisites

Before you connect to your Linux instance from Windows using OpenSSH, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the [Instances](#) page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the username that you should use to connect to your instance, see [Get information about your instance](#).

Verify your Windows version

To connect to your Linux instance from Windows using OpenSSH, the Windows version must be Windows Server 2019 and later.

Verify PowerShell prerequisites

To install OpenSSH on your Windows OS using PowerShell, you must be running PowerShell version 5.1 or later, and your account must be a member of the built-in Administrators group. Run `$PSVersionTable.PSVersion` from PowerShell to check your PowerShell version.

To check whether you are a member of the built-in Administrators group, run the following PowerShell command:

```
(New-Object  
Security.Principal.WindowsPrincipal([Security.Principal.WindowsIdentity]::GetCurrent())).Is
```

If you are a member of the built-in Administrators group, the output is True.

Install OpenSSH for Windows using PowerShell

To install OpenSSH for Windows using PowerShell, run the following PowerShell command:

```
Add-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

Expected output:

```
Path          :  
Online        : True  
RestartNeeded : False
```

Connect to your Linux instance from Windows using OpenSSH

After you install OpenSSH, use the following procedure to connect to your Linux instance from Windows using OpenSSH. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

To connect to your instance using OpenSSH

1. In PowerShell or the Command Prompt, use the **ssh** command to connect to the instance. You specify the path and file name of the private key (. pem), the username for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the username for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set permissions](#) and [Get information about your instance](#). To connect to your instance, use one of the following commands.

- (Public DNS) To connect using your instance's public DNS name, enter the following command.

```
ssh -i /path/key-pair-name.pem instance-user-name@instance-public-dns-name
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.

```
ssh -i /path/key-pair-name.pem instance-user-name@instance-IPv6-address
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)' can't be established.  
ECDSA key fingerprint is 14UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY.  
Are you sure you want to continue connecting (yes/no/[fingerprint])?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint](#). If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.
3. Enter **yes**.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to the list of known hosts.
```

Uninstall OpenSSH from Windows using PowerShell

To uninstall OpenSSH from Windows using PowerShell, run the following PowerShell command:

```
Remove-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

Expected output:

```
Path          :  
Online        : True  
RestartNeeded : True
```

Connect to your Linux instance from Windows with PuTTY

If you're running Windows Server 2019 or later, we recommend using OpenSSH, which is an open source connectivity tool for remote login with the SSH protocol. For steps to connect to a Linux instance from Windows using OpenSSH, see [Connect to your Linux instance from Windows with OpenSSH](#).

The following instructions explain how to connect to your instance using PuTTY, a free SSH client for Windows. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

Contents

- [Prerequisites](#)
 - [Convert your private key using PuTTYgen](#)
- [Connect to your Linux instance](#)
- [Transfer files to your Linux instance using the PuTTY Secure Copy client](#)
- [Transfer files to your Linux instance using WinSCP](#)

Prerequisites

Before you connect to your Linux instance using PuTTY, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the [Instances](#) page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the username that you should use to connect to your instance, see [Get information about your instance](#).

Install PuTTY on your local computer

Download and install PuTTY from the [PuTTY download page](#). If you already have an earlier version of PuTTY installed, we recommend that you download the latest version. Be sure to install the entire suite.

Convert your private .pem key to .ppk using PuTTYgen

For the key pair that you specified when you launched the instance, if you chose to create the private key in the .pem format, you must convert it to a .ppk file for use with PuTTY. Locate the private .pem file, and then follow the steps in the next section.

Convert your private key using PuTTYgen

PuTTY does not natively support the PEM format for SSH keys. PuTTY provides a tool named PuTTYgen, which converts PEM keys to the required PPK format for PuTTY. You must convert your private key (.pem file) into this format (.ppk file) as follows in order to connect to your instance using PuTTY.

To convert your private .pem key to .ppk

1. From the **Start** menu, choose **All Programs**, **PuTTY**, **PuTTYgen**.
2. Under **Type of key to generate**, choose **RSA**. If your version of PuTTYgen does not include this option, choose **SSH-2 RSA**.

3. Choose **Load**. By default, PuTTYgen displays only files with the extension .ppk. To locate your .pem file, choose the option to display files of all types.

4. Select your .pem file for the key pair that you specified when you launched your instance and choose **Open**. PuTTYgen displays a notice that the .pem file was successfully imported. Choose **OK**.
5. To save the key in the format that PuTTY can use, choose **Save private key**. PuTTYgen displays a warning about saving the key without a passphrase. Choose **Yes**.

Note

A passphrase on a private key is an extra layer of protection. Even if your private key is discovered, it can't be used without the passphrase. The downside to using a passphrase is that it makes automation harder because human intervention is needed to log on to an instance, or to copy files to an instance.

6. Specify the same name for the key that you used for the key pair (for example, key-pair-name) and choose **Save**. PuTTY automatically adds the .ppk file extension.

Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.

Connect to your Linux instance

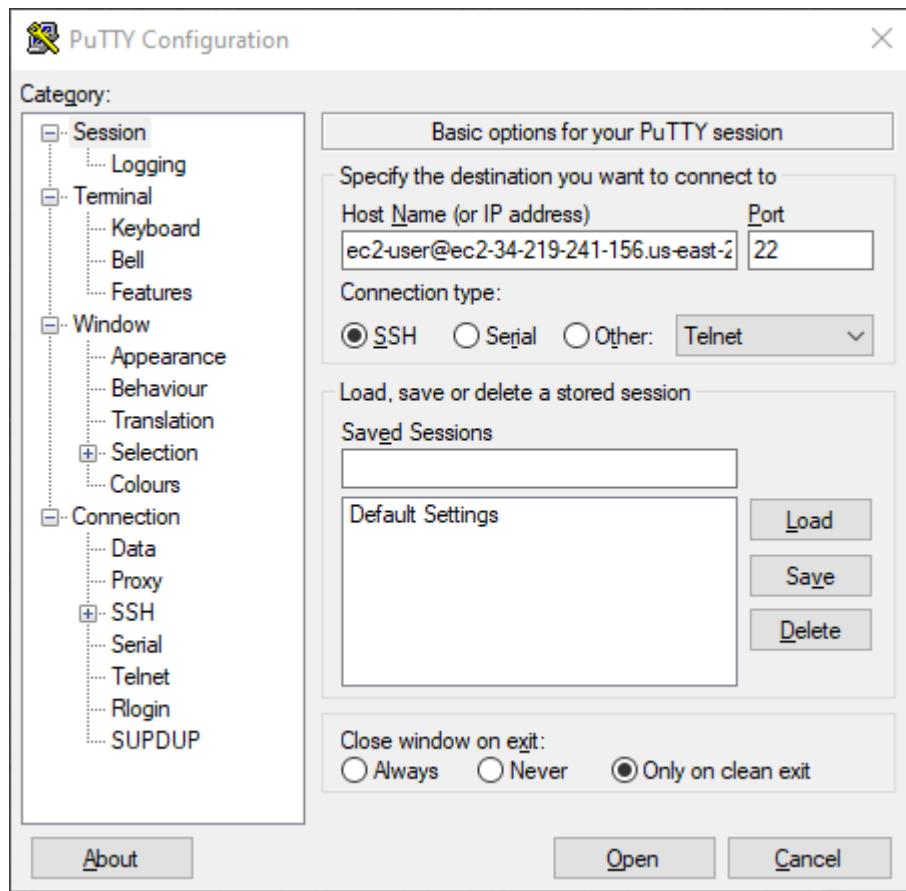

Use the following procedure to connect to your Linux instance using PuTTY. You need the .ppk file that you created for your private key. For more information, see [Convert your private key using PuTTYgen](#) in the preceding section. If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

Last tested version of PuTTY: .78

To connect to your instance using PuTTY

1. Start PuTTY (from the **Start** menu, search for **PuTTY** and then choose **Open**).
2. In the **Category** pane, choose **Session** and complete the following fields:
 - a. In the **Host Name** box, do one of the following:
 - (Public DNS) To connect using your instance's public DNS name, enter *instance-user-name@instance-public-dns-name*.
 - (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter *instance-user-name@instance-IPv6-address*.
 - b. Ensure that the **Port** value is 22.
 - c. Under **Connection type**, select **SSH**.

For information about how to get the username for your instance, and the public DNS name or IPv6 address of your instance, see [Get information about your instance](#).

3. (Optional) You can configure PuTTY to automatically send 'keepalive' data at regular intervals to keep the session active. This is useful to avoid disconnecting from your instance due to session inactivity. In the **Category** pane, choose **Connection**, and then enter the required interval in **Seconds between keepalives**. For example, if your session disconnects after 10 minutes of inactivity, enter 180 to configure PuTTY to send keepalive data every 3 minutes.
4. In the **Category** pane, expand **Connection**, **SSH**, and **Auth**. Choose **Credentials**.
5. Next to **Private key file for authentication**, choose **Browse**. In the **Select private key file** dialog box, select the .ppk file that you generated for your key pair. You can either double-click the file or choose **Open** in the **Select private key file** dialog box.
6. (Optional) If you plan to connect to this instance again after this session, you can save the session information for future use. In the **Category** pane, choose **Session**. Enter a name for the session in **Saved Sessions**, and then choose **Save**.
7. To connect to the instance, choose **Open**.
8. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host to which you are connecting.

- a. (Optional) Verify that the fingerprint in the security alert dialog box matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
- b. Choose **Accept**. A window opens and you are connected to your instance.

 **Note**

If you specified a passphrase when you converted your private key to the PuTTY format, you must provide that passphrase when you log in to the instance.

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

Transfer files to your Linux instance using the PuTTY Secure Copy client

The PuTTY Secure Copy client (PSCP) is a command line tool that you can use to transfer files between your Windows computer and your Linux instance. If you prefer a graphical user interface (GUI), you can use an open source GUI tool named WinSCP. For more information, see [Transfer files to your Linux instance using WinSCP](#).

To use PSCP, you need the private key you generated in [Convert your private key using PuTTYgen](#). You also need the public DNS name of your Linux instance, or the IPv6 address if your instance has one.

The following example transfers the file `Sample_file.txt` from the `C:\` drive on a Windows computer to the `instance-user-name` home directory on an Amazon Linux instance. To transfer a file, use one of the following commands.

- (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
pscp -i C:\\path\\my-key-pair.ppk C:\\path\\Sample_file.txt instance-user-name@instance-public-dns-name:/home/instance-user-name/Sample_file.txt
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer a file using your instance's IPv6 address, enter the following command. The IPv6 address must be enclosed in square brackets ([]).

```
pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt instance-user-name@[instance-  
IPv6-address]:/home/instance-user-name/Sample_file.txt
```

Transfer files to your Linux instance using WinSCP

WinSCP is a GUI-based file manager for Windows that you can use to upload and transfer files to a remote computer using the SFTP, SCP, FTP, and FTPS protocols. With WinSCP, you can drag and drop files from your Windows computer to your Linux instance or synchronize entire directory structures between the two systems.

Requirements

- You must have the private key that you generated in [Convert your private key using PuTTYgen](#).
- You must have the public DNS name of your Linux instance.
- Your Linux instance must have scp installed. For some operating systems, you install the openssh-clients package. For others, such as the Amazon ECS-optimized AMI, you install the scp package. Check the documentation for your Linux distribution.

To connect to your instance using WinSCP

1. Download and install WinSCP from <http://winscp.net/eng/download.php>. For most users, the default installation options are OK.
2. Start WinSCP.
3. At the **WinSCP login** screen, for **Host name**, enter one of the following:
 - (Public DNS or IPv4 address) To log in using your instance's public DNS name or public IPv4 address, enter the public DNS name or public IPv4 address for your instance.
 - (IPv6) Alternatively, if your instance has an IPv6 address, to log in using your instance's IPv6 address, enter the IPv6 address for your instance.
4. For **User name**, enter the default username for your AMI.
 - For AL2023, Amazon Linux 2, or the Amazon Linux AMI, the user name is ec2-user.
 - For a CentOS AMI, the user name is centos or ec2-user.
 - For a Debian AMI, the user name is admin.
 - For a Fedora AMI, the user name is fedora or ec2-user.

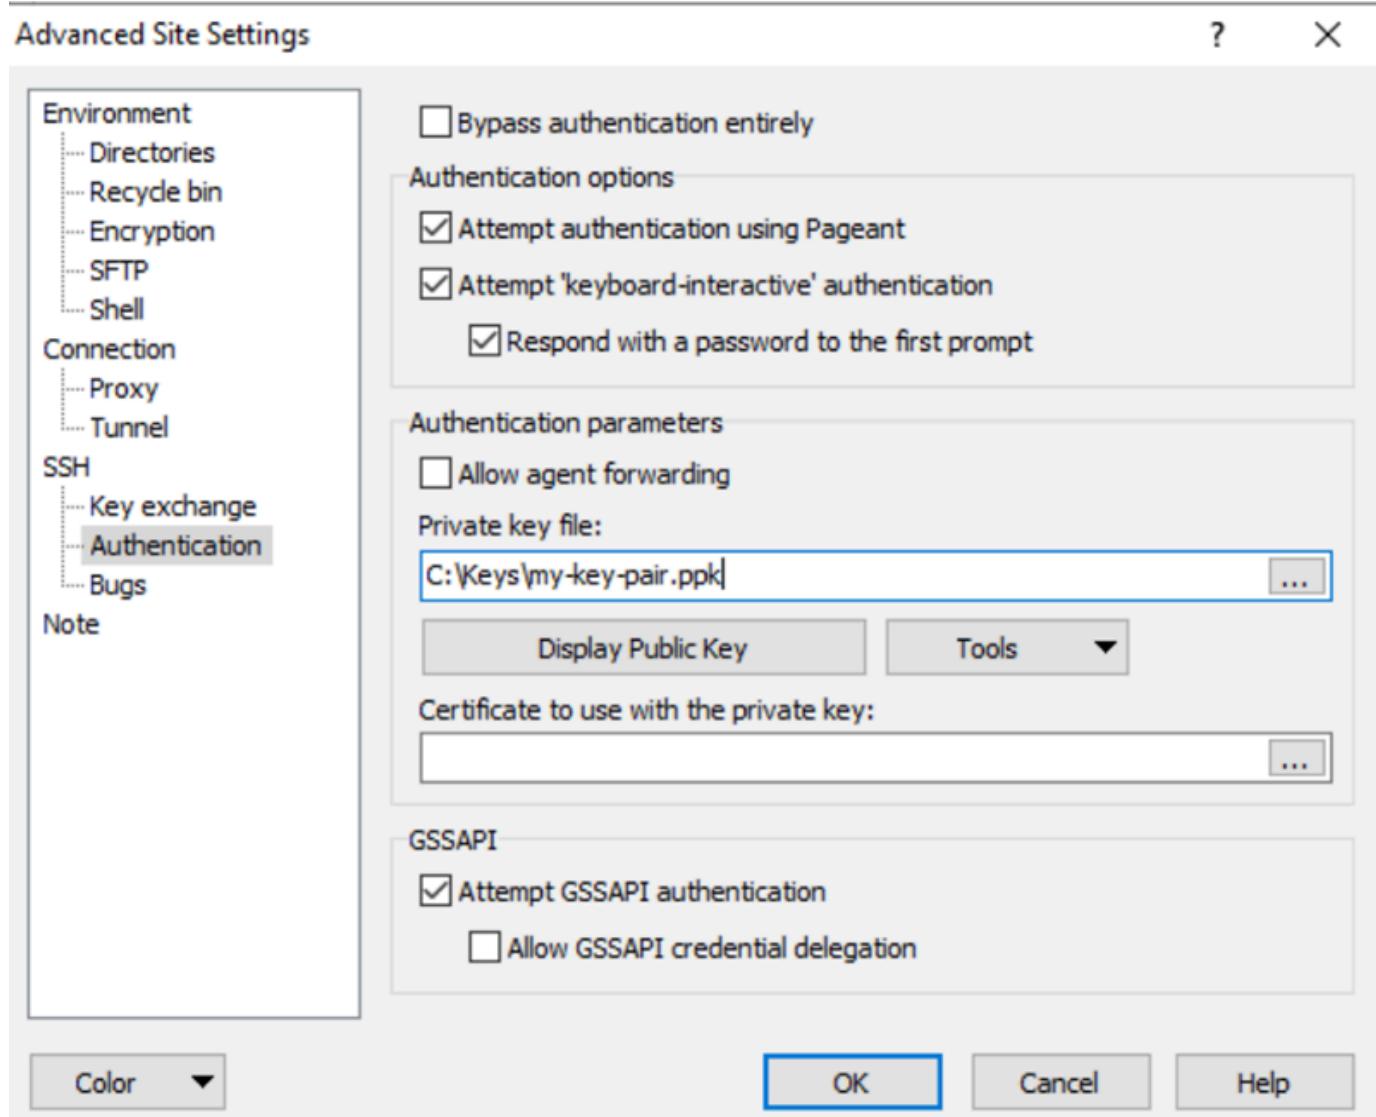

- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- For an Oracle AMI, the user name is `ec2-user`.
- For a Bitnami AMI, the user name is `bitnami`.

 **Note**

To find the default user name for other Linux distributions, check with the AMI provider.

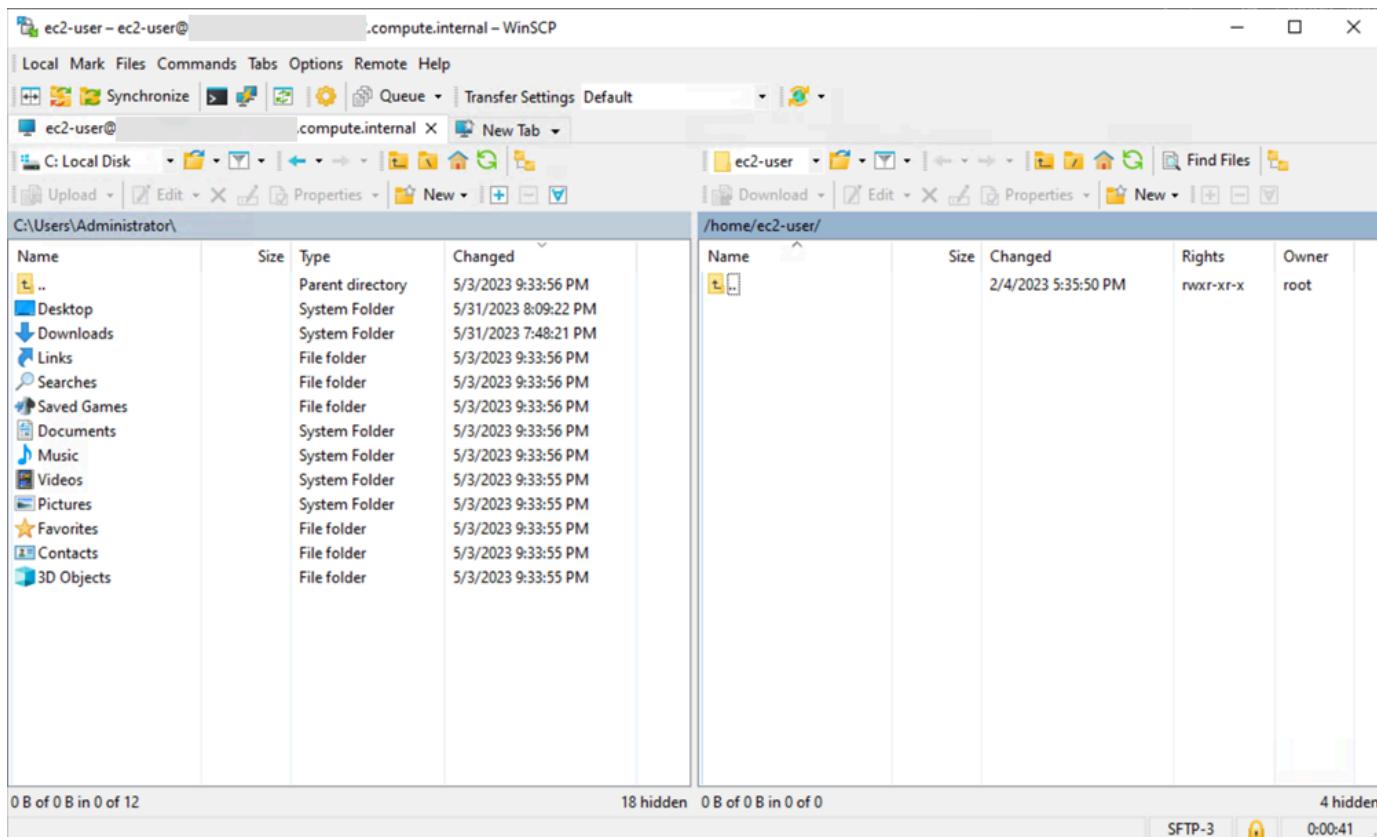

5. Specify the private key file for your instance.
 - a. Choose the **Advanced...** button.
 - b. Under SSH, choose **Authentication**.
 - c. Specify the path for your private key file, or choose the ... button to browse to the key pair file.
 - d. Choose **OK**.

Here is a screenshot from WinSCP version 6.1:

WinSCP requires a PuTTY private key file (.ppk). You can convert a .pem security key file to the .ppk format using PuTTYgen. For more information, see [Convert your private key using PuTTYgen](#).

6. (Optional) In the left panel, choose **Directories**. For **Remote directory**, enter the path for the directory to which to add files. To open the advanced site settings for newer versions of WinSCP, choose **Advanced**. To find the **Remote directory** setting, under **Environment**, choose **Directories**.
7. Choose **Login**. To add the host fingerprint to the host cache, choose **Yes**.

- After the connection is established, in the connection window your Linux instance is on the right and your local machine is on the left. You can drag and drop files between the remote file system and your local machine. For more information on WinSCP, see the project documentation at <http://winscp.net/eng/docs/start>.

If you receive an error that you cannot run SCP to start the transfer, verify that you installed `scp` on the Linux instance.

Connect to your Linux instance from Windows with Windows Subsystem for Linux (WSL)

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance with a Linux distribution on the Windows Subsystem for Linux (WSL). WSL is a free download and enables you to run native Linux command line tools directly on Windows, alongside your traditional Windows desktop, without the overhead of a virtual machine.

By installing WSL, you can use a native Linux environment to connect to your Linux EC2 instances instead of using PuTTY or PuTTYgen. The Linux environment makes it easier to connect to your

Linux instances because it comes with a native SSH client that you can use to connect to your Linux instances and change the permissions of the .pem key file. The Amazon EC2 console provides the SSH command for connecting to the Linux instance, and you can get verbose output from the SSH command for troubleshooting. For more information, see the [Windows Subsystem for Linux Documentation](#).

Note

After you've installed the WSL, all the prerequisites and steps are the same as those described in [Connect to your Linux instance from Linux or macOS using SSH](#), and the experience is just like using native Linux.

If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

Contents

- [Prerequisites](#)
- [Connect to your Linux instance using WSL](#)
- [Transfer files to Linux instances from Linux using SCP](#)
- [Uninstall WSL](#)

Prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the **Instances** page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see [Get information about your instance](#).

Install the Windows Subsystem for Linux (WSL) and a Linux distribution on your local computer

Install the WSL and a Linux distribution using the instructions in the [Windows 10 Installation Guide](#). The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

Copy the private key from Windows to WSL

In a WSL terminal window, copy the . pem file (for the key pair that you specified when you launched the instance) from Windows to WSL. Note the fully-qualified path to the . pem file on WSL to use when connecting to your instance. For information about how to specify the path to your Windows hard drive, see [How do I access my C drive?](#). For more information about key pairs and Windows instances, see [Amazon EC2 key pairs and Windows instances](#).

```
cp /mnt/<Windows drive letter>/path/my-key-pair.pem ~/WSL-path/my-key-pair.pem
```

Connect to your Linux instance using WSL

Use the following procedure to connect to your Linux instance using the Windows Subsystem for Linux (WSL). If you receive an error while attempting to connect to your instance, see [Troubleshoot connecting to your instance](#).

To connect to your instance using SSH

1. In a terminal window, use the **ssh** command to connect to the instance. You specify the path and file name of the private key (. pem), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set permissions](#) and [Get information about your instance](#). To connect to your instance, use one of the following commands.
 - (Public DNS) To connect using your instance's public DNS name, enter the following command.

```
ssh -i /path/key-pair-name.pem instance-user-name@my-instance-public-dns-name
```

- (IPv6) Alternatively, if your instance has an IPv6 address, you can connect to the instance using its IPv6 address. Specify the **ssh** command with the path to the private key (.pem) file, the appropriate user name, and the IPv6 address.

```
ssh -i /path/key-pair-name.pem instance-user-name@my-instance-IPv6-address
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.  
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.  
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint](#). If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.
3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)  
to the list of known hosts.
```

Transfer files to Linux instances from Linux using SCP

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- **Verify the general prerequisites for transferring files to your instance.**

Before you transfer files between your local machine and your instance, take the following actions to ensure that you have all of the information you need.

- [Get information about your instance](#)
- [Locate the private key and set permissions](#)
- [\(Optional\) Get the instance fingerprint](#)
- **Install an SCP client**

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see <https://www.openssh.com>.

The following procedure steps you through using SCP to transfer a file. If you've already connected to the instance with SSH and have verified its fingerprints, you can start with the step that contains the SCP command (step 4).

To use SCP to transfer a file

- Transfer a file to your instance using the instance's public DNS name. For example, if the name of the private key file is `key-pair-name`, the file to transfer is `SampleFile.txt`, the user name is `instance-user-name`, and the public DNS name of the instance is `my-instance-public-dns-name` or the IPv6 address is `my-instance-IPv6-address`, use one of the following commands to copy the file to the `instance-user-name` home directory.
 - (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
scp -i /path/key-pair-name.pem /path/SampleFile.txt instance-user-name@my-instance-public-dns-name:~
```

- (IPv6) Alternatively, if your instance has an IPv6 address, you can transfer a file using the instance's IPv6 address. The IPv6 address must be enclosed in square brackets ([]), which must be escaped (\).

```
scp -i /path/key-pair-name.pem /path/SampleFile.txt instance-user-name@[my-instance-IPv6-address]:~
```

You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.  
RSA key fingerprint is 1f:51:ae:28:bf:89:e9:d8:1f:25:5d:37:2d:7d:b8:ca:9f:f5:f1:6f.  
Are you sure you want to continue connecting (yes/no)?
```

- (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in [\(Optional\) Get the instance fingerprint](#). If these fingerprints don't

match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA)
to the list of known hosts.
Sending file modes: C0644 20 SampleFile.txt
Sink: C0644 20 SampleFile.txt
SampleFile.txt                                         100%   20      0.0KB/s  00:00
```

If you receive a "bash: scp: command not found" error, you must first install **scp** on your Linux instance. For some operating systems, this is located in the **openssh-clients** package. For Amazon Linux variants, such as the Amazon ECS-optimized AMI, use the following command to install **scp**:

```
[ec2-user ~]$ sudo yum install -y openssh-clients
```

4. To transfer files in the other direction (from your Amazon EC2 instance to your local computer), reverse the order of the host parameters. For example, to transfer the **SampleFile.txt** file from your EC2 instance back to the home directory on your local computer as **SampleFile2.txt**, use one of the following commands on your local computer.
 - (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

```
scp -i /path/key-pair-name.pem instance-user-
name@ec2-198-51-100-1.compute-1.amazonaws.com:~/SampleFile.txt ~/
SampleFile2.txt
```

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer files in the other direction using the instance's IPv6 address, enter the following command.

```
scp -i /path/key-pair-name.pem instance-user-name@
\[2001:db8:1234:1a00:9691:9503:25ad:1761\]:~/SampleFile.txt ~/SampleFile2.txt
```

Connect to your Linux instance with EC2 Instance Connect

Amazon EC2 Instance Connect provides a simple and secure way to connect to your Linux instances with Secure Shell (SSH). With EC2 Instance Connect, you use AWS Identity and Access Management (IAM) [policies](#) and [principals](#) to control SSH access to your instances, removing the need to share and manage SSH keys. All connection requests using EC2 Instance Connect are [logged to AWS CloudTrail so that you can audit connection requests](#).

You can use EC2 Instance Connect to connect to your instances using the Amazon EC2 console or an SSH client of your choice.

When you connect to an instance using EC2 Instance Connect, the Instance Connect API pushes an SSH public key to the [instance metadata](#) where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata. The SSH daemon uses `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, which are configured when Instance Connect is installed, to look up the public key from the instance metadata for authentication, and connects you to the instance.

You can use EC2 Instance Connect to connect to instances that have public or private IP addresses. For more information, see [Connect using EC2 Instance Connect](#).

For a blog post that discusses how to improve the security of your bastion hosts using EC2 Instance Connect, see [Securing your bastion hosts with Amazon EC2 Instance Connect](#).

Tip

EC2 Instance Connect is one of the options to connect to your Linux instance. For other options, see [Connect to your Linux instance](#). To connect to a Windows instance, see [Connect to your Windows instance](#).

Prerequisites

The following are the prerequisites for installing EC2 Instance Connect and for using EC2 Instance Connect to connect to an instance:

- [AWS Regions](#)
- [Local Zones](#)
- [AMIs](#)
- [Install EC2 Instance Connect](#)
- [IPv4 address](#)
- [Network access](#)
- [Security group rule](#)
- [Grant permissions](#)
- [Local computer setup](#)
- [Username](#)

AWS Regions

Supported in all AWS Regions except Canada West (Calgary).

Local Zones

Not supported.

AMIs

EC2 Instance Connect comes preinstalled on the following AMIs:

- AL2023
- Amazon Linux 2 2.0.20190618 or later
- macOS Sonoma 14.2.1 or later

- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

EC2 Instance Connect is not preinstalled on the following AMIs, but you can install it on instances that are launched using the following AMIs:

- Amazon Linux 2 prior to version 2.0.20190618
- CentOS Stream 8 and 9
- macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2
- Red Hat Enterprise Linux (RHEL) 8 and 9
- Ubuntu 16.04 or 18.04

Install EC2 Instance Connect

To use EC2 Instance Connect to connect to an instance, the instance must have EC2 Instance Connect installed. You can either launch the instance using an AMI that comes preinstalled with EC2 Instance Connect, or you can install EC2 Instance Connect on instances that are launched with supported AMIs. For the supported AMIs, see the preceding section. For the installation instructions, see [Install EC2 Instance Connect on your EC2 instances](#).

IPv4 address

Your instance must have an IPv4 address (either private or public). EC2 Instance Connect does not support connecting using an IPv6 address.

Network access

Instances can be configured to allow users to connect to your instance over the internet or through the instance's private IP address. Depending on how your users will connect to your instance using EC2 Instance Connect, you must configure the following network access:

- If your users will connect to your instance over the internet, then your instance must have a public IP address and be in a public subnet. For more information, see [Enable internet access](#) in the *Amazon VPC User Guide*.
- If your users will connect to your instance through the instance's private IP address, then you must establish private network connectivity to your VPC, such as by using AWS Direct Connect,

AWS Site-to-Site VPN, or VPC peering, so that your users can reach the instance's private IP address.

If your instance does not have a public IPv4 address and you prefer not to configure the network access as described above, you can consider EC2 Instance Connect Endpoint as an alternative to EC2 Instance Connect. EC2 Instance Connect Endpoint allows you to connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address. For more information, see [Connect to your Linux instance using the Amazon EC2 console](#).

Security group rule

Ensure that the security group associated with your instance [allows inbound SSH traffic](#) on port 22 from your IP address or from your network. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard allows incoming SSH traffic by default. For more information, see [Authorize inbound traffic for your Linux instances](#).

EC2 Instance Connect uses specific IP address ranges for browser-based SSH connections to your instance (when users use the Amazon EC2 console to connect to an instance). If your users will use the Amazon EC2 console to connect to an instance, ensure that the security group associated with your instance allows inbound SSH traffic from the IP address range for EC2_INSTANCE_CONNECT. To identify the address range, download the JSON file provided by AWS and filter for the subset for EC2 Instance Connect, using EC2_INSTANCE_CONNECT as the service value. These IP address ranges differ between AWS Regions. For more information about downloading the JSON file and filtering by service, see [AWS IP address ranges](#) in the *Amazon VPC User Guide*.

Grant permissions

You must grant the required permissions to every IAM user who will use EC2 Instance Connect to connect to an instance. For more information, see [Grant IAM permissions for EC2 Instance Connect](#).

Local computer setup

If your users will connect using SSH, they must ensure that their local computer has an SSH client.

A user's local computer most likely has an SSH client installed by default. They can check for an SSH client by typing **ssh** at the command line. If their local computer doesn't recognize the command, they can install an SSH client. For information about installing an SSH client on Linux or macOS X, see <http://www.openssh.com>. For information about installing an SSH client on Windows 10, see [OpenSSH in Windows](#).

There is no need to install an SSH client on a local computer if your users only use the Amazon EC2 console to connect to an instance.

Username

When using EC2 Instance Connect to connect to an instance, the username must meet the following prerequisites:

- First character: Must be a letter (A-Z, a-z), a digit (0-9), or an underscore (_)
- Subsequent characters: Can be letters (A-Z, a-z), digits (0-9), or the following characters: @ . _ -
- Minimum length: 1 character
- Maximum length: 31 characters

Grant IAM permissions for EC2 Instance Connect

To connect to an instance using EC2 Instance Connect, you must create an IAM policy that grants your users permissions for the following actions and condition:

- `ec2-instance-connect:SendSSHPublicKey` action – Grants permission to push the public key to an instance.
- `ec2:osuser` condition – Specifies the name of the OS user that can push the public key to an instance. Use the default user name for the AMI that you used to launch the instance. The default user name for AL2023 and Amazon Linux 2 is `ec2-user`, and for Ubuntu it's `ubuntu`.
- `ec2:DescribeInstances` action – Required when using the EC2 console because the wrapper calls this action. Users might already have permission to call this action from another policy.

Consider restricting access to specific EC2 instances. Otherwise, all IAM principals with permission for the `ec2-instance-connect:SendSSHPublicKey` action can connect to all EC2 instances. You can restrict access by specifying resource ARNs or by using resource tags as [condition keys](#).

For more information, see [Actions, resources, and condition keys for Amazon EC2 Instance Connect](#).

For information about creating IAM policies, see [Creating IAM policies](#) in the *IAM User Guide*.

Allow users to connect to specific instances

The following IAM policy grants permission to connect to specific instances, identified by their resource ARNs.

In the following example IAM policy, the following actions and condition are specified:

- The `ec2-instance-connect:SendSSHPublicKey` action grants users permission to connect to two instances, specified by the resource ARNs. To grant users permission to connect to *all* EC2 instances, replace the resource ARNs with the `*` wildcard.
- The `ec2:osuser` condition grants permission to connect to the instances only if the `ami-username` is specified when connecting.
- The `ec2:DescribeInstances` action is specified to grant permission to users who will use the console to connect to your instances. If your users will only use an SSH client to connect to your instances, you can omit `ec2:DescribeInstances`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the Resource element.

    "Statement": [  
        {"Effect": "Allow",  
         "Action": "ec2-instance-connect:SendSSHPublicKey",  
         "Resource": [  
             "arn:aws:ec2:region:account-id:instance/i-1234567890abcdef0",  
             "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"  
         ],  
         "Condition": {  
             "StringEquals": {  
                 "ec2:osuser": "ami-username"

         }  
     },  
     {  
         "Effect": "Allow",  
         "Action": "ec2:DescribeInstances",  
         "Resource": "*"  
     }  
    ]  
}
```

Allow users to connect to instances with specific tags

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. You can use resource tags to control

access to an instance. For more information about using tags to control access to your AWS resources, see [Controlling access to AWS resources](#) in the *IAM User Guide*.

In the following example IAM policy, the `ec2-instance-connect:SendSSHPublicKey` action grants users permission to connect to any instance (indicated by the `*` wildcard in the resource ARN) on condition that the instance has a resource tag with `key=tag-key` and `value=tag-value`.

The `ec2:DescribeInstances` action is specified to grant permission to users who will use the console to connect to your instances. If your users will only use an SSH client to connect to your instances, you can omit `ec2:DescribeInstances`. Note that the `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the Resource element.

```

    "Statement": [{  
        "Effect": "Allow",  
        "Action": "ec2-instance-connect:SendSSHPublicKey",  
        "Resource": "arn:aws:ec2:region:account-id:instance/*",  
        "Condition": {  
            "StringEquals": {  
                "aws:ResourceTag/tag-key": "tag-value"  
            }  
        }  
    },  
    {  
        "Effect": "Allow",  
        "Action": "ec2:DescribeInstances",  
        "Resource": "*"  
    }

```

Install EC2 Instance Connect on your EC2 instances

To connect to an instance using EC2 Instance Connect, the instance must have EC2 Instance Connect installed.

The following AMIs come preinstalled with EC2 Instance Connect:

- AL2023

- Amazon Linux 2 2.0.20190618 or later
- macOS Sonoma 14.2.1 or later
- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

If your instance was launched with one of the AMIs in the preceding list, you can skip this procedure.

 **Note**

If you configured the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` settings for SSH authentication, the EC2 Instance Connect installation will not update them. As a result, you cannot use EC2 Instance Connect.

Prerequisites for installing EC2 Instance Connect

- **Launch the instance with one of the following supported AMIs:**

Amazon Linux 2 prior to version 2.0.20190618

CentOS Stream 8 and 9

macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2

Red Hat Enterprise Linux (RHEL) 8 and 9

Ubuntu 16.04 and 18.04

If your instance was launched with a later version of Amazon Linux 2, macOS Sonoma, Ventura, or Monterey, or Ubuntu, it comes preinstalled with EC2 Instance Connect and you can skip this procedure.

- **Verify the general prerequisites for EC2 Instance Connect.**

For more information, see [Prerequisites](#).

- **Verify the prerequisites for connecting to your instance using an SSH client on your local machine.**

If your local machine is Linux or macOS, see [Connect to your Linux instance from Linux or macOS using SSH](#). If your local machine is Windows, see [Prerequisites](#).

For more information, see [SSH connection prerequisites](#).

- **Get the ID of the instance.**

You can get the ID of your instance using the Amazon EC2 console (from the **Instance ID** column). If you prefer, you can use the [describe-instances](#) (AWS CLI) or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) command.

- **Install an SSH client on your local computer.**

Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing **ssh** at the command line. If your local computer doesn't recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X, see <http://www.openssh.com>. For information about installing an SSH client on Windows 10, see [OpenSSH in Windows](#).

- **(Ubuntu) Install the AWS CLI on your instance.**

To install EC2 Instance Connect on an Ubuntu instance, you must use the AWS CLI on the instance. For more information about installing the AWS CLI, see [Installing the AWS CLI](#) in the [AWS Command Line Interface User Guide](#).

Install EC2 Instance Connect

Installing EC2 Instance Connect configures the SSH daemon on the instance.

Use one of the following procedures for installing EC2 Instance Connect depending on the operating system of your instance.

Amazon Linux 2

To install EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default user name of

the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is `ec2-user`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. Install the EC2 Instance Connect package on your instance.

```
[ec2-user ~]$ sudo yum install ec2-instance-connect
```

You should see three new scripts in the `/opt/aws/bin/` folder:

```
eic_curlAuthorizedKeys  
eic_parseAuthorizedKeys  
eic_runAuthorizedKeys
```

3. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_runAuthorizedKeys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_runAuthorizedKeys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

Note

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

CentOS

To install EC2 Instance Connect on an instance launched with CentOS

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For CentOS, the default user name is `centos` or `ec2-user`.

```
$ ssh -i my_ec2_private_key.pem centos@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session.

If you're not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:

```
$ export http_proxy=http://hostname:port
$ export https_proxy=https://hostname:port
```

- For an HTTPS proxy server, run the following commands:

```
$ export http_proxy=https://hostname:port
$ export https_proxy=https://hostname:port
```

3. Install the EC2 Instance Connect package on your instance by running the following commands.

The EC2 Instance Connect configuration files for CentOS are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for CentOS 8 and CentOS 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

Use the command block for your operating system and CPU architecture.

- CentOS 8

Intel/AMD (x86_64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-

[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-
connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-

[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-
connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

- CentOS 9

Intel/AMD (x86_64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
```

```
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm  
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm  
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

You should see the following new script in the /opt/aws/bin/ folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

- For CentOS 8:

```
[ec2-user ~]$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

- For CentOS 9:

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

 **Note**

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

macOS

To install EC2 Instance Connect on an instance launched with macOS

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For macOS instances, the default user name is `ec2-user`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. Update Homebrew using the following command. The update will list the software that Homebrew knows about. The EC2 Instance Connect package is provided via Homebrew on macOS instances. For more information, see [Update the operating system and software](#).

```
[ec2-user ~]$ brew update
```

3. Install the EC2 Instance Connect package on your instance. This will install the software and configure sshd to use it.

```
[ec2-user ~]$ brew install ec2-instance-connect
```

You should see the following new script in the /opt/aws/bin/ folder:

```
eic_runAuthorizedKeys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_runAuthorizedKeys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- AuthorizedKeysCommand sets the eic_runAuthorizedKeys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

 **Note**

If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

RHEL

To install EC2 Instance Connect on an instance launched with Red Hat Enterprise Linux (RHEL)

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For RHEL, the default user name is ec2-user or root.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. If you use an HTTP or HTTPS proxy, you must set the http_proxy or https_proxy environment variables in the current shell session.

If you're not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:

```
$ export http_proxy=http://hostname:port  
$ export https_proxy=https://hostname:port
```

- For an HTTPS proxy server, run the following commands:

```
$ export http_proxy=https://hostname:port  
$ export https_proxy=https://hostname:port
```

3. Install the EC2 Instance Connect package on your instance by running the following commands.

The EC2 Instance Connect configuration files for RHEL are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for RHEL 8 and RHEL 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

Use the command block for your operating system and CPU architecture.

- RHEL 8

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm  
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

ARM (AArch64)

```
[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
```

```
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect.rpm  
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_amd64/ec2-instance-connect-selinux.noarch.rpm -o /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm  
[ec2-user ~]$ sudo yum install -y /tmp/ec2-instance-connect/ec2-instance-connect.rpm /tmp/ec2-instance-connect/ec2-instance-connect-selinux.rpm
```

You should see the following new script in the /opt/aws/bin/ folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

- For RHEL 8:

```
[ec2-user ~]$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

- For RHEL 9:

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

Note

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

Ubuntu

To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and use the default user name of the AMI that you used to launch your instance. For an Ubuntu AMI, the user name is `ubuntu`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. (Optional) Ensure your instance has the latest Ubuntu AMI.

Run the following commands to update all the packages on your instance.

```
ubuntu:~$ sudo apt-get update
```

```
ubuntu:~$ sudo apt-get upgrade
```

3. Install the EC2 Instance Connect package on your instance.

```
ubuntu:~$ sudo apt-get install ec2-instance-connect
```

You should see three new scripts in the `/usr/share/ec2-instance-connect/` folder:

```
eic_curlAuthorizedKeys  
eic_parseAuthorizedKeys  
eic_runAuthorizedKeys
```

4. (Optional) Verify that Instance Connect was successfully installed on your instance.

```
ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_runAuthorizedKeys %  
%u %%f  
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_runAuthorizedKeys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

 **Note**

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

For more information about the EC2 Instance Connect package, see [aws/aws-ec2-instance-connect-config](#) on the GitHub website.

Connect using EC2 Instance Connect

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect.

Decide which connection option to use. The connection option to use depends on whether your instance has a public IPv4 address:

- Amazon EC2 console – To connect using the Amazon EC2 console, the instance must have a public IPv4 address.
- SSH client – If the instance does not have a public IP address, you can connect to the instance over a private network using an SSH client. For example, you can connect from within the same VPC or through a VPN connection, transit gateway, or AWS Direct Connect.

EC2 Instance Connect does not support connecting using an IPv6 address.

 **Tip**

EC2 Instance Connect is one of the options to connect to your Linux instance. For other options, see [Connect to your Linux instance](#). To connect to a Windows instance, see [Connect to your Windows instance](#).

Connection options for EC2 Instance Connect

- [Connect using the Amazon EC2 console](#)
- [Connect using your own key and SSH client](#)
- [Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI](#)
- [Troubleshoot](#)

Connect using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console by selecting the instance from the console and choosing to connect using EC2 Instance Connect. Instance Connect handles the permissions and provides a successful connection.

To connect using the Amazon EC2 console, the instance must have a public IPv4 address. Before connecting, be sure to review all the [prerequisites](#).

To connect to your instance using the browser-based client from the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. Choose **EC2 Instance Connect**.

5. Verify the user name and choose **Connect** to open a terminal window.

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

Requirements

- Requirements for key pairs
 - Supported types: RSA (OpenSSH and SSH2) and ED25519
 - Supported lengths: 2048 and 4096
 - For more information, see [Create a key pair using a third-party tool and import the public key to Amazon EC2](#).
- When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as [AWS Direct Connect](#), [AWS Site-to-Site VPN](#), or [VPC peering](#).

Before connecting, be sure to review all the [prerequisites](#).

To connect to your instance using your own key and any SSH client

1. (Optional) Generate new SSH private and public keys

You can generate new SSH private and public keys, `my_key` and `my_key.pub`, using the following command:

```
$ ssh-keygen -t rsa -f my_key
```

2. Push your SSH public key to the instance

Use the [send-ssh-public-key](#) command to push your SSH public key to the instance. If you launched your instance using AL2023 or Amazon Linux 2, the default user name for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default user name for the AMI is `ubuntu`.

The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`.

```
$ aws ec2-instance-connect send-ssh-public-key \
  --region us-west-2 \
  --availability-zone us-west-2b \
  --instance-id i-001234a4bf70dec41EXAMPLE \
  --instance-os-user ec2-user \
  --ssh-public-key file://my_key.pub
```

3. Connect to the instance using your private key

Use the `ssh` command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default user name for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the `ssh` config and the specified key are used for the connection.

```
$ ssh -o "IdentitiesOnly=yes" -i my_key ec2-
user@ec2-198-51-100-1.compute-1.amazonaws.com
```

Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI

If you know your instance ID, you can use Amazon EC2 Instance Connect to connect to your instance using an SSH client. If you don't specify a connection type, EC2 Instance Connect automatically tries to connect to your instance's public IPv4 address. If your instance doesn't have a public IPv4 address, EC2 Instance Connect then tries to connect to your instance's private IPv4 address through an [EC2 Instance Connect Endpoint](#). If your instance doesn't have a private IPv4 address or your VPC doesn't have an EC2 Instance Connect Endpoint, then EC2 Instance Connect tries to connect to your instance's IPv6 address.

Before you connect with this method, ensure that you have configured the AWS CLI, including the credentials that it uses, and that you're using the latest version of the AWS CLI. For more information, see [Installing or updating the latest version of the AWS CLI](#) and [Configuring the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Connection types

auto (default)

The CLI tries to connect using the instance's IP addresses in the following order and with the corresponding connection type:

- Public IPv4: direct
- Private IPv4: eice
- IPv6: direct

direct

The CLI tries to connect using the instance's IP addresses in the following order (it does not connect over an EC2 Instance Connect Endpoint):

- Public IPv4
- IPv6
- Private IPv4

eice

The CLI always uses the instance's private IPv4 address.

Note

In the future, we might change the behavior of the auto connection type. To ensure that your desired connection type is used, we recommend that you explicitly set the --connection-type to either direct or eice.

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the [instance metadata](#) where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata.

For more information about EC2 Instance Connect, see [Connect to your Linux instance with EC2 Instance Connect](#).

To connect to an instance using the instance ID

If you only know the instance ID, and want to let EC2 Instance Connect determine the connection type to use when connecting to your instance, use the `ec2-instance-connect` CLI and specify the `ssh` command and the instance ID.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example
```

To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you want to connect to your instance over an [EC2 Instance Connect Endpoint](#), use the preceding command and also specify the `--connection-type` parameter with the `eice` value.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --connection-type eice
```

To connect to an instance using the instance ID and your own private key file

If you want to connect to your instance over an EC2 Instance Connect Endpoint using your own private key, specify the instance ID and the path to the private key file. Do not include `file://` in the path; the following example will fail: `file:///path/to/key`.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --private-key-file /  
path/to/key.pem
```

Troubleshoot

If you receive an error while attempting to connect to your instance, see the following:

- [Troubleshoot connecting to your instance](#)
- [How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?](#)

Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your instance and uninstall the `ec2-instance-connect` package that is installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the

sshd configuration. If you modified the sshd configuration after installing EC2 Instance Connect, you must update it manually.

Amazon Linux

You can uninstall EC2 Instance Connect on AL2023 and Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

To uninstall EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the AL2023 or Amazon Linux 2 AMI, which is ec2-user.

For example, the following **ssh** command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the **yum** command.

```
[ec2-user ~]$ sudo yum remove ec2-instance-connect
```

Ubuntu

To uninstall EC2 Instance Connect on an instance launched with an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Ubuntu AMI, which is `ubuntu`.

For example, the following **ssh** command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

2. Uninstall the `ec2-instance-connect` package using the **apt-get** command.

```
ubuntu:~$ sudo apt-get remove ec2-instance-connect
```

Connect to your Linux instance with AWS Systems Manager Session Manager

Session Manager is a fully managed AWS Systems Manager capability that lets you manage your Amazon EC2 instances through an interactive one-click browser-based shell or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run bash commands as you would through any other connection type. For more information about Session Manager, see [AWS Systems Manager Session Manager](#) in the [AWS Systems Manager User Guide](#).

Prerequisites

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information and instructions, see [Setting up Session Manager](#).

To connect to a Linux instance using Session Manager with the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. Choose **Session Manager**.
5. Choose **Connect**.

Troubleshooting

If you receive an error that you're not authorized to perform one or more Systems Manager actions (`ssm:command-name`), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information, see [Sample IAM policies for Session Manager](#) in the [AWS Systems Manager User Guide](#).

Connect to your instances without requiring a public IPv4 address using EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint allows you to connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address.

How it works

First, you create an EC2 Instance Connect Endpoint in a [subnet](#) in your virtual private cloud (VPC). Then, when you want to connect to an instance, you specify the ID of the instance. You can optionally provide the EC2 Instance Connect Endpoint. The endpoint acts as a private tunnel to the instance.

Once you create an EC2 Instance Connect Endpoint in a subnet, you can use the endpoint to connect to any instance in any subnet in your VPC provided your VPC is configured to allow subnets to communicate.

Note

If you use an EC2 Instance Connect Endpoint in one subnet to connect to an instance in another subnet that is in a different Availability Zone, there is an [additional charge for data transfer](#) across Availability Zones.

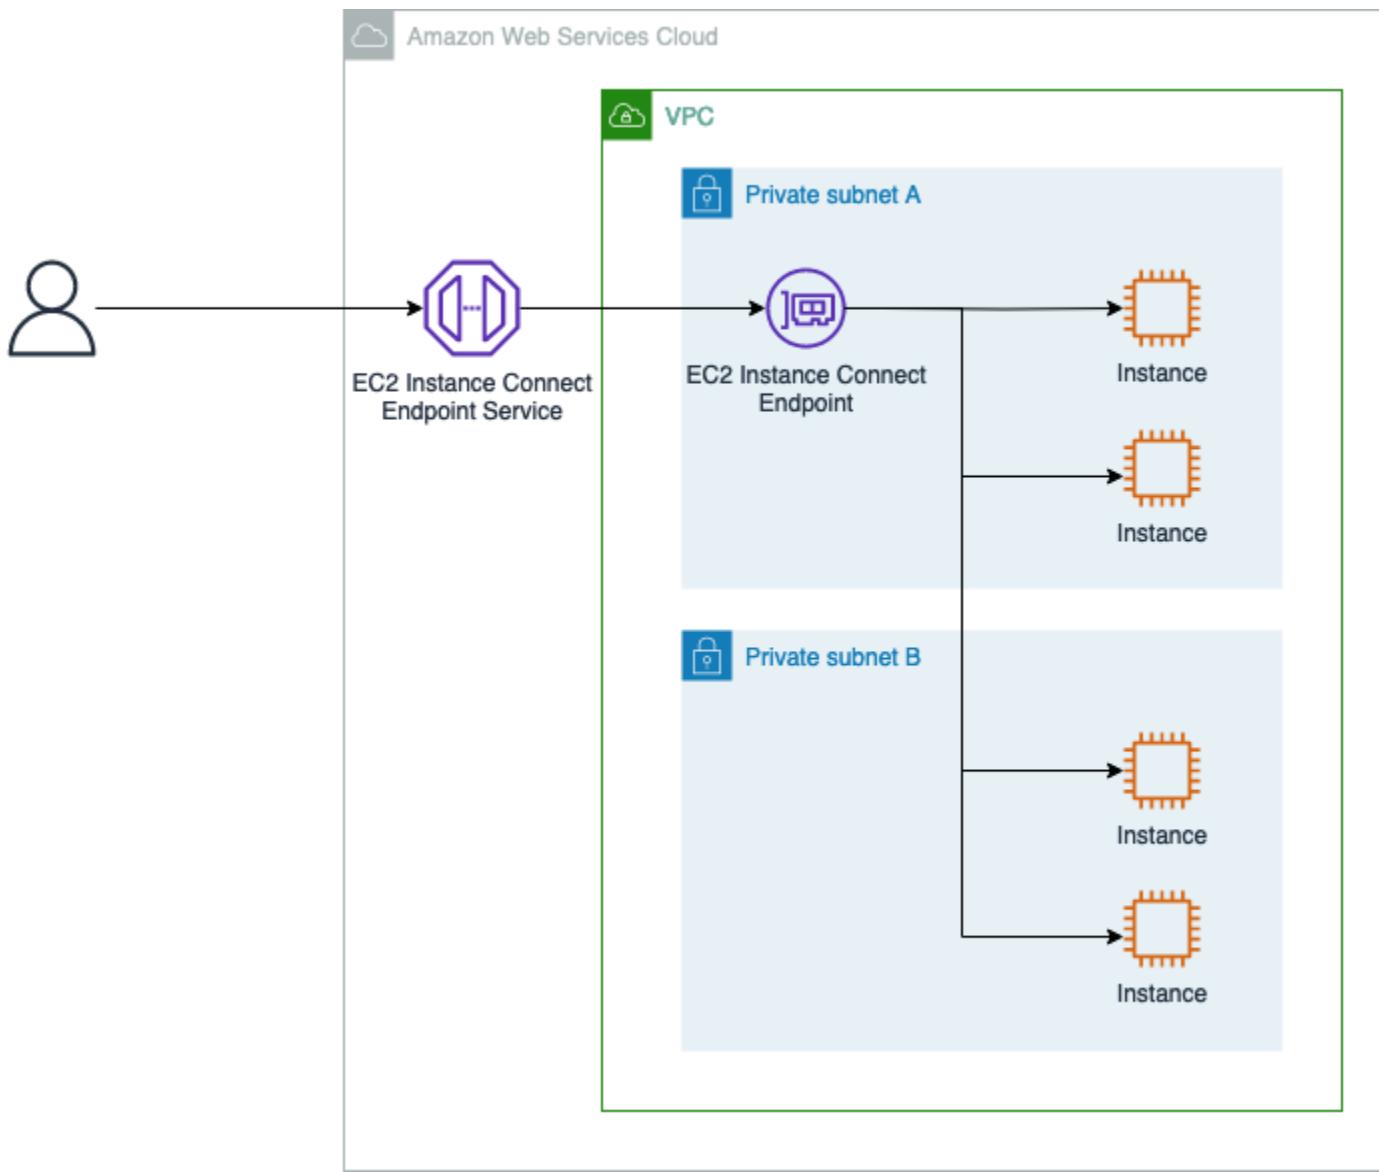

The following diagram shows a user from the internet connecting to their instances, which are located in private subnets in a VPC. The diagram illustrates the following key components:

- The **EC2 Instance Connect Endpoint Service** is an AWS service that allows the user to use the EC2 Instance Connect Endpoint to connect from the internet to their instances that are in private subnets.
- The **EC2 Instance Connect Endpoint** in Private subnet A acts as a private tunnel so that the user can connect to their instances that are in the private subnets.

Access to create and connect to EC2 Instance Connect Endpoints is controlled by [IAM permissions](#). You can [configure additional security group rules](#) on your instances to restrict inbound traffic. For example, you can use inbound rules on your instances to only allow traffic on management ports from the EC2 Instance Connect Endpoint.

- **Private subnet A** has an EC2 Instance Connect Endpoint, but **Private subnet B** does not. Based on your VPC configuration, if Private subnet A and Private subnet B are allowed to communicate,

then you can use the EC2 Instance Connect Endpoint in Private subnet A to connect to an instance in Private subnet B.

Benefits

EC2 Instance Connect Endpoint provides the following benefits:

- You can connect to your instances without requiring the instances to have a public IPv4 address. AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the **Public IPv4 Address** tab on the [Amazon VPC pricing page](#).

- You can connect to your instances from the internet without requiring your VPC to have an [internet gateway](#).
- You can control access to the creation and use of the EC2 Instance Connect Endpoints to connect to instances with [IAM policies and permissions](#).
- All attempts to connect to instances, both successful and unsuccessful, are logged to [CloudTrail](#).

Prerequisites

The following are the prerequisites for using EC2 Instance Connect Endpoint to connect to an instance:

- [AWS Regions](#)
- [AMIs](#)
- [IPv4 address](#)
- [Security groups](#)
- [Grant permissions](#)

AWS Regions

Supported in all AWS Regions except Canada West (Calgary).

AMIs

The supported AMIs are dependent on how you connect to your instance with EC2 Instance Connect Endpoint.

You can connect to your instance using one of the following methods: EC2 console, SSH, or RDP.

Console

If you use the EC2 console to connect to your instance using EC2 Instance Connect Endpoint, the instance must have EC2 Instance Connect installed.

EC2 Instance Connect comes preinstalled on the following AMIs:

- AL2023
- Amazon Linux 2 2.0.20190618 or later
- macOS Sonoma 14.2.1 or later
- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

EC2 Instance Connect is not preinstalled on the following AMIs, but you can install it on instances that are launched using the following AMIs:

- Amazon Linux 2 prior to version 2.0.20190618
- CentOS Stream 8 and 9
- macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2
- Red Hat Enterprise Linux (RHEL) 8 and 9
- Ubuntu 16.04 or 18.04

For the installation instructions, see [Install EC2 Instance Connect on your EC2 instances](#).

SSH

If you use SSH to connect to your instance using EC2 Instance Connect Endpoint, the supported AMIs are dependent on whether you use your own key pair or you want EC2 Instance Connect to handle the ephemeral key.

If you use your own key pair

You can use any Linux AMI.

If you want EC2 Instance Connect to handle the ephemeral key

The instance must have EC2 Instance Connect installed.

EC2 Instance Connect comes preinstalled on the following AMIs:

- AL2023
- Amazon Linux 2 2.0.20190618 or later
- macOS Sonoma 14.2.1 or later
- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

EC2 Instance Connect is not preinstalled on the following AMIs, but you can install it on instances that are launched using the following AMIs:

- Amazon Linux 2 prior to version 2.0.20190618
- CentOS Stream 8 and 9
- macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2
- Red Hat Enterprise Linux (RHEL) 8 and 9
- Ubuntu 16.04 or 18.04

For the installation instructions, see [Install EC2 Instance Connect on your EC2 instances](#).

RDP

If you use RDP to connect to your instance using EC2 Instance Connect Endpoint, you must use a Windows AMI.

IPv4 address

Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting using an IPv6 address.

Security groups

The EC2 Instance Connect Endpoint and the instance that you want to connect to are each assigned security groups. For the recommended way to configure the security group rules, see [Security groups for EC2 Instance Connect Endpoint](#).

Grant permissions

You must grant the required permissions to every IAM user who will use EC2 Instance Connect Endpoint to connect to an instance. For more information, see [Grant IAM permissions to use EC2 Instance Connect Endpoint](#).

Grant IAM permissions to use EC2 Instance Connect Endpoint

To create or use an EC2 Instance Connect Endpoint, you must create an IAM policy that grants your users permissions for the following:

- Create, describe, and delete EC2 Instance Connect Endpoints
- Use the `ec2-instance-connect:OpenTunnel` action to use EC2 Instance Connect Endpoint to connect to instances

For information about creating IAM policies, see [Creating IAM policies](#) in the *IAM User Guide*.

Example IAM policies for EC2 Instance Connect Endpoint

- [Allow users to create, describe, and delete EC2 Instance Connect Endpoints](#)
- [Allow users to use EC2 Instance Connect Endpoint to connect to instances](#)
- [Allow users to connect only from a specified source IP address range](#)

Allow users to create, describe, and delete EC2 Instance Connect Endpoints

To create an EC2 Instance Connect Endpoint, users require permissions for the following actions:

- `ec2:CreateInstanceConnectEndpoint`
- `ec2:CreateNetworkInterface`
- `ec2:CreateTags`
- `iam:CreateServiceLinkedRole`

To describe and delete EC2 Instance Connect Endpoints, users require permissions for the following actions:

- `ec2:DescribeInstanceConnectEndpoints`
- `ec2>DeleteInstanceConnectEndpoint`

You can create a policy that grants permission to create, describe, and delete EC2 Instance Connect Endpoints in all subnets. Alternatively, you can restrict actions for specified subnets only by specifying the subnet ARNs as the allowed Resource or by using the `ec2:SubnetID` condition key. You can also use the `aws:ResourceTag` condition key to explicitly allow or deny endpoint creation with certain tags. For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Example IAM policy

In the following example IAM policy, the Resource section grants permission to create and delete endpoints in all subnets, specified by the asterisk (*). The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

```

            "ec2:CreateInstanceConnectEndpoint",  
            "ec2:DeleteInstanceConnectEndpoint",  
            "ec2>CreateNetworkInterface",  
            "ec2>CreateTags",  
            "iam>CreateServiceLinkedRole"  
        ],  
        "Effect": "Allow",  
        "Resource": "arn:aws:ec2:region:account-id:subnet/*"  
    },  
    {  
        "Action": [

        "ec2:DescribeInstanceConnectEndpoints"  
    ],  
    "Effect": "Allow",  
    "Resource": "*"  
}  
]  
}
```

Allow users to use EC2 Instance Connect Endpoint to connect to instances

The `ec2-instance-connect:OpenTunnel` action grants permission to establish a TCP connection to an instance to connect over the EC2 Instance Connect Endpoint. You can specify the EC2 Instance Connect Endpoint to use. Alternatively, a Resource with an asterisk (*) allows users to use any available EC2 Instance Connect Endpoint. You can also restrict access to instances based on the presence or absence of resource tags as condition keys.

Conditions

- `ec2-instance-connect:remotePort` – Specifies the port on the instance that can be used to establish a TCP connection. When this condition key is used, attempting to connect to an instance on any other port other than the port specified in the policy results in a failure.
- `ec2-instance-connect:privateIpAddress` – Specifies the destination private IP address associated with the instance that you want to establish a TCP connection with. You can specify a single IP address, such as `10.0.0.1/32`, or a range of IPs through CIDRs, such as `10.0.1.0/28`. When this condition key is used, attempting to connect to an instance with a different private IP address or outside the CIDR range results in a failure.
- `ec2-instance-connect:maxTunnelDuration` – Specifies the maximum duration for an established TCP connection. The unit is seconds and the duration ranges from a minimum of 1 second to a maximum of 3,600 seconds (1 hour). If the condition is not specified, the default duration is set to 3,600 seconds (1 hour). Attempting to connect to an instance for longer than the specified duration in the IAM policy or for longer than the default maximum results in a failure. The connection is disconnected after the specified duration.

If `maxTunnelDuration` is specified in the IAM policy and the value specified is less than 3,600 seconds (the default), then you must specify `--max-tunnel-duration` in the command when

connecting to an instance. For information about how to connect to an instance, see [Connect using EC2 Instance Connect Endpoint to a Linux instance](#).

A user can also be granted access to establish connections to instances based on the presence of resource tags on the EC2 Instance Connect Endpoint. For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

The `ec2-instance-connect:SendSSHPublicKey` action grants permission to push the public key to an instance. The `ec2:osuser` condition specifies the name of the OS (operating system) user that can push the public key to an instance. Use the [default username for the AMI](#) that you used to launch the instance. For more information, see [Grant IAM permissions for EC2 Instance Connect](#).

Example IAM policy

The following example IAM policy allows an IAM principal to connect to an instance using only the specified EC2 Instance Connect Endpoint, identified by the specified endpoint ID `eice-123456789abcdef`. The connection is successfully established only if all the conditions are satisfied, for example, if the SSH connection is established on port 22 of the instance, if the private IP address of the instance lies within the range of `10.0.1.0/31` (between `10.0.1.0` and `10.0.1.1`), and the `maxTunnelDuration` is less than or equal to 3600 seconds. The connection is disconnected after 3600 seconds (1 hour).

The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

Allow users to connect only from a specified source IP address range

The following example IAM policy allows an IAM principal to connect to an instance on condition they are connecting from an IP address within the IP address range specified in the policy. If the IAM principal calls OpenTunnel from an IP address not within 192.0.2.0/24 (the example IP address range in this policy), the response will be Access Denied. For more information, see [aws:SourceIp](#) in the *IAM User Guide*.

Security groups for EC2 Instance Connect Endpoint

The EC2 Instance Connect Endpoint and the instance that you want to connect to are each assigned security groups. We recommend that you configure the [security group rules](#) in the way described in this topic.

Topics

- [EC2 Instance Connect Endpoint security group rule](#)
- [Instance security group rule](#)
- [Example](#)

EC2 Instance Connect Endpoint security group rule

When you create the EC2 Instance Connect Endpoint, if you don't specify a security group, the default security group for the VPC is assigned. The default outbound rule allows all outbound traffic to all destinations. To limit connectivity to only the instances in the VPC, we recommend that the outbound rule only allows traffic to the specified destination.

Recommended outbound rule

- Allow outbound traffic to the specified destination (a security group or the VPC CIDR, depending on your security needs).

Instance security group rule

The instance needs at least one inbound rule to allow traffic from the EC2 Instance Connect Endpoint.

Recommended inbound rules

Specify one or more of the following rules, depending on your security needs and whether client IP preservation is enabled:

- Allow inbound traffic from the EC2 Instance Connect Endpoint security group.
- Allow inbound traffic from the client IP address.
- Allow inbound traffic from the VPC CIDR so that any instances in the VPC can send traffic to the destination instance.

The inbound rule that you specify is dependent on whether the EC2 Instance Connect Endpoint is configured to enable client IP preservation. Not all instance types support client IP preservation.

For more information, see [Limitations](#).

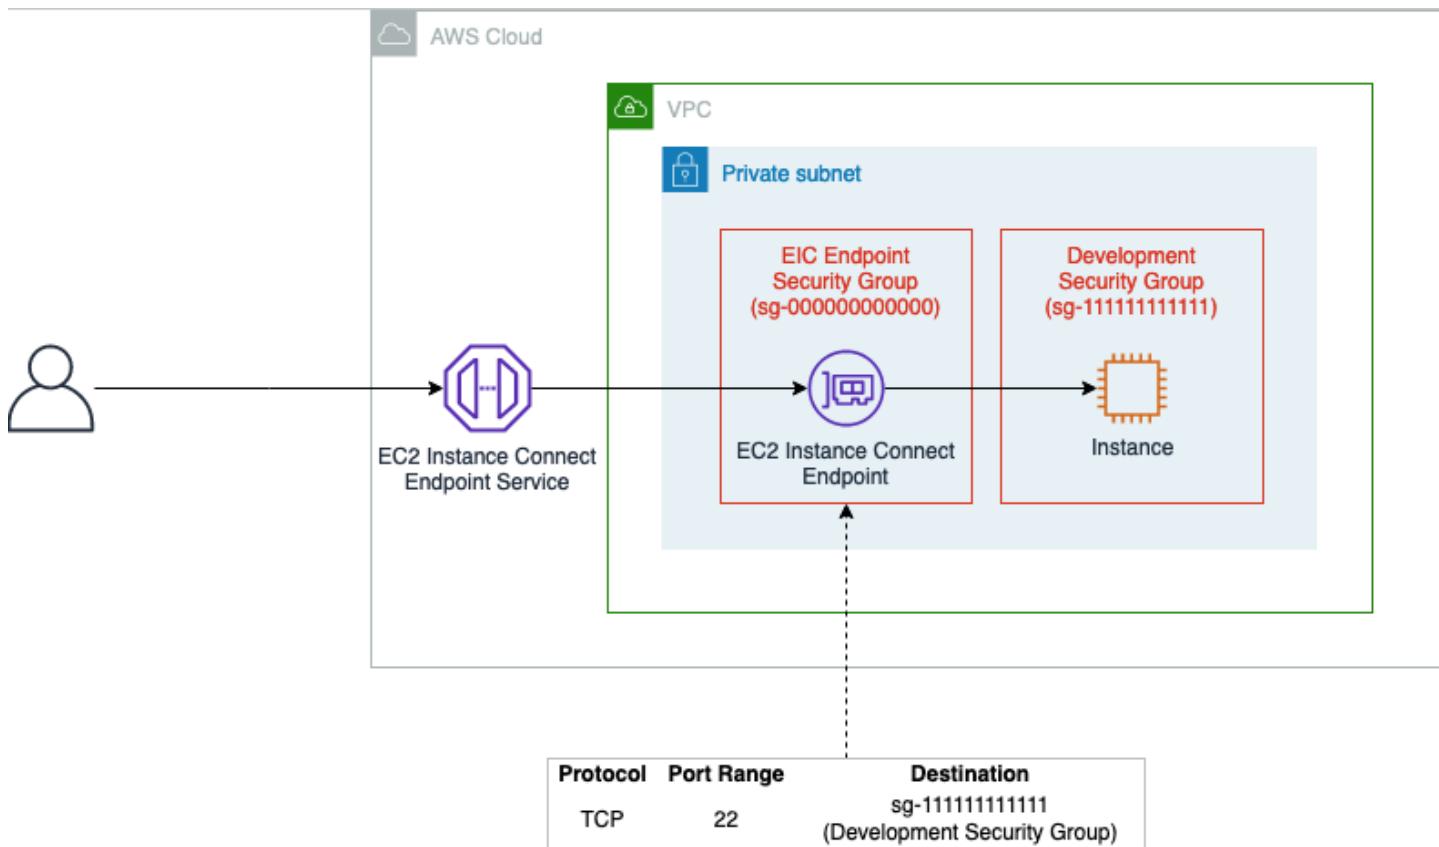

The following table lists the security group rules for the instance that can be configured depending on the value set for `preserveClientIp`.

Client IP preservation	Supported security group rules for the instance
<code>preserveClientIp=false</code>	<ul style="list-style-type: none">Allow inbound traffic from the EC2 Instance Connect Endpoint security group.

Client IP preservation	Supported security group rules for the instance
preserveClientIp=true	<ul style="list-style-type: none">Allow inbound traffic from the VPC CIDR.Allow inbound traffic from the EC2 Instance Connect Endpoint security group.Allow inbound traffic from the client IP address.

Example

In the following image, the EC2 Instance Connect Endpoint is assigned the security group **EIC Endpoint Security Group**. The **EIC Endpoint Security Group** has one outbound rule that allows TCP traffic to the **Development Security Group**. This configuration means that the EC2 Instance Connect Endpoint can only send traffic to instances that are assigned the **Development Security Group**. In the image, the instance is assigned the **Development Security Group**, which means that, in this example, the EC2 Instance Connect Endpoint can send TCP traffic to the instance.

Create an EC2 Instance Connect Endpoint

You can create an EC2 Instance Connect Endpoint in a subnet in your VPC. You can then use the EC2 Instance Connect Endpoint to connect to instances in your VPC without requiring the instances to have a public IPv4 address.

EC2 Instance Connect Endpoint supports client IP preservation. You can configure the EC2 Instance Connect Endpoint to use your client's IP address as the source (`preserveClientIp` parameter is `true`) when connecting to an instance.

When you create an EC2 Instance Connect Endpoint, a service-linked role is automatically created for the Amazon EC2 service in AWS Identity and Access Management (IAM). Amazon EC2 uses the service-linked role to provision network interfaces in your account, which are required when creating EC2 Instance Connect Endpoints. For more information, see [Service-linked role for EC2 Instance Connect Endpoint](#).

Note

You can't modify an EC2 Instance Connect Endpoint after you've created it. If you want different endpoint settings, you'll need to delete the EC2 Instance Connect Endpoint and create a new one with the desired settings.

Prerequisites

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see [Allow users to create, describe, and delete EC2 Instance Connect Endpoints](#).

Create an EC2 Instance Connect Endpoint

Use one of the following methods to create an EC2 Instance Connect Endpoint.

Console

To create an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**, and then complete the settings in the dialog box, as follows:

Endpoint settings

Name tag - optional
Creates a tag with a key of 'Name' and a value that you specify.

my-endpoint

Service category
Select the service category

AWS services
Services provided by Amazon

PrivateLink Ready partner services
Services with an AWS Service Ready designation

EC2 Instance Connect Endpoint

Additional settings

Preserve Client IP

EC2 Instance Connect Endpoint supports client IP preservation. You can configure the EC2 Instance Connect Endpoint to use your client's IP address as the source (preserveClientIp parameter is true) when connecting to a resource.

Add new tag

You can add 49 more tags.

Cancel **Create endpoint**

- a. (Optional) For **Name tag**, enter a name for the endpoint.
- b. For **Service category**, choose **EC2 Instance Connect Endpoint**.
- c. For **VPC**, select the VPC in which to create the endpoint.
- d. Expand **Additional settings**, and for **Preserve Client IP** do one of the following:
 - If you want your client's IP address to be used as the source when you connect to an instance, select the check box.

Note: When **Preserve Client IP** is turned on, your instance's security group must allow traffic from your client IP address. For more information, see [Instance security group rule](#).

- e. (Optional) For **Security groups**, select the security group to associate with the endpoint. If you don't select a security group, the default security group for your VPC will be associated with the endpoint. For more information, see [Security groups for EC2 Instance Connect Endpoint](#).
- f. For **Subnet**, select the subnet in which to create the endpoint.
- g. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.
- h. Choose **Create endpoint**.

The initial status is **Pending**. Before you can connect to an instance using this endpoint, wait until the status is **Available**. This can take a few minutes. To monitor the endpoint status, see [Describe an EC2 Instance Connect Endpoint](#).

AWS CLI

To create an EC2 Instance Connect Endpoint

Use the [create-instance-connect-endpoint](#) AWS CLI command and specify the subnet in which to create your EC2 Instance Connect Endpoint. Make sure you're using the latest version of the AWS CLI.

```
aws ec2 create-instance-connect-endpoint --region us-east-1 --subnet-id subnet-0123456789example
```

Example output

```
{  
    "VpcId": "vpc-0123abcd",  
    "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",

```

The initial value for the State field is `create-in-progress`. Before you can connect to an instance using this endpoint, wait until the state is `create-complete`. This can take a few minutes. To monitor the endpoint state, see [Describe an EC2 Instance Connect Endpoint](#).

Describe an EC2 Instance Connect Endpoint

Use one of the following methods to describe an EC2 Instance Connect Endpoint.

Console

To view an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.

3. Find the endpoint in the table and select it to view its details. To use the endpoint to connect to an instance, the **Status** field must display **Available**.

AWS CLI

To describe an EC2 Instance Connect Endpoint

Use the [describe-instance-connect-endpoints](#) AWS CLI command and specify the EC2 Instance Connect Endpoint ID.

```
aws ec2 describe-instance-connect-endpoints --region us-east-1 --instance-connect-endpoint-ids eice-0123456789example
```

Example output - To use the endpoint for connecting to an instance, the State field must show **create-complete**.

Connect using EC2 Instance Connect Endpoint to a Linux instance

EC2 Instance Connect Endpoint allows you to connect to an instance without requiring the instance to have a public IPv4 address. You can connect to any instances that support TCP.

To connect to an instance, specify the instance ID. You can optionally provide the EC2 Instance Connect Endpoint.

For information about how to connect to a **Windows instance**, see [Connect using EC2 Instance Connect Endpoint to a Windows instance](#) in the *Amazon EC2 User Guide for Windows Instances*.

Topics

- [Limitations](#)
- [Prerequisites](#)
- [Connect to your Linux instance using the Amazon EC2 console](#)
- [Connect to your Linux instance using SSH](#)
- [Troubleshoot](#)

Limitations

- Only ports 22 and 3389 are supported.
- EC2 Instance Connect Endpoint doesn't support connections to an instance using IPv6 addresses.
- Each EC2 Instance Connect Endpoint can support up to 20 concurrent connections.
- EC2 Instance Connect Endpoint is intended specifically for management traffic use cases and not for high volume data transfers. High volume data transfers are throttled.
- Maximum duration for an established TCP connection: 1 hour (3,600 seconds). You can specify the maximum *allowed* duration in an IAM policy, which can be 3,600 seconds or less. For more information, see [Allow users to use EC2 Instance Connect Endpoint to connect to instances](#).
- When client IP preservation is enabled, the instance to connect to must be in the same VPC as the EC2 Instance Connect Endpoint.
- Client IP preservation is not supported when traffic is routed through an AWS Transit Gateway.
- The following instance types do not support client IP preservation: C1, CG1, CG2, G1, HI1, M1, M2, M3, and T1. If you are using these instance types, set the `preserveClientIp` parameter to `false`, otherwise attempting to connect to these instance types using EC2 Instance Connect

Endpoint will fail. For more information about the `preserveClientIp` parameter, see step 3.d in the [Create an EC2 Instance Connect Endpoint](#) console procedure.

Prerequisites

- You must have the required IAM permission to connect to an EC2 Instance Connect Endpoint. For more information, see [Allow users to use EC2 Instance Connect Endpoint to connect to instances](#).
- The EC2 Instance Connect Endpoint must be in the **Available** (console) or `create-complete` (AWS CLI) state. To monitor the endpoint state, see [Describe an EC2 Instance Connect Endpoint](#).
- To use the EC2 console to connect to your instance, or to use the CLI to connect and have EC2 Instance Connect handle the ephemeral key, your instance must have EC2 Instance Connect installed. For more information, see [AMIs](#).
- Ensure that the security group of the instance that you want to connect to is configured correctly for inbound traffic. For more information, see [Instance security group rule](#).
- If you're using the AWS CLI, make sure that you have configured the AWS CLI, including the credentials that it uses, and that you're using the latest version of the AWS CLI. For more information, see [Installing or updating the latest version of the AWS CLI](#) and [Configuring the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Connect to your Linux instance using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console by selecting the instance from the console and choosing to connect using EC2 Instance Connect, which handles the permissions and provides a successful connection.

To connect to your instance using the browser-based client from the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, choose **Connect**, and then do the following:

Connect to instance Info

Connect

- a. Choose the **EC2 Instance Connect** tab.
- b. For **Connection type**, choose **Connect using EC2 Instance Connect Endpoint**.
- c. For **EC2 Instance Connect Endpoint**, choose the EC2 Instance Connect Endpoint in the instance's VPC. If there is no endpoint to choose, see [Create an EC2 Instance Connect Endpoint](#).

- d. For **Username**, verify the username.
- e. For **Max tunnel duration (seconds)**, enter the maximum allowed duration for the SSH connection.

The duration must comply with the `maxTunnelDuration` condition specified in the IAM policy. If you don't have access to the IAM policy, ask your administrator to verify it. If `maxTunnelDuration` is not specified in the IAM policy, enter the default, which is **3600** seconds (1 hour).

- f. Choose **Connect** to open a terminal window.

Connect to your Linux instance using SSH

You can use SSH to connect to your Linux instance, and use the `open-tunnel` command to establish a private tunnel. You can use `open-tunnel` in single connection or multi-connection mode.

For information about using the AWS CLI to connect to your instance using SSH, see [Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI](#).

The following examples use [OpenSSH](#). You can use any other SSH client that supports a proxy mode.

Single connection

To allow only a single connection to an instance using SSH and the `open-tunnel` command

Use ssh and the [open-tunnel](#) AWS CLI command as follows. The `-o` proxy command encloses the `open-tunnel` command that creates the private tunnel to the instance.

```
ssh -i my-key-pair.pem ec2-user@i-0123456789example \
    -o ProxyCommand='aws ec2-instance-connect open-tunnel --instance-
    id i-0123456789example'
```

For:

- `-i` – Specify the key pair that was used to launch the instance.
- `ec2-user@i-0123456789example` – Specify the username of the AMI that was used to launch the instance, and the instance ID.

- **--instance-id** – Specify the ID of the instance to connect to. Alternatively, specify %h, which extracts the instance ID from the user.

Multi-connection

To allow multiple connections to an instance, first run the [open-tunnel](#) AWS CLI command to start listening for new TCP connections, and then use ssh to create a new TCP connection and a private tunnel to your instance.

To allow multiple connections to your instance using SSH and the open-tunnel command

1. Run the following command to start listening for new TCP connections on the specified port on your local machine.

```
aws ec2-instance-connect open-tunnel \
--instance-id i-0123456789example \
--local-port 8888
```

Expected output

```
Listening for connections on port 8888.
```

2. In a *new terminal window*, run the following ssh command to create a new TCP connection and a private tunnel to your instance.

```
ssh -i my-key-pair.pem ec2-user@localhost -p 8888
```

Expected output – In the *first* terminal window, you'll see the following:

```
[1] Accepted new tcp connection, opening websocket tunnel.
```

You might also see the following:

```
[1] Closing tcp connection.
```

Troubleshoot

Use the following information to help diagnose and fix issues that you might encounter when using EC2 Instance Connect Endpoint to connect an instance.

Can't connect to your instance

The following are common reasons why you might not be able to connect to your instance.

- Security groups – Check the security groups assigned to the EC2 Instance Connect Endpoint and your instance. For more information about the required security group rules, see [Security groups for EC2 Instance Connect Endpoint](#).
- Instance state – Verify that your instance is in the running state.
- Key pair – If the command you're using to connect requires a private key, verify that your instance has a public key and that you have the corresponding private key.
- IAM permissions – Verify that you have the required IAM permissions. For more information, see [Grant IAM permissions to use EC2 Instance Connect Endpoint](#).

For more troubleshooting tips, see [Troubleshoot connecting to your instance](#).

ErrorCode: AccessDeniedException

If you receive an `AccessDeniedException` error, and the `maxTunnelDuration` condition is specified in the IAM policy, be sure to specify the `--max-tunnel-duration` parameter when connecting to an instance. For more information about this parameter, see [open-tunnel](#) in the [AWS CLI Command Reference](#).

Log connections established over EC2 Instance Connect Endpoint

You can log resource operations and audit connections established over the EC2 Instance Connect Endpoint with AWS CloudTrail logs.

For more information about using AWS CloudTrail with Amazon EC2, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail](#).

Log EC2 Instance Connect Endpoint API calls with AWS CloudTrail

EC2 Instance Connect Endpoint resource operations are logged to CloudTrail as management events. When the following API calls are made, the activity is recorded as a CloudTrail event in **Event history**:

- `CreateInstanceConnectEndpoint`
- `DescribeInstanceConnectEndpoints`
- `DeleteInstanceConnectEndpoint`

You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail Event history](#) in the *AWS CloudTrail User Guide*.

Use AWS CloudTrail to audit users who connect to an instance using EC2 Instance Connect Endpoint

Connection attempts to instances via EC2 Instance Connect Endpoint are logged in CloudTrail in **Event history**. When a connection to an instance is initiated through an EC2 Instance Connect Endpoint, the connection is logged as a CloudTrail management event with the `eventName` of `OpenTunnel`.

You can create Amazon EventBridge rules that route the CloudTrail event to a target. For more information, see the [Amazon EventBridge User Guide](#).

The following is an example of an `OpenTunnel` management event that was logged in CloudTrail.

Remove EC2 Instance Connect Endpoint

To remove EC2 Instance Connect Endpoint from your VPC, delete the endpoint that was created in a subnet.

When you delete an EC2 Instance Connect Endpoint, it first enters the **Deleting** (console) or **delete-in-progress** (AWS CLI) state, and then the **delete-complete** (AWS CLI) state. In the console, a deleted endpoint no longer appears. If the delete action fails, the state is **delete-failed**, and the **Status message** (console) or **StateMessage** (AWS CLI) provides the failure reason.

Use one of the following methods to delete an EC2 Instance Connect Endpoint.

Console

To delete an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Select the endpoint.
4. Choose **Actions, Delete VPC endpoints**.
5. When prompted for confirmation, enter **delete**.
6. Choose **Delete**.

AWS CLI

To delete an EC2 Instance Connect Endpoint

Use the [delete-instance-connect-endpoints](#) AWS CLI command and specify the ID of the EC2 Instance Connect Endpoint to delete.

```
aws ec2 delete-instance-connect-endpoint --instance-connect-endpoint-id eice-03f5e49b83924bbc7
```

Example output

```
{  
    "InstanceConnectEndpoint": {  
        "OwnerId": "111111111111",  
        "InstanceConnectEndpointId": "eice-0123456789example",  
        "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",

Service-linked role for EC2 Instance Connect Endpoint

Amazon EC2 uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon EC2. Service-linked roles are predefined by Amazon EC2 and include all the permissions that Amazon EC2 requires to call other AWS services on your behalf. For more information, see [Using service-linked roles](#) in the *IAM User Guide*.

When you create an EC2 Instance Connect Endpoint, the service-linked role named **AWSServiceRoleForEC2InstanceConnect** and the managed policy named **EC2InstanceConnectEndpoint** are automatically created in your AWS account, and the managed policy is automatically attached to the service-linked role.

Amazon EC2 uses **AWSServiceRoleForEC2InstanceConnect** to manage network interfaces in your account that are required when creating EC2 Instance Connect Endpoints.

Permissions granted by AWSServiceRoleForEC2InstanceConnect

Amazon EC2 uses **AWSServiceRoleForEC2InstanceConnect** to complete the following actions:

- `ec2:CreateNetworkInterface` – Create network interfaces
- `ec2:DeleteNetworkInterface` – Delete network interfaces
- `ec2:DescribeNetworkInterfaces` – Describe network interfaces
- `ec2:DescribeAvailabilityZones` – Describe Availability Zones
- `ec2:ModifyNetworkInterfaceAttribute` – Disable source and destination checks

Use service-linked roles

EC2 Instance Connect Endpoint uses the service-linked role named **AWSServiceRoleForEC2InstanceConnect** to provision network interfaces in your account that are required to use the service.

If you create an EC2 Instance Connect Endpoint, the **EC2InstanceConnectEndpoint** managed policy is automatically created in your AWS account and attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Service Linked Roles for EC2 Instance Connect Endpoint

The **AWSServiceRoleForEC2InstanceConnect** service-linked role trusts the following services to assume the role:

- `ec2-instance-connect.amazonaws.com`

The role permissions policy, named **EC2InstanceConnectEndpoint**, allows EC2 Instance Connect Endpoint to complete the following actions on the specified resources:

- Action: `ec2:CreateNetworkInterface` – On all subnets and all network interfaces with the non-null tag key **InstanceConnectEndpointId** to create network interfaces for EC2 Instance Connect Endpoint
- Action: `ec2:CreateTags` – On all network interfaces created for an EC2 Instance Connect Endpoint at creation time with the tag key **InstanceConnectEndpointId**
- Action: `ec2:DeleteNetworkInterface` – On network interfaces created for an EC2 Instance Connect Endpoint with tag key **InstanceConnectEndpointId**
- Action: `ec2:DescribeNetworkInterfaces` – On network interfaces for an Instance Connect Endpoint
- Action: `ec2:DescribeAvailabilityZones` – For internal mapping of customer's Availability Zone
- Action: `ec2:ModifyNetworkInterfaceAttribute` – On all network interfaces to disable source and destination checks

Creating a service-linked role for EC2 Instance Connect Endpoint

When you create an EC2 Instance Connect Endpoint, the service-linked role **AWSServiceRoleForEC2InstanceConnect** is automatically created for you.

Important

Ensure that the AWS account used to create the EC2 Instance Connect Endpoint has an IAM policy attached to it that permits the `iam:CreateServiceLinkedRole` action.

Editing a service-linked role for EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint doesn't allow you to edit the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Deleting a service-linked role for EC2 Instance Connect Endpoint

If you no longer need to use EC2 Instance Connect Endpoint, we recommend that you delete the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Note

You can delete the service-linked role only after you delete all EC2 Instance Connect Endpoint resources.

Use the AWS CLI to delete the service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Follow these steps to delete the service-linked role using the AWS CLI:

1. Delete all EC2 Instance Connect Endpoints using the `delete-instance-connect-endpoint` command, this will also remove the associated resources.
2. Delete the service linked role using the `delete-service-linked-role` command. Deleting the service-linked role will also delete the associated managed policy.

EC2 Instance Connect Endpoint supports using the **AWSServiceRoleForEC2InstanceConnect** service-linked role in every AWS Region where the service is available.

AWS managed policies for EC2 Instance Connect Endpoint

AWS managed policy: EC2InstanceConnectEndpoint

This policy is attached to a service-linked role that allows EC2 Instance Connect Endpoint to perform actions on your behalf. For more information, see [EC2InstanceConnectEndpoint](#).

To view the permissions for this policy, see [Ec2InstanceConnectEndpoint](#) in the AWS Management Console.

Quotas

You can create a maximum number of EC2 Instance Connect Endpoints per AWS Region as follows:

Description	Quota
Maximum number of EC2 Instance Connect Endpoints per AWS account per AWS Region	5
Maximum number of EC2 Instance Connect Endpoints per VPC	1
Maximum number of EC2 Instance Connect Endpoints per subnet	1

Each EC2 Instance Connect Endpoint can support a maximum number of concurrent connections as follows:

Description	Quota
Maximum number of concurrent connections per EC2 Instance Connect Endpoint	20

Connect your EC2 instance to an AWS resource

After you launch an instance, you can connect it to one or more AWS resources.

This section describes how to automatically connect an Amazon EC2 instance to an Amazon RDS database.

Automatically connect an EC2 instance to an RDS database

You can use the automatic connection functionality in the Amazon EC2 console to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.

For more information, see [How the connection is automatically configured](#). For a detailed walkthrough, which includes other ways to connect an EC2 instance and an RDS database, see [Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database](#).

Topics

- [Costs](#)
- [Prerequisites](#)
- [Automatically connect an instance and a database](#)
- [How the connection is automatically configured](#)

Costs

While there is no charge to automatically connect your EC2 instance to an RDS database, you are charged for the underlying services. Data transfer fees will apply if your EC2 instance and RDS database are in different Availability Zones. For information about data transfer fees, see [Data Transfer](#) on the Amazon EC2 On-Demand Pricing page.

Prerequisites

Before you can automatically connect an EC2 instance to an RDS database, check the following:

- The EC2 instances must be in the **Running** state. You can't connect an EC2 instance if it's in another state.
- The EC2 instances and the RDS database must be in the same virtual private cloud (VPC). The automatic connection feature is not supported if an EC2 instance and RDS database are in different VPCs.

Automatically connect an instance and a database

You can automatically connect an EC2 instance to an RDS database immediately after you've launched your instance, or later.

Automatically connect immediately after launch

Use the following steps to automatically connect an EC2 instance to an RDS database immediately after you've launched the EC2 instance.

To view an animation of these steps, see [View an animation: Automatically connect a newly-launched EC2 instance to an RDS database](#).

To automatically connect a newly-launched EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console dashboard, choose **Launch instances**, and then follow the steps to [launch an instance](#).
3. On the instance launch confirmation page, choose **Connect an RDS database**.
4. In the **Connect RDS Database** dialog box, do the following:
 - a. For **Database role**, choose either **Cluster** or **Instance**.
 - b. For **RDS database**, select a database to connect to.

 **Note**

The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.

- c. Choose **Connect**.

Automatically connect an existing instance

Use the following steps to automatically connect an existing EC2 instance to an RDS database.

To view an animation of these steps, see [View an animation: Automatically connect an existing EC2 instance to an RDS database](#).

To automatically connect an existing EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select one or more EC2 instances to connect to an RDS database, and then choose **Actions**, **Networking**, **Connect RDS database**.

If **Connect RDS database** is not available, check that the EC2 instances are in the **Running** state and that they are in the same VPC.

4. In the **Connect RDS Database** dialog box, do the following:

- For **Database role**, choose either **Cluster or Instance**.
- For **RDS database**, select a database to connect to.

Note

The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.

- Choose **Connect**.

The screenshot shows the Amazon EC2 Dashboard. On the left, there's a sidebar with various navigation links like New EC2 Experience, EC2 Dashboard, Instances, Images, Elastic Block Store, Network & Security, and more. The main area has three main sections: Resources, Service health, and Account attributes.

- Resources:** Shows a summary of resources in the Europe (Stockholm) Region. It includes tables for Instances (running), Dedicated Hosts, Elastic IPs, Instances, Key pairs, Load balancers, Placement groups, Security groups, and Snapshots. Below this is a "Learn more about the latest in AWS Compute from AWS re:Invent by viewing the EC2 Videos." link.
- Service health:** Shows the status of the EC2 service in the Europe (Stockholm) region, which is operating normally. It also lists available zones: eu-north-1a, eu-north-1b, and eu-north-1c.
- Account attributes:** Lists supported platforms (VPC), default VPC (vpc-78678c11), settings, EBS encryption, zones, EC2 Serial Console, default credit specification, and console experiments.

For information about how to use the Amazon RDS console to automatically connect an EC2 instance to an RDS database, see [Configure automatic network connectivity with an EC2 instance](#) in the *Amazon RDS User Guide*.

How the connection is automatically configured

When you use the EC2 console to automatically configure the connection between an EC2 instance and an RDS database to allow traffic between them, the connection is configured by [security groups](#).

The security groups are automatically created and added to the EC2 instance and RDS database, as follows:

- Amazon EC2 creates a security group called **ec2-rds-x** and adds it to the EC2 instance. It has one outbound rule that allows traffic to the database by specifying **rds-ec2-x** (the database security group) as its destination.
- Amazon RDS creates a security group called **rds-ec2-x** and adds it to the database. It has one inbound rule that allows traffic from the EC2 instance by specifying **ec2-rds-x** (the EC2 instance security group) as its source.

The security groups reference each other as the destination and source, and only allow traffic on the database port. You can reuse these security groups so that any database with the **rds-ec2-x** security group can talk to any EC2 instance with the **ec2-rds-x** security group.

The security group names follow a pattern. For the security groups created by Amazon EC2, the pattern is **ec2-rds-x**, and for the security groups created by Amazon RDS, the pattern is **rds-ec2-x**. **x** is a number, which increases by 1 each time a new security group is automatically created.

Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database

Tutorial objective

The objective of this tutorial is to learn how to configure a secure connection between an Amazon EC2 instance and an Amazon RDS database by using the AWS Management Console.

There are different options for configuring the connection. In this tutorial, we explore the following three options:

- [Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console](#)

Use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- [Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console](#)

Use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- [Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature](#)

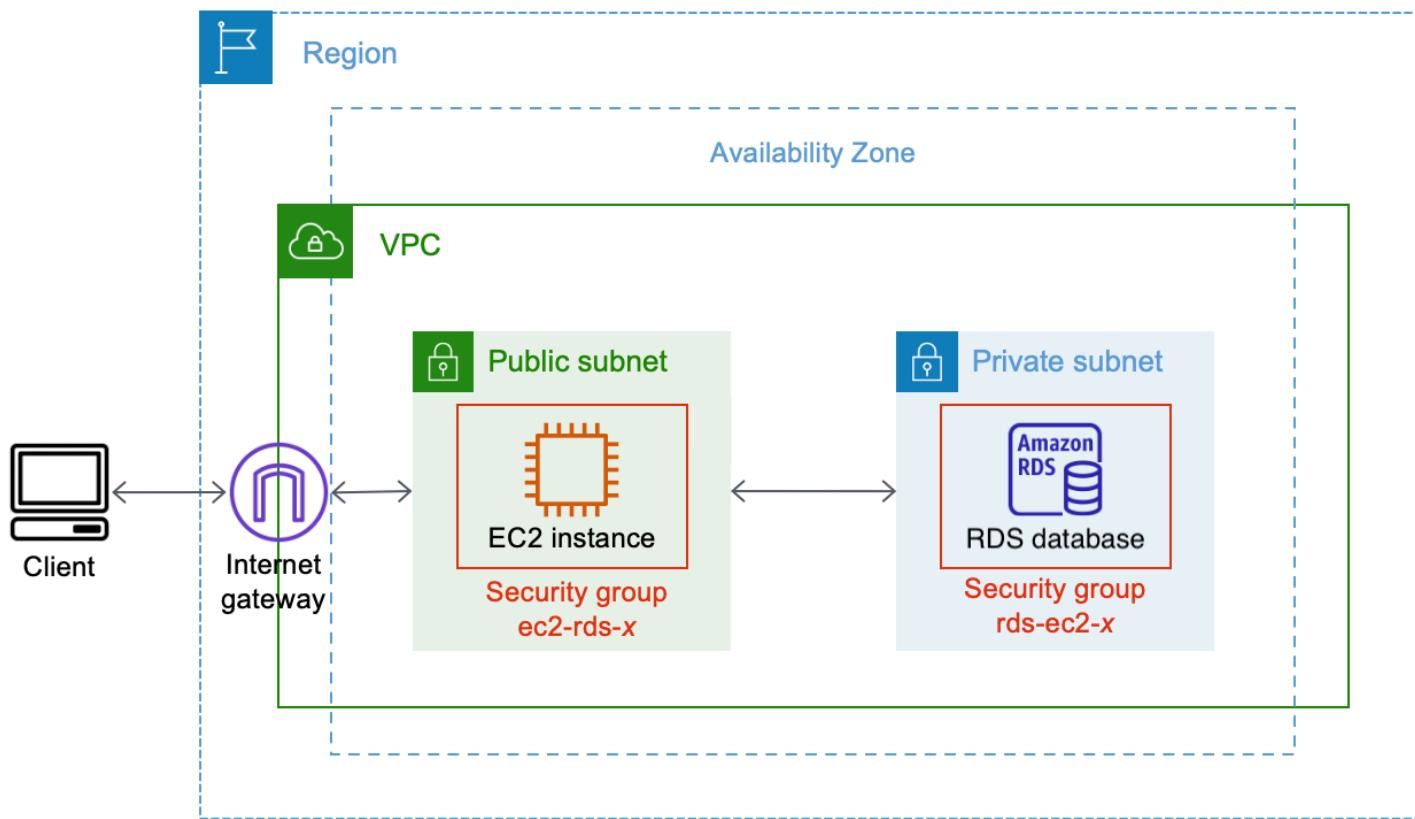

Configure the connection between your EC2 instance to your RDS database by manually configuring and assigning the security groups to reproduce the configuration that is automatically created by the automatic connection feature in Option 1 and Option 2.

Context

As context for why you'd want to configure a connection between your EC2 instance and an RDS database, let's consider the following scenario: Your website presents a form to your users to fill in. You need to capture the form data in a database. You can host your website on an EC2 instance that's been configured as a web server, and you can capture the form data in an RDS database. The EC2 instance and the RDS database need to be connected to each other so that the form data can go from the EC2 instance to the RDS database. This tutorial explains how to configure that connection. Note that this is just one example of a use case for connecting an EC2 instance and an RDS database.

Architecture

The following diagram shows the resources that are created and the architectural configuration that results from completing all the steps in this tutorial.

The diagram illustrates the following resources that you'll create:

- You'll create an EC2 instance and an RDS database in the same AWS Region, VPC, and Availability Zone.
- You'll create the EC2 instance in a public subnet.
- You'll create the RDS database in a private subnet.

When you use the RDS console to create the RDS database and automatically connect the EC2 instance, the VPC, DB subnet group, and public access settings for the database are automatically selected. The RDS database is automatically created in a private subnet within the same VPC as the EC2 instance.

- Internet users can connect to the EC2 instance by using SSH or HTTP/HTTPS via an Internet gateway.
- Internet users cannot connect directly to the RDS database; only the EC2 instance is connected to the RDS database.
- When you use the automatic connection feature to allow traffic between the EC2 instance and the RDS database, the following security groups are automatically created and added:

- Security group **ec2-rds-x** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-x** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-x** security group.
- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.

By using separate security groups (one for the EC2 instance, and one for the RDS database), you have better control over the security of the instance and the database. If you were to use the same security group on both the instance and the database, and then modified the security group to suit, say, only the database, the modification would affect both the instance and the database. In other words, if you were to use one security group, you could unintentionally modify the security of a resource (either the instance or the database) because you'd forgotten that the security group was attached to it.

The security groups that are automatically created also respect least privilege as they only allow the mutual connection for this workload on the database port by creating a workload-specific security group pair.

Considerations

Consider the following when you complete the tasks in this tutorial:

- **Two consoles** – You will use the following two consoles for this tutorial:
 - Amazon EC2 console – You will use the EC2 console to launch instances, to automatically connect an EC2 instance to an RDS database, and for the manual option to configure the connection by creating the security groups.
 - Amazon RDS console – You will use the RDS console to create an RDS database and to automatically connect an EC2 instance to an RDS database.
- **One VPC** – To use the automatic connection feature, your EC2 instance and your RDS database must be in the same VPC.

If you were to manually configure the connection between your EC2 instance and your RDS database, you could launch your EC2 instance in one VPC and your RDS database in another VPC; however, you'd need to set up additional routing and VPC configuration. This scenario is not covered in this tutorial.

- **One AWS Region** – The EC2 instance and RDS database must be located in the same Region.

- **Two security groups** – The connectivity between the EC2 instance and the RDS database is configured by two security groups—a security group for your EC2 instance, and a security group for your RDS database.

When you use the automatic connection feature in the EC2 console or RDS console to configure the connectivity (Option 1 and Option 2 of this tutorial), the security groups are automatically created and assigned to the EC2 instance and RDS database.

If you do not use the automatic connection feature, you'll need to manually create and assign the security groups. You do this in Option 3 of this tutorial.

Time to complete the tutorial

30 minutes

You can complete the entire tutorial in one sitting, or you can complete it one task at a time.

Costs

By completing this tutorial, you might incur costs for the AWS resources that you create.

You can use Amazon EC2 under the [free tier](#) provided your AWS account is less than 12 months old and you configure your resources according to the free tier requirements.

If your EC2 instance and your RDS database are in different Availability Zones, you will incur data transfer fees. To avoid incurring these fees, the EC2 instance and the RDS database must be in the same Availability Zone. For information about data transfer fees, see [Data Transfer](#) on the Amazon EC2 On-Demand Pricing page.

To prevent incurring costs after you've completed the tutorial, make sure to delete the resources if they are no longer needed. For the steps to delete the resources, see [Clean up](#).

Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console

Objective

The objective of Option 1 is to explore the automatic connection feature in the EC2 console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 1 to create a new RDS database.
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 2 to create a new EC2 instance.
- Permissions to call the following operations:
 - `ec2:AssociateRouteTable`
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2>CreateRouteTable`
 - `ec2:CreateSecurityGroup`
 - `ec2:CreateSubnet`
 - `ec2:DescribeInstances`
 - `ec2:DescribeNetworkInterfaces`
 - `ec2:DescribeRouteTables`
 - `ec2:DescribeSecurityGroups`
 - `ec2:DescribeSubnets`
 - `ec2:ModifyNetworkInterfaceAttribute`
 - `ec2:RevokeSecurityGroupEgress`

Tasks to complete Option 1

- [Task 1: Create an RDS database – optional](#)
- [Task 2: Launch an EC2 instance – optional](#)
- [Task 3: Automatically connect your EC2 instance to your RDS database](#)
- [Task 4: Verify the connection configuration](#)

Task 1: Create an RDS database – *optional*

Note

Creating a Amazon RDS database is not the focus of this tutorial. If you already have an RDS database and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to create an RDS database so that you can complete Task 3 where you configure the connection between your EC2 instance and your RDS database. If you have an RDS database that you can use, you can skip this task.

Important

If you use an existing RDS database, make sure that it is in the same VPC as your EC2 instance so that you can use the automatic connection feature.

Steps to create an RDS database

Use the following steps to create an RDS database.

To view an animation of these steps, see [View an animation: Create an RDS database](#).

RDS database configuration

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database-1**
- DB instance class: db.t3.micro

Important

In a production environment, you should configure your database to meet your specific needs.

To create a MySQL RDS database

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose an AWS Region. The database and the EC2 instance must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the VPC selector is not available. You must ensure that your database is in the same VPC as your EC2 instance in order to use the automatic connection feature in the EC2 console.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create a database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
 - a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **tutorial-database-1**.
 - b. For **Master username**, leave the default name, which is **admin**.
 - c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account is less than 12 months, you can use this database class for free. Other restrictions apply. For more information, see [AWS Free Tier](#).
9. Under **Connectivity**, for **Compute resource**, choose **Don't connect to an EC2 compute resource** because you'll connect the EC2 instance and the RDS database later in Task 3.

(Later, in Option 2 of this tutorial, you'll try out the automatic connection feature in the RDS console by choosing **Connect to an EC2 compute resource**.)

10. For **Virtual private cloud (VPC)**, choose a VPC. The VPC must have a DB subnet group. To use the automatic connection feature, your EC2 instance and RDS database must be in the same VPC.
11. Keep all the default values for the other fields on this page.

12. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

View an animation: Create an RDS database

The screenshot shows the Amazon RDS Dashboard. On the left, a sidebar lists various resources: Dashboard, Databases, Performance Insights, Snapshots, Automated backups, Reserved instances, Proxies, Subnet groups, Parameter groups, Option groups, Custom engine versions, Events, Event subscriptions, and Certificate update. The main content area has a header with an info icon and text: "Try the new Amazon RDS Multi-AZ deployment option for MySQL and PostgreSQL. For your Amazon RDS for MySQL and PostgreSQL workloads, improve transactional commit latencies by deploying the Multi-AZ DB cluster." It features a large orange "Create database" button with a cursor icon hovering over it, and a link "Or, Restore Multi-AZ DB Cluster from Snapshot". Below this is a "Resources" section with usage statistics and links to manage them. At the bottom, there's a "Create database" section with descriptive text about RDS.

Resource Type	Count	Quota
DB Instances	3/40	
Allocated storage	0.3 TB/100 TB	
Parameter groups	2

You're now ready for [Task 2: Launch an EC2 instance – optional](#).

Task 2: Launch an EC2 instance – *optional*

Note

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

Important

If you use an existing EC2 instance, make sure that it is in the same VPC as your RDS database so that you can use the automatic connection feature.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see [View an animation: Launch an EC2 instance](#).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance-1**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
 - Allow SSH from your IP address
 - Allow HTTPS traffic from anywhere
 - Allow HTTP traffic from anywhere

⚠ Important

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Region selector (at top right), choose an AWS Region. The instance and the RDS database must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the **EC2 Dashboard**, choose **Launch instance**.
4. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **tutorial-instance-1**. While the instance name is not mandatory, when you select your instance in the EC2 console, the name will help you easily identify it.
5. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux 2**.
6. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

ⓘ Note

You can use Amazon EC2 under the [Free tier](#) provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

7. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
8. Under **Network settings**, do the following:
 - a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

If you have made changes to your default VPC or subnets, check the following:

- i. The instance must be in the same VPC as the RDS database to use the automatic connection feature. By default you have only one VPC.

- ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
 - iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.
- b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

- c. To allow traffic from the internet to your instance, select the following check boxes:
 - **Allow HTTPS traffic from the internet**
 - **Allow HTTP traffic from the internet**

9. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.
10. Keep the confirmation page open. You'll need it for the next task when you automatically connect your instance to your database.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard](#).

The main content area is titled 'Resources' and displays resource counts: Instances (running) 2, Dedicated Hosts 0, Elastic IPs 0, Instances 2, Key pairs 1, Load balancers 0, Placement groups 0, Security groups 10, and Volumes 3. A callout box says 'Learn more about the latest in AWS Compute from AWS re:Invent by viewing the EC2 Videos.' Below this is the 'Launch instance' section, which includes a large orange 'Launch instance' button with a dropdown arrow, a 'Migrate a server' button, and a note stating 'To get started, launch an Amazon EC2 instance, which is a virtual server in the cloud.' The 'Scheduled events' section shows 'Europe (Stockholm)' with 'No scheduled events'. To the right, the 'Service health' section shows the 'Region' as 'Europe (Stockholm)' and the 'Status' as 'This service is operating normally'. The 'Zones' section lists three zones: 'eu-north-1a' (Zone ID: 'eun1-az1'), 'eu-north-1b' (Zone ID: 'eun1-az2'), and 'eu-north-1c' (Zone ID: 'eun1-az3').

Task 3: Automatically connect your EC2 instance to your RDS database

Task objective

The objective of this task is to use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database.

Steps to connect your EC2 instance and RDS database

Use the following steps to connect your EC2 instance and RDS database using the automatic feature in the EC2 console.

To view an animation of these steps, see [View an animation: Automatically connect a newly-launched EC2 instance to an RDS database.](#)

To automatically connect an EC2 instance to an RDS database using the EC2 console

1. On the instance launch confirmation page (it should be open from the previous task), choose **Connect an RDS database**.

If you closed the confirmation page, follow these steps:

- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
- b. In the navigation pane, choose **Instances**.
- c. Select the EC2 instance that you just created, and then choose **Actions, Networking, Connect RDS database**.

If **Connect RDS database** is not available, check that the EC2 instance is in the **Running** state.

2. For **Database role**, choose **Instance**. *Instance* in this case refers to the database instance.
3. For **RDS database**, choose the RDS database that you created in Task 1.

 **Note**

The EC2 instance and the RDS database must be in the same VPC in order to connect to each other.

4. Choose **Connect**.

You're now ready for [Task 4: Verify the connection configuration](#).

Task 4: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the EC2 console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.

- Security group **ec2-rds-x** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-x** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-x** security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see [View an animation: Verify the connection configuration](#).

To verify the connection configuration using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation page, choose **Databases**.
3. Choose the RDS database that you created for this tutorial.
4. On the **Connectivity & security** tab, under **Security, VPC security groups**, verify that a security group called **rds-ec2-x** is displayed.
5. Choose the **rds-ec2-x** security group. The **Security Groups** screen in the EC2 console opens.
6. Choose the **rds-ec2-x** security group to open it.
7. Choose the **Inbound rules** tab.
8. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Source: **sg-0987654321example / ec2-rds-x** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
 - Description: **Rule to allow connections from EC2 instances with sg-1234567890example attached**
9. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
10. In the navigation pane, choose **Instances**.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
12. Under **Security details, Security groups**, verify that a security group called **ec2-rds-x** is in the list. **x** is a number.

13. Choose the **ec2-rds-x** security group to open it.
14. Choose the **Outbound rules** tab.
15. Verify that the following security group rule exists, as follows:

- Type: **MySQL/Aurora**
- Port range: **3306**
- Destination: **sg-1234567890example / rds-ec2-x**
- Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

You have completed Option 1 of this tutorial. You can now either complete Option 2, which teaches you how to use the RDS console to automatically connect an EC2 instance to an RDS database, or you can complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 1.

Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console

Objective

The objective of Option 2 is to explore the automatic connect feature in the RDS console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- Permissions to call the following operations:
 - `ec2:AssociateRouteTable`
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2>CreateRouteTable`
 - `ec2:CreateSecurityGroup`
 - `ec2:CreateSubnet`
 - `ec2:DescribeInstances`
 - `ec2:DescribeNetworkInterfaces`
 - `ec2:DescribeRouteTables`
 - `ec2:DescribeSecurityGroups`
 - `ec2:DescribeSubnets`
 - `ec2:ModifyNetworkInterfaceAttribute`
 - `ec2:RevokeSecurityGroupEgress`

Task 2: Create an RDS database and automatically connect it to your EC2 instance

Task objective

The objective of this task is to create an RDS database and use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database.

Steps to create an RDS database

Use the following steps to create an RDS database and connect it to your EC2 instance using the automatic feature in the RDS console.

To view an animation of these steps, see [View an animation: Create an RDS database and automatically connect it to an EC2 instance.](#)

DB instance configuration

The steps in this task configure the DB instance as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database**
- DB instance class: db.t3.micro

Important

In a production environment, you should configure your instance to meet your specific needs.

To create an RDS database and automatically connect it to an EC2 instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the RDS database must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the automatic connection feature is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create an RDS database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
 - a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **tutorial-database**.
 - b. For **Master username**, leave the default name, which is **admin**.
 - c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.

8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account is less than 12 months, you can use this instance for free. Other restrictions apply. For more information, see [AWS Free Tier](#).
9. Under **Connectivity**, for **Compute resource**, choose **Connect to an EC2 compute resource**. This is the automatic connection feature in the RDS console .
10. For **EC2 instance**, choose the EC2 instance that you want to connect to. For the purposes of this tutorial, you can either choose the instance that you created in the previous task, which you named **tutorial-instance**, or choose another existing instance. If you don't see your instance in the list, choose the refresh icon to the right of **Connectivity**.

When you use the automatic connection feature, a security group is added to this EC2 instance, and another security group is added to the RDS database. The security groups are automatically configured to allow traffic between the EC2 instance and the RDS database. In the next task, you'll verify that the security groups were created and assigned to the EC2 instance and RDS database.

11. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

To learn more, see [Configure automatic network connectivity with an EC2 instance](#) in the *Amazon RDS User Guide*.

Task 3: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and the database.

When you use the automatic connection feature in the RDS console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.
- Security group **ec2-rds-x** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-x** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-x** security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see [View an animation: Verify the connection configuration](#).

To verify the connection configuration using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
4. Under **Security details, Security groups**, verify that a security group called **ec2-rds-x** is in the list. **x** is a number.
5. Choose the **ec2-rds-x** security group to open it.
6. Choose the **Outbound rules** tab.
7. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Destination: **sg-1234567890example / rds-ec2-x**
 - Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**
8. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
9. In the navigation page, choose **Databases**.

10. Choose the RDS database that you created for this tutorial.
11. On the **Connectivity & security** tab, under **Security, VPC security groups**, verify that a security group called **rds-ec2-x** is displayed.
12. Choose the **rds-ec2-x** security group. The **Security Groups** screen in EC2 console opens.
13. Choose the **rds-ec2-x** security group open it.
14. Choose the **Inbound rules** tab.
15. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Source: **sg-0987654321example / ec2-rds-x** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
 - Description: **Rule to allow connections from EC2 instances with sg-1234567890example attached**

By verifying that these security groups and security group rules exist and that they are assigned to the EC2 instance and RDS database as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature

Objective

The objective of Option 3 is to learn how to manually configure the connection between an EC2 instance and an RDS database by manually reproducing the configuration of the automatic connection feature.

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 2 to create a new database.
- Permissions to call the following operations. If you have completed Option 1 of this tutorial, you already have these permissions.
 - ec2:AssociateRouteTable
 - ec2:AuthorizeSecurityGroupEgress
 - ec2>CreateRouteTable
 - ec2>CreateSecurityGroup
 - ec2>CreateSubnet
 - ec2:DescribeInstances

5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

 **Note**

You can use Amazon EC2 under the [Free tier](#) provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
7. Under **Network settings**, do the following:
 - a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

If you have made changes to your default VPC or subnets, check the following:

 - i. The instance must be in the same VPC as the RDS database. By default you have only one VPC.
 - ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
 - iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.
 - b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

- c. To allow traffic from the internet to your instance, select the following check boxes:

- Allow HTTPs traffic from the internet
 - Allow HTTP traffic from the internet
8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.
9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the running state.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard](#).

Task 2: Create an RDS database – *optional*

Note

Creating an RDS database is not the focus of this part of the tutorial. If you already have an RDS database and would like to use it for this tutorial, you can skip this task.

Task objective

The objective of this task is to create an RDS database. You'll use this instance in Task 3 when you connect it to your EC2 instance.

Steps to create an RDS database

Use the following steps to create an RDS database for Option 3 of this tutorial.

To view an animation of these steps, see [View an animation: Create a DB instance](#).

RDS database configuration

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database-manual**
- DB instance class: db.t3.micro

Important

In a production environment, you should configure your instance to meet your specific needs.

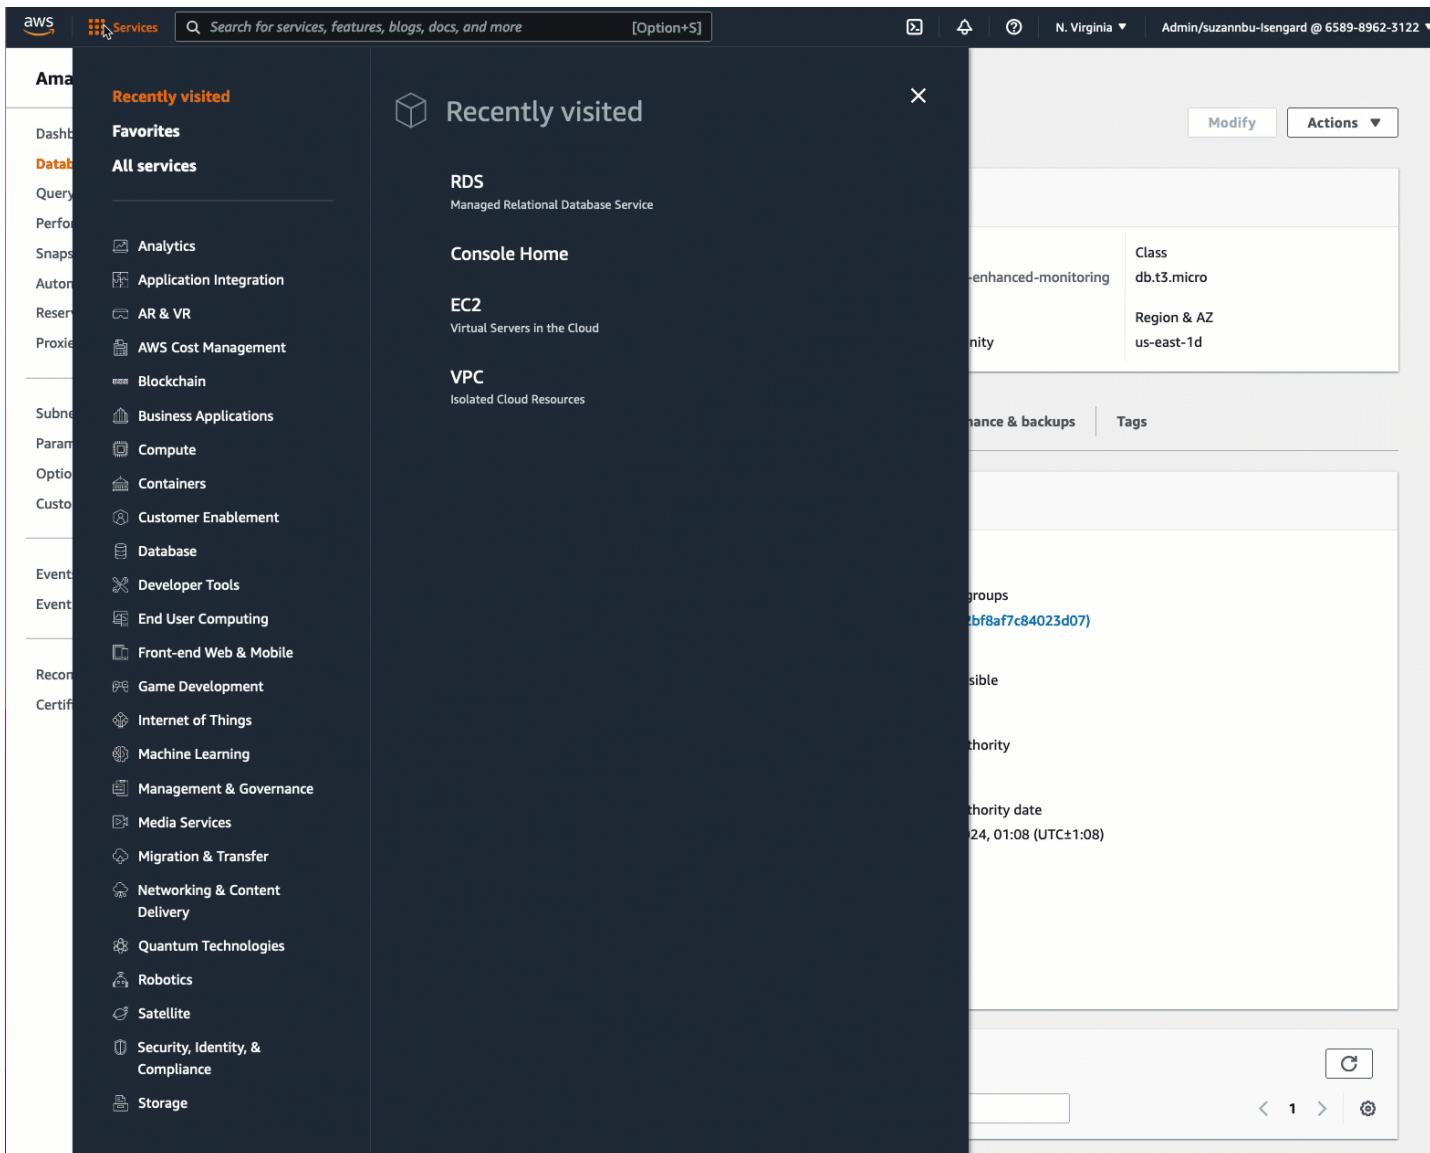

To create a MySQL DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the DB instance must be in the same Region.

3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, choose **Easy create**. When you choose this option, the automatic connection feature to automatically configure the connection is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier** enter a name for the RDS database. For this tutorial, enter **tutorial-database-manual**.
8. For **Master username**, leave the default name, which is **admin**.
9. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
10. Choose **Create database**.

On the **Databases** screen, the **Status** of the new DB instance is **Creating** until the DB instance is ready to use. When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

View an animation: Create a DB instance

You are now ready for [Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances.](#)

Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances

Task objective

The objective of this task is to reproduce the connection configuration of the automatic connection feature by performing the following manually: You create two new security groups, and then add a security group each to the EC2 instance and the RDS database.

Steps to create new security groups and add them to the instances

Use the following steps to connect an EC2 instance to your RDS database by creating two new security groups. You then add a security group each to the EC2 instance and the RDS database.

To create two new security groups and assign one each to the EC2 instance and RDS database

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. First create the security group to add to the EC2 instance, as follows:
 - a. In the navigation pane, choose **Security Groups**.
 - b. Choose **Create security group**.
 - c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **ec2-rds-manual-configuration**.
 - d. For **Description**, enter a brief description. For this tutorial, enter **EC2 instance security group to allow EC2 instance to securely connect to RDS database**.
 - e. Choose **Create security group**. You'll come back to this security group to add an outbound rule after you've created the RDS database security group.
3. Now, create the security group to add to the RDS database, as follows:
 - a. In the navigation pane, choose **Security Groups**.
 - b. Choose **Create security group**.
 - c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **rds-ec2-manual-configuration**.
 - d. For **Description**, enter a brief description. For this tutorial, enter **RDS database security group to allow EC2 instance to securely connect to RDS database**.
 - e. Under **Inbound rules**, choose **Add rule**, and do the following:
 - i. For **Type**, choose **MySQL/Aurora**.
 - ii. For **Source**, choose the EC2 instance security group **ec2-rds-manual-configuration** that you created in Step 2 of this procedure.
 - f. Choose **Create security group**.
4. Edit the EC2 instance security group to add an outbound rule, as follows:

- a. In the navigation pane, choose **Security Groups**.
 - b. Select the EC2 instance security group (you named it **ec2-rds-manual-configuration**), and choose the **Outbound rules** tab.
 - c. Choose **Edit outbound rules**.
 - d. Choose **Add rule**, and do the following:
 - i. For **Type**, choose **MYSQL/Aurora**.
 - ii. For **Source**, choose the RDS database security group **rds-ec2-manual-configuration** that you created in Step 3 of this procedure.
 - iii. Choose **Save rules**.
5. Add the EC2 instance security group to the EC2 instance as follows:
 - a. In the navigation pane, choose **Instances**.
 - b. Select your EC2 instance, and choose **Actions, Security, Change security groups**.
 - c. Under **Associated security groups**, choose the **Select security groups** field, choose **ec2-rds-manual-configuration** that you created earlier, and then choose **Add security group**.
 - d. Choose **Save**.
 6. Add the RDS database security group to the RDS database as follows:
 - a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - b. In the navigation pane, choose **Databases** and select your database.
 - c. Choose **Modify**.
 - d. Under **Connectivity**, for **Security group**, choose **rds-ec2-manual-configuration** that you created earlier, and then choose **Continue**.
 - e. Under **Scheduling of modifications**, choose **Apply immediately**.
 - f. Choose **Modify DB instance**.

You have now completed the manual steps that mimic the automatic steps that occur when you use the automatic connection feature.

You have completed Option 3 of this tutorial. If you've completed Options 1, 2, and 3, and you no longer need the resources that were created in this tutorial, you should delete them to prevent incurring unnecessary costs. For more information, see [Clean up](#).

Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

Topics

- [Terminate your EC2 instance](#)
- [Delete your RDS database](#)

Terminate your EC2 instance

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you created for this tutorial, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

Delete your RDS database

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Select the RDS database that you created for this tutorial, and choose **Actions, Delete**.
4. Enter **delete me** in the box, and then choose **Delete**.

Configure your Amazon Linux instance

After you have successfully launched and logged into your Amazon Linux instance, you can make changes to it. There are many different ways you can configure an instance to meet the needs of a specific application. The following are some common tasks to help get you started.

Common configuration scenarios

The base distribution of Amazon Linux contains the software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code. For more information on installing and building software from these locations, see [Manage software on your Amazon Linux instance](#).

Amazon Linux instances come pre-configured with an `ec2-user`, but you may want to add other users that do not have super-user privileges. For more information on adding and removing users, see [Manage users on your Linux instance](#).

The default time configuration for Amazon Linux instances uses Amazon Time Sync Service to set the system time on an instance. The default time zone is UTC. For more information on setting the time zone for an instance or using your own time server, see [Set the time for your Linux instance](#).

If you have your own network with a domain name registered to it, you can change the hostname of an instance to identify itself as part of that domain. You can also change the system prompt to show a more meaningful name without changing the hostname settings. For more information, see [Change the hostname of your Amazon Linux instance](#). You can configure an instance to use a dynamic DNS service provider. For more information, see [Set up dynamic DNS on your Amazon Linux instance](#).

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: cloud-init directives and shell scripts. For more information, see [Run commands on your Linux instance at launch](#).

Manage software on your Amazon Linux instance

The base distribution of Amazon Linux contains the software packages and utilities that are required for basic server operations.

This information applies to Amazon Linux 2 and Amazon Linux. For information about AL2023, see [Managing packages and operating system updates](#) in the *AL2023 User Guide*.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. For more information, see [Update instance software on your Amazon Linux instance](#).

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: `amzn2-core` and `amzn2extra-docker`
- Amazon Linux AMI: `amzn-main` and `amzn-updates`

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository. For more information, see [Add repositories on an Amazon Linux instance](#). For help finding and installing packages in enabled repositories, see [Find and install software packages on an Amazon Linux instance](#).

Not all software is available in software packages stored in repositories; some software must be compiled on an instance from its source code. For more information, see [Prepare to compile software on an Amazon Linux instance](#).

Amazon Linux instances manage their software using the yum package manager. The yum package manager can install, remove, and update software, as well as manage all of the dependencies for each package. Debian-based Linux distributions, like Ubuntu, use the `apt-get` command and `dpkg` package manager, so the `yum` examples in the following sections do not work for those distributions.

Update instance software on your Amazon Linux instance

It is important to keep software up to date. Packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. When you first launch and connect to an Amazon Linux instance, you might see a message asking you to update software packages for security purposes. This section shows how to update an entire system, or just a single package.

This information applies to Amazon Linux 2 and Amazon Linux. For information about AL2023, see [Managing packages and operating system updates](#) in the *AL2023 User Guide*.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about

the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

For information about changes and updates to Amazon Linux 2, see [Amazon Linux 2 release notes](#).

For information about changes and updates to AL2023, see [AL2023 release notes](#).

⚠️ Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

⚠️ Important

If you launched an EC2 instance that uses an Amazon Linux 2 AMI into an IPv6-only subnet, you must connect to the instance and run `sudo amazon-linux-https disable`. This lets your AL2 instance connect to the yum repository in S3 over IPv6 using the http patch service.

To update all packages on an Amazon Linux instance

1. (Optional) Start a **screen** session in your shell window. Sometimes you might experience a network interruption that can disconnect the SSH connection to your instance. If this happens during a long software update, it can leave the instance in a recoverable, although confused state. A **screen** session allows you to continue running the update even if your connection is interrupted, and you can reconnect to the session later without problems.

- a. Execute the **screen** command to begin the session.

```
[ec2-user ~]$ screen
```

- b. If your session is disconnected, log back into your instance and list the available screens.

```
[ec2-user ~]$ screen -ls
```

```
There is a screen on:
```

```
17793.pts-0.ip-12-34-56-78 (Detached)
1 Socket in /var/run/screen/S-ec2-user.
```

- c. Reconnect to the screen using the **screen -r** command and the process ID from the previous command.

```
[ec2-user ~]$ screen -r 17793
```

- d. When you are finished using **screen**, use the **exit** command to close the session.

```
[ec2-user ~]$ exit
[screen is terminating]
```

2. Run the **yum update** command. Optionally, you can add the **--security** flag to apply only security updates.

```
[ec2-user ~]$ sudo yum update
```

3. Review the packages listed, enter **y**, and press Enter to accept the updates. Updating all of the packages on a system can take several minutes. The **yum** output shows the status of the update while it is running.
4. (Optional) [Reboot your instance](#) to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

To update a single package on an Amazon Linux instance

Use this procedure to update a single package (and its dependencies) and not the entire system.

1. Run the **yum update** command with the name of the package to update.

```
[ec2-user ~]$ sudo yum update openssl
```

2. Review the package information listed, enter **y**, and press Enter to accept the update or updates. Sometimes there will be more than one package listed if there are package dependencies that must be resolved. The **yum** output shows the status of the update while it is running.

3. (Optional) [Reboot your instance](#) to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

Add repositories on an Amazon Linux instance

This information applies to Amazon Linux 2 and Amazon Linux. For information about AL2023, see [Using Deterministic upgrades through versioned repository](#) in the *AL2023 User Guide*.

 **Note**

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: amzn2-core and amzn2extra-docker
- Amazon Linux AMI: amzn-main and amzn-updates

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository.

 **Important**

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a different repository with **yum**, you need to add the repository information to the `/etc/yum.conf` file or to its own `repository.repo` file in the `/etc/`

`yum.repos.d` directory. You can do this manually, but most yum repositories provide their own `repository.repo` file at their repository URL.

To determine what yum repositories are already installed

- List the installed yum repositories with the following command:

```
[ec2-user ~]$ yum repolist all
```

The resulting output lists the installed repositories and reports the status of each. Enabled repositories display the number of packages they contain.

To add a yum repository to `/etc/yum.repos.d`

1. Find the location of the `.repo` file. This will vary depending on the repository you are adding. In this example, the `.repo` file is at `https://www.example.com/repository.repo`.
2. Add the repository with the `yum-config-manager` command.

```
[ec2-user ~]$ sudo yum-config-manager --add-repo https://  
www.example.com/repository.repo  
Loaded plugins: priorities, update-motd, upgrade-helper  
adding repo from: https://www.example.com/repository.repo  
grabbing file https://www.example.com/repository.repo to /etc/  
yum.repos.d/repository.repo  
repository.repo | 4.0 kB 00:00  
repo saved to /etc/yum.repos.d/repository.repo
```

After you install a repository, you must enable it as described in the next procedure.

To enable a yum repository in `/etc/yum.repos.d`

- Use the `yum-config-manager` command with the `--enable` `repository` flag. The following command enables the Extra Packages for Enterprise Linux (EPEL) repository from the Fedora project. By default, this repository is present in `/etc/yum.repos.d` on Amazon Linux AMI instances, but it is not enabled.

```
[ec2-user ~]$ sudo yum-config-manager --enable epel
```

Note

To enable the EPEL repository on Amazon Linux 2, use the following command:

```
[ec2-user ~]$ sudo yum install https://dl.fedoraproject.org/pub/epel/epel-release-latest-7.noarch.rpm
```

For information on enabling the EPEL repository on other distributions, such as Red Hat and CentOS, see the EPEL documentation at <https://fedoraproject.org/wiki/EPEL>.

Find and install software packages on an Amazon Linux instance

You can use a package management tool to find and install software packages. In Amazon Linux 2 and Amazon Linux, the default software package management tool is YUM. In AL2023, the default software package management tool is DNF. For more information about AL2023, see [Package management tool](#) in the *AL2023 User Guide*.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

Find software packages on an Amazon Linux instance

You can use the **yum search** command to search the descriptions of packages that are available in your configured repositories. This is especially helpful if you don't know the exact name of the package you want to install. Simply append the keyword search to the command; for multiple word searches, wrap the search query with quotation marks.

⚠ Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

```
[ec2-user ~]$ yum search "find"
```

The following is example output for Amazon Linux 2.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd

```

Multiple word search queries in quotation marks only return results that match the exact query. If you don't see the expected package, simplify your search to one keyword and then scan the results. You can also try keyword synonyms to broaden your search.

Install software packages on an Amazon Linux instance

In Amazon Linux 2 and Amazon Linux, the yum package management tool searches all of your enabled repositories for different software packages and handles any dependencies in the software installation process. For information about installing software packages in AL2023, see [Managing packages and operating system updates](#) in the *AL2023 User Guide*.

To install a package from a repository

Use the **yum install *package*** command, replacing *package* with the name of the software to install. For example, to install the **links** text-based web browser, enter the following command.

```
[ec2-user ~]$ sudo yum install links
```

To install RPM package files that you have downloaded

You can also use **yum install** to install RPM package files that you have downloaded from the internet. To do this, append the path name of an RPM file to the installation command instead of a repository package name.

```
[ec2-user ~]$ sudo yum install my-package.rpm
```

To list installed packages

To view a list of installed packages on your instance, use the following command.

```
[ec2-user ~]$ yum list installed
```

Prepare to compile software on an Amazon Linux instance

Open-source software is available on the internet that has not been pre-compiled and made available for download from a package repository. You might eventually discover a software package that you need to compile yourself, from its source code. For your system to be able to compile software in Amazon Linux 2 and Amazon Linux, you need to install several development tools, such as **make**, **gcc**, and **autoconf**.

Note

The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post [Update on Amazon Linux AMI end-of-life](#). We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Because software compilation is not a task that every Amazon EC2 instance requires, these tools are not installed by default, but they are available in a package group called "Development Tools" that is easily added to an instance with the **yum groupinstall** command.

```
[ec2-user ~]$ sudo yum groupinstall "Development Tools"
```

Software source code packages are often available for download (from websites such as <https://github.com/> and <http://sourceforge.net/>) as a compressed archive file, called a tarball. These tarballs will usually have the `.tar.gz` file extension. You can decompress these archives with the **tar** command.

```
[ec2-user ~]$ tar -xzf software.tar.gz
```

After you have decompressed and unarchived the source code package, you should look for a README or INSTALL file in the source code directory that can provide you with further instructions for compiling and installing the source code.

To retrieve source code for Amazon Linux packages

Amazon Web Services provides the source code for maintained packages. You can download the source code for any installed packages with the **yumdownloader --source** command.

- Run the **yumdownloader --source *package*** command to download the source code for *package*. For example, to download the source code for the htop package, enter the following command.

```
[ec2-user ~]$ yumdownloader --source htop

Loaded plugins: priorities, update-motd, upgrade-helper
Enabling amzn-updates-source repository
Enabling amzn-main-source repository
amzn-main-source
| 1.9 kB 00:00:00
amzn-updates-source
| 1.9 kB 00:00:00
(1/2): amzn-updates-source/latest/primary_db
| 52 kB 00:00:00
(2/2): amzn-main-source/latest/primary_db
| 734 kB 00:00:00
htop-1.0.1-2.3.amzn1.src.rpm
```

The location of the source RPM is in the directory from which you ran the command.

Manage users on your Linux instance

Each Linux instance launches with a default Linux system user. You can add users to your instance and delete users.

For the default user, the [default user name](#) is determined by the AMI that was specified when you launched the instance.

Note

By default, password authentication and root login are disabled, and sudo is enabled. To log in to your instance, you must use a key pair. For more information about logging in, see [Connect to your Linux instance](#).

You can allow password authentication and root login for your instance. For more information, see the documentation for your operating system.

Note

Linux system users should not be confused with IAM users. For more information, see [IAM users](#) in the *IAM User Guide*.

Default user names

The default user name for your EC2 instance is determined by the AMI that was specified when you launched the instance.

The default user names are:

- For AL2023, Amazon Linux 2, or the Amazon Linux AMI, the user name is `ec2-user`.
- For a CentOS AMI, the user name is `centos` or `ec2-user`.
- For a Debian AMI, the user name is `admin`.
- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.

- For an Oracle AMI, the user name is `ec2-user`.
- For a Bitnami AMI, the user name is `bitnami`.

 **Note**

To find the default user name for other Linux distributions, check with the AMI provider.

Considerations

Using the default user is adequate for many applications. However, you may choose to add users so that individuals can have their own files and workspaces. Furthermore, creating users for new users is much more secure than granting multiple (possibly inexperienced) users access to the default user, because the default user can cause a lot of damage to a system when used improperly. For more information, see [Tips for Securing Your EC2 Instance](#).

To enable users SSH access to your EC2 instance using a Linux system user, you must share the SSH key with the user. Alternatively, you can use EC2 Instance Connect to provide access to users without the need to share and manage SSH keys. For more information, see [Connect to your Linux instance with EC2 Instance Connect](#).

Create a user

First create the user, and then add the SSH public key that allows the user to connect to and log into the instance.

To create a user

1. [Create a new key pair](#). You must provide the `.pem` file to the user for whom you are creating the user. They must use this file to connect to the instance.
2. Retrieve the public key from the key pair that you created in the previous step.

```
$ ssh-keygen -y -f /path_to_key_pair/key-pair-name.pem
```

The command returns the public key, as shown in the following example.

```
ssh-rsa  
AAAAAB3NzaC1yc2EAAAQABAAQClKsfkNkuSevGj3eYhCe53pcjqP3maAhDFcvBS706Vhz2ItxCih  
+PnDSUaw+WNQn/mZphTk/a/gU8jEzo0WbkM4xyyb/wB96xbiFveSFJu0p/
```

```
d6RJhJ0I0iBXrlsLnBItnckij7FbtJMXMLvvwJryDUilBMTjYtwB+QhYXUM0zce5Pjz5/  
i8SeJtjnV3iAoG/cQk+0FzZqaeJAAHco  
+CY/5WrUBkrHmFJr6HcXkvJdWPkYQS3xqC0+FmUZofz221CBt5IMucxXPkX4rWi  
+z7wB3RbBQoQzd8v7yeb70z1PnW0yN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
```

3. Connect to the instance.
4. Use the **adduser** command to create the user and add it to the system (with an entry in the `/etc/passwd` file). The command also creates a group and a home directory for the user. In this example, the user is named *newuser*.
 - Amazon Linux and Amazon Linux 2

With Amazon Linux and Amazon Linux 2, the user is created with password authentication disabled by default.

```
[ec2-user ~]$ sudo adduser newuser
```

- Ubuntu

Include the `--disabled-password` parameter to create the user with password authentication disabled.

```
[ubuntu ~]$ sudo adduser newuser --disabled-password
```

5. Switch to the new user so that the directory and file that you create will have the proper ownership.

```
[ec2-user ~]$ sudo su - newuser
```

The prompt changes from `ec2-user` to `newuser` to indicate that you have switched the shell session to the new user.

6. Add the SSH public key to the user. First create a directory in the user's home directory for the SSH key file, then create the key file, and finally paste the public key into the key file, as described in the following sub-steps.
 - a. Create a `.ssh` directory in the `newuser` home directory and change its file permissions to `700` (only the owner can read, write, or open the directory).

```
[newuser ~]$ mkdir .ssh
```

```
[newuser ~]$ chmod 700 .ssh
```

 **Important**

Without these exact file permissions, the user will not be able to log in.

- b. Create a file named `authorized_keys` in the `.ssh` directory and change its file permissions to `600` (only the owner can read or write to the file).

```
[newuser ~]$ touch .ssh/authorized_keys
```

```
[newuser ~]$ chmod 600 .ssh/authorized_keys
```

 **Important**

Without these exact file permissions, the user will not be able to log in.

- c. Open the `authorized_keys` file using your favorite text editor (such as `vim` or `nano`).

```
[newuser ~]$ nano .ssh/authorized_keys
```

Paste the public key that you retrieved in **Step 2** into the file and save the changes.

 **Important**

Ensure that you paste the public key in one continuous line. The public key must not be split over multiple lines.

The user should now be able to log into the `newuser` user on your instance, using the private key that corresponds to the public key that you added to the `authorized_keys` file. For more information about the different methods of connecting to a Linux instance, see [Connect to your Linux instance](#).

Remove a user

If a user is no longer needed, you can remove that user so that it can no longer be used.

Use the **userdel** command to remove the user from the system. When you specify the **-r** parameter, the user's home directory and mail spool are deleted. To keep the user's home directory and mail spool, omit the **-r** parameter.

```
[ec2-user ~]$ sudo userdel -r olduser
```

Processor state control for your EC2 instance

C-states control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off).

P-states control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo Boost Technology to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

C-states and P-states

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- General purpose: m4.10xlarge | m4.16xlarge | m5.metal | m5d.metal | m5n.metal | m5zn.metal | m6i.metal | m6id.metal | m7i.metal-24x1 | m7i.metal-48x1

AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.

You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However,

if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.

The following sections describe the different processor state configurations and how to monitor the effects of your configuration. These procedures were written for, and apply to Amazon Linux; however, they may also work for other Linux distributions with a Linux kernel version of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

Note

The examples on this page use the following:

- The **turbostat** utility to display processor frequency and C-state information. The **turbostat** utility is available on Amazon Linux by default.
- The **stress** command to simulate a workload. To install **stress**, first enable the EPEL repository by running **sudo amazon-linux-extras install epel**, and then run **sudo yum install -y stress**.

If the output does not display the C-state information, include the **--debug** option in the command (**sudo turbostat --debug stress <options>**).

Highest performance with maximum Turbo Boost frequency

This is the default processor state control configuration for the Amazon Linux AMI, and it is recommended for most workloads. This configuration provides the highest performance with lower variability. Allowing inactive cores to enter deeper sleep states provides the thermal headroom required for single or dual core processes to reach their maximum Turbo Boost potential.

The following example shows a c4.8xlarge instance with two cores actively performing work reaching their maximum processor Turbo Boost frequency.

```
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10

In this example, vCPUs 21 and 28 are running at their maximum Turbo Boost frequency because the other cores have entered the C6 sleep state to save power and provide both power and thermal headroom for the working cores. vCPUs 3 and 10 (each sharing a processor core with vCPUs 21 and 28) are in the C1 state, waiting for instruction.

In the following example, all 18 cores are actively performing work, so there is no headroom for maximum Turbo Boost, but they are all running at the "all core Turbo Boost" speed of 3.2 GHz.

High performance and low latency by limiting deeper C-states

C-states control the sleep levels that a core may enter when it is inactive. You may want to control C-states to tune your system for latency versus performance. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work. For example, if a core that is assigned to handle network packet interrupts is asleep, there may be a delay in servicing that interrupt. You can configure the system to not use deeper C-states, which reduces the processor reaction latency, but that in turn also reduces the headroom available to other cores for Turbo Boost.

A common scenario for disabling deeper sleep states is a Redis database application, which stores the database in system memory for the fastest possible query response time.

To limit deeper sleep states on Amazon Linux 2

1. Open the /etc/default/grub file with your editor of choice.

```
[ec2-user ~]$ sudo vim /etc/default/grub
```

2. Edit the GRUB_CMDLINE_LINUX_DEFAULT line and add the intel_idle.max_cstate=1 and processor.max_cstate=1 options to set C1 as the deepest C-state for idle cores.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0
biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1
processor.max_cstate=1"
```

```
GRUB_TIMEOUT=0
```

The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

5. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

To limit deeper sleep states on Amazon Linux AMI

1. Open the `/boot/grub/grub.conf` file with your editor of choice.

```
[ec2-user ~]$ sudo vim /boot/grub/grub.conf
```

2. Edit the `kernel` line of the first entry and add the `intel_idle.max_cstate=1` and `processor.max_cstate=1` options to set C1 as the deepest C-state for idle cores.

```

The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-

based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Reboot your instance to enable the new kernel option.

```

In this example, the cores for vCPUs 19 and 28 are running at 3.2 GHz, and the other cores are in the C1 C-state, awaiting instruction. Although the working cores are not reaching their maximum Turbo Boost frequency, the inactive cores will be much faster to respond to new requests than they would be in the deeper C6 C-state.

Baseline performance with the lowest variability

You can reduce the variability of processor frequency with P-states. P-states control the desired performance (in CPU frequency) from a core. Most workloads perform better in P0, which requests

Turbo Boost. But you may want to tune your system for consistent performance rather than bursty performance that can happen when Turbo Boost frequencies are enabled.

Intel Advanced Vector Extensions (AVX or AVX2) workloads can perform well at lower frequencies, and AVX instructions can use more power. Running the processor at a lower frequency, by disabling Turbo Boost, can reduce the amount of power used and keep the speed more consistent. For more information about optimizing your instance configuration and workload for AVX, see the [Intel website](#).

CPU idle drivers control P-state. Newer CPU generations require updated CPU idle drivers that correspond to the kernel level as follows:

- Linux kernel versions 5.6 and higher (for example, m6i) – Supports Intel Icelake.
- Linux kernel versions 5.10 and higher (for example, m6a) – Supports AMD Milan.

To detect if a running system's kernel recognizes the CPU, run the following command.

```
if [ -d /sys/devices/system/cpu/cpu0/cpuidle ]; then echo "C-state control enabled";  
else echo "Kernel cpuidle driver does not recognize this CPU generation"; fi
```

If the output of this command indicates a lack of support, we recommend that you upgrade the kernel.

This section describes how to limit deeper sleep states and disable Turbo Boost (by requesting the P1 P-state) to provide low-latency and the lowest processor speed variability for these types of workloads.

To limit deeper sleep states and disable Turbo Boost on Amazon Linux 2

1. Open the /etc/default/grub file with your editor of choice.

```
[ec2-user ~]$ sudo vim /etc/default/grub
```

2. Edit the GRUB_CMDLINE_LINUX_DEFAULT line and add the intel_idle.max_cstate=1 and processor.max_cstate=1 options to set C1 as the deepest C-state for idle cores.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0  
biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1  
processor.max_cstate=1"
```

```
GRUB_TIMEOUT=0
```

The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

```
[ec2-user ~]$ grub2-mkconfig -o /boot/grub2/grub.cfg
```

5. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

6. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

```
[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

7. When your workload is finished, you can re-enable Turbo Boost with the following command.

```
[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

To limit deeper sleep states and disable Turbo Boost on Amazon Linux AMI

1. Open the `/boot/grub/grub.conf` file with your editor of choice.

```
[ec2-user ~]$ sudo vim /boot/grub/grub.conf
```

2. Edit the kernel line of the first entry and add the `intel_idle.max_cstate=1` and `processor.max_cstate=1` options to set C1 as the deepest C-state for idle cores.

```
# created by imagebuilder
default=0
timeout=1
hiddenmenu

title Amazon Linux 2014.09 (3.14.26-24.46.amzn1.x86_64)
```

```
root (hd0,0)
kernel /boot/vmlinuz-3.14.26-24.46.amzn1.x86_64 root=LABEL=/ console=ttyS0
intel_idle.max_cstate=1 processor.max_cstate=1
initrd /boot/initramfs-3.14.26-24.46.amzn1.x86_64.img
```

The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Reboot your instance to enable the new kernel option.

```
[ec2-user ~]$ sudo reboot
```

5. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

```
[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

6. When your workload is finished, you can re-enable Turbo Boost with the following command.

```
[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
```

The following example shows a c4.8xlarge instance with two vCPUs actively performing work at the baseline core frequency, with no Turbo Boost.

I/O scheduler

The I/O scheduler is a part of the Linux operating system that sorts and merges I/O requests and determines the order in which they are processed.

I/O schedulers are particularly beneficial for devices such as magnetic hard drives, where seek time can be expensive and where it is optimal to merge co-located requests. I/O schedulers have less of an effect with solid state devices and virtualized environments. This is because for solid state devices, sequential and random access don't differ, and for virtualized environments, the host provides its own layer of scheduling.

This topic discusses the Amazon Linux I/O scheduler. For more information about the I/O scheduler used by other Linux distributions, refer to their respective documentation.

Topics

- [Supported schedulers](#)
- [Default scheduler](#)
- [Change the scheduler](#)

Supported schedulers

Amazon Linux supports the following I/O schedulers:

- **deadline** — The *Deadline* I/O scheduler sorts I/O requests and handles them in the most efficient order. It guarantees a start time for each I/O request. It also gives I/O requests that have been pending for too long a higher priority.

- **cfq** — The *Completely Fair Queueing* (CFQ) I/O scheduler attempts to fairly allocate I/O resources between processes. It sorts and inserts I/O requests into per-process queues.
- **noop** — The *No Operation* (noop) I/O scheduler inserts all I/O requests into a FIFO queue and then merges them into a single request. This scheduler does not do any request sorting.

Default scheduler

No Operation (noop) is the default I/O scheduler for Amazon Linux. This scheduler is used for the following reasons:

- Many instance types use virtualized devices where the underlying host performs scheduling for the instance.
- Solid state devices are used in many instance types where the benefits of an I/O scheduler have less effect.
- It is the least invasive I/O scheduler, and it can be customized if needed.

Change the scheduler

Changing the I/O scheduler can increase or decrease performance based on whether the scheduler results in more or fewer I/O requests being completed in a given time. This is largely dependent on your workload, the generation of the instance type that's being used, and the type of device being accessed. If you change the I/O scheduler being used, we recommend that you use a tool, such as **iotop**, to measure I/O performance and to determine whether the change is beneficial for your use case.

You can view the I/O scheduler for a device using the following command, which uses nvme0n1 as an example. Replace nvme0n1 in the following command with the device listed in /sys/block on your instance.

```
$ cat /sys/block/nvme0n1/queue/scheduler
```

To set the I/O scheduler for the device, use the following command.

```
$ echo cfq/deadline/noop > /sys/block/nvme0n1/queue/scheduler
```

For example, to set the I/O scheduler for an **xvda** device from noop to cfq, use the following command.

```
$ echo cfq > /sys/block/xvda/queue/scheduler
```

Set the time for your Linux instance

A consistent and accurate time reference on your Linux instance is crucial for many server tasks and processes. Time stamps in system logs play an essential role in identifying when issues occurred and the chronological order of events. When you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time settings are inaccurate, it can result in a discrepancy between the date in the signature and the date of the request, leading to AWS rejecting your requests.

To address this important aspect, Amazon offers the Amazon Time Sync Service, which is accessible from all EC2 instances and used by various AWS services. The service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate and current time readings of the Coordinated Universal Time (UTC) global standard.

The Amazon Time Sync Service either uses the Network Time Protocol (NTP), or provides a local Precision Time Protocol (PTP) hardware clock on [supported instances](#). The PTP hardware clock supports either NTP or a direct PTP connection. The NTP and direct PTP connections use the same highly accurate time source, but the direct PTP connection is more accurate than the NTP connection. The NTP connection to the Amazon Time Sync Service supports leap smearing while the PTP connection to the PTP hardware clock does not smear time. For more information, see [Leap seconds](#).

For a backup to the local Amazon Time Sync Service on your instance, and to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the public Amazon Time Sync Service located at `time.aws.com`. The public Amazon Time Sync Service, like the local Amazon Time Sync Service, automatically smears any leap seconds that are added to UTC. The public Amazon Time Sync Service is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region.

For Windows instances, see [Set the time for your Windows instance](#).

Set your instance to use the local Amazon Time Sync Service

Your instances can access the local Amazon Time Sync Service as follows:

- Through NTP at the following IP address endpoints:
 - IPv4: 169.254.169.123
 - IPv6: fd00:ec2::123 (Only accessible by [instances built on the AWS Nitro System.](#))
- Through a direct PTP connection to connect to a local PTP hardware clock:
 - PHC0

NTP and PTP connections do not require any VPC configuration changes, and your instance does not require access to the internet.

The PTP hardware clock is part of the [AWS Nitro System](#), so it is directly accessible on [supported bare metal and virtualized EC2 instances](#) without using any customer resources.

The NTP endpoints to the PTP hardware clock are the same as the regular Amazon Time Sync Service connection over IPv4 or IPv6. If your software is configured to the NTP endpoint and is running on an instance with a PTP hardware clock, it will be connected to the PTP hardware clock automatically over NTP.

AL2023 and the latest versions of Amazon Linux 2 and Amazon Linux AMIs are configured to use the Amazon Time Sync Service IPv4 endpoint by default. No further configuration is required for instances launched from these AMIs unless you want to use the IPv6 endpoint or connect directly to the PTP hardware clock. For the IPv6 configuration instructions, see [Connect to the IPv6 endpoint of the Amazon Time Sync Service](#). For the PTP hardware clock configuration instructions, see [Connect to the PTP hardware clock](#).

If you're using an AMI that doesn't have the Amazon Time Sync Service configured by default, use one of the following procedures to configure the Amazon Time Sync Service on your instance using the `chrony` client.

Connect to the IPv4 endpoint of the Amazon Time Sync Service

This section describes how to configure your instance to use the local Amazon Time Sync Service through the IPv4 endpoint. It requires adding a server entry for the Amazon Time Sync Service to the `chrony` configuration file. On the latest versions of these AMIs, `chrony` is already installed and configured to use the Amazon Time Sync Service IPv4 endpoint.

Use the instructions for your instance's operating system.

Amazon Linux

 **Note**

On AL2023 and the latest versions of Amazon Linux 2 and Amazon Linux AMI, `chrony` is already installed and configured to use the Amazon Time Sync Service IPv4 endpoint. If you're using one of these latest AMIs, you can skip this procedure.

To connect to the IPv4 endpoint of the Amazon Time Sync Service on Amazon Linux using `chrony`

1. Connect to your instance and uninstall the NTP service.

```
[ec2-user ~]$ sudo yum erase 'ntp*'
```

2. Install the `chrony` package.

```
[ec2-user ~]$ sudo yum install chrony
```

3. Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`). Verify that the file includes the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If the line is present, then the Amazon Time Sync Service is already configured to use the IPv4 endpoint of the Amazon Time Sync Service and you can go to the next step. If not, add

the line after any other server or pool statements that are already present in the file, and save your changes.

4. Restart the chrony daemon (`chronyd`).

```
[ec2-user ~]$ sudo service chronyd restart
```

Starting chronyd:

[OK]

Note

On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. To configure `chronyd` to start at each system boot, use the `chkconfig` command.

```
[ec2-user ~]$ sudo chkconfig chronyd on
```

6. Verify that `chrony` is using the 169.254.169.123 IPv4 endpoint to synchronize the time.

```
[ec2-user ~]$ chronyc sources -v
```

Ubuntu

To connect to the IPv4 endpoint of the Amazon Time Sync Service on Ubuntu using chrony

1. Connect to your instance and use apt to install the chrony package.

```
ubuntu:~$ sudo apt install chrony
```

 **Note**

If necessary, update your instance first by running `sudo apt update`.

2. Open the `/etc/chrony/chrony.conf` file using a text editor (such as `vim` or `nano`). Add the following line before any other server or pool statements that are already present in the file, and save your changes:

```

SUSE Linux

Starting with SUSE Linux Enterprise Server 15, chrony is the default implementation of NTP.

To connect to IPv4 endpoint of the Amazon Time Sync Service on SUSE Linux using chrony

1. Open the /etc/chrony.conf file using a text editor (such as **vim** or **nano**).
2. Verify that the file contains the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If this line is not present, add it.

3. Comment out any other server or pool lines.
4. Open yaST and enable the chrony service.

Connect to the IPv6 endpoint of the Amazon Time Sync Service

This section explains how the steps described in [Connect to the IPv4 endpoint of the Amazon Time Sync Service](#) differ if you are configuring your instance to use the local Amazon Time Sync Service through the IPv6 endpoint. It doesn't explain the entire Amazon Time Sync Service configuration process.

The IPv6 endpoint is only accessible on [instances built on the AWS Nitro System](#).

Note

We don't recommend using both the IPv4 and IPv6 endpoint entries together in your chrony.conf file. The IPv4 and IPv6 NTP packets come from the same local server for your instance. Configuring both IPv4 and IPv6 endpoints is unnecessary and will not improve the accuracy of the time on your instance.

Depending on the Linux distribution you are using, when you reach the step to edit the chrony.conf file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (fd00:ec2::123) rather than the IPv4 endpoint (169.254.169.123):

```
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that chrony is using the fd00:ec2::123 IPv6 endpoint to synchronize time:

```
[ec2-user ~]$ chronyc sources -v
```

In the output, if you see the fd00:ec2::123 IPv6 endpoint, the configuration is complete.

Connect to the PTP hardware clock

This section describes how to configure your instance to use the local Amazon Time Sync Service through the PTP hardware clock using a direct PTP connection. It requires adding a server entry for the PTP hardware clock to the chrony configuration file.

If your instance has a PTP hardware clock and you configured the NTP connection (to either the IPv4 or the IPv6 endpoint), your instance time is automatically sourced from the PTP hardware clock. The steps below configure the *direct* PTP connection, which will give you more accurate time than the NTP connection.

Requirements

The PTP hardware clock is available on an instance when the following requirements are met:

- Supported AWS Regions: US East (N. Virginia) and Asia Pacific (Tokyo)
- Supported instance family: R7g
- ENA driver version 2.10.0 or later installed on a supported operating system. For more information about supported operating systems, see the driver [prerequisites](#) on *GitHub*.

To connect to the PTP hardware clock

1. Connect to your instance and install the Linux kernel driver for Elastic Network Adapter (ENA) version 2.10.0 or later. For the installation instructions, see [Linux kernel driver for Elastic Network Adapter \(ENA\) family](#) on *GitHub*.
2. Verify that the /dev/ptp0 device shows up on your instance.

```
[ec2-user ~]$ ls /dev/ptp0
```

The following is the expected output. If /dev/ptp0 is not in the output, the ENA driver was not correctly installed. Review step 1 in this procedure for installing the driver.

```
/dev/ptp0
```

3. Edit /etc/chrony.conf using a text editor and add the following line anywhere in the file.

```
refclock PHC /dev/ptp0 poll 0 delay 0.000010 prefer
```

4. Restart chrony using the following command.

```
[ec2-user ~]$ sudo systemctl restart chronyd
```

5. Verify that chrony is using the PTP hardware clock to synchronize the time on this instance.

```
[ec2-user ~]$ chronyc sources
```

Expected output

MS Name/IP address	Stratum	Poll	Reach	LastRx	Last sample
#* PHC0	0	0	377	1	+2ns[+1ns] +/- 5031ns

In the output that's returned, * indicates the preferred time source. PHC0 corresponds to the PTP hardware clock. You might need to wait a few seconds after restarting chrony for the asterisk to appear.

Set your instance or any internet-connected device to use the public Amazon Time Sync Service

You can set your instance, or any internet-connected device such as your local computer or an on-prem server, to use the public Amazon Time Sync Service, which is accessible over the internet at `time.amazonaws.com`. You can use the public Amazon Time Sync Service as a backup for the local Amazon Time Sync Service and to connect resources outside of AWS to the Amazon Time Sync Service.

Depending on the operating system of your instance or device, use one of the following procedures to set your instance or device to use the public Amazon Time Sync Service.

Linux

To set your Linux instance or device to use the public Amazon Time Sync Service using chrony or ntpd

1. Edit /etc/chrony.conf (if you use chrony) or /etc/ntp.conf (if you use ntpd) using a text editor as follows:
 - a. To prevent your instance or device from trying to mix smeared and non-smeared servers, remove or comment out lines starting with server except any existing connection to the local Amazon Time Sync Service.

 **Important**

If you're setting your EC2 instance to connect to the public Amazon Time Sync Service, do not remove the following line which sets your instance to connect to the local Amazon Time Sync Service. The local Amazon Time Sync Service is a more direct connection and will provide better clock accuracy. The public Amazon Time Sync Service should only be used as a backup.

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

- b. Add the following line to connect to the public Amazon Time Sync Service.

```
pool time.aws.com iburst
```

2. Restart the daemon using one of the following commands.

- chrony

```
sudo service chronyd force-reload
```

- ntpd

```
sudo service ntp reload
```

macOS

To set your macOS instance or device to use the public Amazon Time Sync Service

1. Open **System Preferences**.
2. Choose **Date & Time**, and then choose the **Date & Time** tab.
3. To make changes, choose the lock icon, and enter your password when prompted.
4. For **Set date and time automatically**, enter **time.aws.com**.

Windows

To set your Windows instance or device to use the public Amazon Time Sync Service

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Time** tab. This tab is not available if your PC is part of a domain. In this case, it will synchronize time with the domain controller. You can configure the controller to use the public Amazon Time Sync Service.
4. Choose **Change settings**.
5. Select the check box for **Synchronize with an Internet time server**.
6. Next to **Server**, enter **time.aws.com**.

To set your Windows Server instance or device to use the public Amazon Time Sync Service

- Follow [Microsoft's instructions](#) to update your registry.

Compare timestamps

If you're using the Amazon Time Sync Service, you can compare the timestamps on your Amazon EC2 instances with ClockBound to determine the true time of an event. ClockBound measures the clock accuracy of your EC2 instance, and allows you to check if a given timestamp is in the past or future with respect to your instance's current clock. This information is valuable for determining the order and consistency of events and transactions across EC2 instances, independent of each instance's geographic location.

ClockBound is an open source daemon and library. To learn more about ClockBound, including installation instructions, see [ClockBound](#) on *GitHub*.

If you're using the direct PTP connection to the PTP hardware clock, your time daemon, such as chrony, will underestimate the clock error bound. This is because a PTP hardware clock does not pass the correct error bound information to chrony, the way that NTP does. As a result, your clock synchronization daemon assumes the clock is accurate to UTC and thus has an error bound of 0. To measure the full error bound, the Nitro System calculates the error bound of the PTP hardware clock, and makes it available it to your EC2 instance over the ENA driver sysfs filesystem. You can read this directly as a value, in nanoseconds, using the following command:

```
cat /sys/devices/pci0000:00/0000:00:05.0/phc_error_bound
```

The output is the clock error bound of the PTP hardware clock, in nanoseconds.

To calculate the correct clock error bound at a specific point in time when using the direct PTP connection to the PTP hardware clock, you must add the clock error bound from chrony or ClockBound at the time that chrony polls the PTP hardware clock. For more information about measuring and monitoring clock accuracy, see [Manage Amazon EC2 instance clock accuracy using Amazon Time Sync Service and Amazon CloudWatch – Part 1](#).

Change the time zone on your instance

Amazon Linux instances are set to the UTC (Coordinated Universal Time) time zone by default. You can change the time on an instance to the local time zone or to another time zone in your network.

Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To change the time zone on an AL2023 or Amazon Linux 2 instance

1. View the system's current time zone setting.

```
[ec2-user ~]$ timedatectl
```

2. List the available time zones.

```
[ec2-user ~]$ timedatectl list-timezones
```

- Set the chosen time zone.

```
[ec2-user ~]$ sudo timedatectl set-timezone America/Vancouver
```

- (Optional) Confirm that the current time zone is updated to the new time zone by running the `timedatectl` command again.

```
[ec2-user ~]$ timedatectl
```

To change the time zone on an Amazon Linux instance

- Identify the time zone to use on the instance. The `/usr/share/zoneinfo` directory contains a hierarchy of time zone data files. Browse the directory structure at that location to find a file for your time zone.

```
[ec2-user ~]$ ls /usr/share/zoneinfo
Africa      Chile     GB          Indian      Mideast    posixrules  US
America    CST6CDT  GB-Eire    Iran        MST        PRC        UTC
Antarctica Cuba      GMT        iso3166.tab MST7MDT   PST8PDT   WET
Arctic      EET       GMT0       Israel      Navajo    right      W-SU
...
...
```

Some of the entries at this location are directories (such as `America`), and these directories contain time zone files for specific cities. Find your city (or a city in your time zone) to use for the instance.

- Update the `/etc/sysconfig/clock` file with the new time zone. In this example, we use the time zone data file for Los Angeles, `/usr/share/zoneinfo/America/Los_Angeles`.
 - Open the `/etc/sysconfig/clock` file with a text editor (such as `vim` or `nano`). You need to use `sudo` with your editor command because `/etc/sysconfig/clock` is owned by root.

```
[ec2-user ~]$ sudo nano /etc/sysconfig/clock
```

- b. Locate the ZONE entry, and change it to the time zone file (omitting the /usr/share/zoneinfo section of the path). For example, to change to the Los Angeles time zone, change the ZONE entry to the following:

```
ZONE="America/Los_Angeles"
```

 **Note**

Do not change the UTC=true entry to another value. This entry is for the hardware clock, and does not need to be adjusted when you're setting a different time zone on your instance.

- c. Save the file and exit the text editor.
3. Create a symbolic link between /etc/localtime and the time zone file so that the instance finds the time zone file when it references local time information.

```
[ec2-user ~]$ sudo ln -sf /usr/share/zoneinfo/America/Los_Angeles /etc/localtime
```

4. Reboot the system to pick up the new time zone information in all services and applications.

```
[ec2-user ~]$ sudo reboot
```

5. (Optional) Confirm that the current time zone is updated to the new time zone by using the **date** command. The current time zone appears in the output. In the following example, the current time zone is PDT, which refers to the Los Angeles time zone.

```
[ec2-user ~]$ date
Sun Aug 16 05:45:16 PDT 2020
```

Leap seconds

Leap seconds, introduced in 1972, are occasional one-second adjustments to UTC time to factor in irregularities in the earth's rotation in order to accommodate differences between International Atomic Time (TAI) and solar time (UT1). To manage leap seconds on behalf of customers, we designed leap second smearing within the Amazon Time Sync Service. For more information, see [Look Before You Leap – The Coming Leap Second and AWS](#).

Leap seconds are going away, and we are in full support of the decision made at the [27th General Conference on Weights and Measures to abandon leap seconds by or before 2035](#).

To support this transition, we still plan on smearing time during a leap second event when accessing the Amazon Time Sync Service over the local NTP connection or our public NTP pools (`time.aws.com`). The PTP hardware clock, however, does not provide a smeared time option. In the event of a leap second, the PTP hardware clock will add the leap second following UTC standards. Leap-smeared and leap second time sources are the same in most cases. But because they differ during a leap second event, we do not recommend using both smeared and non-smeared time sources in your time client configuration during a leap second event.

Configure your GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

To get started with a GPU-based instance, you must install the appropriate drivers.

Install NVIDIA drivers on Linux instances

An instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, must have the appropriate NVIDIA driver installed. Depending on the instance type, you can either download a

public NVIDIA driver, download a driver from Amazon S3 that is available only to AWS customers, or use an AMI with the driver pre-installed.

To install AMD drivers on a Linux instance with an attached AMD GPU, such as a G4ad instance, see [Install AMD drivers](#) instead. To install NVIDIA drivers on a Windows instance, see [Install NVIDIA drivers on Windows instances](#).

Types of NVIDIA drivers

The following are the main types of NVIDIA drivers that can be used with GPU-based instances.

Tesla drivers

These drivers are intended primarily for compute workloads, which use GPUs for computational tasks such as parallelized floating-point calculations for machine learning and fast Fourier transforms for high performance computing applications.

GRID drivers

These drivers are certified to provide optimal performance for professional visualization applications that render content such as 3D models or high-resolution videos. You can configure GRID drivers to support two modes. Quadro Virtual Workstations provide access to four 4K displays per GPU. GRID vApps provide RDSH App hosting capabilities.

Gaming drivers

These drivers contain optimizations for gaming and are updated frequently to provide performance enhancements. They support a single 4K display per GPU.

NVIDIA control panel

The NVIDIA control panel is supported with GRID and Gaming drivers. It is not supported with Tesla drivers.

Supported APIs for Tesla, GRID, and gaming drivers

- OpenCL, OpenGL, and Vulkan
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding

Available drivers by instance type

The following table summarizes the supported NVIDIA drivers for each GPU instance type.

Instance type	Tesla driver	GRID driver	Gaming driver
G3	Yes	Yes	No
G4dn	Yes	Yes	Yes
G5	Yes	Yes	Yes
G5g	Yes ¹	No	No
P2	Yes	No	No
P3	Yes	No	No
P4d	Yes	No	No
P4de	Yes	No	No

¹ This Tesla driver also supports optimized graphics applications specific to the ARM64 platform

² Using Marketplace AMIs only

Installation options

Use one of the following options to get the NVIDIA drivers required for your GPU instance.

Options

- [Option 1: AMIs with the NVIDIA drivers installed](#)
- [Option 2: Public NVIDIA drivers](#)
- [Option 3: GRID drivers \(G5, G4dn, and G3 instances\)](#)
- [Option 4: NVIDIA gaming drivers \(G5 and G4dn instances\)](#)

Option 1: AMIs with the NVIDIA drivers installed

AWS and NVIDIA offer different Amazon Machine Images (AMI) that come with the NVIDIA drivers installed.

- [Marketplace offerings with the Tesla driver](#)
- [Marketplace offerings with the GRID driver](#)
- [Marketplace offerings with the Gaming driver](#)

To update the driver version installed using one of these AMIs, you must uninstall the NVIDIA packages from your instance to avoid version conflicts. Use this command to uninstall the NVIDIA packages:

```
[ec2-user ~]$ sudo yum erase nvidia cuda
```

The CUDA toolkit package has dependencies on the NVIDIA drivers. Uninstalling the NVIDIA packages erases the CUDA toolkit. You must reinstall the CUDA toolkit after installing the NVIDIA driver.

Option 2: Public NVIDIA drivers

The options offered by AWS come with the necessary license for the driver. Alternatively, you can install the public drivers and bring your own license. To install a public driver, download it from the NVIDIA site as described here.

Alternatively, you can use the options offered by AWS instead of the public drivers. To use a GRID driver on a P3 instance, use the AWS Marketplace AMIs as described in [Option 1](#). To use a GRID driver on a G5, G4dn, or G3 instance, use the AWS Marketplace AMIs, as described in Option 1 or install the NVIDIA drivers provided by AWS as described in [Option 3](#).

To download a public NVIDIA driver

Log on to your Linux instance and download the 64-bit NVIDIA driver appropriate for the instance type from <http://www.nvidia.com/Download/Find.aspx>. For **Product Type**, **Product Series**, and **Product**, use the options in the following table.

Instance	Product Type	Product Series	Product
G3	Tesla	M-Class	M60
G4dn	Tesla	T-Series	T4
G5 ¹	Tesla	A-Series	A10
G5g ²	Tesla	T-Series	NVIDIA T4G
P2	Tesla	K-Series	K80
P3	Tesla	V-Series	V100
P4d	Tesla	A-Series	A100
P4de	Tesla	A-Series	A100
P5 ³	Tesla	H-Series	H100

¹ G5 instances require driver version 470.00 or later

² G5g instances require driver version 470.82.01 or later. The operating system is Linux aarch64

³ P5 instances require driver version 530 or later.

To install the NVIDIA driver on Linux

For more information about installing and configuring the driver, see the [NVIDIA Driver Installation Quickstart Guide](#).

Option 3: GRID drivers (G5, G4dn, and G3 instances)

These downloads are available to AWS customers only. By downloading, in order to adhere to requirements of the AWS solution referred to in the NVIDIA GRID Cloud End User License Agreement (EULA), you agree to use the downloaded software only to develop AMIs for use with the NVIDIA A10G, NVIDIA Tesla T4, or NVIDIA Tesla M60 hardware. Upon installation of the

software, you are bound by the terms of the [NVIDIA GRID Cloud End User License Agreement](#). For information about the version of the NVIDIA GRID driver for your operating system, see the [NVIDIA® Virtual GPU \(vGPU\) Software Documentation](#) on the *NVIDIA website*.

Considerations

- G5 instances require GRID 13.1 or later (or GRID 12.4 or later).
- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- [IMDSv2](#) is only supported with NVIDIA driver version 14.0 or greater.

Amazon Linux and Amazon Linux 2

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance.
2. Install the AWS CLI on your Linux instance and configure default credentials. For more information, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

 **Important**

Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.

3. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install gcc make
```

4. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

5. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

6. Reconnect to your instance after it has rebooted.
7. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
```

8. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linux-nvidia-drivers/latest/ .
```

Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linux-nvidia-drivers/
```

9. Add permissions to run the driver installation utility using the following command.

```
[ec2-user ~]$ chmod +x NVIDIA-Linux-x86_64*.run
```

10. Run the self-install script as follows to install the GRID driver that you downloaded. For example:

```
[ec2-user ~]$ sudo /bin/sh ./NVIDIA-Linux-x86_64*.run
```

 **Note**

If you are using Amazon Linux 2 with kernel version 5.10, use the following command to install the GRID driver.

```
[ec2-user ~]$ sudo CC=/usr/bin/gcc10-cc ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Confirm that the driver is functional. The response for the following command lists the installed version of the NVIDIA driver and details about the GPUs.

```
[ec2-user ~]$ nvidia-smi -q | head
```

12. If you are using NVIDIA vGPU software version 14.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information, on why this is required visit [NVIDIA's documentation](#).

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/modprobe.d/nvidia.conf
```

13. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

14. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.
 - a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#).
 - b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in [Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances](#).

CentOS 7 and Red Hat Enterprise Linux 7

To install the NVIDIA GRID driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot

4. Reconnect to your instance after it has rebooted.

5. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
```

6. Disable the nouveau open source driver for NVIDIA graphics cards.
 - a. Add nouveau to the /etc/modprobe.d/blacklist.conf blacklist file. Copy the following code block and paste it into a terminal.

```
[ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

- b. Edit the /etc/default/grub file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

- c. Rebuild the Grub configuration.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. Download the GRID driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://ec2-linu-nvidia-drivers/latest/ .
```

Multiple versions of the GRID driver are stored in this bucket. You can see all of the available versions using the following command.

```
[ec2-user ~]$ aws s3 ls --recursive s3://ec2-linu-nvidia-drivers/
```

8. Add permissions to run the driver installation utility using the following command.

Ubuntu and Debian

To install the NVIDIA GRID driver on your instance

- Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
- Update your package cache and get the package updates for your instance.

```
$ sudo apt-get update -y
```

3. (Ubuntu) Upgrade the `linux-aws` package to receive the latest version.

```
$ sudo apt-get upgrade -y linux-aws
```

(Debian) Upgrade package to receive the latest version.

```
$ sudo apt-get upgrade -y
```

4. Reboot your instance to load the latest kernel version.

```
$ sudo reboot
```

5. Reconnect to your instance after it has rebooted.

6. Install the `gcc` compiler and the kernel headers package for the version of the kernel you are currently running.

```
$ sudo apt-get install -y gcc make linux-headers-$(uname -r)
```

7. Disable the nouveau open source driver for NVIDIA graphics cards.

- a. Add nouveau to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

```
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf

```

14. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.
- To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#).
 - NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in [Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances](#).
 - Install the GUI desktop/workstation package.

```
$ sudo apt-get install -y lightdm ubuntu-desktop
```

Option 4: NVIDIA gaming drivers (G5 and G4dn instances)

These drivers are available to AWS customers only. By downloading them, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA A10G and NVIDIA Tesla T4 hardware. Upon installation of the software, you are bound by the terms of the [NVIDIA GRID Cloud End User License Agreement](#).

Considerations

- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- [IMDSv2](#) is only supported with NVIDIA driver version 495.x or greater.

Amazon Linux and Amazon Linux 2

To install the NVIDIA gaming driver on your instance

- Connect to your Linux instance.
- Install the AWS CLI on your Linux instance and configure default credentials. For more information, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

⚠ Important

Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.

3. Install **gcc** and **make**, if they are not already installed.

```
[ec2-user ~]$ sudo yum install gcc make
```

4. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

5. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

6. Reconnect to your instance after it has rebooted.
7. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y gcc kernel-devel-$(uname -r)
```

8. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

9. Extract the gaming driver installation utility from the downloaded .zip archive.

```
[ec2-user ~]$ unzip latest-driver-name.zip -d nvidia-drivers
```

10. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/NVIDIA-Linux-x86_64*-grid.run
```

11. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./nvidia-drivers/NVIDIA-Linux-x86_64*.run
```

Note

If you are using Amazon Linux 2 with kernel version 5.10, use the following command to install the NVIDIA gaming drivers.

```
[ec2-user ~]$ sudo CC=/usr/bin/gcc10-cc ./NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

12. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf  
vGamingMarketplace=2  
EOF
```

13. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2023_9_22.cert"
```

- For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

- For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"
```

14. If you are using NVIDIA driver version 510.x or greater on the G4dn, G5, or G5g instances, disable GSP with the following commands. For more information, on why this is required visit [NVIDIA's documentation](#).

```
[ec2-user ~]$ sudo touch /etc/modprobe.d/nvidia.conf
```

```
[ec2-user ~]$ echo "options nvidia NVreg_EnableGpuFirmware=0" | sudo tee --append /etc/modprobe.d/nvidia.conf
```

15. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

16. (Optional) To help take advantage of a single display of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#).

CentOS 7 and Red Hat Enterprise Linux 7

To install the NVIDIA gaming driver on your instance

1. Connect to your Linux instance. Install **gcc** and **make**, if they are not already installed.
2. Update your package cache and get the package updates for your instance.

```
[ec2-user ~]$ sudo yum update -y
```

3. Reboot your instance to load the latest kernel version.

```
[ec2-user ~]$ sudo reboot
```

4. Reconnect to your instance after it has rebooted.
5. Install the **gcc** compiler and the kernel headers package for the version of the kernel you are currently running.

```
[ec2-user ~]$ sudo yum install -y unzip gcc kernel-devel-$(uname -r)
```

6. Disable the nouveau open source driver for NVIDIA graphics cards.
 - a. Add nouveau to the `/etc/modprobe.d/blacklist.conf` blacklist file. Copy the following code block and paste it into a terminal.

```
[ec2-user ~]$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

- b. Edit the `/etc/default/grub` file and add the following line:

```
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

- c. Rebuild the Grub configuration.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. Download the gaming driver installation utility using the following command:

```
[ec2-user ~]$ aws s3 cp --recursive s3://nvidia-gaming/linux/latest/ .
```

Multiple versions of the gaming driver are stored in this bucket. You can see all of the available versions using the following command:

```
[ec2-user ~]$ aws s3 ls --recursive s3://nvidia-gaming/linux/
```

8. Extract the gaming driver installation utility from the downloaded `.zip` archive.

```
[ec2-user ~]$ unzip vGPUSW-*vGaming-Linux-Guest-Drivers.zip -d nvidia-drivers
```

9. Add permissions to run the driver installation utility using the following command:

```
[ec2-user ~]$ chmod +x nvidia-drivers/Linux/NVIDIA-Linux-x86_64*-grid.run
```

10. Run the installer using the following command:

```
[ec2-user ~]$ sudo ./nvidia-drivers/Linux/NVIDIA-Linux-x86_64*.run
```

When prompted, accept the license agreement and specify the installation options as required (you can accept the default options).

11. Use the following command to create the required configuration file.

```
[ec2-user ~]$ cat << EOF | sudo tee -a /etc/nvidia/gridd.conf

EOF
```

12. Use the following command to download and rename the certification file.

- For version 460.39 or later:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCertLinux_2023_9_22.cert"
```

- For version 440.68 to 445.48:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2020_04.cert"
```

- For earlier versions:

```
[ec2-user ~]$ sudo curl -o /etc/nvidia/GridSwCert.txt "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/GridSwCert-Linux_2019_09.cert"

Install an additional version of CUDA

After you install an NVIDIA graphics driver on your instance, you can install a version of CUDA other than the version that is bundled with the graphics driver. The following procedure demonstrates how to configure multiple versions of CUDA on the instance.

To install the CUDA toolkit

1. Connect to your Linux instance.
2. Open the [NVIDIA website](#) and select the version of CUDA that you need.
3. Select the architecture, distribution, and version for the operating system on your instance. For **Installer Type**, select **runfile (local)**.
4. Follow the instructions to download the install script.

5. Add run permissions to the install script that you downloaded using the following command.

```
[ec2-user ~]$ chmod +x downloaded_installer_file
```

6. Run the install script as follows to install the CUDA toolkit and add the CUDA version number to the toolkit path.

```
[ec2-user ~]$ sudo sh downloaded_installer_file --silent --override --toolkit --samples --toolkitpath=/usr/local/cuda-version --samplespath=/usr/local/cuda --no-opengl-libs
```

7. (Optional) Set the default CUDA version as follows.

```
[ec2-user ~]$ sudo ln -s /usr/local/cuda-version /usr/local/cuda
```

Install AMD drivers on Linux instances

An instance with an attached AMD GPU, such as a G4ad instance, must have the appropriate AMD driver installed. Depending on your requirements, you can either use an AMI with the driver preinstalled or download a driver from Amazon S3.

To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a G4dn instance, see [Install NVIDIA drivers](#) instead. To install AMD drivers on a Windows instance, see [Install AMD drivers on Windows instances](#).

Contents

AMD Radeon Pro Software for Enterprise Driver

The AMD Radeon Pro Software for Enterprise Driver is built to deliver support for professional-grade graphics use cases. Using the driver, you can configure your instances with two 4K displays per GPU.

Supported APIs

- OpenGL, OpenCL
- Vulkan
- AMD Advanced Media Framework
- Video Acceleration API

AMIs with the AMD driver installed

AWS offers different Amazon Machine Images (AMI) that come with the AMD drivers installed.

Open [Marketplace offerings with the AMD driver](#).

AMD driver download

If you aren't using an AMI with the AMD driver installed, you can download the AMD driver and install it on your instance. The AMD driver is only supported on Amazon Linux 2 with kernel version 4.14.

 **Note**

AMD driver version **amdgpu-pro-20.20-1184451** and newer driver releases require kernel version 5.15 or higher.

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the AMD Radeon Pro V520 hardware. Upon installation of the software, you are bound by the terms of the [AMD Software End User License Agreement](#).

To install the AMD driver on your Linux instance

1. Connect to your Linux instance.
2. Install the AWS CLI on your Linux instance and configure default credentials. For more information, see [Installing the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

⚠️ Important

Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.

3. Install **gcc** and **make**, if they are not already installed.

```
$ sudo yum install gcc make
```

4. Update your package cache and get the package updates for your instance.

- For Amazon Linux 2:

```
$ sudo amazon-linux-extras install epel -y  
$ sudo yum update -y
```

- For Ubuntu 22.04:

```
$ wget https://repo.radeon.com/.preview/a0e4ef1dffbc95b4abb54e891f265e61/amdgpu-install/5.5.02.05.2/ubuntu/jammy/amdgpu-install_5.5.02.05.50502-1_all.deb  
$ sudo apt install ./amdgpu-install_5.5.02.05.50502-1_all.deb  
$ sudo sed -i 's#repo.radeon.com#&/.preview/a0e4ef1dffbc95b4abb54e891f265e61#' /etc/apt/sources.list.d/{amdgpu.list,rocm.list,amdgpu-proprietary.list}
```

- For other Ubuntu versions:

```
$ sudo dpkg --add-architecture i386  
$ sudo apt-get update -y && sudo apt upgrade -y
```

- For CentOS:

```
$ sudo yum install epel-release -y  
$ sudo yum update -y
```

5. Reboot the instance.

```
$ sudo reboot
```

6. Reconnect to the instance after it reboots.

7. Download the latest AMD driver.

 **Note**

Skip this step for Ubuntu 22.04.

```
$ aws s3 cp --recursive s3://ec2-amd-linux-drivers/latest/ .
```

8. Extract the file.

- For Amazon Linux 2 and CentOS:

```
$ tar -xf amdgpu-pro-*rhel*.tar.xz
```

- For Ubuntu:

 **Note**

Skip this step for Ubuntu 22.04.

```
$ tar -xf amdgpu-pro*ubuntu*.xz
```

9. Change to the folder for the extracted driver.

10. Add the missing modules for the driver installation.

- For Amazon Linux 2 and CentOS:

Skip this step.

- For Ubuntu:

 **Note**

Skip this step for Ubuntu 22.04.

```
$ sudo apt install linux-modules-extra-$(uname -r) -y
```

11. Run the self install script to install the full graphics stack.

- For Ubuntu 22.04:

```
$ sudo amdgpu-install --usecase=workstation --vulkan=pro --opencl=rocr,legacy -y
```

- For Amazon Linux 2 and CentOS and other Ubuntu versions:

```
$ ./amdgpu-pro-install -y --opencl=pal,legacy
```

12. Reboot the instance.

```
$ sudo reboot
```

13. Confirm that the driver is functional.

```
$ dmesg | grep amdgpu
```

The response should look like the following:

```
Initialized amdgpu
```

Set up an interactive desktop

After you confirm that your instance has the AMD GPU driver installed and amdgpu is in use, you can install an interactive desktop manager. We recommend the MATE desktop environment for the best compatibility and performance.

Prerequisite

Open a text editor and save the following as a file named `xorg.conf`. You'll need this file on your instance.

To set up an interactive desktop on Amazon Linux 2

1. Install the EPEL repository.

```
$ sudo amazon-linux-extras install epel -y
```

2. Install the MATE desktop.

```
$ sudo amazon-linux-extras install mate-desktop1.x -y
$ sudo yum groupinstall "MATE Desktop" -y
$ sudo systemctl disable firewalld
```

3. Copy the xorg.conf file to /etc/X11/xorg.conf.
4. Reboot the instance.

```
$ sudo reboot
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.

To set up an interactive desktop on Ubuntu

1. Install the MATE desktop.

```
$ sudo apt install xorg-dev ubuntu-mate-desktop -y
$ sudo apt purge ifupdown -y
```

2. Copy the xorg.conf file to /etc/X11/xorg.conf.
3. Reboot the instance.

```
$ sudo reboot
```

4. Install the AMF encoder for the appropriate version of Ubuntu.

```
$ sudo apt install ./amdgpu-pro-20.20-*/amf-amdgpu-pro_20.20-*_amd64.deb
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.
6. After the DCV installation give the DCV User video permissions:

```
$ sudo usermod -aG video dcv
```

To set up an interactive desktop on CentOS

1. Install the EPEL repository.

```
$ sudo yum update -y  
$ sudo yum install epel-release -y
```

2. Install the MATE desktop.

```
$ sudo yum groupinstall "MATE Desktop" -y  
$ sudo systemctl disable firewalld
```

3. Copy the xorg.conf file to /etc/X11/xorg.conf.

4. Reboot the instance.

```
$ sudo reboot
```

5. (Optional) [Install the NICE DCV server](#) to use NICE DCV as a high-performance display protocol, and then [connect to a NICE DCV session](#) using your preferred client.

Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances

To activate the GRID Virtual Applications on G3, G4dn, and G5 instances (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver in the /etc/nvidia/gridd.conf file.

To activate GRID Virtual Applications on Linux instances

1. Create the /etc/nvidia/gridd.conf file from the provided template file.

```
[ec2-user ~]$ sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
```

2. Open the /etc/nvidia/gridd.conf file in your favorite text editor.
3. Find the FeatureType line, and set it equal to 0. Then add a line with IgnoreSP=TRUE.

```
FeatureType=0  
IgnoreSP=TRUE
```

4. Save the file and exit.
5. Reboot the instance to pick up the new configuration.

```
[ec2-user ~]$ sudo reboot
```

Set up Dual 4K displays on G4ad instances

Launch a G4ad instance

1. Connect to your Linux instance to get the PCI Bus address of the GPU you want to target for dual 4K (2x4k):

```
lspci -vv | grep -i amd
```

You will get output similar to the following:

```
00:1e.0 Display controller: Advanced Micro Devices, Inc. [*AMD*/ATI] Device 7362 (rev c3)  
Subsystem: Advanced Micro Devices, Inc. [AMD/ATI] Device 0a34
```

2. Note the PCI bus address is 00:1e.0 in the above output. Create a file named /etc/modprobe.d/amdgpu.conf and add:

```
options amdgpu virtual_display=0000:00:1e.0,2
```
3. Follow the instructions [here](#) to install the AMD drivers on Linux. If you already have the AMD GPU driver installed, you will need to rebuild the amdgpu kernel modules through dkms.
4. Use the below xorg.conf file to define the dual (2x4K) screen topology and save the file in /etc/X11/xorg.conf:

```
~$ cat /etc/X11/xorg.conf

Get started with P5 instances

P5 instances provide 8 NVIDIA H100 GPUs with 640 GB of high-bandwidth GPU memory. They feature 3rd generation AMD EPYC processors and provide 2 TB of system memory, 30 TB of local NVMe instance storage, 3,200 Gbps aggregated network bandwidth, and GPUDirect RDMA support. P5 instances also support Amazon EC2 UltraCluster technology, which provides lower latency and improved network performance using EFA.

The following table provides a summary of the p5.48xlarge specifications.

vCPUs	System memory	GPUs	GPU memory	Network bandwidth	GPUDirect RDMA	GPU peer to peer	Instance storage
192	2 TiB	8 NVIDIA H100 GPUs	640 GB	3200 Gbps with EFAv2 HBM3	Supported	900 GB/s	8 x 3,800 GB NVMe SSD NVSwi volumes

Software configuration

The easiest way to get started with P5 instances is to launch an instance using an AWS Deep Learning AMI that is preconfigured with all of the required software. For the latest AWS Deep Learning AMI for use with P5 instances, see the [AWS Deep Learning Base GPU AMI \(Ubuntu 20.04\)](#).

If you need to build a custom AMI for use with P5 instances, we recommend installing the following minimum software versions:

- NVIDIA driver 535.54.03 or later
- CUDA 12.1 or later
- NVIDIA GDRCopy 2.3 or later
- EFA installer 1.24.1 or later
- NCCL 2.18.3 or later
- aws-ofi-nccl plugin 1.7.2-aws or later

We also recommend that you configure the instance to not use deeper C-states. For more information, see [High performance and low latency by limiting deeper C-states](#). The latest AWS Deep Learning Base GPU AMI is preconfigured to not use deeper C-states.

Ubuntu 20.04 specific recommendations

The following recommendations for Ubuntu 20.04 help prevent unpredictable interface naming on boot:

- Ensure you are running systemd 245.4-4ubuntu3.19 or later with the following command:

```
systemd --version
```

- Ensure you have configured GRUB:
 - Open the /etc/default/grub configuration file in a text editor.
 - Edit the GRUB_CMDLINE_LINUX_DEFAULT entry to include net.naming-scheme=v247.
 - Reboot your instance by running sudo update-grub.

Networking and EFA configuration

P5 instances deliver 3200 Gbps of networking bandwidth by using multiple EFA interfaces. P5 instances support 32 network cards. We recommend that you define a single EFA network interface per network card. To configure these interfaces at launch we recommend the following settings:

- For network interface 0, specify device index 0
- For network interfaces 1 through 31, specify device index 1

For more information about how to configure your P5 instances for EFA see [Get started with P5 instances and EFA](#).

Optimize GPU settings on Amazon EC2 instances

There are several GPU setting optimizations that you can perform to achieve the best performance on NVIDIA GPU instances. With some of these instance types, the NVIDIA driver uses an autoboot feature, which varies the GPU clock speeds. By disabling autoboot and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances. The following procedure helps you to configure the GPU settings to be persistent, disable the autoboot feature if needed, and set the GPU clock speeds to their maximum frequency.

The following steps are for optimizing GPU settings on a Linux instance. For Windows instances, see [Optimize GPU settings](#) in the *Amazon EC2 User Guide for Windows Instances*.

To optimize GPU settings

1. Configure the GPU settings to be persistent. This command can take several minutes to run.

```
[ec2-user ~]$ sudo nvidia-persistenced
```

2. [G3, and P2 instances only] Disable the autoboot feature for all GPUs on the instance.

```
[ec2-user ~]$ sudo nvidia-smi --auto-boost-default=0
```

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

- G3 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,1177
```

- G4dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 5001,1590
```

- G5 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 6250,1710
```

- P2 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2505,875
```

- P3 and P3dn instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 877,1530
```

- P4d instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 1215,1410
```

- P4de instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 1593,1410
```

- P5 instances:

```
[ec2-user ~]$ sudo nvidia-smi -ac 2619,1980
```

Optimize CPU options

Many Amazon EC2 instances support simultaneous multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an m5.xlarge instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a thread of a CPU core, except for T2 instances, M7a instances, Apple silicon Mac instances, and 64-bit ARM platforms such as instances powered by AWS Graviton processors.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores:** You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core:** You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with default CPU options.

Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

- You can't specify CPU options for bare metal instances.
- CPU options can only be specified during instance launch and cannot be modified after launch.
- When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see [Specify CPU options for your instance](#).
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see [CPU cores and threads per CPU core per instance type](#).
- To disable multithreading, specify one thread per core.
- When you [change the instance type](#) of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
- The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.
